Writing Interlanguage
Communication Applications
Language Environment
Writing Interlanguage
Communication Applications
This is a major revision of SA22-7563-06.

This edition applies to Language Environment in Version 1 Release 11 of z/OS (5694-A01) and to all subsequent releases and modifications until otherwise indicated in new editions.

IBM welcomes your comments. A form for readers' comments may be provided at the back of this publication, or you may address your comments to the following address:

## Contents

**Figures** ........................................... xi

**Tables** ........................................... xiii

**About this book** ........................................ xv

- Using your documentation ................................ xvi
- Where to find more information ......................... xvii
  - Information updates on the web ..................... xvii
  - The z/OS Basic Skills Information Center ............ xvii

**Summary of Changes** .................................... xix

**Chapter 1. Getting Started with Language Environment ILC** ........... 1

- The Benefits of ILC under Language Environment ............ 1
- Writing ILC Applications .................................. 1

**Chapter 2. Communicating with XPLINK Applications** ............ 3

- XPLINK Compatibility Support .......................... 3
- ILC calls between XPLINK and Non-XPLINK routines ........... 3
- ILC between XPLINK and Non-XPLINK C ..................... 4
- ILC between XPLINK and Non-XPLINK C++ ................... 4
- ILC between XPLINK and COBOL ........................... 5
- ILC between XPLINK and PL/I .............................. 6
- ILC between XPLINK and Assembler ........................ 6
- ILC between XPLINK and Fortran .......................... 7
- PIPI XPLINK considerations .............................. 7

**Chapter 3. Communicating between C and C++** ............ 9

- Preparing for ILC ................................ 9
  - Language Environment ILC Support ..................... 9
  - Determining the Main Routine .......................... 9
  - Declaring C to C++ ILC ............................... 10
  - Building a Reentrant C to C++ Application .......... 11
- Calling between C and C++ ................................ 11
- Passing Data between C and C++ .......................... 11
  - Passing Data by Value between C and C++ ............. 11
  - Passing Data by Reference between C and C++ ......... 12
  - Passing C++ Objects .................................. 13
  - Supported Data Types Passed between C and C++ ....... 14
  - Using Aggregates .................................... 14
- Data Equivalents .................................. 15
  - Equivalent Data Types for C to C++ ................. 15
  - Equivalent Data Types for C++ to C .................. 17
  - Name Scope and Name Space ........................... 19
  - Enhancing Performance with Packed Structures and Unions ........................................ 21
  - Using Storage Functions in C to C++ ILC .......... 23
  - Directing Output in ILC Applications ................. 23
  - C to C++ Condition Handling ........................... 23
  - Sample C to C++ Applications .......................... 24

**Chapter 4. Communicating between C and COBOL** ............ 27

- Preparing for ILC ................................ 27
  - Language Environment ILC Support ..................... 27
Chapter 6. Communicating between C and Fortran

Preparing for ILC
- Language Environment ILC Support
- Migrating ILC Applications
- Determining the Main Routine
- Declaring C to Fortran ILC

Calling between C and Fortran
- Types of Calls Permitted
- Dynamic Call/Fetch Considerations
- Invoking Functions with Returned Values
- Calling Fortran Library Routines

Passing Data between C and Fortran
- Supported Data Types between C and Fortran
- Supported Data Types for Passing by Value
- Supported Data Types for Passing Function Return Values
- Passing an Alternate Return Code from Fortran to C
- Passing Character Data
- Mapping Arrays between C and Fortran

Data Equivalents
- Equivalent Data Types for C to Fortran
- Equivalent Data Types for Fortran to C

External Data
- Directing Output in ILC Applications
- C to Fortran Condition Handling
- Enclave-Terminating Language Constructs
- Exception Occurs in C
- Exception Occurs in Fortran

Sample ILC Applications

Chapter 7. Communicating between C++ and Fortran

Preparing for ILC
- Language Environment ILC Support
- Determining the Main Routine
- Declaring C++ to Fortran ILC

Calling between C++ and Fortran
- Types of Calls Permitted
- Dynamic Call/Fetch Considerations
- Invoking Functions with Returned Values
- Calling Fortran Library Routines

Passing Data between C++ and Fortran
- Supported Data Types between C++ and Fortran
- Supported Data Types for Passing by Value
- Supported Data Types for Passing Function Return Values
- Passing an Alternate Return Code from Fortran to C++
- Passing Character Data
- Mapping Arrays between C++ and Fortran

Data Equivalents
- Equivalent Data Types for C++ to Fortran
- Equivalent Data Types for Fortran to C++

External Data
- Directing Output in ILC Applications
- C++ to Fortran Condition Handling
- Enclave-Terminating Language Constructs
## Chapter 14. Communicating between Assembler and HLLs

- Calling between Assembler and an HLL ........................................... 239
  - Using the CEEFETCH Macro ......................................................... 239
  - Using the CEERELES Macro ....................................................... 239
  - Using the CEELOAD Macro ......................................................... 239
  - Passing Arguments between HLL and Assembler Routines ............. 240
  - Cancelling or Releasing Assembler ........................................... 242
- Calling COBOL from Assembler ..................................................... 242
- AMODE Considerations ................................................................. 242
- Cancelling COBOL Programs ......................................................... 243
- Non-Language Environment-Conforming Assembler Invoking an HLL Main Routine .......................................................... 243
- Language Environment-Conforming Assembler Invoking an HLL Main Routine .......................................................... 243
- Assembler Main Calling HLL Subroutines for Better Performance .... 244

## Chapter 15. ILC under CICS

- Language Pairs Supported in ILC under CICS .................................. 247
  - C/C++ and COBOL ........................................................................ 248
  - z/OS XL C/C++ and PL/I ............................................................... 248
  - COBOL and PL/I ........................................................................... 249
  - Assembler .................................................................................... 249
- Link-Editing ILC Applications under CICS ....................................... 250
- CICS ILC Application ...................................................................... 250

## Appendix A. Condition-Handling Responses ...................................... 255

## Appendix B. Using Nested Enclaves .................................................... 257
- Understanding the Basics ................................................................ 257
- COBOL Considerations ................................................................. 257
- PL/I Considerations ....................................................................... 257
- Determining the Behavior of Child Enclaves ................................... 258
  - Creating Child Enclaves Using EXEC CICS LINK or EXEC CICS XCTL 258
  - Creating Child Enclaves by Calling a Second Main Without an RB Crossing 259
  - Creating Child Enclaves Using SVC LINK or CMSCALL ................. 259
  - Creating Child Enclaves Using the C system() Function ............... 262
  - Creating Child Enclaves That Contain a PL/I Fetchable Main ....... 263
- Other Nested Enclave Considerations ............................................. 264
  - What the Enclave Returns from CEE3PRM ..................................... 264
  - Finding the Return and Reason Code from the Enclave .................. 265
  - Assembler User Exit ..................................................................... 266
  - Message File ................................................................................. 266
  - AMODE Considerations ............................................................... 266

## Appendix C. Accessibility ................................................................. 267
- Using assistive technologies .......................................................... 267
- Keyboard navigation of the user interface ....................................... 267
- z/OS information .......................................................................... 267

## Notices .......................................................................................... 269
- Policy for unsupported hardware .................................................... 270
- Programming Interface Information .............................................. 270
- Trademarks ................................................................................... 270

## Bibliography .................................................................................... 271
- Language Products Publications .................................................... 271
- Related Publications ...................................................................... 272
Index .................................................. 275

IBM® z/OS Language Environment (also called Language Environment) provides common services and language-specific routines in a single run-time environment for C, C++, COBOL, Fortran (z/OS only; no support for z/OS UNIX System Services or CICS®), PL/I, and assembler applications. It offers consistent and predictable results for language applications, independent of the language in which they are written.

Language Environment is the prerequisite run-time environment for applications generated with the following IBM compiler products:
- z/OS XL C/C++ (feature of z/OS)
- z/OS C/C++
- OS/390 C/C++
- C/C++ for MVS/ESA™
- C/C++ for z/VM
- XL C/C++ for z/VM
- AD/Cycle® C/370™
- VisualAge for Java, Enterprise Edition for OS/390
- Enterprise COBOL for z/OS
- Enterprise COBOL for z/OS and OS/390
- COBOL for OS/390 & VM
- COBOL for MVS & VM (formerly COBOL/370)
- Enterprise PL/I for z/OS
- Enterprise PL/I for z/OS and OS/390
- VisualAge PL/I
- PL/I for MVS & VM (formerly PL/I MVS™ & VM)
- VS FORTRAN and FORTRAN IV (in compatibility mode)

Although not all compilers listed are currently supported, Language Environment supports the compiled objects that they created.

Language Environment supports, but is not required for, an interactive debug tool for debugging applications in your native z/OS environment.

Debug Tool is also available as a standalone product. Debug Tool Utilities and Advanced Functions is also available. For more information, see http://www.ibm.com/software/awdtools/debugtool/.

Language Environment supports, but is not required for, VS FORTRAN Version 2 compiled code (z/OS only).

Language Environment consists of the common execution library (CEL) and the run-time libraries for C/C++, COBOL, Fortran, and PL/I.

For more information on VisualAge for Java, Enterprise Edition for OS/390, program number 5655-JAV, see the product documentation.

This book is written for application programmers and developers to create and run interlanguage communication (ILC) applications under the z/OS IBM Language Environment product.
Language Environment improves ILC between conforming high-level languages (HLLs) because it creates one common run-time environment and it defines data types and constructs that are equivalent across languages.

For application programming, you will need to use this book, *z/OS Language Environment Programming Guide* and *z/OS Language Environment Programming Reference*. Descriptions of these books are found below, in “Using your documentation.” You will also need to use the programming guides of the HLLs you are programming with.

This book is organized into pair-wise chapters that discuss ILC between two languages. There is also a chapter that discusses applications developed in more than two languages (Chapter 13, “Communicating between Multiple HLLs,” on page 231). ILC with assembler is discussed in Chapter 14, “Communicating between Assembler and HLLs,” on page 239 and ILC under CICS is discussed in Chapter 15, “ILC under CICS,” on page 247.

### Using your documentation

The publications provided with Language Environment are designed to help you:

- Manage the run-time environment for applications generated with a Language Environment-conforming compiler.
- Write applications that use the Language Environment callable services.
- Develop interlanguage communication applications.
- Customize Language Environment.
- Debug problems in applications that run with Language Environment.
- Migrate your high-level language applications to Language Environment.

Language programming information is provided in the supported high-level language programming manuals, which provide language definition, library function syntax and semantics, and programming guidance information.

Each publication helps you perform different tasks, some of which are listed in Table 1. All books are available in printable (PDF) and BookManager softcopy formats. For a complete list of publications that you may need, see “Bibliography” on page 271.

Where to find more information

Please see z/OS Information Roadmap for an overview of the documentation associated with z/OS.

Information updates on the web

For the latest information updates that have been provided in PTF cover letters and Documentation APARs for z/OS®, see the online document at: [http://publibz.boulder.ibm.com/cgi-bin/bookmgr_OS390/Shelves/ZDOCAPAR](http://publibz.boulder.ibm.com/cgi-bin/bookmgr_OS390/Shelves/ZDOCAPAR)

This document is updated weekly and lists documentation changes before they are incorporated into z/OS publications.

The z/OS Basic Skills Information Center

The z/OS Basic Skills Information Center is a Web-based information resource intended to help users learn the basic concepts of z/OS, the operating system that runs most of the IBM mainframe computers in use today. The Information Center is designed to introduce a new generation of Information Technology professionals to basic concepts and help them prepare for a career as a z/OS professional, such as a z/OS system programmer.

Specifically, the z/OS Basic Skills Information Center is intended to achieve the following objectives:

- Provide basic education and information about z/OS without charge
- Shorten the time it takes for people to become productive on the mainframe
- Make it easier for new people to learn z/OS.

To access the z/OS Basic Skills Information Center, open your Web browser to the following Web site, which is available to all users (no login required): [http://publib.boulder.ibm.com/infocenter/zos/basics/index.jsp](http://publib.boulder.ibm.com/infocenter/zos/basics/index.jsp)
Summary of Changes

Summary of Changes
for SA22-7563-07
z/OS Version 1 Release 11

This book contains information previously presented in SA22-7563-06, which supports z/OS Version 1 Release 10.

Changed Information

- Updates are made to Chapter 14, “Communicating between Assembler and HLLs,” on page 239.
- Minor editorial service updates are included.

This book contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

You may notice changes in the style and structure of some content in this book—for example, headings that use uppercase for the first letter of initial words only, and procedures that have a different look and format. The changes are ongoing improvements to the consistency and retrievability of information in our books.

Summary of Changes
for SA22-7563-06
z/OS Version 1 Release 10

This book contains information previously presented in SA22-7563-05, which supports z/OS Version 1 Release 8.

Changed Information

- Updates are made to the chapter on XPLINK.
- Minor editorial service updates are included.

Summary of Changes
for SA22-7563-05
z/OS Version 1 Release 8

This book contains information previously presented in SA22-7563-04, which supports z/OS Version 1 Release 7.

Changed Information

- Updates are made to the chapter on Chapter 15, “ILC under CICS,” on page 247 about assembler main routines.
- Minor service updates are included.
Interlanguage communication (ILC) applications are applications built of two or more high-level languages (HLLs) and frequently assembler. ILC applications run outside of the realm of a single language's environment, which creates special conditions, such as how the languages' data maps across load module boundaries, how conditions are handled, or how data can be called and received by each language.

This book helps you create ILC applications using Language Environment-conforming compilers. Most of the book is organized into "pairwise" chapters, which compare how each language handles different aspects of ILC, such as calling, data, reentrance, condition handling, and storage.

If your application contains more than two languages, you should read the section for each pair of languages first. For example, if your application consists of a C main routine that calls a COBOL subroutine, and the C main later calls a PL/I subroutine, read the chapters on C to COBOL and C to PL/I ILC. Then read Chapter 13, "Communicating between Multiple HLLs," on page 231 for additional information on developing multiple-language applications. If you have ILC with assembler or under CICS, see Chapter 14, "Communicating between Assembler and HLLs," on page 239 and Chapter 15, "ILC under CICS," on page 247.

The Benefits of ILC under Language Environment

Performance improves under the single run-time environment. Language Environment ILC applications run in one environment, giving you cooperative ILC support for running mixed-language applications, without the overhead of multiple libraries and library initialization.

The environment is tailored to HLLs at initialization. When you run your ILC applications in Language Environment, the initialization process establishes the Language Environment environment, tailored to the set of HLLs in the main load module. ILC applications follow the Language Environment program model, making program execution consistent and predictable.

Coordinated cleanup is performed at termination. Language Environment terminates in an orderly manner. Resources obtained during the execution of the application are released, regardless of the mix of programming languages in the application.

Cooperative condition handling provides consistency. All languages participating in the ILC application handle conditions cooperatively, making exception and condition handling consistent and predictable.

All ILC applications can reside above the line. Applications can be linked AMODE(31) RMODE(ANY) to reside above the 16M line in storage.

Writing ILC Applications

Here are the steps you need to follow to develop an ILC application:

1. Decide which languages to use.

   Your application code will need to follow the rules in the compiler programming guides and the z/OS Language Environment Programming Guide. Use the pairwise language chapters to identify what levels of HLLs you should be using.
2. **Make sure all your ILC applications are Language Environment-conforming.**

   Each chapter gives the basics of what you need to do to get your ILC applications to be Language Environment-conforming (adhering to Language Environment's common interface). For detailed information on migration, see the language migration guides.

3. **Decide which language will have the main routine.**

   Language Environment allows only one routine to be the main routine in an enclave. Each chapter describes how to determine the main routine in an ILC application. If you are using a multiple language application, see [Chapter 13](#) "Communicating between Multiple HLLs," on page 231 to determine how to designate a main routine.

4. **Learn how to declare and use data across HLLs.**

   Each chapter describes how to use data in an ILC application.

5. **Learn how to mix HLL and Language Environment operations.** Each HLL has a unique way of using storage, return codes, and performing condition handling. Each chapter describes how to mix these HLL-specific constructs.
Chapter 2. Communicating with XPLINK Applications

This chapter describes compatibility between AMODE 31 XPLINK and non-XPLINK programs.

Extra Performance Linkage (XPLINK) offers enhanced linkage between programs, potentially increasing performance significantly when frequent calls are made between small programs. The main focus of XPLINK is to improve speed and efficiency of subroutine calls, through a downward-growing stack, and by passing parameters in registers. Secondary objectives include reducing the function footprint and removing restrictions on function pointers for C and C++ functions compiled with XPLINK. For additional information, refer to z/OS Language Environment Programming Guide.

XPLINK applications are supported under the IMS environment.

XPLINK Compatibility Support

XPLINK Compatibility Support is defined as the ability for routines (functions) compiled with NOXPLINK (these may be non-XPLINK C or C++, COBOL, PL/I, or OS Linkage Assembler) to "transparently" call routines that are compiled with XPLINK, and vice versa.

This transparent compatibility is provided at the Program Object (or Load Module, for compatibility with prelinker-built executables) boundary. That is, a Program Object (or Load Module) containing a caller of one linkage type (XPLINK or NOXPLINK) may call a routine compiled with the opposite linkage type as long as the called routine resides in a different Program Object (or Load Module). Program Objects can reside in either a PDSE or the HFS, while Load Modules must reside in a PDS.

The main "call linkage" supporting XPLINK Compatibility is the DLL call mechanism, but C's fetch() and Language Environment's CEEFETCH assembler macro are also supported.

The following are not supported for XPLINK in z/OS:

- COBOL dynamic call of an XPLINK function
- PL/I fetch
- Language Environment's CEELOAD assembler macro (traditional LOAD/BALR)

There are other environments that are not supported in an XPLINK environment (the XPLINK(ON) runtime option is in effect), such as AMODE-24 applications. Full details of supported environments are in z/OS Language Environment Programming Guide.

ILC calls between XPLINK and Non-XPLINK routines

For calls made across a Program Object boundary (such as calls to a DLL or a C fetch()ed function), Language Environment will insert the necessary glue code to perform a transition from XPLINK to non-XPLINK, or vice versa. This glue code must perform the following tasks:

- Switch between the downward-growing stack that XPLINK routines use and the upward-growing stack of non-XPLINK routines.
- Switch between XPLINK and non-XPLINK register conventions.
The details of the differences between these different linkage types are documented in [z/OS Language Environment Vendor Interfaces](#).

Because of the extra overhead added by the glue code for calls between XPLINK and non-XPLINK routines, an application's overall performance can be affected if the number of calls between XPLINK and non-XPLINK routines is high. Applications that will benefit the most from being recompiled XPLINK are those that make a large number of calls to small functions, all of which have been recompiled XPLINK. C++ applications are typically coded to this model. You should also try to minimize calls made between XPLINK and non-XPLINK routines, even if this means not compiling C or C++ routines that have a high interaction with non-XPLINK routines as XPLINK. For more details on selecting candidate applications for XPLINK, see [z/OS Language Environment Programming Guide](#).

### ILC between XPLINK and Non-XPLINK C

The parameter list format passed by non-XPLINK C is identical to one built in the argument area of an XPLINK caller, except that in the XPLINK case certain parameters may be passed in registers. The argument list may contain addresses of arguments passed indirectly (by reference) or values of arguments passed directly (by value). The end of the parameter list is not marked by the high order bit of the last parameter being turned on. Since the end of the argument list is not identified the programmer must ensure that the callee only accesses as many parameters as the caller had arguments.

When an XPLINK function calls a non-XPLINK C function, glue code will use the information encoded at the call site to determine which registers contain parameters. These parameters will be stored in the argument area to construct a complete, contiguous parameter list. When the non-XPLINK C program is given control, register 1 will point to this complete parameter list. Upon return, the returned value is transferred from C to XPLINK conventions by the glue code, again using information encoded at the call site.

When a non-XPLINK C function calls an XPLINK function, glue code will use the interface-mapping flags in the PPA1 of the XPLINK callee to determine which registers should contain parameters. These registers will be loaded from the parameter list, and the rest of the parameter list will be copied into the argument area of the "caller" (in this case, a transitional stack frame). Upon return, the returned value is transferred from XPLINK to C conventions by the glue code, again using information in the interface-mapping flags.

### ILC between XPLINK and Non-XPLINK C++

The parameter list format passed by FASTLINK C++ is identical to that built in the argument area of an XPLINK caller. In both the FASTLINK and XPLINK cases, some parameters may be passed in registers, although the rules differ about which registers get loaded and when. In the FASTLINK case, any remaining parameters not passed in registers are passed in an argument area at a fixed location in the callee's stack frame. In the XPLINK case, remaining parameters are passed in an argument area at a fixed location in the caller's stack frame.
ILC between XPLINK and COBOL

The only way a COBOL routine can call an XPLINK-compiled routine is if the caller is compiled with the Enterprise COBOL for z/OS or COBOL for OS/390 & VM compiler with the DLL compiler option, and the target of the call is in a separate DLL, or vice versa.

COBOL Dynamic Call to XPLINK is not supported.

Since XPLINK compatibility is only provided to Language Environment-conforming languages, OS/VS COBOL programs and VS COBOL II programs are not supported in an XPLINK(ON) environment.

The COBOL reusable environment support (the RTEREUS run-time option or the callable interfaces ILBOSTP0 and IGZERRE) cannot be used in an XPLINK(ON) environment.

COBOL ILC with an XPLINK function in a separate DLL can employ either of two parameter passing techniques:

- The "pragmaless" style, where the COBOL programmer explicitly specifies syntax indicating that arguments are to be passed BY VALUE, and uses RETURNING syntax to access C function results.
  RETURNING values and BY VALUE arguments are implemented using pre-XPLINK C linkage conventions, and are designed to enable pragma-less ILC with C or with C++ using EXTERN C. This technique also works with XPLINK. In this case, the glue code will load the necessary XPLINK parameter registers when called from a COBOL function, or store them into the argument area when calling a COBOL function.

- The #pragma linkage(..., COBOL) style, where the COBOL programmer specifies normal BY REFERENCE argument conventions, the C functions specify normal C by-value conventions, and the XL C/C++ compiler introduces code to accommodate both.
  An XPLINK program can identify a called function as using a COBOL-style parameter list (R1 => list of addresses, with the High Order Bit (HOB) of the last parameter turned on):
  #pragma linkage(called_rtn,COBOL)

  In this case the XPLINK compiler will generate a list of addresses to the actual parameters. The only difference is that XPLINK will load up to the first 3 of these addresses into registers 1, 2, and 3. When the glue code receives control from the XPLINK caller to swap the stack before giving control to the called COBOL function, it will also create a complete by-reference parameter list and set register 1 with the address of this parameter list.
  An XPLINK function can also specify that it receives COBOL-style parameters as input:
  #pragma linkage(this_rtn,COBOL)

  Processing via glue code is similar – when the XPLINK function receives control, the first 3 parameter addresses have been loaded into the parameter registers.
ILC between XPLINK and PL/I

The only way a PL/I program can call an XPLINK-compiled routine is if the caller is compiled with the EnterprisePL/I for z/OS compiler with the DLL compiler option and the target of the call is in a separate DLL, or vice versa.

PL/I FETCH of an XPLINK program object is not supported.

PL/I Multitasking is not supported in an XPLINK environment.

The processing of ILC calls between PL/I and XPLINK will be very similar to COBOL.
- PL/I parameter list is either pragma-less (by using the BYVALUE PROCEDURE attribute) or specified in the XPLINK program using #pragma linkage(...,PLI).
- Calls from XPLINK to PL/I through glue code will establish an environment conforming to PL/I linkage conventions before giving the PL/I function control.
- Calls from PL/I to XPLINK through glue code will convert from PL/I linkage conventions to XPLINK conventions.

ILC between XPLINK and Assembler

The processing of ILC calls between Language Environment-conforming assembler and XPLINK will be identical to COBOL.

Since the assembler programmer has direct control over the format of the parameter list, it can be constructed as either a “C-style” parameter list, or as an OS linkage parameter list. In the latter case, the XPLINK program must specify #pragma linkage(...,OS) at its interface with the assembler program.

The format of an OS linkage parameter list, as defined by an XPLINK function, is that the address of the first parameter will be passed in register 1, the address of the second parameter will be passed in register 2, the address of the third parameter will be passed in register 3, and any remaining parameters will be passed by placing their address in the caller’s argument area. The high-order bit of the last parameter will be turned on. Note that this is different from the expected “R1 points to a list of addresses”, but has better performance characteristics and allows the glue routine to issue the instruction STM R1,R3 to build a complete OS linkage parameter list. It can then set R1 to the address of this list for a call to an OS linkage routine.

There are three flavors of OS linkage that can be used by an XPLINK program:
- **OS_UPSTACK**
  In general, parts compiled XPLINK cannot be combined with parts compiled NOXPLINK in the same program object. One exception to this rule is OS linkage routines that are defined in an XPLINK-compiled caller as OS_UPSTACK. In this case, the XPLINK compiler will generate a call to glue code that performs a transition from the XPLINK caller to the OS linkage callee. The callee will get control with OS linkage conventions (parameter list and registers) and running on an Language Environment-conforming upward-growing stack.
  From XPLINK C code, specified as one of:
  - #pragma linkage(function_name,OS_UPSTACK)
  - #pragma linkage(function_name,OS) with the OSCALL(UPSTACK) compiler option
  From XPLINK C++ code, specified as one of:
The other exception allowing XPLINK and NOXPLINK parts in the same program object is that XPLINK-compiled routines can call OS linkage routines defined as OS_NOSTACK. In this case, the XPLINK compiler will generate an OS linkage style call (parameter list and registers) directly to the callee. There is no intervening glue code to provide a stack swap. Instead, a 72-byte savearea is provided. This provides much better performance characteristics over OS_UPSTACK calls when the called routine does not require an LE-conforming stack.

From XPLINK C code, specified as one of:
- #pragma linkage(function_name,OS_NOSTACK)
- #pragma linkage(function_name,OS) with the OSCALL(NOSTACK) compiler option (this is the default)

From XPLINK C++ code, specified as one of:
- extern "OS_NOSTACK" function_prototype
- extern "OS" function_prototype with the OSCALL(NOSTACK) compiler option

**OS_DOWNSTACK**
This defines calls between XPLINK-compiled routines that pass an OS linkage "by reference" parameter list. XPLINK calling conventions are used.

From XPLINK C code, specified as one of:
- #pragma linkage(function_name,OS_DOWNSTACK)
- #pragma linkage(function_name,OS) with the OSCALL(DOWNSTACK) compiler option

From XPLINK C++ code, specified as one of:
- extern "OS_DOWNSTACK" function_prototype
- extern "OS" function_prototype with the OSCALL(DOWNSTACK) compiler option

---

**ILC between XPLINK and Fortran**

XPLINK compatibility with Fortran is not supported.

**PIPI XPLINK considerations**

Language Environment Version 1 Release 3 adds support to the preinitialization services (PIPI) to support programs that have been compiled XPLINK. Specifically, it allows programs and subroutines that have been compiled XPLINK to be defined in the PIPI table. For more details, refer to the [z/OS Language Environment Programming Guide](zos_language_environment_programming_guide).
Chapter 3. Communicating between C and C++

This chapter describes Language Environment’s support for C and C++ ILC applications. If you are running a C to C++ ILC application under CICS you should also consult Chapter 15, “ILC under CICS,” on page 247.

General Facts about C to C++ ILC

- C++ is reentrant by default. If you wish to create a reentrant C to C++ application you should compile the C program with the RENT compiler option. (See “Building a Reentrant C to C++ Application” on page 11.)
- If your C code was not compiled with RENT, your C++ code must contain special directives so it can use global variables defined in the C or C++ program. This information can be found in “Data Equivalents” on page 15.

Preparing for ILC

This section describes the topics you should consider before writing a C to C++ ILC application. For help in determining how different versions of C and C++ work together, refer to z/OS Language Environment Run-Time Application Migration Guide.

Language Environment ILC Support

Table 2. Supported Languages for Language Environment ILC

<table>

<td></td>
</tr>
<tr>
<td></td>
<td>• z/OS XL C/C++ compilers</td>
<td></td>
</tr>
</tbody>
</table>

Determining the Main Routine

In C and C++ the main routine is the function called main(). In a C to C++ ILC application only one main() function is allowed. Multiple main() functions will result in errors. Recursive calls to the main() function are not supported in C++.

An entry point is defined for each supported HLL. Table 3 identifies the desired entry point. The table assumes that your code has been compiled using the Language Environment-conforming compilers.

See z/OS XL C/C++ Run-Time Library Reference for the description of the requirements for fetching C++.

Table 3. Determining the Entry Point

<table>
<thead>
<tr>
<th>HLL</th>
<th>Main Entry Point</th>
<th>Fetched Entry Point</th>

</tr>
<tr>
<td>C++</td>
<td>CEESTART</td>
<td>CEESTART or routine name, if #pragma linkage(fetchable) is not used.</td>
</tr>
</tbody>
</table>
Declaring C to C++ ILC

If a C function invokes a C++ function or a C++ function invokes a C function, all entry declarations are contained solely within the C++ source. No special declaration is required in the C code.

For C to C++ ILC, the C++ extern "C" linkage specification lets the C++ compiler generate parameter lists for C or accept parameter lists from C.

The extern "C" linkage specification has the following format:

```c
extern "C" {declaration}
```

`declaration` is a valid C++ prototype of the C function(s) being called by C++, or the C++ routine being called by C. The braces {} are not required if only one declaration is specified.

If your C or C++ application is compiled with XPLINK or LP64 (which implies AMODE 64 XPLINK), the linkage and parameter passing mechanisms for C and C++ are identical. If you link to a C function from a C++ program, you should still specify extern "C" to avoid name mangling.

### Declaration for C Calling C++

<table>
<thead>
<tr>
<th>C Function</th>
<th>C++ Function</th>

</tr>
<tr>
<td></td>
<td><code>   CFUNC(x);</code></td>
</tr>
<tr>
<td></td>
<td><code>}</code></td>
</tr>
</tbody>
</table>
Building a Reentrant C to C++ Application

The XL C++ compiler creates reentrant code by default. However, to create a reentrant C to C++ ILC application, you need to follow the following process:

1. Compile your C++ code.
2. Compile your C code with the RENT, LONGNAME, and DLL parameters. (LONGNAME and DLL are not required but make the prelinking and linking process simpler.)
3. Prelink all C++ and C text decks together using the Language Environment prelinker.
   The Prelink step can be eliminated when the target library for the executable module is either the HFS or a PDSE and the DFSMS Binder is used to link all C++ and C text decks together.
4. Link the text deck created by the prelinker to create your module.

See z/OS Language Environment Programming Guide for more information on reentrant applications.

Calling between C and C++

Table 4 describes the types of calls between C and C++ that Language Environment allows:

<table>
<thead>
<tr>
<th>Direction of Call</th>
<th>Static Calls</th>
<th>Dynamic Calls Using DLLs</th>
<th>Fetch/Fetchep</th>
</tr>
</thead>
<tbody>
<tr>
<td>C to C++</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>C++ to C</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Notes:
1. The fetch() function can be used to fetch modules, compiled DLL, or modules containing C++ routines, but exported data will not be available.
2. Any of the C or C++ functions can be compiled with the XPLINK option, with the single restriction that you can not mix XPLINK and non-XPLINK in the same module (i.e. XPLINK and non-XPLINK C or C++ can not be statically bound together).

As of C/C++ for MVS/ESA V3, the compiler provides support for dynamic load libraries (DLLs) which can be used to dynamically access C or C++ functions or data. For more information on DLLs, see z/OS XL C++ Programming Guide.

Passing Data between C and C++

There are two ways to pass data with C and C++: by value and by reference. By value means a temporary copy of the argument is passed to the called function or procedure. By reference means that the address of the argument is passed.

Passing Data by Value between C and C++

In general, value parameters are passed and received by C++ in the same manner as under C; a non-pointer or reference variable is passed in the parameter list. Any change that happens to a value parameter in the called function will not affect the variable in the caller, as in the following example, where an integer is passed by value from C++ to C:
Sample C++ Usage
#include <stdio.h>
extern "C" int cfunc(int);

main() { 
  int result, y;
  y=5;
  result=cfunc(y); /* by value */
  if (y==5 && result==6)
    printf("It worked!\n");
}

C Subroutine
#include <stdio.h>

int cfunc(int newval) 
{ 
  ++newval;
  return newval;
}

Similarly, to pass an int by value from C to C++:

Sample C Usage
#include <stdio.h>
int cppfunc(int);
main() { 
  int result, y;
  y=5;
  result=cppfunc(y); /* by value */
  if (y==5 && result==6)
    printf("It worked!\n");
}

C++ Subroutine
#include <stdio.h>
extern "C" {
int cppfunc(int);
}

int cppfunc(int newval) 
{ // receive into pointer
  ++newval;
  return newval;
}

Passing Data by Reference between C and C++

In C, you can pass data by reference by passing a pointer to the item or passing the address of the item. In C++, you can pass a pointer, the address of the item, or a reference variable.

A pointer passed from C to C++ may be received as a pointer or as a reference variable, as in the following example:

Sample C Usage
#include <stdio.h>
main() {
  int result, y;
  int *x;
  y=5;
  x= &y;
  result=cppfunc(x); /* by reference */
  if (y==6)
    printf("It worked!\n");
}

C++ Subroutine
#include <stdio.h>
extern "C" {
int cppfunc(int *
{ 
  ++(*newval);
  return *newval;
}
A pointer, or the address of a variable, passed from C++ to C must be received as a pointer, as in the following example:

```c
#include <stdio.h>
extern "C" {
    int cfunc(int *);
}
main() {
    int result, y;
    int *x;
    y=5;
    x= &y;
    result=cfunc(x); /* by reference */
    if (y==6)
        printf("It worked!\n");
}
```

Similarly, a reference variable passed from C++ to C must be received as a pointer, as in the following example:

```c
#include <stdio.h>
extern "C" {
    int cfunc(int *);
}
main() {
    int result, y;
    int *x;
    y=5;
    x= &y;
    result=cfunc(x); /* by reference */
    if (y==6)
        printf("It worked!\n");
}
```

### Passing C++ Objects

Objects can pass freely between C and C++ if the layout of the object in C and C++ is identical. In the following example, cobj (C) and cxxobj (C++) are identical:

```c
struct cobj {
    int age;
    char* name;
};
class cxxobj {
```
A C++ structure is just a class declared with the keyword `struct`; its members and base classes are public by default. Therefore, a C++ class is the same as a C++ structure if all data is public. A union is a class declared with the keyword `union`; its members are public by default and holds only one member at a time. In C, a structure is a simple variant of the C++ class.

If a C++ class using features not available to C (for example, virtual functions, virtual base class, private and protected data, or static data members) is passed to C, the results are undefined.

### Supported Data Types Passed between C and C++

<td>types created by typedef</td>
</tr>
</tbody>
</table>

### Notes:

1. C functions invoked from C++ or C++ functions invoked from C must be declared as `extern "C"` in the C++ source.
2. Packed decimal is not supported by C++. If you need to use packed decimal data, declare and modify it in C code using C functions.
3. If C++ classes, using features that are not available in C (see "Passing C++ Objects" on page 13 for examples), are passed to C, the results are undefined.

### Using Aggregates

C structures and unions may map differently than C++ structures, classes, and unions. The C and C++ AGGREGATE compiler options provide a layout of aggregates to help you perform the mapping.
Data Equivalents

This section shows how C and C++ data types correspond to each other.

Equivalent Data Types for C to C++

The following examples illustrate how C and C++ routines within a single ILC application might code the same data types.

Signed One-Byte Character Data

<table>
<thead>
<tr>
<th>Sample C Usage</th>
<th>C++ Subroutine</th>
</tr>
</thead>
<tbody>
<tr>
<td>#include &lt;stdio.h&gt;</td>
<td>#include &lt;stdio.h&gt;</td>
</tr>
<tr>
<td>int cplusf( signed char mc );</td>
<td>#include &lt;stdlib.h&gt;</td>
</tr>
<tr>

<tr>
<td>signed char myc='c';</td>
<td>{ myc='d';</td>
</tr>
<tr>
<td>rc=cplusf(myc); /* by value */</td>
<td>printf(&quot;myc=%c, rc=%d\n&quot;,myc,myc);</td>
</tr>
<tr>
<td>printf(&quot;myc=%c rc=%d\n&quot;,myc,rc);</td>
<td>return((int)myc);</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

32-Bit Unsigned Binary Integer

<table>
<thead>
<tr>
<th>Sample C Usage</th>
<th>C++ Subroutine</th>
</tr>
</thead>
<tbody>
<tr>
<td>#include &lt;stdio.h&gt;</td>
<td>#include &lt;stdio.h&gt;</td>
</tr>
<tr>
<td>int cplusf( unsigned int mi );</td>
<td>#include &lt;stdlib.h&gt;</td>
</tr>
<tr>
<td>int main()</td>
<td>extern &quot;C&quot; int cplusf(unsigned int myi);</td>
</tr>
<tr>
<td>{ int rc;</td>
<td>int cplusf(unsigned int myi)</td>
</tr>
<tr>
<td>unsigned int myi=32;</td>
<td>{ myi=33;</td>
</tr>
<tr>
<td>rc=cplusf(myi); /* by value */</td>
<td>printf(&quot;myi=%u, rc=%d\n&quot;,myi,myi);</td>
</tr>
<tr>
<td>printf(&quot;myi=%u rc=%d\n&quot;,myi,rc);</td>
<td>return((int)myi);</td>
</tr>
<tr>
<td>}</td>
<td></td>
</tr>
</tbody>
</table>
Sample C Usage

```c
#include <stdio.h>

int cplusf(unsigned int *mi);

int main()
{
    int rc;
    unsigned int myi=32;
    rc=cplusf(&myi);
    /* by reference */
    printf("myi=%u rc=%d
",myi,rc);
}
```

C++ Subroutine

```c
#include <stdio.h>
#include <stdlib.h>

extern "C" int cplusf(unsigned int *myi);

int cplusf(unsigned int *myi)
{
    *myi=33;
    printf("myi=%u, rc=%d
",myi,*myi);
    return((int)*myi);
}
```

Structures and Typedefs

Sample C Usage

```c
#include <stdio.h>

typedef struct {
    int x;
    float y;
} coord;

double cplusf(coord &mycoord);

int main()
{
    double rc;
    coord xyval, *xy;
    xyval.x=2;
    xyval.y=4;
    xy=&xyval;
    rc=cplusf(xy);
    /* by reference */
    printf("xyval.x=%d xyval.y=%f
    rc=%f\n",xyval.x,xyval.y,rc);
}
```

C++ Subroutine

```c
#include <stdio.h>
#include <stdlib.h>

typedef struct {
    int x;
    float y;
} coord;

extern "C" double cplusf(coord &; mycoord);

double cplusf(coord &; xy)
{
    double rc;
    xy.x=4;
    xy.y=10;
    rc=xy.x * xy.y;
    printf("xy.x=%d, xy.y=%f, rc=%f\n", xy.x,xy.y,rc);
    return(rc);
}
```
**Function Pointers**

**Sample C Usage**

```c
#include <stdio.h>

typedef int(FUNC) (int);

void cplusf (FUNC *myfnc);

int myfunc( int value )
{
    int rc;
    rc = printf( "The given value was %d\n", value);
    return(rc);
}

int main()
{
    int rc;
    rc = myfunc(3);
    printf("rc=%d\n",rc);
    cplusf(myfunc);
}
```

**C++ Subroutine**

```c
#include <stdio.h>
#include <stdlib.h>

extern "C" {
    typedef int(FUNC) (int);
    void cplusf (FUNC *myfnc);
}

void cplusf(FUNC *myfunc)
{
    int rc;
    rc=myfunc(3);
    printf("rc=%d\n",rc);
}
```

---

**Equivalent Data Types for C++ to C**

The following examples illustrate how C++ and C routines within a single ILC application might code the same data types.

### 16-Bit Signed Binary Integer

**Sample C++ Usage**

```c
#include <stdio.h>
#include <stdlib.h>

extern "C" int cfunc(short int msi);

int main()
{
    int rc;
    short mysi = 2;
    rc=cfunc(mysi); /* by value */
    printf("rc=%d\n",rc);
}
```

**C Subroutine**

```c
#include <stdio.h>
#include <stdlib.h>

int cfunc(short mysi)
{
    mysi=5;
    printf("msi=%hd, rc=%d\n",msi,rc);
    return((int)msi);
}
```
Sample C++ Usage
#include <stdio.h>
#include <stdlib.h>
extern "C" int cfunc( short int *msi );

int main()
{
    int rc;
    short mysi = 2;
    short *pmysi;

    pmysi=&mysi;
    rc=cfunc(pmysi);
    /* by reference */
    printf("mysi=%hd rc=%d\n",mysi,rc);
}

C Subroutine
#include <stdio.h>
#include <stdlib.h>
int cfunc(short *mysi);

int cfunc(short int *mysi)
{
    *mysi=5;
    printf("mysi=%hd, rc=%d\n",*mysi,*mysi);
    return((int)*mysi);
}

Short Floating-Point Number
Sample C++ Usage
#include <stdio.h>
#include <stdlib.h>
extern "C" int cfunc( float mf );

int main()
{
    int rc;
    float myf=32;

    rc=cfunc(myf);
    /* by value */
    printf("myf=%f rc=%f\n",myf,rc);
}

C Subroutine
#include <stdio.h>
#include <stdlib.h>
int cfunc(float myf);

int cfunc(float myf)
{
    myf=33;
    printf("myf=%f, rc=%f\n",myf,33);
    return(33);
}

Sample C++ Usage
#include <stdio.h>
#include <stdlib.h>
extern "C" int cfunc( float *mf );

int main()
{
    int rc;
    float myf=32;

    rc=cfunc(&myf);
    /* by reference */
    printf("myf=%f rc=%f\n",myf,rc);
}

C Subroutine
#include <stdio.h>
#include <stdlib.h>
int cfunc(float *myf);

int cfunc(float *myf)
{
    *myf=33;
    printf("myf=%f, rc=%f\n",*myf,*myf);
    return(33);
}
### Pointer to Character

**Sample C++ Usage**
```cpp
#include <stdio.h>

extern "C" void cfunc( char * stuff);

int main()
{
    char *mystuff="fun fun``";
    cfunc(mystuff);
    /* by reference */
    printf("mystuff is %s\n",mystuff);
}
```

**C Subroutine**
```c
#include <stdio.h>

void cfunc(char *stuff);

void cfunc(char *stuff)
{
    *(stuff+1)='U';
    printf("stuff is %s\n",stuff);
}
```

### Function Pointers

**Sample C++ Usage**
```cpp
#include <stdio.h>

extern "C" {
    typedef int(FUNC) (int);
    int myfunc( int value );
    void cfunc (FUNC *myfnc);
}

int myfunc( int value )
{
    int rc;
    rc= printf("The given value was &d\n", value);
    return(rc);
}

int main()
{
    int rc;
    rc = myfunc(3);
    printf("rc=%d\n",rc);
    cfunc(myfunc);
}
```

**C Subroutine**
```c
#include <stdio.h>

typedef int(FUNC) (int);
void cfunc(FUNC *myfunc)
{
    int rc;
    rc=myfunc(3);
    printf("rc=%d\n",rc);
}
```

### Name Scope and Name Space

In programming languages, the *name scope* is defined as the portion of an application within which a particular declaration applies or is known. *Name space* is defined as the portion of a load module within which a particular declaration applies or is known. These two concepts determine whether a particular declaration in one language will map to a reference in another language.

In C, the name space is determined by compiler options or specific compiler directives. Programs compiled with NORENT place variable declarations in CSECTs. Programs compiled with RENT refer to a writable static area that contains static, external, and string literal variables. For more information about the writable static area, see [z/OS XL C/C++ Programming Guide](#).

The XL C++ compiler acts as if everything was compiled with RENT.

The two techniques for creating an executable program are:
• When the executable program is to be stored in a PDSE or HFS, use the binder to combine the output from the XL C/C++ compiler.

• When the executable program is to be stored in a PDS, use the Language Environment Prelinker Utility to combine the output from the XL C/C++ compiler and pass the prelinker output to the binder.

To map data in C to C++ ILC, there are 3 major cases:

1. C compiled with the RENT option statically bound to C++
   C++ and C storage areas that result from compiling with RENT are mapped together at prelink time or at bind time when the Prelinker is not used and the output from the binder goes to the HFS or to a member in a PDSE. The name scope is the module boundary and external data will map to each other. The LONGNAME compiler option or the #pragma map preprocessor directive may be required to allow mixed-case, or long named external references, to resolve.

2. C compiled without the RENT option statically bound to C++
   C++ storage is placed in a different location than C NORENT storage. Therefore, by default, C++ will not look for NORENT C storage in the right place unless you give the XL C++ compiler the #pragma variable(varname,norent) directive.

### Sample C Usage
```c
#include <stdio.h>
float mynum = 2;
main() {
  int result, y;
  int *x;
  y=5;
  x=&y;
  result = cppfunc(x);
  // by reference
  if (y==6 && mynum==3)
    printf("It worked!\n");
}
```

### C++ Subroutine
```c
#include <stdio.h>
#pragma variable(mynum,norent)
extern float mynum;
extern "C" {
  int extern cppfunc( int * );
}
cppfunc( int *newval ) {
  // receive into pointer
  *newval = *newval + 1;
  mynum = mynum + 1;
  return *newval;
}
```

Alternatively, you can specify to the XL C++ compiler that a specific variable is RENT by specifying #pragma variable(varname,rent) in C.

### Sample C Usage
```c
#include <stdio.h>
#pragma variable(mynum,rent)
float mynum = 2;
main() {
  int result, y;
  int *x;
  y=5;
  x=&y;
  result = cppfunc(x);
  // by reference
  if (y==6 && mynum==3)
    printf("It worked!\n");
}
```

### C++ Subroutine
```c
#include <stdio.h>
extern float mynum;
extern "C" {
  int extern cppfunc( int * );
}
cppfunc( int *newval ) {
  // receive into pointer
  *newval = *newval + 1;
  mynum = mynum + 1;
  return *newval;
}
```

3. A C to C++ DLL application
A DLL application can access any declaration in its own module as well as referencing, implicitly or explicitly, any declaration from another DLL in the same enclave. For further information on what DLLs are and how to use them, refer to z/OS XL C/C++ Programming Guide.

Enhancing Performance with Packed Structures and Unions

Data elements of a structure or union are stored in memory on an address boundary specific for that data type. For example, a double value is stored in memory on a doubleword (8-byte) boundary. Gaps can be left in memory between elements of a structure to align elements on their natural boundaries. You can reduce the padding of bytes within a structure by packing that structure with the _Packed qualifier in C or by using the #pragma pack(packed) directive in C++ prior to the structure declaration.

The memory saved using packed structures might affect run-time performance. Most CPUs access data much more efficiently if it is aligned on appropriate boundaries. With packed structures, members are generally not aligned on appropriate (halfword, fullword, or doubleword) boundaries; the result is that member-accessing operations (. and ->) might be slower. The _Packed qualifier in C and #pragma pack(packed) in C++ have the same alignment rules for the same structures or unions. _Packed affects the definition, and #pragma pack(packed) affects the declaration.

Example of Packed Structures

In the following C example, fredc is a packed structure with its members, a, b, c, aligned on 1-byte boundaries.

```
struct ss{
   int a;
   char b;
   double c;
};

_Packed struct ss fredc;
```

In the following C++ example, fredcplus is a packed structure with its members, a, b, c, aligned on 1-byte boundaries.

```
#pragma pack(packed)

struct ss{
   int a;
   char b;
   double c;
};

struct ss fredcplus;
```

Both fredc and fredcplus have the same storage mapping.

Calling Packed Structures and Unions

Packed and unpacked objects can have different memory layouts. You can use ILC calls with arguments that are packed structures by using the #pragma pack(packed) support in C++.

Chapter 3. Communicating between C and C++  21
```c
#ifndef __cplusplus /* if compiled with C++ compiler */
    #ifndef _Packed /* define _Packed */
        #define _Packed
    #endif

    #pragma pack(packed) /* 1-byte alignment is used */
    #endif

struct ss {
    int i;
    char j;
    int k;
};

typedef _Packed struct ss packss;

#include "common.h" /* include common header file */

void callcxx(packss);

main() {
    packss packed;
    packed.i = 10;
    packed.j = 'a';
    packed.k = 33;
    callcxx(packed);
}
```

*Figure 1. Common Header File (common.h)*

*Figure 2. Common Header File in C*
Using Storage Functions in C to C++ ILC

Use the following guidelines if you mix HLL storage constructs:

- If the storage was allocated using Language Environment services, free it using Language Environment services.
- If the storage was allocated using C functions such as malloc(), calloc, or realloc(), free it using free();
- If the storage was allocated using the C++ new keyword then it must be deleted with delete.
- If your program requires that storage be allocated in one language and deleted in another, use the Language Environment services.

Directing Output in ILC Applications

When writing output to a standard stream from a C to C++ ILC application, both the C and C++ code should use the C I/O functions such as printf and puts, which allow the output to be written in the expected order. If your C++ program is directing output to cout (the default), you may get output in an unexpected order. See z/OS XL C++ Programming Guide chapter on IOSTREAMS for further information.

There is no restriction on passing file pointers from C to C++; a file opened using fopen in a C program may be closed by using fclose in a C++ program, and vice versa.

C to C++ Condition Handling

C++ exception handling uses throw() / try() / catch(), whereas C uses signal() / raise() or sigaction() / kill(). Mixing C and C++ exception handling in a C to C++ ILC module will result in undefined behavior. If you use only the C
exception handling model, a C++ routine can register a signal handler via signal to handle exceptions (software/hardware) raised by either a C or C++ routine. However, the behavior of running destructors for static/automatic objects is undefined.

If you use only the C++ exception handling model, only C++ routines will be able to catch() / handle() thrown objects. C routines do not have try() / catch() / throw() abilities nor can they use signal() to register a handler for thrown objects. A C++ routine cannot register a handler via signal() to catch thrown objects; it must use catch() clauses. C routines will ignore thrown objects.

Sample C to C++ Applications

/* Module/File Name: EDCXC */
/* CPROGRAM, compile with rent and longname */
#include <stdio.h>
#include <stdlib.h>

typedef struct {
    int length;
    int width;
} rectngl;

extern void printrec( rectngl r );
extern void change_width( rectngl* r , int w);

int CFUNC( rectngl *mine )
{
    int rc;
    printrec( *mine);
    change_width( mine, 5);
    #ifdef debug
    printrec( *mine);
    #endif
    printrec( *mine);
    if (mine->width !=5)
        return(1);
    else
        return(0);
}

Figure 4. C++ Main Routine
/* Module/File Name: EDCCXCT */
/* ................................................................./
/* CXXPROG - prelink with CPROG */
/* ................................................................./
#include <stdio.h>
#include <stdlib.h>
#include "verify.h"

class rectangle {
  public:
    int length;
    int width;

    rectangle(int l, int w) { length = l; width = w; }
    void show()
      { printf("Length: %d Width: %d\n",length,width); }
    void set_width( int size ) { width=size; }
    void set_length( int size) { length=size; }
};

extern "C" {
  int CFUNC( rectangle *small );
  void printrec( rectangle r ) { r.show();}
  void change_width( rectangle* r, int nw) { r->set_width(nw);}
};

int main( )
{
  int rc;

  rectangle myrec(10,2);
  rc=CFUNC( &myrec);

  if (rc == 1)
    fail(__FILE__,__LINE__);
  else
    check(__FILE__);
}

Figure 5. C Subroutine
Chapter 4. Communicating between C and COBOL

This chapter describes Language Environment’s support for C and COBOL ILC applications. If you are running a C to COBOL ILC application under CICS, you should also consult Chapter 15, “ILC under CICS,” on page 247.

General Facts about C to COBOL ILC

- With Enterprise COBOL for z/OS, COBOL for OS/390 & VM, or COBOL for MVS & VM, the #pragma linkage directive is not required for most calls between C and COBOL routines (although it can still be used). See “Calling between C and COBOL” on page 31 for the cases that require it. With COBOL/370 and VS COBOL II, #pragma linkage is required in the C routines.
- A C to COBOL application can be constructed to be reentrant.
- Language Environment does not support the automatic passing of return codes between C and COBOL routines in an ILC application.
- There is no ILC support between AMODE 31 and AMODE 64 applications. COBOL does not support AMODE 64.
- ILC is not supported in the C multitasking facility environment.

Preparing for ILC

This section describes topics you might want to consider before writing an application that uses ILC. For help in determining how different versions of HLLs work together, refer to the migration guides for the HLLs you plan to use.

Language Environment ILC Support

Language Environment provides ILC support between the following combinations of C and COBOL:

<table>
<thead>
<tr>
<th>HLL Pair</th>
<th>C (31-bit mode only)</th>
<th>COBOL</th>
</tr>
</thead>
<tbody>
<tr>
<td>C to COBOL</td>
<td>- C/370 Version 1 Release 2</td>
<td>- VS COBOL II Version 1</td>
</tr>
<tr>
<td></td>
<td>- C/370 Version 2 Release 1</td>
<td>- COBOL/370 Release 1</td>
</tr>
<tr>
<td></td>
<td>- IBM C/C++ for MVS/ESA</td>
<td>- COBOL for MVS &amp; VM Release 2</td>
</tr>
<tr>
<td></td>
<td>- z/OS XL C/C++ Compilers</td>
<td>- COBOL for OS/390 &amp; VM</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Enterprise COBOL for z/OS</td>
</tr>
</tbody>
</table>

Note: C refers to both the pre-Language Environment-conforming and Language Environment-conforming versions of C. COBOL refers to VS COBOL II, COBOL/370, COBOL for MVS & VM, COBOL for OS/390 & VM, and Enterprise COBOL for z/OS.

Language Environment does not support ILC between OS/VS COBOL and C. See Chapter 15, “ILC under CICS,” on page 247 for the allowable ILC on CICS.

Migrating ILC Applications

Relinking

ILC applications that contain load modules with pre-Language Environment-conforming C routines or VS COBOL II programs must be relinked, either under
Language Environment or with the migration tool provided in C/370 Version 2 Release 2. You should relink using the migration tool if your application will be used under both C/370 Version 2 Release 2 and Language Environment.

When you relink under Language Environment, explicitly include the following:

- The @@C2CBL and @@CBL2C routines. @@C2CBL is called when a C routine calls a COBOL program. @@CBL2C is called (in C) when a C routine is designated as linkage COBOL.
- IGZEBST or IGZENRI, depending on whether the COBOL program was compiled with RES or NORES, respectively.

**Recompiling**

You do not need to recompile an existing ILC application with a Language Environment-conforming compiler, but you can do so in order to take advantage of Language Environment’s condition handling behavior.

### Compiling and Linking Considerations

#### Compiling

If the C library is installed above the 16M line, compile your COBOL program using the RENT compiler option.

#### Linking

When link-editing ILC application load modules, there are different considerations for the main load module (the load module that contains the main routine) and for a load module that is fetched or dynamically called.

For the main load module, you should present your main routine to the linkage editor first in order to avoid an incorrectly chosen entry point. See “Determining the Main Routine” for information on how to identify the main routine.

For load modules that will be fetched or dynamically called, the entry point of the load module must be as follows:

- When C is the called routine and it does not specify any #pragma linkage, then the routine name must be the entry point.
- When C is the called routine and it specifies #pragma linkage(...,C08L), then the routine name must be the entry point.
- When C is the called routine and it specifies #pragma linkage(...,fetchable), then CEESTART or the routine name must be the entry point.
- When COBOL is the called routine, the program name must be the entry point.

To specify the entry point of a load module, use the binder’s ENTRY control statement.

#### Determining the Main Routine

In Language Environment, only one routine can be the main routine; no other routine in the enclave can use syntax that indicates it is main. If you write the main routine in C, you must use language syntax to identify the routine as the main routine. If you use COBOL as the first program in the enclave that is to gain control, the program is effectively designated main by being the first to run.

In C, the same routine can serve as both the main routine and subroutines if recursively called. In such a case, the new invocation of the routine is not considered a second main routine within the enclave, but a subroutine. With a VS
COBOL II or COBOL/370 single enclave, a recursively called main program is not permitted; Enterprise COBOL for z/OS, COBOL for OS/390 & VM and COBOL for MVS & VM support recursion.

Table 6 describes how C and COBOL identify the main routine.

<table>
<thead>
<tr>
<th>Language</th>
<th>When Determined</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>Compilation</td>
<td>Determined in the C source file by declaring a C function named main. The same routine can be used both as a main and subroutine if it is recursively called.</td>
</tr>
<tr>
<td>COBOL</td>
<td>Run time</td>
<td>Determined dynamically. If it is the first program to run, it is a main program. COBOL for MVS &amp; VM, COBOL for OS/390 &amp; VM, and Enterprise COBOL for z/OS support recursion, but the main program cannot be called recursively within a single enclave in VS COBOL II or COBOL/370.</td>
</tr>
</tbody>
</table>

An entry point is defined for each supported HLL. Table 7 identifies the desired entry point. The table assumes that your code has been compiled using the Language Environment-conforming compilers.

<table>
<thead>
<tr>
<th>HLL</th>
<th>Main Entry Point</th>
<th>Fetched or Dynamically Called Entry Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>CEESTART</td>
<td>CEESTART or routine name if #pragma linkage(fetchable) is used. In all other cases, the routine name.</td>
</tr>
<tr>
<td>COBOL</td>
<td>Name of the first object program to get control in the object module</td>
<td>Program name</td>
</tr>
</tbody>
</table>

Note: Specify ENTRY statement on link for the function name when not going through prelinker. Use #pragma map to remap a name and use the remapped name on ENTRY statement when prelinking.

C and COBOL routines that make up an ILC application are executed together in a single run unit (the equivalent of a Language Environment enclave). However, unlike in earlier versions of COBOL (VS COBOL II and OS/VS COBOL), the first COBOL program in a run unit is no longer necessarily considered the main program. If the first COBOL program is not the first program in the enclave to run, it is considered a subroutine in the Language Environment enclave.

**Declaring C to COBOL ILC**

No special linkage declaration is required for ILC between C and Enterprise COBOL for z/OS, COBOL for OS/390 & VM, or COBOL for MVS & VM. However, for COBOL/370 and VS COBOL II, a C #pragma linkage directive is required for both static and dynamic calls. The C #pragma linkage directive can still be used with Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM, but it is no longer required, as these levels of the COBOL products support direct use of C-style linkage conventions via language constructs such as BY VALUE arguments and function RETURNING values. Further, with the support of DLL linkage conventions in the Enterprise COBOL for z/OS and COBOL for OS/390 & VM products, COBOL applications may directly interoperate with reentrant C modules that are linked as DLLs.
When a `#pragma linkage` directive is required, all entry declarations are made in the C code, both in the case where C calls COBOL and vice versa. The C `#pragma linkage` directive lets the C compiler generate parameter lists for COBOL or accept them from COBOL. It also ensures that writable static pointers are passed correctly for reentrant C modules and, for calls from pre-Language Environment-conforming COBOL, verifies that Language Environment has been properly established.

The `#pragma linkage` directive has the following format:

```
#pragma linkage(function_name, COBOL)
```

`function_name` can be up to eight characters (Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM allow 160 characters). `function_name` is either the COBOL program being called by C, or the C routine being called by COBOL.

### Note

When declaring without `#pragma linkage` the reference to COBOL is for Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM. When declaring with `#pragma linkage` the reference to COBOL is for Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, and VS COBOL II.

#### Declaring C to COBOL ILC without `#pragma Linkage`

**Declaration for C Calling COBOL:**

<table>
<thead>
<tr>
<th>C Function</th>
<th>COBOL Program</th>
</tr>
</thead>
<tbody>
<tr>
<td>void COBRTN(int);</td>
<td>01 X PIC S9(9) BINARY.</td>
</tr>
<tr>
<td>COBRTN(x); /* x by value */</td>
<td>PROCEDURE DIVISION USING BY VALUE X.</td>
</tr>
</tbody>
</table>

**Declaration for COBOL Calling C:**

<table>
<thead>
<tr>
<th>COBOL Program</th>
<th>C Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>01 X PIC S9(9) BINARY.</td>
<td>void CENTRY(int x) {</td>
</tr>
<tr>
<td>CALL &quot;CENTRY&quot; USING BY VALUE X.</td>
<td>}</td>
</tr>
</tbody>
</table>

#### Declaring C to COBOL ILC with `#pragma Linkage`

**Declaration for C Calling COBOL:**

<table>
<thead>
<tr>
<th>C Function</th>
<th>COBOL Program</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>#pragma linkage(CBLRTN,COBOL)</code></td>
<td>01 P1 PIC S9(9) USAGE IS BINARY</td>

**Calling between C and COBOL**

This section describes the types of calls permitted between C and COBOL, and considerations when using dynamic calls and fetch.

**Types of Calls Permitted**

The following tables describe the types of calls that are supported between C and COBOL when running with Language Environment.

- [Table 8 on page 32](#) shows which calls are supported from COBOL programs to C routines that use #pragma linkage(...,COBOL).
- [Table 9 on page 33](#) shows which calls are supported from COBOL programs to C routines that do not use #pragma linkage(...,COBOL).
- [Table 10 on page 33](#) shows which calls are supported from C routines to COBOL programs.

</tr>
</tbody>
</table>

Notes:
1. When the caller is VS COBOL II or COBOL/370, all calls must be to void functions.
2. Static calls are supported from VS COBOL II to reentrant C in the following cases:
   - The call is done in the main load module.
   - The call is done in a load module whose entry point is an LE-conforming program or routine that was called using COBOL dynamic call.
   - The call is done in a load module whose entry point is not an LE-conforming program or routine that was called using COBOL dynamic call, and there are no C routines in the main load module, and no reentrant C routines have been previously called in any other load module.
   - The call is done in a module that was called using C fetch.
3. Dynamically called load modules cannot contain any DLL routines that export functions or variables.
4. In this case, the C code can also be compiled with the XPLINK option. The XPLINK option implies the DLL option — all XPLINK compiled code is automatically DLL-enabled. The XPLINK C code must reside in a separate module from the COBOL caller.
5. COBOL for MVS & VM, COBOL for OS/390 & VM, or Enterprise COBOL for z/OS.
6. COBOL for OS/390 & VM or Enterprise COBOL for z/OS

</tbody>
</table>

Notes:
1. For VS COBOL II or COBOL/370, #pragma linkage(...,COBOL) is required.
2. Static calls are supported for calls from COBOL for MVS & VM, COBOL for OS/390 & VM, or Enterprise COBOL for z/OS compiled with NODLL to reentrant C that exports functions or variables in the following cases:
   - The call is done in the main load module.
   - The call is done in a DLL that was called using DLL linkage.
3. Dynamically called load modules cannot contain any DLL routines that export functions or variables.
4. In this case, the C code can also be compiled with the XPLINK option. The XPLINK option implies the DLL option — all XPLINK compiled code is automatically DLL-enabled. The XPLINK C code must reside in a separate module from the COBOL caller.
5. COBOL for MVS & VM, COBOL for OS/390 & VM, or Enterprise COBOL for z/OS.
6. COBOL for OS/390 & VM or Enterprise COBOL for z/OS.

Notes:
1. When the target of the call is VS COBOL II or COBOL/370, the called COBOL program must be declared as a void function.
2. Fetched COBOL load modules cannot contain any DLL routines that export functions or variables.
3. COBOL for MVS & VM, COBOL for OS/390 & VM, or Enterprise COBOL for z/OS.
4. COBOL for OS/390 & VM or Enterprise COBOL for z/OS.

Performance Considerations
The performance of COBOL calling C is best when #pragma linkage(...,COBOL) is not used.
Dynamic Call/Fetch Considerations - non-DLL Modules

Both C and COBOL provide language constructs that support the dynamic loading, execution, and deletion of user-written routines. The C fetch() library function dynamically loads a load module that you specify into main storage. The module can be invoked subsequently from a C application (see z/OS XL C/C++ Programming Guide for more information about fetch()). In COBOL, you can use the dynamic CALL statement to dynamically load a load module into main storage (see Enterprise COBOL for z/OS Programming Guide, COBOL for OS/390 & VM Programming Guide, or COBOL for MVS & VM Programming Guide for more information about the CALL statement).

Both C and COBOL support multiple-level fetches or dynamic calls (for example, Routine 1 fetches Routine 2, which in turn fetches Routine 3, and so forth).

User-written condition handlers registered using CEEHDLR can be fetched, but must be written in the same language as the fetching language.

C Fetching C with COBOL Statically Linked
ILC between C and COBOL is supported within both a fetching C load module and a fetched C load module.

C Fetching COBOL
You can use the C fetch() function to fetch a COBOL program and invoke it later using a function pointer. The declaration of a COBOL fetched program within a C routine is shown in Figure 6. The figure indicates C fetching either an Enterprise COBOL for z/OS or COBOL for OS/390 & VM program or a COBOL for MVS & VM program. If COBOL/370 or VS COBOL II were used, the C #pragma linkage directive would be used, as #pragma linkage(CBL_FUNC, COBOL).

```
typedef void CBL_FUNC();
   ...
   ...

CBL_FUNC *fetch_ptr;
fetch_ptr = (CBL_FUNC*) fetch("COBEP"); /* fetch the routine */
fetch_ptr(args); /* call COBEP */
```

Figure 6. C Fetching a COBOL Program

You can use the C release() function to release a COBOL program that was explicitly loaded by fetch(). A COBOL CANCEL cannot be issued against any routine dynamically loaded using the C fetch() function.

COBOL Dynamically Calling COBOL with C Statically Linked
ILC between COBOL and C is supported within both a dynamically calling COBOL load module and a dynamically called COBOL load module.

Restriction: COBOL cannot dynamically call a C function that has been compiled XPLINK.
**COBOL Dynamically Calling Non-LE Conforming Assembler with C Statically Linked**

COBOL can dynamically call non-LE conforming assembler which then calls a statically linked C routine provided the C routine is non-reentrant or naturally reentrant (no writable static). The C routine must have the #pragma linkage(...,COBOL) directive coded.

**Note:** If C has not yet been initialized, calling a reentrant C routine will work. The C routine must have the #pragma linkage(...,COBOL) directive coded. Due to the difficulty of the user insuring that C has not yet been initialized, IBM recommends the use of one of the methods described below.

A preferable method would be to have COBOL dynamically call the C routine directly or have COBOL dynamically call LE conforming assembler which then calls a statically linked C routine. In these cases there would be no reentrancy restrictions.

**Cancel Considerations**

A COBOL program can use the CANCEL statement to cancel a load module that contains C.

**COBOL Dynamically Calling C**

A COBOL program can dynamically CALL a C routine.

**Dynamic Call/Fetch Considerations - DLL Modules**

A DLL module differs from a regular load module in that the original source code was compiled using the DLL option of the XL C or COBOL compiler, and then uses the prelinker or binder facilities to import or export symbols.

**Restriction:** The DLL approach versus the COBOL dynamic call/C fetch approach are two different mechanisms for achieving the goal of structuring the application as multiple, separate modules. The two approaches don’t mix, however. One or the other should be chosen. [Enterprise COBOL for z/OS Programming Guide] and [COBOL for OS/390 & VM Programming Guide] explain this in some detail and gives some trade-offs between the DLL approach and the dynamic call approach. See also [z/OS Language Environment Programming Guide] or [z/OS XL C/C++ Programming Guide].

**Passing Data between C and COBOL**

In VS COBOL II and COBOL/370, you can pass parameters two ways:

**By reference (indirect)**

COBOL BY REFERENCE

**By value (indirect)**

COBOL BY CONTENT

In Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM, you can pass parameters three ways:

**By reference (indirect)**

COBOL BY REFERENCE

**By value (indirect)**

COBOL BY CONTENT
By value (direct)  
COBOL BY VALUE

Under Language Environment, the term by value means that a temporary copy of the argument is passed to the called function or procedure. Any changes to the parameter made by the called routine will not alter the original parameter passed by the calling routine. Under Language Environment, the term by reference means that the actual address of the argument is passed. Any changes to the parameter made by the called routine can alter the original parameter passed by the calling routine.

Further, the term direct means that the argument is passed in the parameter list. The term indirect means that a pointer to the argument is passed in the parameter list.

There are two ways to pass data between C and COBOL: one way uses #pragma linkage in the C routine; the other does not. Both methods are discussed separately below.

Passing Data between C and COBOL without #pragma

Passing Data by Value between C and COBOL
Copies of variables can be passed between C and COBOL. On return, the actual value of the variable remains unchanged, regardless of how it may have been modified in the called routine.

Passing by Value (Direct): To pass data by value (direct) from C to COBOL, the variables are passed by C as arguments on a function call and received by COBOL as BY VALUE parameters. Conversely, to pass data by value (direct) from COBOL to C, the variables are passed by COBOL as BY VALUE arguments and received by C as function parameters. In all cases, the variable must be declared in C and COBOL with compatible base data types. For example, if a C function called FROMCOB is to receive a parameter passed by value (direct) of type int, the function prototype declaration would look like this:

```c
void FROMCOB(int)
```

Passing by Value (Indirect): Data cannot be passed from C to COBOL; however, data can be passed by value (indirect) from COBOL to C. In this case, the variable is passed as a BY CONTENT argument and received by C as a pointer to the given type. For example, if a C function called FROMCOB is to receive a parameter passed by value (indirect) of type int, the function prototype declaration would look like this:

```c
void FROMCOB(int *)
```

The C function must dereference the pointer to access the actual value. If the value of the pointer is modified by the C function, as opposed to modifying the value that the pointer points to, the results on return to COBOL are unpredictable. Thus,
passing values by value (indirect) from COBOL to C should be used with caution, and only in cases where the exact behavior of the C function is known. Table 11 shows the supported data types for passing by value (direct) and Table 12 on page 39 shows the supported data types for passing by value (indirect).

**Passing Data by Reference (Indirect) between C and COBOL**

A parameter can be passed by reference (indirect) between C and COBOL. By reference (indirect) means that the actual address of the argument is passed to the called function or procedure; any changes to the parameter made by the called routine can alter the original parameter passed by the calling routine.

To pass data by reference (indirect) from C to COBOL, the variables are passed by C as function arguments, which are pointers to a given type or the address of a given variable, and received by COBOL as BY REFERENCE parameters. Conversely, to pass data by reference (indirect) from COBOL to C, the variables are passed by COBOL as BY REFERENCE arguments and received by the C function as pointers to a given type.

The C function must dereference the pointer to access the actual value. If the value of the pointer is modified by the C function, as opposed to modifying the value that the pointer points to, the results on return to COBOL are unpredictable. Thus, passing values by reference (indirect) from COBOL to C should be used with caution, and only in cases where the exact behavior of the C function is known.

Table 12 on page 39 shows the supported data types for passing by reference (indirect).

**Supported Data Types Passed by Value (Direct) between C and COBOL**

Table 11 identifies the data types that can be passed by value (direct) as parameters between C and COBOL applications.

<table>
<thead>
<tr>

</tbody>
</table>

**Note:** The COBOL program should be compiled with the TRUNC(BIN) compiler option if it receives int parameters from the C calling function that may have a value larger than that declared as the maximum size by the COBOL picture clause. (See [Enterprise COBOL for z/OS Programming Guide](https://www.ibm.com/docs/en/cobol-aparj06509) or [COBOL for OS/390 & VM Programming Guide](https://www.ibm.com/docs/en/cobol-aparj06509) for more information about the TRUNC(BIN) compiler option.)
Supported Data Types Passed between C and COBOL by Reference (Indirect) and from COBOL to C either by Value (Indirect) or by Reference (Indirect)

Table 12 identifies the data types that can be passed between C and COBOL by Reference (Indirect) and from COBOL to C either by Value (Indirect) or by Reference (Indirect).

Table 12. Supported Data Types Passed between C and COBOL by Reference (Indirect) and from COBOL to C either by Value (Indirect) or by Reference (Indirect) without #pragma

<table>
<thead>
<tr>
<th>C (Pointer To...)</th>
<th>COBOL (BY CONTENT/BY REFERENCE)</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>
<td>PIC X, PIC A</td>
</tr>
<tr>

<td>USAGE IS PACKED-DECIMAL</td>
</tr>
<tr>
<td>struct</td>
<td>Groups</td>
</tr>
<tr>
<td>type array[n]</td>
<td>Tables (OCCURS n TIMES)</td>
</tr>
</tbody>
</table>

Notes:

1. You must specify a size for type array.

2. The COBOL program should be compiled with the TRUNC(BIN) compiler option if it receives int parameters from the C calling function that may have a value larger than that declared as the maximum size by the COBOL picture clause. (See Enterprise COBOL for z/OS Programming Guide or COBOL for OS/390 & VM Programming Guide for more information about the TRUNC(BIN) compiler option.)

3. COBOL turns on the high order bit of the address of the last parameter when it is passed by reference. This can cause problems in the C program if it is using the address (since it will be treated as a negative number). If a C program does need to use the address of the last parameter, one of the following techniques can be used to bypass this problem:

   • If the COBOL program is an Enterprise COBOL program, instead of passing the parameter by reference, pass the address of the item by value. For example, use a call statement that looks like this:

     ```
     CALL "C" using by value address of C-PARM1
      by value address of C-PARM2
     ```

   • If the COBOL program is not Enterprise COBOL, code needs to be added to mask out the high-order bit in the C routine. The sample code below shows how to do this:

     ```c
     #include <stdio.h>
     #include <string.h>
     void A1CC01BA(char* myString)
     {
         myString = (char*)((int)myString & 0x7fffffff);
         printf("My String: %s \n", myString);
         return;
     }
     ```
Handling Function Returns between C and COBOL

In COBOL, values can be returned to COBOL programs as COBOL returning variables from C functions using standard C function returns. This is the recommended approach for passing modified values back from a C function to a COBOL program.

**Note:** When a COBOL program calls a void C function, the RETURN-CODE special register contents will be unpredictable upon return from the call.

The following examples illustrate how to declare data types for using function returns in C to COBOL applications.

### Declaration for C Calling COBOL

**Sample C Usage**

```c
#include <stdio.h>
void cobrtn (int);

int main()
{
    int x,y;
    x=1;
    y=cobrtn(x); /* x by value */
    printf("y=%i.",y);
}
```

**COBOL Subroutine**

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 A PIC 9(9) USAGE IS BINARY.
01 B PIC 9(9) USAGE IS BINARY.
PROCEDURE DIVISION USING BY VALUE A
RETURNING B.
    COMPUTE B = A + 1
    GOBACK.
END PROGRAM COBRTN.
```

### Declaration for COBOL Calling C

**COBOL Program**

```
LINKAGE SECTION.
01 A PIC 9(9) USAGE IS BINARY
01 B PIC 9(9) USAGE IS BINARY
CALL 'CFUNC' USING BY VALUE A
    RETURNING B.
```

**C Function**

```c
int CFUNC(int p1){
    int p2;
    p2=p1;
    return p2;
}
```

### Passing Data between C and COBOL with #pragma

**Note**

The reference to COBOL with #pragma applies to VS COBOL II, COBOL/370, COBOL for MVS & VM, COBOL for OS/390 & VM, and Enterprise COBOL for z/OS.

When data is passed between C and COBOL with #pragma linkage (COBOL), the C compiler generates the appropriate addressing code which introduces an extra level of indirection on the C side for non-pointer types. Pointers, however, are passed directly, meaning that for COBOL to receive a pointer to a C data type, C must pass a pointer to a pointer to the C data type. Conversely, if COBOL returns a pointer to a data type, C receives a pointer to a pointer to the data type.
Passing Data by Value (Indirect) between C and COBOL

Copies of variables can be passed between C and COBOL routines. On return, the actual value of the variables remains unchanged regardless of how it may have been modified in the called routine.

Value arguments can be passed BY CONTENT from COBOL programs and received as C function parameters when declared with the appropriate base type. Conversely, C function arguments can be passed by value from C functions and received as COBOL parameters. The C compiler generates the appropriate addressing code required to access the parameter values; you can write your C function, which interoperates with COBOL, as if it were in a C-only environment. It can be moved to a C-only environment simply by removing the #pragma linkage directive. For example, if a C function called FROMCOB is to receive a parameter passed BY CONTENT of type int, the function prototype declaration would look like this:

```c
void FROMCOB(int)
```

Table 13 shows the supported data types for passing by value (indirect).

Supported Data Types Passed by Value (Indirect) between C and COBOL

Table 13 identifies the data types that can be passed by value (indirect) as parameters between C and COBOL.

<table>
<thead>
<tr>
<th>C Type</th>
<th>COBOL Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed int, signed long int</td>
<td>PIC S9(9) USAGE IS BINARY</td>
</tr>
<tr>
<td>double</td>
<td>COMP-2</td>
</tr>

<td>POINTER, ADDRESS OF</td>
</tr>
<tr>
<td>struct</td>
<td>Groups</td>
</tr>
<tr>
<td>type array[n]</td>
<td>Tables (OCCURS n TIMES)</td>
</tr>
</tbody>
</table>

Passing Data by Reference (Indirect) between C and COBOL

A parameter can be passed by reference (indirect) between C and COBOL, which means the actual address of the argument is passed to the called function or procedure; any changes to the parameter made by the called routine can alter the original parameter passed by the calling routine.

To pass data by reference (indirect) from C to COBOL, the variables are passed by C as function arguments, which are pointers to a given type or the address of a given variable, and received as COBOL parameters. Conversely, to pass data by reference (indirect) from COBOL to C, the variables are passed from COBOL as BY REFERENCE arguments and received by a C function as pointers to a given type. For example, if a C function called FROMCOB is to receive a parameter passed by reference (indirect) of type int, the function prototype declaration would look like this:

```c
void FROMCOB(int *)
```

The C function must dereference the pointer to access the actual value. If the value of the pointer is modified by the C function, as opposed to modifying the value that the pointer points to, the results on return to COBOL are unpredictable. Therefore, passing values by reference (indirect) from COBOL to C should be used with caution, and only in cases where the exact behavior of the C function is known.
Table 14 shows the supported data types for passing by reference (indirect).

**Supported Data Types Passed by Reference (Indirect) between C and COBOL**

Table 14 identifies the data types that can be passed by reference (indirect) between C and COBOL.

**Passing Strings between C and COBOL**

C and COBOL have different string data types:

**C strings**

Available as logically unbounded length and are terminated by a NULL (the last byte of the string contains X’00’)

**COBOL PIC X**(n)

Available as fixed-length string of characters of length **n**

You can pass strings between COBOL and C routines, but you must match what the routine interface demands with what is physically passed. Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM both have strings like previous COBOLs, as well as null-terminated literal strings like C.

Refer to "Sample ILC Applications" on page 57 to see how string data is passed between C and COBOL.

**Using Aggregates**

Aggregates (arrays, strings, or structures) are mapped differently by C and COBOL and are not automatically mapped. You must completely declare every byte in the structure to ensure that the layouts of structures passed between the two languages map to one another correctly. The XL C compile-time option AGGREGATE and the COBOL compiler option MAP provide a layout of structures to help you perform the mapping.

**Data Equivalents**

This section describes how C and COBOL data types correspond to each other.

**Equivalent Data Types for C to COBOL**

The following examples illustrate how C and COBOL routines within a single ILC application might code the same data types.
Note

In the declarations that follow, examples showing the use of COBOL without #pragma apply only to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM. The examples showing COBOL with #pragma apply to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, and VS COBOL II.

One-Byte Character Data without #pragma

Sample C Usage
```c
#include <stdio.h>
void cobrtn (char);

int main()
{
    char x;
    x='a';
    cobrtn(x); /* x by value */
}
```

COBOL Subroutine
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
01 X PIC X.
PROCEDURE DIVISION USING BY VALUE X.
   DISPLAY X.
   GOBACK.
END PROGRAM COBRTN.
```

One-Byte Character Data with #pragma

Sample C Usage
```c
#include <stdio.h>
void cobrtn (char*);

int main()
{
    char x;
    x='a';
    cobrtn(&x); /* x by reference */
}
```

COBOL Subroutine
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
01 X PIC X.
PROCEDURE DIVISION USING X.
   DISPLAY X.
   GOBACK.
END PROGRAM COBRTN.
```

16-Bit Signed Binary Integer without #pragma

Sample C Usage
```c
#include <stdio.h>
void cobrtn (short int);

int main()
{
    short int x;
    x=5;
    cobrtn(x); /* x by value */
}
```

COBOL Subroutine
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
01 X PIC 9(4) BINARY.
PROCEDURE DIVISION USING BY VALUE X.
   DISPLAY X.
   GOBACK.
END PROGRAM COBRTN.
```
16-Bit Signed Binary Integer with #pragma

Sample C Usage
```c
#include <stdio.h>
void cobrtn (short int *);

int main()
{
    short int x;
    x=5;
    cobrtn(&x); /* x by reference */
}
```

COBOL Subroutine
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 X PIC S9(4) BINARY.
PROCEDURE DIVISION USING X.
    DISPLAY X
    GOBACK.
END PROGRAM COBRTN.
```

32-Bit Signed Binary Integer without #pragma

Sample C Usage
```c
#include <stdio.h>
void cobrtn (int);

int main()
{
    int x;
    x=5;
    cobrtn(x); /* x by value */
}
```

COBOL Subroutine
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 X PIC S9(9) BINARY.
PROCEDURE DIVISION USING BY VALUE X.
    DISPLAY X.
    GOBACK.
END PROGRAM COBRTN.
```

32-Bit Signed Binary Integer with #pragma

Sample C Usage
```c
#include <stdio.h>
void cobrtn (int, int *);

int main()
{
    int x,y;
    x=5;
    y=6;
    cobrtn(x,y); /* x by value */
    /* y by reference */
}
```

COBOL Subroutine
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 X PIC S9(9) BINARY.
01 Y PIC S9(9) BINARY.
PROCEDURE DIVISION USING X Y.
    DISPLAY X Y.
    GOBACK.
END PROGRAM COBRTN.
```

Long Floating-Point Number without #pragma

Sample C Usage
```c
#include <stdio.h>
void cobrtn (double);

int main()
{
    double x;
    x=3.14159265;
    cobrtn(x); /* x by value */
}
```

COBOL Subroutine
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 X COMP-2.
PROCEDURE DIVISION USING BY VALUE X.
    DISPLAY Y.
    GOBACK.
END PROGRAM COBRTN.
```
## Long Floating-Point Number with #pragma

**Sample C Usage**
```c
#include <stdio.h>
void cobrtn (double, double*);

int main()
{
    double x,y;
    x=3.14159265;
    y=4.14159265;
    cobrtn(x,&y); /* x by value */
} /* y by reference */
```

**COBOL Subroutine**
```
IDENTIFICATION DIVISION.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
  01 X COMP-2.
  01 Y COMP-2.
PROCEDURE DIVISION USING X Y.
    DISPLAY X Y.
    GOBACK.
END PROGRAM COBRTN.
```

## Structure with #pragma

**Sample C Usage**
```c
#include <stdio.h>
#include <string.h>
struct stype {
    int s1;
    int s2;
};
void cobrtn (struct stype, struct stype*);

int main()
{
    struct stype struc1, struc2;
    struc1.s1=1;
    struc1.s2=2;
    struc2.s1=3;
    struc2.s2=4;
    cobrtn(struc1,&struc2); /* struc1 by value */
} /* struc2 by reference */
```

**COBOL Subroutine**
```
IDENTIFICATION DIVISION.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
  01 STRUC1.
    05 S11 PIC S9(9) BINARY.
    05 S12 PIC S9(9) BINARY.
  01 STRUC2.
    05 S21 PIC S9(9) BINARY.
    05 S22 PIC S9(9) BINARY.
PROCEDURE DIVISION USING STRUC1 STRUC2.
    DISPLAY S11 S12 S21 S22.
    GOBACK.
END PROGRAM COBRTN.
```

## Array with #pragma

**Sample C Usage**
```c
#include <stdio.h>
void cobrtn (int array[2]);

int main()
{
    int array[2];
    array[0]=1;
    array[1]=2;
    cobrtn(array); /* array by reference */
}
```

**COBOL Subroutine**
```
IDENTIFICATION DIVISION.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
  01 ARRAY.
    05 ELE PIC S9(9) BINARY OCCURS 2.
PROCEDURE DIVISION USING ARRAY.
    DISPLAY ELE(1) ELE(2).
    GOBACK.
END PROGRAM COBRTN.
```

## Fixed-Length Decimal Data with #pragma

**Sample C Usage**
```c
#include <stdio.h>
#include <decimal.h>
void cobrtn (decimal(5,2)*);

int main()
{
    decimal(5,2) x;
    x=123.45d;
    cobrtn(&x); /* x by reference */
}
```

**COBOL Subroutine**
```
IDENTIFICATION DIVISION.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
  01 X PIC 999999999999999 COMP-3.
PROCEDURE DIVISION USING X.
    DISPLAY X.
    GOBACK.
END PROGRAM COBRTN.
```
Equivalent Data Types for COBOL to C

The following examples illustrate how COBOL to C routines within a single ILC application might code the same data types.

**Note**

In the declarations that follow, examples showing the use of COBOL without #pragma apply only to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM. The examples showing COBOL with #pragma apply to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, and VS COBOL II.

### 32-Bit Signed Binary Integer without #pragma

**Sample COBOL Usage**

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
01 X PIC S9(9) BINARY.
01 Y PIC S9(9) BINARY.
PROCEDURE DIVISION.
   MOVE1 TO X.
   * X BY VALUE ***
   CALL "CENTRY" USING BY VALUE X
   GOBACK.
END PROGRAM COBRTN.
```

**C Function**

```c
#include <stdio.h>

int centry(int x)
{
    int y=2;
    printf("%d %d \n",x,y);
    return y;
}
```

### 32-bit Signed Binary Integer with #pragma

**Sample COBOL Usage**

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
01 X PIC S9(9) BINARY.
01 Y PIC S9(9) BINARY.
PROCEDURE DIVISION.
   MOVE1 TO X.
   MOVE2 TO Y.
   * X BY VALUE, Y BY REFERENCE ***
   CALL "CENTRY" USING BY CONTENT X
   BY REFERENCE Y.
   GOBACK.
END PROGRAM COBRTN.
```

**C Function**

```c
#pragma linkage (centry,COBOL)
#include <stdio.h>

void centry (int x, int *y)
{
    printf("%d %d \n",x,*y);
    return;
}
```
Long Floating-Point Number without #pragma

Sample COBOL Usage
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
01 X COMP-2.
01 Y COMP-2.
PROCEDURE DIVISION.
MOVE 3.14159265 TO X.
* X BY VALUE ***
   CALL "CENTRY" USING BY VALUE X
   RETURNING Y.
GOBACK.
END PROGRAM COBRTN.

C Function
#include <stdio.h>
double centry (double x)
{
    double y=4.14159265;
    printf("%f %f \n",x,y);
    return y;
}

Long Floating-Point Number with #pragma

Sample COBOL Usage
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
01 X COMP-2.
01 Y COMP-2.
PROCEDURE DIVISION.
MOVE 3.14159265 TO X.
* X BY VALUE ***
   CALL "CENTRY" USING BY CONTENT X
   BY REFERENCE Y.
GOBACK.
END PROGRAM COBRTN.

C Function
#pragma linkage (centry,COBOL)
#include <stdio.h>
void centry (double x, double *y)
{
    printf("%f %f \n",x,*y);
    return;
}

Structure without #pragma

Sample COBOL Usage
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
01 STRUC1.
   05 S11 PIC S9(9) BINARY.
   05 S12 PIC S9(9) BINARY.
PROCEDURE DIVISION.

GOBACK.
END PROGRAM COBRTN.

C Function
#include <stdio.h>
struct stype {
    int s1;
    int s2; ;};
struct stype centry()
{
    struct stype struc2;
    struc2.s1=3;
    struc2.s2=4;
    return struc2;
}
**Structure with #pragma**

Sample COBOL Usage

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
 01 STRUC1.
    05 S11 PIC S9(9) BINARY VALUE 1.
    05 S12 PIC S9(9) BINARY VALUE 2.
 01 STRUC2.
    05 S21 PIC S9(9) BINARY VALUE 3.
    05 S22 PIC S9(9) BINARY VALUE 4.
PROCEDURE DIVISION.
  * STRUC1 BY VALUE**
  * STRUC2 BY REFERENCE ***
    CALL "CENTRY" USING BY CONTENT STRUC1
                    BY REFERENCE STRUC2.
GOBACK.
END PROGRAM COBRTN.
```

C Function

```c
#include <stdio.h>
struct stype {
    int s1;
    int s2;
};
void centry (struct stype struc1,  
             struct stype *struc2)  
{  
    printf("%d %d %d %d \n",struc1.s1,  
                struc1.s2,struc2->s1,struc2->s2);
    return;
}
```

**Fixed-Length Decimal Data without #pragma**

Sample COBOL Usage

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
 01 X PIC 999V99 COMP-3.
PROCEDURE DIVISION.
    CALL "CENTRY" RETURNING X.
GOBACK.
END PROGRAM COBRTN.
```

C Function

```c
#include <stdio.h>
#include <decimal.h>
decimal(5,2) centry()  
{  
    decimal(5,2) x=123.45;  
    printf("%D(5,2)\n",x);  
    return x;
}
```

**Fixed-Length Decimal Data with #pragma**

Sample COBOL Usage

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
 01 X PIC 999V99 COMP-3.
PROCEDURE DIVISION.
    MOVE 123.45 TO X.
    * X BY REFERENCE ***
    CALL "CENTRY" USING X.
GOBACK.
END PROGRAM COBRTN.
```

C Function

```c
#pragma linkage (centry,COBOL)
#include <stdio.h>
#include <decimal.h>
void centry (decimal(5,2) x)  
{  
    printf("%D(5,2)\n",x);  
    return;
}
```

**Name Scope of External Data**

In programming languages, the name scope is defined as the portion of an application within which a particular declaration applies or is known. The name scope of external data differs between C and COBOL. The scope of external data under C is the load module; under COBOL, it is the enclave (or run unit). Figures 7 on page 49 and Figure 8 on page 50 illustrate these differences.

Because the name scope for C and COBOL is different, external variables do not map between C and COBOL; external variables with the same name are considered separate between C and COBOL.

If your application relies on the separation of external data, do not give the data the same name in both languages within a single application. If you give the data in
each load module a different name, you can change the language mix in the application later, and your application still behaves as you expect it to.

**DLL Considerations**

In DLL code, external variables are mapped across the load module boundary. DLLs are shared at the enclave level. Therefore, a single copy of a DLL applies to all modules in an enclave, regardless of whether the DLL is loaded implicitly (through a reference to a function or variable) or explicitly (through `dllload()`). See [z/OS Language Environment Programming Guide](http://example.com) for information on building and managing DLL code in your applications.

COBOL data declared with the EXTERNAL attribute are independent of DLL support. These data items are managed by the COBOL run-time, and are accessible by name from any COBOL program in the run-unit that declares them, regardless of whether the programs are in DLLs or not.

In particular, the facilities for exporting and importing external variables from DLLs implemented in z/OS C/C++ do not apply to COBOL external data. Hence C/C++ external data and COBOL external data are always in separate name spaces, regardless of DLL considerations.

For C/C++, non-DLL applications have external data which is only shared within the load module.

However, for DLL applications, C/C++ external data is now (optionally) accessible to all C/C++ routines in the enclave.

**Name Scope of External Data in a C Application**

![Diagram showing name scope of external variables for C fetch](image)

*Figure 7. Name Scope of External Variables for C Fetch*

In Figure 7, external data declared in C Routine 1 maps to that declared in C Routine 2 in the same load module. When a fetch to C Routine 3 in another load module is made, the external data does not map, because the name scope of external data in C is the load module.
Name Scope of External Data in a COBOL Run Unit

In Figure 8, Routines 1, 2, and 3 comprise a COBOL run unit. External data declared in COBOL Program 1 maps to that declared in COBOL Program 2 in the same load module. When a dynamic CALL to COBOL Program 3 in another load module is made, the external data still maps, because the name scope of external data in COBOL is the enclave.

Name Space of External Data

In programming languages, the name space is defined as the portion of a load module within which a particular declaration applies or is known. Like the name scope, the name space of external data differs between C and COBOL.

Figure 9 and Figure 10 illustrate that within the same load module, the name space of COBOL programs is the same. However, the name spaces of a COBOL program and a C routine within the same load module are not the same. If you give external data the same name in both languages, an incompatibility in external data mapping can occur.
Directing Output in ILC Applications

C and COBOL do not share files, except the Language Environment message file (the ddname specified in the Language Environment MSGFILE run-time option). You must manage all other files to ensure that no conflicts arise. Performing I/O operations on the same ddname might cause abnormal termination.

Under C, run-time messages and other related output are directed to the default MSGFILE ddname. stderr output is also by default directed to the MSGFILE ddname. stdout is not by default directed to the MSGFILE ddname, but can be redirected to do so. Also, output from printf can be interspersed with output from the COBOL DISPLAY statement and output from Language Environment by redirecting stdout to stderr (for example, passing 1>&2 as a command line parameter).

For more information on how to redirect C output, see z/OS XL C/C++ Programming Guide.

Under COBOL, run-time messages and other related output are directed to the MSGFILE ddname. Output from COBOL DISPLAY UPON SYSOUT is directed to the default MSGFILE ddname only when the OUTDD compiler option ddname matches the MSGFILE ddname; this applies to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, and VS COBOL II.

Interspersing Output When C is the Main Routine

To intersperse output from C and COBOL when the main routine is in C, compile your COBOL program with the default OUTDD (OUTDD=SYSOUT) if you are using the default MSGFILE ddname. If you have overridden the default MSGFILE ddname, you must compile your COBOL program using an OUTDD that specifies the same name as the MSGFILE. You must redirect stdout to stderr for the main C routine.

Interspersing Output when COBOL is the Main Routine

To intersperse output from C and COBOL when the main program is in COBOL, compile your COBOL program with the default OUTDD (OUTDD=SYSOUT). In the C routine, redirect stdout to stderr by placing the line stdout=stderr in your
program. If you have overridden the default MSGFILE ddname, you must compile your COBOL program using an OUTDD ddname that specifies the same name as the MSGFILE.

C POSIX Multithreading

COBOL programs can run in more than one thread as long as all of the COBOL programs used in the enclave are enabled for multithreading.

A COBOL program is enabled for multithreading when it is compiled with the Enterprise COBOL for z/OS compiler using the THREAD compiler option.

A COBOL program is not enabled for multithreading when it is compiled with any of the following compilers:

- Enterprise COBOL for z/OS (with the NOTHREAD compiler option)
- COBOL for OS/390 & VM
- COBOL for MVS & VM
- COBOL/370
- VS COBOL II

POSIX-conforming C/C++ applications can communicate with COBOL programs enabled for multithreading on one or more threads.

POSIX-conforming C/C++ applications can communicate with COBOL programs not enabled for multithreading; however, there are limitations in the support:

- COBOL can only be used in one thread.
- When COBOL is run in a thread that is not the initial process thread (IPT), there is no support to dynamically call a program that contains C/C++ writeable static.
- When COBOL is run in a thread that is not the initial thread and the thread terminates, COBOL frees the resources it acquired except for any DLLs it loaded. The freeing of resources includes deleting any load modules it loaded for dynamic call processing.

POSIX-conforming C/370 applications can communicate with assembler routines on any thread when the assembler routines use the CEEENTRY/CEETERM macros or the EDCPRLG/EDCEPIL macros provided by C/C++.

C to COBOL Condition Handling

This section provides two scenarios of condition handling behavior in a C to COBOL ILC application. If an exception occurs in a C routine, the set of possible actions is as described in "Exception Occurs in C" on page 53. If an exception occurs in a COBOL program, the set of possible actions is as described in "Exception Occurs in COBOL" on page 55.

Keep in mind that some conditions can be handled only by the HLL of the routine in which the exception occurred. For example, in a COBOL program, a statement can have a clause that adds condition handling to a verb, such as the ON SIZE ERROR clause of a COBOL DIVIDE verb (which includes the logical equivalent of a divide-by-zero condition). This type of condition is handled completely within COBOL.

For a detailed description of Language Environment condition handling, see z/OS Language Environment Programming Guide.
Enclave-Terminating Language Constructs

Enclaves can be terminated for reasons other than an unhandled condition of severity 2 or greater. In Language Environment ILC, you can issue an HLL language construct to terminate a C to COBOL enclave from either a COBOL or C routine.

**C**

Examples of C language constructs that terminate the enclave are: `kill()`, `abort()`, `raise(SIGTERM)`, `raise(SIGABND)`, and `exit()`. When you use a C language construct to terminate an enclave, the T_I_S (Termination Imminent Due to STOP) condition is raised. After T_I_S has been processed and all user code has been removed from the stack, the C atexit list is honored.

**COBOL**

The COBOL language constructs that cause the enclave to terminate are:

- **STOP RUN**
  
  STOP RUN is equivalent to the C `exit()` function. If you code a STOP RUN statement, the T_I_S (Termination Imminent Due to STOP) condition is raised. After T_I_S has been processed and all user code has been removed from the stack, the C atexit list is honored.

- **Call to ILBOABN0 or CEE3ABD**

  Calling ILBOABN0 or CEE3ABD causes T_I_U to be signaled. Condition handlers are given a chance to handle the abend. If the abend remains unhandled, normal Language Environment termination activities occur. For example, the C atexit list is honored and the Language Environment assembler user exit gains control.

  User-written condition handlers written in COBOL must be compiled with Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, or COBOL/370.

Exception Occurs in C

In this scenario, a COBOL main program invokes a C subroutine and an exception occurs in the C subroutine. Refer to Figure 11 on page 54 throughout the following discussion.
The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, C determines whether the exception in the C routine should be enabled and treated as a condition. If any of the following are true, the exception is ignored, and processing continues at the next sequential instruction after which the exception occurred:
   - You specified SIG_IGN for the exception in a call to signal().
   - The exception is one of those listed as masked in Table 64 on page 255, and you have not enabled it using the CEE3SPM callable service.
   - You did not specify any action, but the default action for the condition is SIG_IGN (see Table 64 on page 255).
   - You are running under CICS and a CICS handler is pending.

   Note: The system or user abend corresponding to the signal(SIGABND) or the Language Environment message 3250 is not ignored. The enclave is terminated.
   - The exception is one of those listed as masked in Table 64 on page 255, and you have not enabled it using the CEE3SPM callable service.
   - You did not specify any action, but the default action for the condition is SIG_IGN (see Table 64 on page 255).
   - You are running under CICS and a CICS handler is pending.

   If you did none of these things, the condition is enabled and processed as a condition.

2. If a user-written condition handler has been registered using CEEHDLR on the C stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points.

   In this example, there is not a user-written condition handler registered for the condition, so the condition is percolated.

3. The global error table is now examined for signal handlers that have been registered for the condition.

   If there is a signal handler registered for the condition, it is given control. If it issues a resume or a call to longjmp(), the condition handling step ends.
Processing resumes in the routine to which the resume cursor points. You must be careful when issuing a `longjmp()` in an application that contains a COBOL program; see "CEEMRCR and COBOL" on page 57 for details.

In this example no C signal handler is registered for the condition, so the condition is percolated.

4. The condition is still unhandled. If C does not recognize the condition, or if the C default action (listed in Table 64 on page 255) is to terminate, the condition is percolated.

5. If a user-written condition handler has been registered using CEEHDLR on the COBOL stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points. You must be careful when moving the resume cursor in an application that contains a COBOL program; see "CEEMRCR and COBOL" on page 57 for details.

In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

6. If the condition is of severity 0 or 1, the Language Environment default actions take place, as described in Table 63 on page 255.

7. If the condition is of severity 2 or above, Language Environment default action is to promote the condition to T_I_U (Termination Imminent due to an Unhandled condition) and redrive the stack. Condition handling now enters the termination imminent step.

8. If, on the second pass of the stack, no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

**Exception Occurs in COBOL**

In this scenario, a C main routine invokes a COBOL subroutine and an exception occurs in the COBOL subroutine. Refer to Figure 12 on page 56 throughout the following discussion.
The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, COBOL determines if the exception should be ignored or handled as a condition.
   - If the exception is to be ignored, control is returned to the next sequential instruction after where the exception occurred.
   - If the exception is to be enabled and processed as a condition, the condition handling step, described below, takes place.

2. If a user-written condition handler has been registered using CEEHDLR on the COBOL stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points.
   
   In this example, no user-written condition handler is registered for the condition, so the condition is percolated. You must be careful when moving the resume cursor in an application that contains a COBOL program; see CEEMRCR and COBOL for details.

3. If a user-written condition handler has been registered for the condition (as specified in the global error table) using CEEHDLR on the C stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points.
   
   In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

4. If a C signal handler has been registered for the condition, it is given control. If it moves the resume cursor or issues a call to `longjmp()`, the condition handling step ends. Processing resumes in the routine to which the resume cursor points. You must be careful when moving the resume cursor in an application that contains a COBOL program; see "CEEMRCR and COBOL" on page 57 for details.
In this example, no C signal handler is registered for the condition, so the condition is percolated.

5. If the condition has a Facility_ID of IGZ, the condition is COBOL-specific. The COBOL default actions for the condition take place. If COBOL does not recognize the condition, condition handling continues.

6. If the condition is of severity 0 or 1, Language Environment default actions take place, as described in Table 63 on page 255.

7. If the condition is of severity 2 or above, Language Environment default action is to promote the condition to T_I_U (Termination Imminent due to an Unhandled condition) and redrive the stack. Condition handling now enters the termination imminent step.

8. If, on the second pass of the stack, no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

**CEEMRCR and COBOL**

When you make a call to CEEMRCR to move the resume cursor, or issue a call to longjmp(), and a COBOL routine is removed from the stack, the COBOL routine can be re-entered via another call path.

If the terminated routine is one of the following, the routine remains active. If the COBOL program does not specify RECURSIVE in the PROGRAM-ID, a recursion error is raised if you attempt to enter the routine again.

- A VS COBOL II, COBOL/370, COBOL for MVS & VM, or COBOL for OS/390 & VM program compiled with the CMPR2 option
- A VS COBOL II program that does not contain nested programs and is compiled with the NOCMPR2 compiler option
- A COBOL/370, COBOL for MVS & VM, or COBOL for OS/390 & VM program compiled with the NOCMPR2 option that does not use the combination of the INITIAL attribute, nested routines, and file processing in the same compilation unit.
- An Enterprise COBOL for z/OS program that does not use the combination of the INITIAL attribute, nested routines, and file processing in the same compilation unit.

In addition, if the routine is a COBOL routine with the INITIAL attribute and containing files, the files are closed. (COBOL supports VSAM and QSAM files and these files are closed.)

**Sample ILC Applications**

Figure 13 on page 58, Figure 14 on page 59, and Figure 15 on page 60 contain an example of an ILC application. The C C1 routine dynamically calls the COBOL CBL1 program. CBL1 statically calls C routine C2.
/*Module/File Name: EDCCCB */
/**************************************************************************/
/* Illustration of Interlanguage Communication between C/MVS */
/* and COBOL. All parameters passed by reference. */
/* */
/* C1 ==========> CBL1 ---------> C2 */
/* dynamic static */

} /* end of main */

Figure 15. Statically Called C Routine
Chapter 5. Communicating between C++ and COBOL

This chapter describes Language Environment's support for C++ to COBOL ILC applications. If you are running a C++ to COBOL ILC application under CICS, you should also consult Chapter 15, “ILC under CICS,” on page 247.

**General Facts about C++ to COBOL ILC**

- Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM can use the 'C-style' linkage and non-void function return values to pass and receive parameters by value.
- Language Environment does not support the passing of return codes between C++ and COBOL routines in an ILC application.
- There is no ILC support between AMODE 31 and AMODE 64 applications. COBOL does not support AMODE 64.

**Preparing for ILC**

This section describes topics you need to consider before writing a C++ to COBOL ILC application. For help in determining how different versions of HLLs work together, refer to the migration guides for the HLLs you plan to use.

**Language Environment ILC Support**

Language Environment provides ILC support between the following combinations of C++ and COBOL:

<table>
<thead>
<tr>
<th>HLL Pair</th>
<th>C++</th>
<th>COBOL</th>
</tr>
</thead>
<tbody>
<tr>
<td>C++ to COBOL</td>
<td>• IBM C/C++ for MVS/ESA&lt;br&gt;• z/OS XL C/C++ Compilers</td>
<td>• VS COBOL II Version 1&lt;br&gt;Release 3 and later&lt;br&gt;• COBOL/370 Release 1&lt;br&gt;• COBOL for MVS &amp; VM&lt;br&gt;Release 2&lt;br&gt;• COBOL for OS/390 &amp; VM&lt;br&gt;• Enterprise COBOL for z/OS</td>
</tr>
</tbody>
</table>

**Note:** The considerations for ILC support described above apply to all versions of C++ and COBOL listed above, except where otherwise noted. COBOL refers to VS COBOL II, COBOL/370, COBOL for MVS & VM, COBOL for OS/390 & VM, and Enterprise COBOL for z/OS.

**Compiling Considerations**

If the C++ library is installed above the 16M line, compile your COBOL program using the RENT compiler option.

**Determining the Main Routine**

In Language Environment, only one routine can be the main routine; no other routine in the enclave can use syntax that indicates it is main. If you write the main routine in C++, you must use language syntax to identify the routine as the main routine. If you use COBOL as the first program in the enclave that is to gain control, the program is effectively designated main by being the first to run.
Table 16

<table>
<thead>
<tr>
<th>Language</th>
<th>When Determined</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>C++</td>
<td>Compile time</td>
<td>Determined in the C++ source file by declaring a C++ function named main.</td>
</tr>
<tr>
<td>COBOL</td>
<td>Run time</td>
<td>Determined dynamically. If it is the first program to run, it is a main program.</td>
</tr>
</tbody>
</table>

An entry point is defined for each supported HLL. Table 17 identifies the desired entry point. The table assumes that your code has been compiled using the Language Environment-conforming compilers.

Table 17. Determining the Entry Point

<table>
<thead>
<tr>
<th>HLL</th>
<th>Main Entry Point</th>
<th>Fetched Entry Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>C++</td>
<td>CEESTART</td>
<td>Entry point specified as #pragma fetchable, or explicitly named during linkedit</td>
</tr>
<tr>
<td>COBOL</td>
<td>Name of the first object program to get control in the object module</td>
<td>Program name</td>
</tr>
</tbody>
</table>

COBOL and C++ routines that make up an ILC application are executed together in a single run unit (the equivalent of a Language Environment enclave). However, unlike in earlier versions of COBOL (VS COBOL II and OS/VS COBOL), the first COBOL program in a run unit is no longer necessarily considered the main routine. If the first COBOL program is not the first routine in the enclave to run, it is considered a subroutine in the Language Environment enclave.

Declaring C++ to COBOL ILC

If a C++ function invokes a COBOL program or a COBOL program invokes a C++ function, all entry declarations are contained solely within the C++ source. No special declaration is required within the COBOL program.

Declarations for Extern "C" Linkage

With either Enterprise COBOL for z/OS, COBOL for OS/390 & VM, or COBOL for MVS & VM, you can pass and receive parameters using "C-style" linkage and non-void function return values. To use this new function, you must include in your C++ code an extern "C" linkage specification instead of the extern "COBOL" linkage specification.

The extern "C" linkage specification has the following format:

```
extern "C" {declaration}
```

where declaration is a valid C++ prototype of the COBOL program being called by C++, or the C++ routine being called by COBOL

**Note**

The reference to COBOL in the following declarations applies only to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM.
### Declaration for C++ Calling COBOL (extern "C"):

<table>
<thead>
<tr>
<th>C++ Function</th>
<th>COBOL Program</th>
</tr>
</thead>
<tbody>
<tr>
<td>extern &quot;C&quot; { void CBLRTN( double p2 ); }</td>
<td>IDENTIFICATION DIVISION. PROGRAM-ID. CBLRTN. ENVIRONMENT DIVISION. DATA DIVISION. LINKAGE SECTION. 01 X COMP-2. PROCEDURE DIVISION USING BY VALUE X. DISPLAY X GOBACK. END PROGRAM CBLRTN.</td>
</tr>
<tr>
<td>main() { double myval = 5; CBLRTN(myval); printf(&quot;myval=%f\n&quot;,myval); }</td>
<td></td>
</tr>
</tbody>
</table>

### Declaration for COBOL Calling C++ (extern "C"):

<table>
<thead>
<tr>
<th>COBOL Program</th>
<th>C++ Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID DIVISION. PROGRAM-ID. COBPROG. WORKING-STORAGE SECTION. 01 P1 PIC S9(9) USAGE IS BINARY. PROCEDURE DIVISION. CALL 'CPLUSF' USING BY VALUE P1. GOBACK.</td>
<td>extern &quot;C&quot; { void CPLUSF( int p1 ); }</td>
</tr>
<tr>
<td></td>
<td>void CPLUSF( int parm ) { printf(&quot;parm=%d\n&quot;); }</td>
</tr>
</tbody>
</table>

### Declarations for extern "COBOL" Linkage

For C++ to COBOL ILC, the C++ extern "COBOL" linkage specification lets the XL C++ compiler generate parameter lists for or accept them from COBOL.

The extern "COBOL" linkage specification has the following format:

```
extern "COBOL" { declaration }
```

declaration is a valid C++ prototype of the COBOL program(s) being called by C++, or the C++ routine being called by COBOL.

**Note**

The reference to COBOL in the following declarations applies to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, and VS COBOL II.

### Declaration for C++ Calling COBOL (extern "COBOL"):

<table>
<thead>
<tr>
<th>C++ Function</th>
<th>COBOL Program</th>
</tr>
</thead>
<tbody>
<tr>
<td>extern &quot;COBOL&quot; { void CBLRTN( double p2 ); }</td>
<td>IDENTIFICATION DIVISION. PROGRAM-ID. COBRTN. ENVIRONMENT DIVISION. DATA DIVISION. LINKAGE SECTION. 01 X COMP-2. PROCEDURE DIVISION USING BY REFERENCE X. DISPLAY X GOBACK. END PROGRAM COBRTN.</td>
</tr>
<tr>
<td>main() { double myval = 5; CBLRTN(myval); printf(&quot;myval=%f\n&quot;,myval); }</td>
<td></td>
</tr>
</tbody>
</table>
**Declaration for COBOL Calling C++ (extern "COBOL"):**

<table>
<thead>
<tr>
<th>COBOL Program</th>
<th>C++ Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID DIVISION.</td>
<td>extern &quot;COBOL&quot; { void CPLUSF( int p1 ); }</td>
</tr>
<tr>
<td>PROGRAM-ID. COBPROG.</td>
<td></td>
</tr>
<tr>
<td>WORKING-STORAGE SECTION.</td>
<td>void CPLUSF( int parm ) { printf(&quot;parm=%d\n&quot;); }</td>
</tr>
<tr>
<td>01 P1 PIC 9(9) USAGE IS BINARY.</td>
<td></td>
</tr>
<tr>
<td>PROCEDURE DIVISION.</td>
<td></td>
</tr>
<tr>
<td>CALL 'CPLUSF' USING BY REFERENCE P1.</td>
<td></td>
</tr>
<tr>
<td>GOBACK.</td>
<td></td>
</tr>
</tbody>
</table>

**Building a Reentrant C++ to COBOL Application**

By default, the XL C++ compiler generates object modules with constructed reentrancy. Therefore, linking a C++ to COBOL application is a two-step process:

1. Prelink all C++ and COBOL text decks together using the prelinker.
2. Link the text deck generated by the prelinker to create your module.

**Calling between C++ and COBOL**

The following tables describe the types of calls that are supported between C++ and COBOL when running with Language Environment.

- **Table 18 on page 65** shows which calls are supported from COBOL programs to C++ routines.
- **Table 19 on page 66** shows which calls are supported from C++ routines to COBOL programs.

Within a given enclave containing ILC between COBOL and C++, the application may be structured in one of the following ways:

- As a single statically-bound load module.
- As a DLL application, with multiple DLL load modules, each containing DLL-enabled COBOL and/or C++ routines.
- As an application using multiple load modules and using COBOL dynamic CALLs. In this case, all instances of C++ ILC must be statically-bound within the main load module. The only exception would be if extern "COBOL" or extern "C" is specified for all C++ functions called by COBOL that are in dynamically called load modules that do not contain any DLL routines that export functions or variables.
- As an application using multiple load modules and using fetch.
Table 18. Support for CALLs from COBOL to C++

<table>
<thead>
<tr>
<th>Caller</th>
<th>Call Type</th>
<th>C++ with extern &quot;COBOL&quot;</th>
<th>C++ with extern &quot;C&quot;</th>
<th>C++ without extern</th>
</tr>
</thead>
<tbody>
<tr>
<td>VS COBOL II (1)</td>
<td>static</td>

</tr>
<tr>
<td>COBOL (6) compiled with DLL</td>
<td>CALL &quot;literal&quot; to a function within the module</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>COBOL (6) compiled with DLL</td>
<td>CALL &quot;literal&quot; to a function exported from a DLL</td>
<td>Yes (4)</td>
<td>Yes (4)</td>
<td>No</td>
</tr>
<tr>
<td>COBOL (6) compiled with DLL</td>
<td>CALL identifier to a function exported from a DLL</td>
<td>Yes (4)</td>
<td>Yes (4)</td>
<td>No</td>
</tr>
</tbody>
</table>

Notes:
1. When the caller is VS COBOL II or COBOL/370, all calls must be to void functions.
2. Static calls are supported from VS COBOL II to C++ with extern "COBOL" in the following cases:
   • The call is done in the main load module.
   • The call is done in a load module whose entry point is a LE-conforming program or routine that was called using COBOL dynamic call.
   • The call is done in a module that was called using fetch.
   • The call is done in a DLL that was called using DLL linkage.
3. Dynamically called load modules cannot contain any DLL routines that export functions or variables. Use the binder DYNAM(NO) control statement to prevent marking the load module as a DLL.
   The XL C/C++ compiler may mark certain internal symbols as exported, resulting in the C++ executable being a DLL. To prevent the XL C++ compiler from doing this, use the NOEXPORT(NOSYS) compiler option.
4. In this case, the C++ code can also be compiled with the XPLINK option. The XPLINK C++ code must reside in a separate module from the COBOL caller.
5. COBOL for MVS & VM, COBOL for OS/390 & VM, or Enterprise COBOL for z/OS
6. COBOL for OS/390 & VM or Enterprise COBOL for z/OS
Table 19. Support for CALLs from C++ to COBOL

<table>
<thead>
<tr>
<th>Caller</th>

<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Notes:
1. When the target of the call is VS COBOL II or COBOL/370, the called COBOL program must be declared as a void function.
2. Fetched load modules cannot contain any DLL routines that export functions or variables.
3. In this case, the C++ code can also be compiled with the XPLINK option. The XPLINK C++ code must reside in a separate module from the COBOL caller.
4. COBOL for MVS & VM, COBOL for OS/390 & VM, or Enterprise COBOL for z/OS
5. COBOL for OS/390 & VM or Enterprise COBOL for z/OS

Passing Data between C++ and COBOL

In VS COBOL II and COBOL/370, you can pass parameters two ways:

**By reference (indirect)**

COBOL BY REFERENCE

**By value (indirect)**

COBOL BY CONTENT

In Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM, you can pass parameters three ways:

**By reference (indirect)**

COBOL BY REFERENCE

**By value (indirect)**

COBOL BY CONTENT

**By value (direct)**

COBOL BY VALUE

Under Language Environment, the term **by value** means that a temporary copy of the argument is passed to the called function or procedure. Any changes to the parameter made by the called routine will not alter the original parameter passed by the calling routine. Under Language Environment, the term **by reference** means that
the actual address of the argument is passed. Any changes to the parameter made by the called routine can alter the original parameter passed by the calling routine.

Further, the term direct means that the argument is passed in the parameter list. The term indirect means that a pointer to the argument is passed in the parameter list.

There are two ways to pass data between C++ and COBOL: one way uses extern "C" in the C linkage, and the other uses extern "COBOL". Both methods are discussed separately below.

**Passing Data between C++ and COBOL with extern "C"**

**Note**
The reference to COBOL with extern "C" applies only to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM.

When data is passed between XL C++ and Enterprise COBOL for z/OS, COBOL for OS/390 & VM, or COBOL for MVS & VM with extern "C", the standard language linkages are used with no extra level of indirection introduced.

**Passing Data by Value between C++ and COBOL**
Copies of variables can be passed between C++ and COBOL. On return, the actual value of the variable remains unchanged, regardless of how it may have been modified in the called routine.

To pass data by value (direct) from C++ to COBOL, the variables are passed by C++ as arguments on a function call and received by COBOL as BY VALUE parameters. Conversely, to pass data by value (direct) from COBOL to C++, the variables are passed by COBOL as BY VALUE arguments and received by C++ as function parameters. In all cases, the variable must be declared in C++ and COBOL with compatible base data types. For example, if a C++ function called FROMCOB is to receive a parameter passed by value (direct) of type int, the function prototype declaration would look like this:

```
void FROMCOB(int)
```

Data can also be passed by value (indirect) from COBOL to C++. In this case, the variable is passed as a BY CONTENT argument and received by C++ as a pointer to the given type. For example, if a C++ function called FROMCOB is to receive a parameter passed by value (indirect) of type int, the function prototype declaration would look like this:

```
void FROMCOB(int *)
```

The C++ function must dereference the pointer to access the actual value. If the value of the pointer is modified by the C++ function, as opposed to modifying the value that the pointer points to, the results on return to COBOL are unpredictable. Thus, passing values by value (indirect) from COBOL to C++ should be used with caution, and only in cases where the exact behavior of the C++ function is known.

Table 20 on page 69 shows the supported data types for passing by value (direct) and Table 21 on page 70 shows the supported data types for passing by value (indirect).
Passing Data by Reference (Indirect) between C++ and COBOL

A parameter can be passed by reference (indirect) between C++ and COBOL. By reference (indirect) means that the actual address of the argument is passed to the called function or procedure; any changes to the parameter made by the called routine can alter the original parameter passed by the calling routine.

To pass data by reference (indirect) from C++ to COBOL, the variables are passed by C++ as function arguments, which are pointers to a given type or the address of a given variable, and received by COBOL as BY REFERENCE parameters. Conversely, to pass data by reference (indirect) from COBOL to C++, the variables are passed by COBOL as BY REFERENCE arguments and received by C++ function as pointers to a given type.

The C++ function must dereference the pointer to access the actual value. If the value of the pointer is modified by the C++ function, as opposed to modifying the value that the pointer points to, the results on return to COBOL are unpredictable. Thus, passing values by reference (indirect) from COBOL to C++ should be used with caution, and only in cases where the exact behavior of the C++ function is known.

Table 21 on page 70 shows the supported data types for passing by reference (indirect).

Handling Function Returns between C++ and COBOL

In COBOL, values can be returned to COBOL programs as COBOL returning variables from C++ functions using standard C++ function returns. This is the recommended approach for passing modified values back from a C++ function to a COBOL procedure.

Note
In the declarations that follow, COBOL refers to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM.

The following examples illustrate how to declare data types for using function returns in C++ to COBOL ILC applications.

Declaration for COBOL Calling C++:

<table>
<thead>
<tr>
<th>COBOL Program</th>
<th>C++ Function</th>
</tr>
</thead>
</table>
| LINKAGE SECTION.  
| 01 P1 PIC 9(9) USAGE IS BINARY.  
| 01 P2 PIC 9(9) USAGE IS BINARY.  
| CALL 'CFUNC' USING BY VALUE P1  
| RETURNING P2.  | int CFUNC(int p1){  
| | int p2;  
| | p2=p1;  
| | return p2;  
| | }  |
**Declaration for C++ Calling COBOL:**

Sample C Usage COBOL Subroutine

```c
#include <stdio.h>
extern "C" {void cobrtn (int);};

int main()
{
    int x,y;
    x=1;
    y=cobrtn(x); /* x by value */
    printf("y=%i.",y);
}
```

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.

</tbody>
</table>

**Notes:**

1. The COBOL program should be compiled with the TRUNC(BIN) compiler option if it receives int parameters from the C++ calling function that may have a value larger than that declared as the maximum size by the COBOL picture clause. ([See Enterprise COBOL for z/OS Programming Guide](https://www.ibm.com) or [COBOL for OS/390 & VM Programming Guide](https://www.ibm.com) for more information about the TRUNC(BIN) compiler option.)

Supported Data Types Passed by Value (Indirect) or by Reference (Indirect) between C++ and COBOL

Table 21 on page 70 identifies the data types that can be passed by value (indirect) or by reference (indirect) between C++ and COBOL applications.
**Table 21. Supported Data Types Passed by Value (Indirect) or by Reference (Indirect) with extern "C"**

<table>
<thead>
<tr>
<th>C++ (Pointer To...)</th>
<th>COBOL (BY CONTENT/BY REFERENCE)</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>

<td>POINTER, ADDRESS OF</td>
</tr>
<tr>
<td>struct</td>
<td>Groups</td>
</tr>
<tr>
<td>type array[n]</td>
<td>Tables (OCCURS n TIMES)</td>
</tr>
</tbody>
</table>

**Notes:**

1. You must specify a size for type array.
2. The COBOL program should be compiled with the TRUNC(BIN) compiler option if it receives int parameters from the C++ calling function that may have a value larger than that declared as the maximum size by the COBOL picture clause. (See [Enterprise COBOL for z/OS Programming Guide](https://www.ibm.com/docs/en/zos), or [COBOL for OS/390 & VM Programming Guide](https://www.ibm.com/docs/en/zos) for more information about the TRUNC(BIN) compiler option.)
3. COBOL always turns on the high order bit of the address of the last parameter. This can cause problems in the C++ program if it is using the address (since it will be treated as a negative number). If a C++ program does need to use the address of the last parameter, one of the following techniques can be used to bypass this problem:
   - If the COBOL program is an Enterprise COBOL program, instead of passing the parameter by reference, pass the address of the item by value. For example, use a call statement that looks like this:
     ```
     CALL "C" using by value address of C-PARM1
     by value address of C-PARM2
     ```
   - If the COBOL program is not Enterprise COBOL, code needs to be added to mask out the high-order bit in the C++ routine. The sample code below shows how to do this:
     ```c
     #include <stdio.h>
     #include <string.h>
     void A1CC01BI(char* myString)
     {
       myString = (char*)((int)myString & 0x7fffffff);
       printf("My String: %s \n", myString);
       return;
     }
     ```

---

**Passing Data between C++ and COBOL with extern "COBOL"**

**Note**

The reference to COBOL with extern "COBOL", applies to VS COBOL II, COBOL/370, COBOL for MVS & VM, COBOL for OS/390 & VM, and Enterprise COBOL for z/OS.
When data is passed between XL C++ and COBOL with `extern "COBOL"`, the C++ compiler generates the appropriate addressing code which introduces an extra level of indirection on the C++ side for non-pointer types. Pointers, however, are passed directly; meaning that for COBOL to receive a pointer to a C++ data type, C++ must pass a pointer to a pointer to the C++ data type. Conversely, if COBOL returns a pointer to a data type, C++ receives a pointer to a pointer to the data type.

**Passing Data by Value (Indirect) between C++ and COBOL**

Copies of variable can be passed between C++ and COBOL routines. On return, the actual value of the variable remains unchanged regardless of how it may have been modified in the called routine.

Value arguments can be passed BY CONTENT from COBOL programs and received as C++ function parameters when declared with the appropriate base type. Conversely, C++ function arguments can be passed by value (indirect) from C++ functions and received as COBOL parameters. The C++ compiler generates the appropriate addressing code required to access the parameter values; you can write your C++ function, which is interoperable with COBOL, as if it were in a C++-only environment. It can be moved to a C++-only environment simply by removing the `extern "COBOL"`. For example, if a C++ function called FROMCOB is to receive a parameter passed BY CONTENT of type int, the function prototype declaration would look like this:

```c++
void FROMCOB(int)
```

Table 22 shows the supported data types for passing by value (indirect).

**Supported Data Types Passed by Value (Indirect) between C++ and COBOL**

Table 22 identifies the data types that can be passed by value (indirect) as parameters between C++ and COBOL.

<table>
<thead>
<tr>
<th>C++</th>
<th>COBOL</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed int, signed long int</td>
<td>PIC S9(9) USAGE IS BINARY</td>
</tr>
<tr>
<td>double</td>
<td>COMP-2</td>
</tr>
<tr>
<td>pointer to...</td>
<td>POINTER, ADDRESS OF</td>
</tr>
<tr>
<td>struct</td>
<td>Groups</td>
</tr>
<tr>
<td>type array[n]</td>
<td>Tables (OCCURS n TIMES)</td>
</tr>
</tbody>
</table>

**Passing Data by Reference (Indirect) between C++ and COBOL**

A parameter can be passed by reference (indirect) between C++ and COBOL, which means the actual address of the argument is passed to the called function or procedure; any changes to the parameter made by the called routine can alter the original parameter passed by the calling routine.

To pass data by reference (indirect) from C++ to COBOL, the variables are passed by C++ as function arguments, which are pointers to a given type or the address of a given variable, and received as COBOL parameters. Conversely, to pass data by reference (indirect) from COBOL to C++, the variables are passed from COBOL as BY REFERENCE arguments and received by a C++ function as pointers to a given type. For example, if a C++ function called FROMCOB is to receive a parameter passed by reference (indirect) of type int, the function prototype declaration would look like this:

```c++
void FROMCOB(int *)
```
The C++ function must dereference the pointer to access the actual value. If the value of the pointer is modified by the C++ function, as opposed to modifying the value that the pointer points to, the results on return to COBOL are unpredictable. Therefore, passing values by reference (indirect) from COBOL to C++ should be used with caution, and only in cases where the exact behavior of the C++ function is known.

Table 23 shows the supported data types for passing by reference (indirect).

### Supported Data Types Passed by Reference (Indirect) between C++ and COBOL

<table>
<thead>
<tr>
<th>C++</th>

<tr>
<td>struct</td>
<td>Groups</td>
</tr>
<tr>
<td>type array[n]</td>
<td>Tables (OCCURS n TIMES)</td>
</tr>
</tbody>
</table>

### Passing Strings between C++ and COBOL

C++ and COBOL have different string data types:

#### C++ strings

Logically unbounded length and are terminated by a NULL (the last byte of the string contains X'00')

#### COBOL PIC X(n)

Fixed-length string of characters of length n

You can pass strings between COBOL and C++ routines, but you must match what the routine interface demands with what is physically passed.

Enterprising COBOL for z/OS, COBOL for OS/390 & VM, and COBOL for MVS & VM have strings like previous COBOLs, as well as null-terminated literal strings like C++.

Refer to [Sample ILC Applications](#) on page 85 to see how string data is passed between C++ and COBOL.

### Using Aggregates

Aggregates (arrays, strings, or structures) are mapped differently by C++ and COBOL and are not automatically mapped. You must completely declare every byte in the structure to ensure that the layouts of structures passed between the two languages map to one another correctly. The XL C++ compile-time option AGGREGATE and the COBOL compiler option MAP provide a layout of structures to help you perform the mapping.

In C++, a structure is simply a class declared with the struct keyword; its members and base classes are public by default. A C++ class is the same as a C++ structure
if the only data is public. If a C++ class that uses features unavailable to COBOL
(such as virtual functions, virtual base classes, private data, protected data, static
data members, or inheritance) is passed to a COBOL program, the results are
undefined.

Data Equivalents

This section shows how C++ and COBOL data types correspond to each other.

Equivalent Data Types for C++ to COBOL

This section uses language samples to describe data type equivalencies in C++ to
COBOL applications.

Note

In the declarations that follow, examples showing the use of extern "C" apply
only to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, and COBOL
for MVS & VM. The examples showing extern "COBOL" apply to Enterprise
COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM,
COBOL/370, and VS COBOL II.

Signed One-Byte Character Data with extern "C"

Sample C++ Usage

```c
#include <stdio.h>
#include <stdlib.h>
extern "C" {void COBRTN (char);}  

int main()
{
    char x;
    x='a';
    COBRTN(x); /* x by value */
    exit(0);
}
```

COBOL Subroutine

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 X PIC X.
PROCEDURE DIVISION USING BY VALUE X.
   DISPLAY X.
   GOBACK.
END PROGRAM COBRTN.
```

Signed One-Byte Character Data with extern "COBOL"

Sample C++ Usage

```c
#include <stdio.h>
#include <stdlib.h>
extern "COBOL" {void COBRTN (char);}  

int main()
{
    char x;
    x='a';
    COBRTN(&x); /* x by reference */
    exit(0);
}
```

COBOL Subroutine

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 X PIC X.
PROCEDURE DIVISION USING X.
   DISPLAY X.
   GOBACK.
END PROGRAM COBRTN.
```
# 16-Bit Signed Binary Integer with extern "C"

**Sample C++ Usage**
```c
#include <stdio.h>
#include <stdlib.h>
extern "C" {void COBRTN (short int);}  
int main()
{
    short int x;
    x=5;
    COBRTN(x);  /* x by value */
    exit(0);
}
```

---

**COBOL Subroutine**
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 X PIC S9(4) BINARY.
PROCEDURE DIVISION USING BY VALUE X.
   DISPLAY X.
   GOBACK.
END PROGRAM COBRTN.
```

---

# 16-Bit Signed Binary Integer with extern "COBOL"

**Sample C++ Usage**
```c
#include <stdio.h>
#include <stdlib.h>
extern "COBOL" {void COBRTN (short int*);}  
int main()
{
    short int x;
    x=5;
    COBRTN(&x);  /* x by reference */
    exit(0);
}
```

---

**COBOL Subroutine**
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 X PIC S9(4) BINARY.
PROCEDURE DIVISION USING X.
   DISPLAY X.
   GOBACK.
END PROGRAM COBRTN.
```

---

# 32-Bit Signed Binary Integer with extern "C"

**Sample C++ Usage**
```c
#include <stdio.h>
#include <stdlib.h>
extern "C" {void COBRTN (int);}  
int main()
{
    int x;
    x=5;
    COBRTN(x);  /* x by value */
    exit(0);
}
```

---

**COBOL Subroutine**
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 X PIC S9(9) BINARY.
PROCEDURE DIVISION USING BY VALUE X.
   DISPLAY X.
   GOBACK.
END PROGRAM COBRTN.
```

---

# 32-Bit Signed Binary Integer with extern "COBOL"

**Sample C++ Usage**
```c
#include <stdio.h>
#include <stdlib.h>
extern "COBOL" {void COBRTN (int, int*);}  
int main()
{
    int x,y;
    x=5;
    y=6;
    COBRTN(x,&y);  /* x by value */
    /* y by reference */
    exit(0);
}
```

---

**COBOL Subroutine**
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. COBRTN.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
01 X PIC S9(9) BINARY.
01 Y PIC S9(9) BINARY.
PROCEDURE DIVISION USING X Y.
   DISPLAY X Y.
   GOBACK.
END PROGRAM COBRTN.
```
### Long Floating-Point Number with extern "C"

struct stype {
  int S1;
  int S2;
};
extern "COBOL" {void CENTRY
(struct stype struc1,
 struct stype *struc2);}
void CENTRY(struct stype struc1,
 struct stype *struc2)
{
  printf("%d %d %d %d 
",struc1.s1,
struc1.s2,struc2->s1,struc2->s2);
  return;
}
```

### Name Scope of External Data

In programming languages, the name scope is defined as the portion of an application within which a particular declaration applies or is known. The name scope of external data differs between C++ and COBOL. The scope of external data under C++ is the load module; under COBOL, it is the enclave (or run unit). Figure 7 on page 49 and Figure 8 on page 50 illustrate these differences.

Because the name scope for C++ and COBOL is different, external variable mapping between C++ and COBOL routines is not supported. External variables with the same name are considered separate between C++ and COBOL.

If your application relies on the separation of external data, do not give the data the same name in both languages within a single application. If you give the data in each load module a different name you can change the language mix in the application later, and your application still behaves as you expect it to.

### DLL Considerations

In DLL code, external variables are mapped across the load module boundary. DLLs are shared at the enclave level. Therefore, a single copy of a DLL applies to all modules in an enclave, regardless of whether the DLL is loaded implicitly.
COBOL data declared with the EXTERNAL attribute are independent of DLL support. These data items are managed by the COBOL run-time, and are accessible by name from any COBOL program in the run-unit that declares them, regardless of whether the programs are in DLLs or not.

In particular, the facilities for exporting and importing external variables from DLLs implemented in OS/390 C/C++, do not apply to COBOL external data. Hence C/C++ external data and COBOL external data are always in separate name spaces, regardless of DLL considerations.

For C/C++, non-DLL applications have external data which is only shared within the load module.

However, for DLL applications, C/C++ external data is now (optionally) accessible to all C/C++ routines in the enclave.

**Name Space of External Data**

In programming languages, the *name space* is defined as the portion of a load module within which a particular declaration applies or is known. Like the name scope, the name space of external data differs between C++ and COBOL.

**Figure 16. Name Space of External Data for COBOL Static CALL to COBOL**

**Figure 17. Name Space of External Data in COBOL Static CALL to C++**
Figure 16 and Figure 17 illustrate that within the same load module, the name space of COBOL programs is the same. However, the name spaces of a COBOL program and a C++ routine within the same load module are not the same. If you give external data the same name in both languages, an incompatibility in external data mapping can occur.

### Directing Output in ILC Applications

C++ and COBOL do not share files, except the Language Environment message file (the ddname specified in the Language Environment MSGFILE run-time option). You must manage all other files to ensure that no conflicts arise. Performing I/O operations on the same ddname might cause abnormal termination.

Under C++, run-time messages and other related output are directed to the default MSGFILE ddname. stderr output is also by default directed to the MSGFILE ddname. stdout is not by default directed to the MSGFILE ddname, but can be redirected to do so. Also, output from printf can be interspersed with output from the COBOL DISPLAY statement and output from Language Environment by redirecting stdout to stderr (for example, passing `1>&2` as a command line parameter).

For information on redirecting C++ output, see [z/OS XL C/C++ Programming Guide](#).

If you are using the C++ iostreams class, cout is directed to the same place as stdout, and cerr/clog are directed to the same place as stderr.

Under COBOL, run-time messages and other related output are directed to the MSGFILE ddname. Output from COBOL DISPLAY UPON SYSOUT is directed to the default MSGFILE ddname only when the OUTDD compiler option ddname matches the MSGFILE ddname; this applies to Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, and VS COBOL II.

### Interspersing Output When C++ Is the Main Routine

To intersperse output from C++ and COBOL when the main routine is coded in C++, compile your COBOL program using the default OUTDD (OUTDD=SYSOUT) if you are using the default MSGFILE ddname. If you have overridden the default MSGFILE ddname, you must compile your COBOL program using an OUTDD that specifies the same name as the MSGFILE. You must redirect stdout to stderr when C++ is the main routine.

### Interspersing Output When COBOL Is the Main Program

To intersperse output from C++ and COBOL when the main routine is coded in COBOL, compile your COBOL program using the default OUTDD (OUTDD=SYSOUT). In your C++ routine, add a line `stdout = stderr`. If you have overridden the default MSGFILE ddname, you must compile your COBOL program using an OUTDD ddname that specifies the same name as the MSGFILE.

### C++ to COBOL Condition Handling

This section provides two scenarios of condition handling behavior in a C++ to COBOL ILC application. If an exception occurs in a C++ routine, the set of possible actions is as described in [Exception Occurs in C++](#) on page 81. If an exception occurs in a COBOL program, the set of possible actions is as described in [Exception Occurs in COBOL](#) on page 83.
Keep in mind that some conditions can be handled only by the HLL of the routine in which the exception occurred. For example, in a COBOL program, a statement can have a clause that adds condition handling to a verb, such as the ON SIZE clause of a COBOL DIVIDE verb (which includes the logical equivalent of a divide-by-zero condition). This condition is handled completely within COBOL.

C++ exception handling constructs try()/throw()/catch() cannot be used with Language Environment and COBOL condition handling. If you use C exception handling constructs (signal()/raise()) in your C++ routine, condition handling will proceed as described in this section. Otherwise, you will get undefined behavior in your programs if you mix the C++ constructs with the C constructs. For a detailed description of Language Environment condition handling, see z/OS Language Environment Programming Guide.

Enclave-Terminating Language Constructs
Enclaves can be terminated for reasons other than an unhandled condition of severity 2 or greater. In Language Environment ILC, you can issue an HLL language construct to terminate a C++ to COBOL enclave from either a C++ or COBOL routine.

C Language Constructs Available under C++
Among the C language constructs that terminate an enclave are abort(), exit(), raise(SIGABRT), and raise(SIGTERM). Destructors are run at library termination.

If you call abort(), raise(SIGABRT), or exit(), the T_I_S (Termination Imminent Due to STOP) condition is raised. After T_I_S has been processed and all user code has been removed from the stack, the C atexit list is honored.

COBOL Language Constructs
The COBOL language constructs that cause the enclave to terminate are:

- STOP RUN
  COBOL's STOP RUN is equivalent to the C++ exit() function. If you code a COBOL STOP RUN statement, the T_I_S (Termination Imminent Due to STOP) condition is raised. After T_I_S has been processed and all user code has been removed from the stack, the C++ atexit list is honored.

- Call to ILBOABN0 or CEE3ABD
  Calling ILBOABN0 or CEE3ABD causes T_I_U to be signaled. Condition handlers are given a chance to handle the abend. If the abend remains unhandled, normal Language Environment termination activities occur. For example, the C++ atexit list is honored and the Language Environment assembler user exit gains control.
  User-written condition handlers written in COBOL must be compiled with Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM or COBOL/370.

Exception Occurs in C++
In this scenario, a COBOL main program invokes a C++ subroutine and an exception occurs in the C++ subroutine. Refer to Figure 18 on page 82 throughout the following discussion.
The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, C++ determines whether the exception in the C++ routine should be enabled and treated as a condition. If any of the following are true, the exception is ignored, and processing continues at the next sequential instruction after where the exception occurred:
   - You specified `SIG_IGN` for the exception in a call to `signal()`.
   - The system or user abend corresponding to the `signal(SIGABND)` or the Language Environment message 3250 is not ignored. The enclave is terminated.
   - You did not specify any action, but the default action for the condition is `SIG_IGN` (see Table 64 on page 255).
   - You are running under CICS and a CICS handler is pending.

   **Note:** The system or user abend corresponding to the `signal(SIGABND)` or the Language Environment message 3250 is not ignored. The enclave is terminated.

   - The exception is one of those listed as masked in Table 64 on page 255 and you have not enabled it using the CEE3SPM callable service.
   - You did not specify any action, but the default action for the condition is `SIG_IGN` (see Table 64 on page 255).
   - You are running under CICS and a CICS handler is pending.

   If you did none of these things, the condition is enabled and processed as a condition.

2. If a user-written condition handler has been registered using CEEHDLR on the C++ stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points. You must be careful when moving the resume cursor in an application that contains a COBOL program; see "CEEMRCR and COBOL" on page 85 for details.

   In this example, there is not a user-written condition handler registered for the condition, so the condition is percolated.

3. The global error table is now examined for signal handlers that have been registered for the condition.

---

**Figure 18. Stack Contents When the Exception Occurs**

The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, C++ determines whether the exception in the C++ routine should be enabled and treated as a condition. If any of the following are true, the exception is ignored, and processing continues at the next sequential instruction after where the exception occurred:
   - You specified `SIG_IGN` for the exception in a call to `signal()`.
   - The system or user abend corresponding to the `signal(SIGABND)` or the Language Environment message 3250 is not ignored. The enclave is terminated.
   - You did not specify any action, but the default action for the condition is `SIG_IGN` (see Table 64 on page 255).
   - You are running under CICS and a CICS handler is pending.

   **Note:** The system or user abend corresponding to the `signal(SIGABND)` or the Language Environment message 3250 is not ignored. The enclave is terminated.

   - The exception is one of those listed as masked in Table 64 on page 255 and you have not enabled it using the CEE3SPM callable service.
   - You did not specify any action, but the default action for the condition is `SIG_IGN` (see Table 64 on page 255).
   - You are running under CICS and a CICS handler is pending.

   If you did none of these things, the condition is enabled and processed as a condition.

2. If a user-written condition handler has been registered using CEEHDLR on the C++ stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points. You must be careful when moving the resume cursor in an application that contains a COBOL program; see "CEEMRCR and COBOL" on page 85 for details.

   In this example, there is not a user-written condition handler registered for the condition, so the condition is percolated.

3. The global error table is now examined for signal handlers that have been registered for the condition.
If there is a signal handler registered for the condition, it is given control. If it
issues a resume or a call to longjmp(), the condition handling step ends.
Processing resumes in the routine to which the resume cursor points. You must
be careful when issuing a longjmp() in an application that contains a COBOL
program; see “CEEMRCR and COBOL” on page 85 for details.
In this example, no C signal handler is registered for the condition, so the
condition is percolated.

4. The condition is still unhandled. If C++ does not recognize the condition, or if
the C++ default action (listed in Table 64 on page 255) is to terminate, the
condition is percolated.

5. If a user-written condition handler has been registered using CEEHDLR on the
COBOL stack frame, it is given control. If it issues a resume, with or without
moving the resume cursor, the condition handling step ends. Processing
continues in the routine to which the resume cursor points.
In this example, no user-written condition handler is registered for the condition,
so the condition is percolated.

6. If the condition is of severity 0 or 1, the Language Environment default actions
take place, as described in Table 63 on page 255.

7. If the condition is of severity 2 or above, Language Environment default action
is to promote the condition to T_I_U (Termination Imminent due to an
Unhandled condition) and redrive the stack. Condition handling now enters the
termination imminent step.

8. If, on the next pass of the stack, no condition handler moves the resume cursor
and issues a resume, Language Environment terminates the thread.

Exception Occurs in COBOL
In this scenario, a C++ main routine invokes a COBOL subroutine and an exception
occurs in the COBOL subroutine. Refer to Figure 19 on page 84 throughout the
following discussion.
The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, COBOL determines if the exception should be ignored or handled as a condition.
   - If the exception is to be ignored, control is returned to the next sequential instruction after where the exception occurred.
   - If the exception is to be enabled and processed as a condition, the condition handling step, described below, takes place.

2. If a user-written condition handler has been registered using CEEHDLR on the COBOL stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points. Note that you must be careful when moving the resume cursor in an application that contains a COBOL program. See "CEEMRCR and COBOL" on page 85 for details.
   In this example no user-written condition handler is registered for the condition, so the condition is percolated.

3. If a user-written condition handler has been registered for the condition using CEEHDLR on the C++ stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends.
   Processing continues in the routine to which the resume cursor points.
   In this example no user-written condition handler is registered for the condition, so the condition is percolated.

4. If a C signal handler has been registered for the condition, it is given control. If it moves the resume cursor or issues a call to longjmp(), the condition handling step ends. Processing resumes in the routine to which the resume cursor points.
   In this example, no C signal handler is registered for the condition, so the condition is percolated.
5. If the condition has a Facility_ID of IGZ, the condition is COBOL-specific. The COBOL default actions for the condition take place. If COBOL does not recognize the condition, condition handling continues.

6. If the condition is of severity 0 or 1, Language Environment default actions take place, as described in Table 63 on page 255.

7. If the condition is of severity 2 or above, Language Environment default action is to promote the condition to T_I_U (Termination Imminent due to an Unhandled condition) and redrive the stack. Condition handling now enters the termination imminent step.

8. If on the second pass of the stack no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

**CEEMRCR and COBOL**

When you make a call to CEEMRCR to move the resume cursor, or issue a call to `longjmp()`, and a COBOL program is removed from the stack, the COBOL program can be re-entered via another call path. (This will not work for VS COBOL II programs.)

If the COBOL program does not specify RECURSIVE in the PROGRAM-ID, a recursion error is raised if you attempt to enter the routine again.

- A VS COBOL II, COBOL/370, COBOL for MVS & VM, or COBOL for OS/390 & VM program compiled with the CMPR2 option
- A VS COBOL II program compiled with the NOCMPR2 option (which does not use nested routines)
- A COBOL/370, COBOL for MVS & VM, or COBOL for OS/390 & VM program compiled with the NOCMPR2 option that does not use the combination of the INITIAL attribute, nested routines, and file processing in the same compilation unit.
- An Enterprise COBOL for z/OS program that does not use the combination of the INITIAL attribute, nested routines, and file processing in the same compilation unit.

In addition, if the routine is a COBOL routine with the INITIAL attribute and containing files, the files are closed. (COBOL supports VSAM and QSAM files and these files are closed.)

**Sample ILC Applications**

Figure 20 on page 86 and Figure 21 on page 87 contain an example of an ILC application. The C++ routine CPP1 statically calls the COBOL CBL1 program. CBL1 statically CALLs C++ routine CPP2.
/* Module/File Name: EDCXCB */

#include <stdio.h>
#include <stdlib.h>
#include <string.h>

extern "COBOL" {
    void CBL1(short *, long, float, char *);
    void CPP2(int& num, char * newstring);
}

Figure 21. Static CALL from COBOL to C++ Routine
Chapter 6. Communicating between C and Fortran

This chapter describes Language Environment's support for C to Fortran ILC applications.

General Facts about C to Fortran ILC

- A load module consisting of object code compiled with any Fortran compiler link-edited with object code compiled in another language is not reentrant, regardless of whether the Fortran routine was compiled with the RENT compiler option.
- Return codes cannot be passed from a C routine to the Fortran routine that invoked it.
- Fortran routines cannot operate under CICS.
- Support for Fortran on VM is not provided by Language Environment.
- Several C and Fortran library routines have identical names: you must resolve name conflicts before link-editing your C to Fortran ILC applications. See z/OS Language Environment Programming Guide for link-editing information.
- Fortran routines cannot operate in an XPLINK environment, so ILC with C routines compiled XPLINK is not supported.
- There is no ILC support between AMODE 31 and AMODE 64 applications. Fortran does not support AMODE 64.

Preparing for ILC

This section describes topics you might want to consider before writing an ILC application. To determine how different versions of HLLs work together, refer to the migration guides for the HLLs you plan to use.

Language Environment ILC Support

Language Environment provides ILC support between the following combinations of C and Fortran:

<table>
<thead>
<tr>
<th>HLL Pair</th>
<th>C</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>C to Fortran</td>
<td>• C/370 Version 1 Release 2&lt;br&gt;• C/370 Version 2 Release 1&lt;br&gt;• AD/Cycle C/370 Version 1&lt;br&gt;• IBM C/C++ for MVS/ESA&lt;br&gt;• z/OS XL C/C++ compilers</td>
<td>• FORTRAN IV G1&lt;br&gt;• FORTRAN IV H Extended&lt;br&gt;• VS FORTRAN Version 1, except modules compiled with Release 2.0 or earlier and that either pass character arguments to, or receive character arguments from, subprograms.&lt;br&gt;• VS FORTRAN Version 2, except modules compiled with Releases 5 or 6 and whose source contained any parallel language constructs or parallel callable services, or were compiled with either of the compiler options PARALLEL or EC.</td>
</tr>
</tbody>
</table>

**Note:** Dynamic calls from Fortran are available in VS FORTRAN Version 2 Release 6 only.

Migrating ILC Applications

All C to Fortran ILC applications need to be relinked before running. See z/OS Language Environment Programming Guide for information on how to relink.
applications to run with Language Environment. You can find other helpful migration information, especially concerning run-time option compatibility, in z/OS Language Environment Run-Time Application Migration Guide.

Determining the Main Routine

In Language Environment, only one routine can be the main routine; no other routine in the enclave can use syntax that indicates it is main.

A C function is designated as a main routine because its function definition gives its name as `main`. The entry point into the load module is CEESTART. In C, the same routine can serve as both the main routine and subroutine if it is recursively called. In such a case, the new invocation of the routine is not considered a second main routine within the enclave, but a subroutine.

A Fortran routine is designated as a main routine with a PROGRAM statement, which indicates the name of the main routine. A main routine can also be designated by the absence of PROGRAM, SUBROUTINE, or FUNCTION statements, in which case the name of the main routine is the default value `MAIN` (or `MAIN#` for VS FORTRAN Version 2 Releases 5 and 6). The name of the main routine is the entry point into the load module.

An entry point is defined for each supported HLL. Table 25 identifies the main and fetched entry points for each language. The table assumes that your code has been compiled using the Language Environment-conforming compilers.

Table 25. Determining the Entry Point

<table>
<thead>
<tr>
<th>HLL</th>
<th>Main Entry Point</th>
<th>Fetched Entry Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>CEESTART</td>
<td>CEESTART or routine name, if <code>#pragma linkage(fetchable)</code> is not used.</td>
</tr>
<tr>
<td>Fortran</td>
<td>Name on the PROGRAM statement. In the absence of PROGRAM, SUBROUTINE, or FUNCTION statements, the default value is <code>MAIN</code> (or <code>MAIN#</code> in VS FORTRAN Version 2 Releases 5 and 6).</td>
<td>Subprogram name</td>
</tr>
</tbody>
</table>

Declaring C to Fortran ILC

A `#pragma linkage` directive is required for C to call Fortran and for Fortran to call C. All entry declarations are made in the C code; no special declaration is required in the Fortran routine. The directive allows the C routine to pass arguments and return values to and from the Fortran routine using an internal argument list compatible with Fortran.

The `#pragma linkage` directive has the following format:

```
#pragma linkage(identifier, FORTRAN[, RETURNCODE])
```

`identifier` is either the name of the Fortran routine (a function or subroutine), a C function, or, for dynamic calls, the name of a typedef that refers to a Fortran routine.

`RETURNCODE` is optional and applies only to a called Fortran routine; it specifies that `identifier` is a Fortran routine that returns an alternate return code to the C routine.
Example of Declaration for C Calling Fortran

The following example shows a partial C routine that calls a Fortran function. The calling C routine contains the #pragma linkage directive for the Fortran function FORTFCN, the function prototype for the Fortran function, and a static call to the Fortran function.

```
C Function
#pragma linkage (fortfcn, FORTRAN)
:
double fortfcn(int, double [100]);
:
int index;
double list[100];
double value;
:
value=fortfcn(index, list);
```

Example of Declaration for Fortran Calling C

The following example shows a partial Fortran routine that calls a C function. The called C routine contains the #pragma linkage directive for the C function CFCN and the function definition for the C function.

```
Fortran Function
FUNCTION FORTFCN (INDEX, LIST) RESULT (VALUE)
INTEGER*4 INDEX
REAL*8 LIST(0:99)
REAL*8 VALUE
:
VALUE=LIST(INDEX)
END
```

Calling between C and Fortran

This section describes the types of calls permitted between C and Fortran, and considerations when using dynamic calls and fetch.

Types of Calls Permitted

Table 26 describes the types of calls between C and Fortran that Language Environment allows:

<table>
<thead>
<tr>
<th>ILC Direction</th>
<th>Static Calls</th>
<th>Dynamic Calls</th>
</tr>
</thead>
<tbody>
<tr>
<td>C to Fortran</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Fortran to C</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Note: Dynamic call refers to C fetching a Fortran routine or Fortran dynamically calling a C routine.

Dynamic Call/Fetch Considerations

This section describes the dynamic calling/fetching mechanisms supported between C and Fortran.

C Fetching Fortran

In C, dynamic calls are made by invoking the fetch() function and then later invoking the fetched routine with the returned fetch pointer. The fetched routine can either be a C or Fortran routine: the C routine can then fetch or statically call a
Fortran routine; the Fortran routine can then statically call a C routine. (If the
statically linked C routine is within a dynamically loaded module with a Fortran entry
point, the C routine must be either nonreentrant or naturally reentrant.) In the
fetched load module, a routine can dynamically call other C or Fortran routines,
regardless of whether the routines are reentrant.

A C routine that fetches a Fortran routine cannot contain a fork() function.
Although you cannot run an application with fork(), you can run with POSIX(ON).
For a full description of running under POSIX, see z/OS Language Environment
Programming Guide.

Restriction: When a C routine fetches a Fortran routine, the dynamically loaded
module can contain only routines written in those languages that already exist in a
previous load module. (The routine in the previous load module need not be called;
it only needs to be present.) For a Fortran routine to be recognized, ensure that at
least one of the following is present in a previous load module:
- A Fortran main program
- A Fortran routine that causes one or more Fortran run-time library routines to be
  link-edited into the load module. If the Fortran routine contains either an I/O
  statement, a mathematical function reference, or a call to any Fortran callable
  service (such as CPUTIME), then a library routine is included, and this
  requirement is satisfied.
- The Fortran signature CSECT, CEESG007. Use the following linkage editor
  statement to include CEESG007 if neither of the two previous conditions is true:

Fortran Dynamically Calling C
Dynamic calls are made in Fortran by specifying the name of the routine to be
loaded with the DYNAMIC compiler option, and then using the same name in a
CALL statement. The dynamically called routine can be either C or Fortran, and it
can in turn statically call either a C or Fortran routine. (If the statically linked C
routine is within a dynamically loaded module with a Fortran entry point, the C
routine must be either nonreentrant or naturally reentrant.) In the dynamically
loaded module, a routine can dynamically call other C or Fortran routines,
regardless of whether the routines are reentrant.

Neither a C nor a Fortran routine can delete a dynamically loaded routine that was
dynamically loaded in a Fortran routine.

Invoking Functions with Returned Values
Both C and Fortran can invoke the other language as a function that returns a
value: in C, this would be a function that returns something other than void; in
Fortran, a function is a routine that begins with a FUNCTION statement. Only
certain data types, however, can be used as function return values. See Table 29
on page 94 for a list of the supported data types that can be used as function return
values.

Calling Fortran Library Routines
You can statically call a Fortran library routine, such as CPUTIME, from C.
However, you cannot dynamically call a Fortran library routine from C.
Passing Data between C and Fortran

This section describes the data types that can be passed between C and Fortran. In the C-to-Fortran passing direction, most of the data types can be passed by reference only; several can also be passed by value. In the Fortran-to-C passing direction, however, the only passing method allowed is by reference.

Under Language Environment, the term by value means that a temporary copy of the argument is passed to the called function or procedure. Any changes to the parameter made by the called routine will not alter the original parameter passed by the calling routine. Under Language Environment, the term by reference means that the actual address of the argument is passed. Any changes to the parameter made by the called routine can alter the original parameter passed by the calling routine.

This section also includes information on passing an alternate return code from Fortran to C.

Supported Data Types between C and Fortran

Table 27 lists the data types that can be passed between C and Fortran by reference.

<table>
<thead>
<tr>
<th>C</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed short int</td>
<td>INTEGER*2</td>
</tr>
<tr>
<td>signed int, signed long int</td>
<td>INTEGER*4</td>
</tr>
<tr>

<td>INTEGER*1</td>
</tr>
<tr>
<td>unsigned char</td>
<td>UNSIGNED<em>1 or CHARACTER</em>1</td>
</tr>
<tr>
<td>char[n]</td>
<td>CHARACTER*1</td>
</tr>
</tbody>
</table>

Address of supported data types and aggregates

Examples:

Address of an integer

...(int**...)...  POINTER (X,Y)

INTGER*4 Y

Address of an array of integers

...(int(**)[8]...)...  POINTER (X,Y)

INTGER*4 Y(8)

Supported Data Types for Passing by Value

Table 28 lists the data types that can be passed from C to Fortran by value.

<table>
<thead>
<tr>
<th>C</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed int, signed long int</td>
<td>INTEGER*4</td>
</tr>
<tr>
<td>double</td>
<td>REAL*8</td>
</tr>
<tr>
<td>long double</td>
<td>REAL*16</td>
</tr>
</tbody>
</table>

Supported Data Types for Passing Function Return Values

Table 29 on page 94 lists the data types that can be passed as function return values from a C function to a Fortran routine.
Table 29. Supported Data Types for Passing as Function Return Values from C to Fortran

<table>
<thead>
<tr>

<td>long double</td>
<td>REAL*16</td>
</tr>
<tr>
<td>signed char</td>
<td>INTEGER*1</td>
</tr>
<tr>
<td>unsigned char</td>
<td>UNSIGNED*1</td>
</tr>
</tbody>
</table>

Passing an Alternate Return Code from Fortran to C

You can pass an alternate return code to a C routine from a Fortran subroutine by specifying the called Fortran subroutine in the `#pragma linkage` directive. The Fortran subroutine will produce an alternate return code when alternate returns are specified as dummy arguments on the SUBROUTINE statement.

In an all-Fortran application, the alternate returns provide a way to return to a point in the calling program other than to the point immediately following the CALL statement. The following example illustrates how a Fortran routine would call a Fortran subroutine to use an alternate return:

```fortran
CALL FSUB (ARG1, *22, ARG2, *66)
```

In this example, `*22` and `*66` specify two labels (22 and 66) to which control can be passed rather than to the point following the CALL statement. The corresponding subroutine would be coded as follows:

```fortran
SUBROUTINE FSUB (DARG1, DARG2, *, *)
```

When the FSUB subroutine executes the following RETURN statement, control would pass to the calling program at the second alternate return, at label 66.

```fortran
RETURN 2
```

There is no alternate return point feature in C. However, if you specify the RETURNCODE suboption on the `#pragma linkage` directive in your C routine, you can use the `fortrc()` function to get the alternate return code from the RETURN statement in the Fortran subroutine. The `fortrc()` function reference applies to the call to Fortran immediately preceding it; you must not have any C code between the Fortran subroutine and the `fortrc()` function reference.

In the following example, the C routine calls the subroutine FSUB, whose SUBROUTINE and RETURN statements are shown above. The `fortrc()` function returns an alternate return code of 2.

```c
#include <stdlib.h>
#pragma linkage (fsub, FORTRAN, RETURNCODE)
void fsub (float, float);
int rc;
  fsub(1.0,2.0);
  rc=fortrc();
```

The RETURNCODE suboption is optional. It indicates to the C compiler that `fsub` is a Fortran routine returning an alternate return code. You cannot pass return code values from a called C function to a calling Fortran routine.
Passing Character Data

Character data can be received by a Fortran routine only when the routine that receives the data declares the data to be of fixed length. Therefore, the Fortran form CHARACTER(*) cannot be used by a Fortran routine to receive character data. An array of characters can be processed in a C routine only when the Fortran routine or the C routine produces the terminating null character.

Mapping Arrays between C and Fortran

Arrays can be passed between C and Fortran routines when the array passed has its elements in contiguous storage locations. In addition, in a called Fortran routine, the declaration of the array must indicate a constant number of elements along each dimension.

In C, arrays of more than one dimension are arranged in storage in row major order, while in Fortran they are arranged in column major order. You need to reference the corresponding element of the other language by reversing the order of the subscripts. For example, in an array of floating point integers, the C declaration would be float [10][20] while the Fortran declaration would be REAL*4(20,10).

Another difference in using arrays is that unless specified otherwise, the lower bound (the lowest subscript value) of a Fortran array is 1. In C, the lowest subscript value is always 0, so you must adjust either the declared lower bound in the Fortran routine or the subscript you are using when you reference the value in C or Fortran.

For example, the two arrays below have the same storage mapping:

C
float da[10][20];

Fortran
REAL*4 DA(20,10)

The two elements below also represent the same storage:

C
da[4][8]

Fortran
DA(9,5)

Data Equivalents

This section describes how C and Fortran data types correspond to each other.

Equivalent Data Types for C to Fortran

The following examples illustrate how C and Fortran routines within a single ILC application might code the same data types. The examples might be clearer to you if you first read "Passing Data between C and Fortran" on page 93, which describes how a C routine can receive parameters that are passed by value and by reference.
### 16-Bit Signed Binary Integer

**Sample C Usage (by Reference)**
```
#include <stdio.h>
void cfort( short int * );
main()
{
    short int x;
    x=5;
    cfort(&x);
    printf("Updated value in C: %d\n", x);
}
```

**Fortran Subroutine**
```
SUBROUTINE CFORT ( ARG )
INTEGER*2 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
ARG = ARG + 1
END
```

**Note:** Because `short int` is an example of a parameter which must be passed using an C explicit pointer, you cannot code `cfort(x)`, passing `x` by value.

### 32-Bit Signed Binary Integer

**Sample C Usage (by Value)**
```
#include <stdio.h>
int cfort( int *);
main()
{
    int x, y;
    x=5;
    y = cfort(&x);
    printf("Value returned to C: %d\n", y);
}
```

**Fortran Function**
```
FUNCTION CFORT ( ARG )
INTEGER*4 CFORT
INTEGER*4 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
CFORT = ARG
END
```

**Sample C Usage (by Reference)**
```
#include <stdio.h>
int cfort( int *);
main()
{
    int x, y;
    x=5;
    y = cfort(&x);
    printf("Value returned to C: %d\n", y);
}
```

**Fortran Function**
```
FUNCTION CFORT ( ARG )
INTEGER*4 CFORT
INTEGER*4 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
CFORT = ARG
END
```

### Short Floating-Point Number

**Sample C Usage (by Reference)**
```
#include <stdio.h>
float cfort( float *);
main()
{
    float x, y;
    x=5.0F;
    y = cfort(&x);
    printf("Value returned to C: %f\n", y);
}
```

**Fortran Function**
```
FUNCTION CFORT ( ARG )
REAL*4 CFORT
REAL*4 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
CFORT = ARG
END
```
### Long Floating-Point Number

#### Sample C Usage (by Value)
```c
#pragma linkage (cfort,FORTRAN)
#include <stdio.h>
double cfort(double);
main()
{
    double x, y;
    x=12.5;
    y=cfort(x);
    printf("Value returned to C: %f\n", y);
}
```

#### Fortran Function
```fortran
FUNCTION CFORT ( ARG )
REAL*8 CFORT
REAL*8 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
CFORT = ARG
END
```

#### Sample C Usage (by Reference)
```c
#pragma linkage (cfort,FORTRAN)
#include <stdio.h>
double cfort(double *);
main()
{
    double x, y;
    x=12.5;
    y=cfort(&x);
    printf("Value returned to C: %f\n", y);
}
```

#### Fortran Function
```fortran
FUNCTION CFORT ( ARG )
REAL*8 CFORT
REAL*8 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
CFORT = ARG
END
```

### Extended Floating-Point Number

#### Sample C Usage (by Value)
```c
#pragma linkage (cfort,FORTRAN)
#include <stdio.h>
long double cfort(long double);
main()
{
    long double x, y;
    x=12.1L;
    y=cfort(x);
    printf("Value returned to C: %Lf\n", y);
}
```

#### Fortran Function
```fortran
FUNCTION CFORT ( ARG )
REAL*16 CFORT
REAL*16 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
CFORT = ARG
END
```

#### Sample C Usage (by Reference)
```c
#pragma linkage (cfort,FORTRAN)
#include <stdio.h>
long double cfort(long double *);
main()
{
    long double x, y;
    x=12.1L;
    y=cfort(&x);
    printf("Value returned to C: %Lf\n", y);
}
```

#### Fortran Function
```fortran
FUNCTION CFORT ( ARG )
REAL*16 CFORT
REAL*16 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
CFORT = ARG
END
```
### Signed One-Byte Character Data

**Sample C Usage (by Reference)**

```c
#include <stdio.h>

void cfort(signed char *);

main()
{
    signed char x, y;
    x=-5;
    cfort(&x);
    printf("Updated value in C: %d\n", x);
}
```

**Fortran Subroutine**

```fortran
SUBROUTINE CFORT ( ARG )
INTEGER*1 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
ARG = ARG - 1
END
```

### Unsigned One-Byte Character Data

**Sample C Usage (by Reference)**

```c
#include <stdio.h>

void cfort(unsigned char *, unsigned char *);

main()
{
    unsigned char x, y;
    x='a';
    cfort(&x,&y);
    printf("Value returned to C: %c\n", y);
}
```

**Fortran Subroutine**

```fortran
SUBROUTINE CFORT ( ARG1, ARG2 )
CHARACTER*1 ARG1, ARG2
PRINT *, 'FORTRAN ARG1 VALUE: ', ARG1
ARG2 = ARG1
END
```

### Fixed-Length Character Data

**Sample C Usage**

```c
#include <stdio.h>

void cfort(char [10], char [10]);

main()
{
    char x[10] = "1234567890";
    char y[10];
    cfort(x,y);
    printf("Value returned to C: %10.10s\n", y);
}
```

**Fortran Subroutine**

```fortran
SUBROUTINE CFORT ( ARG1, ARG2 )
CHARACTER*10 ARG1, ARG2
PRINT *, 'FORTRAN ARG1 VALUE: ', ARG1
ARG2 = ARG1
END
```
### Array

#### Sample C Usage
```c
#include <stdio.h>

void cfort(float[]);

main()
{
  float matrix[3] = {0.0F,1.0F,2.0F};
  cfort(matrix);
  printf(Updated values in C: \%f \%f \%f\n, matrix[0], matrix[1], matrix[2]);
}
```

#### Fortran Subroutine
```fortran
SUBROUTINE CFORT ( ARG )
  REAL*4 ARG(3)
  PRINT *, 'FORTRAN ARG VALUES:', ARG
  DO J = 1, 3
    ARG(J) = ARG(J) + 1.0
  ENDDO
END
```

#### Address of an Integer

#### Sample C Usage
```c
#include <stdio.h>

void cfort (int **);

main()
{
  int i, *temp;
  i=5;
  temp=&i;
  cfort(&temp);
  printf(Updated integer value in C: %d\n, i);
}
```

#### Fortran Subroutine
```fortran
SUBROUTINE CFORT ( ARG )
  POINTER*4 (ARG, Y)
  INTEGER*4 Y
  PRINT *, 1 'FORTRAN INTEGER ARG VALUE:', Y
  Y=Y+1
END
```

#### Address of an Array

#### Sample C Usage
```c
#include <stdio.h>

void cfort(int(**)[]);

main()
{
  int matrix[3] = {0,1,2};
  int (**temp)[] = &matrix;
  cfort(&temp);
  printf(Updated values in C: \%d \%d \%d\n, matrix[0], matrix[1], matrix[2]);
}
```

#### Fortran Subroutine
```fortran
SUBROUTINE CFORT ( ARG )
  POINTER*4 (ARG, Y)
  INTEGER*4 Y(3)
  PRINT *, 1 'FORTRAN ARRAY ARG VALUES:', Y
  DO J = 1, 3
    Y(J) = Y(J) + 1
  ENDDO
END
```

### Equivalent Data Types for Fortran to C

The following examples illustrate how C and Fortran routines within a single ILC application might code the same data types. The examples might be clearer to you if you first read "Passing Data between C and Fortran" on page 93, which describes how a C routine can receive parameters that are passed by value and by reference.
### 16-Bit Signed Binary Integer

**Sample Fortran Usage**

```fortran
INTEGER*2 X
X = 5
CALL CENTRY(X)
PRINT *,
1 'UPDATED VALUE IN FORTRAN:', X
END
```

**C Function (by Reference)**

```c
#include <stdio.h>

t void centry(short int *x)
{
    printf("C int arg value: %d\n",*x);
    *x += 1;
}
```

### 32-Bit Signed Binary Integer

**Sample Fortran Usage (by Value)**

```fortran
INTEGER*4 X, Y, CENTRY
X = 5
Y = CENTRY((X))
PRINT *,
1 'VALUE RETURNED TO FORTRAN:', Y
END
```

**C Function (by Value)**

```c
#include <stdio.h>

int centry(int x)
{
    printf("C int arg value: %d\n",x);
    return(x);
}
```

### Short Floating-Point Number

**Sample Fortran Usage (by Reference)**

```fortran
REAL*4 X, Y, CENTRY
X = 5.0
Y = CENTRY(X)
PRINT *
1 'VALUE RETURNED TO FORTRAN:', Y
END
```

**C Function (by Reference)**

```c
#include <stdio.h>

float centry(float *x)
{
    printf("C float arg value: %f\n",*x);
    return(*x);
}
```

### Long Floating-Point Number

**Sample Fortran Usage (by Value)**

```fortran
REAL*8 X, Y, CENTRY
X = 12.5D0
Y = CENTRY((X))
PRINT *
1 'VALUE RETURNED TO FORTRAN:', Y
END
```

**C Function (by Value)**

```c
#include <stdio.h>

double centry(double x)
{
    printf("C arg value: %f\n",x);
    return(x);
}
```
**Sample Fortran Usage**

<table>
<thead>
<tr>

</table>
External Data

External data in a C routine can be shared with a common block of the same name in a Fortran routine in the same load module under the following conditions:

- The C static data is declared outside of any functions
- The C external data is NORENT, either from compiling the source file as NORENT, or by marking the variable as NORENT with #pragma variable(xxxx, NORENT).
- The Fortran static common blocks are either used only with one load module in an application or they are declared as private common blocks. A private common block is not shared across load modules and must be created in any of the following ways:
  - Specified or implied by the PC compiler option
  - Referenced by Fortran object code produced by the VS FORTRAN Version 2 Release 4 compiler or earlier
  - In an application that executes with the PC run-time option.

Directing Output in ILC Applications

Language Environment doesn’t provide support to coordinate the use of C and Fortran files. Routines written in Fortran and C do share the Language Environment message file, however (the ddname specified in the Language Environment MSGFILE run-time option). You must manage all other files to ensure that no conflicts arise. For example, performing output operations on the same ddname is likely to cause unpredictable results.

Under C, run-time messages and other related output are directed to the default MSGFILE ddname. stderr output is also by default directed to the MSGFILE ddname. stdout is not by default directed to the MSGFILE ddname, but can be redirected to do so. Also, output from printf can be interspersed with output from the Fortran PRINT statement and output from Language Environment by redirecting stdout to stderr (for example, passing 1>&2 as a command line parameter).

For more information on how to redirect C output, see z/OS XL C/C++ Programming Guide.

Fortran run-time messages, output written to the print unit, and other output (such as output from the SDUMP callable service) are directed to the file specified by the MSGFILE run-time option. To direct this output to the file with the ddname FTnnF001 (where nn is the two-digit error message unit number), specify the run-time option MSGFILE(FTnnF001). If the print unit is different than the error message unit (if the PRTUNIT and the ERRUNIT run-time options have different values), output from a PRINT statement won’t be directed to the Language Environment message file.

C to Fortran Condition Handling

This section provides two scenarios of condition handling behavior in a C to Fortran ILC application. If an exception occurs in a C routine, the set of possible actions is as described in “Exception Occurs in C” on page 104. If an exception occurs in a Fortran program, the set of possible actions is as described in “Exception Occurs in Fortran” on page 106.

Some conditions can be handled only by the HLL of the routine in which the exception occurred. For example, when an ERR or IOSTAT specifier is present on a Fortran I/O statement and an error is detected while executing that statement, the
Fortran semantics take precedence over Language Environment condition handling. In this case, control returns immediately to the Fortran program and no condition is signaled to Language Environment.

See [z/OS Language Environment Programming Guide](#) for a detailed description of Language Environment condition handling. For information on Fortran condition handling semantics, see [VS FORTRAN Version 2 Language and Library Reference](#).

**Enclave-Terminating Language Constructs**

Enclaves can be terminated for reasons other than an unhandled condition of severity 2 or greater. HLL constructs that cause the termination of a single language enclave also cause the termination of a C to Fortran enclave. In Language Environment ILC, you can issue the language construct to terminate the enclave from a C or Fortran routine.

**C**

Examples of C language constructs that terminate the enclave are: `kill()`, `abort()`, `raise(SIGTERM)`, `raise(SIGABND)`, and `exit()`. When you use a C language construct to terminate an enclave, the T_I_S (Termination Imminent Due to STOP) condition is raised. After T_I_S has been processed and all user code has been removed from the stack, the C atexit list is honored.

**Fortran**

The Fortran language constructs that cause the enclave to terminate are:

- A STOP statement
- An END statement in the main routine
- A call to EXIT or SYSRCX
- A call to DUMP or CDUMP

All of the constructs listed above except the END statement cause the T_I_S (Termination Imminent due to STOP) condition to be signaled.

**Exception Occurs in C**

This scenario describes the behavior of an application that contains a C and Fortran routine. In this scenario, a Fortran main routine invokes a C subroutine. An exception occurs in the C subroutine.
The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, C determines whether the exception in the C routine should be enabled and treated as a condition. If any of the following are true, the exception is ignored, and processing continues at the next sequential instruction after where the exception occurred:
   - You specified `SIG_IGN` for the exception in a call to `signal()`.
   - The exception is one of those listed as masked in Table 64 on page 255, and you have not enabled it using the CEE3SPM callable service.
   - You did not specify any action, but the default action for the condition is `SIG_IGN` (see Table 64 on page 255).
   
   **Note:** The system or user abend corresponding to the `signal(SIGABND)` or the Language Environment message 3250 is not ignored. The enclave is terminated.
   - The exception is one of those listed as masked in Table 64 on page 255, and you have not enabled it using the CEE3SPM callable service.
   - You did not specify any action, but the default action for the condition is `SIG_IGN` (see Table 64 on page 255).

   If you did none of these things, the condition is enabled and processed as a condition.

2. If a user-written condition handler has been registered using CEEHDLR on the C stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points.

   In this example, there is not a user-written condition handler registered for the condition, so the condition is percolated.

3. The C global error table is now examined for signal handlers that have been registered for the condition.

   If there is a signal handler registered for the condition, it is given control. If it issues a resume or a call to `longjmp()`, the condition handling step ends. Processing resumes in the routine to which the resume cursor points.
In this example no C signal handler is registered for the condition, so the condition is percolated.

4. The condition is still unhandled. If C does not recognize the condition, or if the C default action (listed in Table 64 on page 255) is to terminate, the condition is percolated.

5. There is no user-written condition handler on the Fortran stack frame (because CEEHDLR cannot be called from a Fortran routine), and the condition is percolated.

6. If the condition is of severity 0 or 1, the Language Environment default actions take place, as described in Table 63 on page 255.

7. If the condition is of severity 2 or above, Language Environment default action is to promote the condition to T_I_U (Termination Imminent due to an Unhandled condition) and redrive the stack. Condition handling now enters the termination imminent step.

8. If, on the second pass of the stack, no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

**Exception Occurs in Fortran**

This scenario describes the behavior of an application that contains a Fortran and a C routine. In this scenario, a C main routine invokes a Fortran subroutine. An exception occurs in the Fortran subroutine. Refer to Figure 23 throughout the following discussion.

![Figure 23. Stack Contents When the Exception Occurs](image)

The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. If an I/O error is detected on a Fortran I/O statement that contains an ERR or IOSTAT specifier, Fortran semantics take precedence. The exception is not signaled to the Language Environment condition handler.
2. In the enablement step, Fortran treats all exceptions as conditions. Processing continues with the condition handling step, described below.

3. There is no user-written condition handler on the Fortran stack frame (because CEEHDLR cannot be called from a Fortran routine), and the condition is percolated.

4. If a user-written condition handler has been registered for the condition (as specified in the global error table) using CEEHDLR on the C stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points.

   In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

5. If a C signal handler has been registered for the condition, it is given control. If it moves the resume cursor or issues a call to `longjmp()`, the condition handling step ends. Processing resumes in the routine to which the resume cursor points.

   In this example, no C signal handler is registered for the condition, so the condition is percolated.

6. If the condition is of severity 0 or 1, Language Environment default actions take place, as described in Table 63 on page 255.

7. If the condition is of severity 2 or above, Language Environment default action is to promote the condition to T_I_U (Termination Imminent due to an Unhandled condition) and redrive the stack. Condition handling now enters the termination imminent step.

8. If on the second pass of the stack no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

Figure 25. C Function Invoked by Fortran Program (Part 2 of 2)
Chapter 7. Communicating between C++ and Fortran

This chapter describes Language Environment's support for C++ and Fortran ILC applications.

General Facts about C++ to Fortran ILC

- A load module consisting of object code compiled with any Fortran compiler link-edited with object code compiled in another language is not reentrant, regardless of whether the Fortran routine was compiled with the RENT compiler option.
- Return codes cannot be passed from a C++ routine to the Fortran routine that invoked it.
- Fortran routines cannot operate under CICS.
- Support for Fortran on VM is not provided by Language Environment.
- Several C++ and Fortran library routines have identical names; you will need to resolve name conflicts before link-editing your C++ to Fortran applications. See z/OS Language Environment Programming Guide for link-editing information.
- C++ is supported on MVS only.
- Fortran routines can not operate in an XPLINK environment, so ILC with C routines compiled XPLINK is not supported.
- There is no ILC support between AMODE 31 and AMODE 64 applications. Fortran does not support AMODE 64.

Preparing for ILC

This section describe topics you might want to consider before writing an ILC application. To determine how different versions of HLLs work together, refer to the migration guides for the HLLs you plan to use.

Language Environment ILC Support

Language Environment provides ILC support between the following combinations of C++ and Fortran:

Table 30. Supported Languages for Language Environment ILC

<table>
<thead>
<tr>
<th>HLL Pair</th>
<th>C++</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>C++ to Fortran</td>
<td>IBM C/C++ for MVS/ESA, z/OS XL C/C++ compilers</td>
<td>FORTRAN IV G1, FORTRAN IV H Extended, VS FORTRAN Version 1, except modules compiled with Release 2.0 or earlier and that either pass character arguments to, or receive character arguments from, subprograms, VS FORTRAN Version 2, except modules compiled with Releases 5 or 6 and whose source contained any parallel language constructs or parallel callable services, or were compiled with either of the compiler options PARALLEL or EC.</td>
</tr>
</tbody>
</table>

Determining the Main Routine

In Language Environment, only one routine can be the main routine; no other routine in the enclave can use syntax that indicates it is main.
A C++ function is designated as a main routine because its function definition gives its name as main. The entry point into the load module is CEESTART. In C++, the same routine can serve as both the main routine and subroutine if it is recursively called. In such a case, the new invocation of the routine is not considered a second main routine within the enclave, but a subroutine.

A Fortran routine is designated as a main routine with a PROGRAM statement, which indicates the name of the main routine. A main routine can also be designated by the absence of PROGRAM, SUBROUTINE, or FUNCTION statements, in which case the name of the main routine is the default value MAIN (or MAIN# for VS FORTRAN Version 2 Releases 5 and 6).

An entry point is defined for each supported HLL. Table 31 identifies the main and fetched entry point for each language. The table assumes that your code has been compiled using the Language Environment-conforming compilers.

\[
\begin{array}{|c|c|c|}
\hline
\text{HLL} & \text{Main Entry Point} & \text{Fetched Entry Point} \\
\hline
\text{C++} & \text{CEESTART} & \text{Not supported} \\
\hline
\text{Fortran} & \text{Name on the PROGRAM statement. In the absence of PROGRAM, SUBROUTINE, or FUNCTION statements, the default value MAIN (or MAIN# in VS FORTRAN Version 2 Releases 5 and 6) is used.} & \text{Subprogram name} \\
\hline
\end{array}
\]

**Declaring C++ to Fortran ILC**

An extern linkage specification is required for C++ to call Fortran and for Fortran to call C++. All entry declarations are made in the C++ code; no special declaration is required in the Fortran routine. The specification allows the C++ routine to pass arguments and return values to and from the Fortran routine using an internal argument list compatible with Fortran.

The extern linkage specification has the following format:

`extern "FORTRAN" {declaration}`

*declaration* is a valid C++ prototype of the Fortran program being called by C++, or the C++ routine being called by Fortran.

**Example of Declaration for C++ Calling Fortran**

The following example shows a partial C++ routine that calls a Fortran function. The calling C++ routine contains the `extern "FORTRAN"` linkage specification for the Fortran function FORTFCN, the function prototype for the Fortran function, and a static call to the Fortran function.

<table>
<thead>
<tr>
<th>C++ Routine</th>
<th>Fortran Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>extern &quot;FORTRAN&quot;</code></td>
<td></td>
</tr>
<tr>
<td><code>{double fortfcn(int, double *);}...</code></td>
<td></td>
</tr>
<tr>
<td><code>double fortfcn(int, double [100]);...</code></td>
<td></td>
</tr>
<tr>
<td><code>int index;</code></td>
<td></td>
</tr>
<tr>
<td><code>double list[100];</code></td>
<td></td>
</tr>
<tr>
<td><code>double value;...</code></td>
<td></td>
</tr>
<tr>
<td><code>value=fortfcn(index, list);</code></td>
<td></td>
</tr>
</tbody>
</table>

FUNCTION FORTFCN
(INDEX, LIST) RESULT (VALUE)
INTEGER=4 INDEX
REAL=8 LIST(0:99)
REAL=8 VALUE
... 
VALUE=LIST(INDEX)
END
Example of Declaration for Fortran Calling C++

The following example shows a partial Fortran routine that calls a C++ function. The called C++ function contains the extern "FORTRAN" linkage specification for the C++ function CFCN and the function definition for the C++ function.

<table>
<thead>
<tr>
<th>Fortran Routine</th>
<th>C++ Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER*4 INDEX</td>
<td>extern &quot;FORTRAN&quot;</td>
</tr>
<tr>
<td>REAL*8 LIST(0:99)</td>
<td>{double cfcn(int *, double *);}</td>
</tr>
<tr>
<td>REAL*8 VALUE</td>
<td></td>
</tr>
<tr>
<td>REAL*8 CFCN</td>
<td>double cfcn(int *index, double list [])</td>
</tr>
<tr>
<td>VALUE=CFCN(INDEX, LIST)</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>return list[*index];</td>
</tr>
</tbody>
</table>

Calling between C++ and Fortran

This section describes the types of calls permitted between C++ and Fortran, and considerations when using dynamic calls and fetch.

Types of Calls Permitted

Table 32 describes the types of calls between C++ and Fortran that Language Environment allows:

<table>
<thead>
<tr>
<th>ILC Direction</th>
<th>Static Calls</th>
<th>Dynamic Calls</th>
<th>Fetch</th>
</tr>
</thead>
<tbody>
<tr>
<td>C++ to Fortran</td>
<td>Yes</td>
<td>N/A</td>
<td>C++ doesn't support fetch()</td>
</tr>
<tr>
<td>Fortran to C++</td>
<td>Yes</td>
<td>Yes</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Dynamic Call/Fetch Considerations

All of the rules described here for dynamic call and fetch assume that compiled code conforms to the list of supported products in Chapter 7, “Communicating between C++ and Fortran,” on page 111.

Fortran Dynamically Calling C++

Dynamic calls are made in Fortran by specifying the name of the routine to be loaded with the DYNAMIC compiler option, and then using the same name in a CALL statement. The dynamically called routine can be either C++ or Fortran, and it can in turn statically call either a C++ or Fortran routine. (If the statically linked C++ routine is within a dynamically loaded module with a Fortran entry point, the C++ routine must be either nonreentrant or naturally reentrant.) In the dynamically loaded module, a routine can dynamically call other C++ or Fortran routines, regardless of whether the routines are reentrant.

Neither a C++ nor a Fortran routine can delete a dynamically loaded routine that was dynamically loaded in a Fortran routine.

Invoking Functions with Returned Values

Both C++ and Fortran can invoke the other language as a function that returns a value: in C++, this would be a function that returns something other than void; in Fortran, the equivalent of a function is a routine that begins with a FUNCTION
Calling Fortran Library Routines

You can statically call a Fortran library routine, such as CPUTIME, from C++. However, you cannot dynamically call a Fortran library routine from C++.

Passing Data between C++ and Fortran

This section describes the data types that can be passed between C++ and Fortran. In the C++-to-Fortran passing direction, most of the data types can be passed by reference only; several can be passed by value. In the Fortran-to-C++ passing direction, however, the only passing method allowed is by reference.

Under Language Environment, the term by value means that a temporary copy of the argument is passed to the called function or procedure. Any changes to the parameter made by the called routine will not alter the original parameter passed by the calling routine. Under Language Environment, the term by reference means that the actual address of the argument is passed. Any changes to the parameter made by the called routine can alter the original parameter passed by the calling routine.

Supported Data Types between C++ and Fortran

Table 33 lists the data types that can be passed between C++ and Fortran by reference.

<table>
<thead>
<tr>
<th>C++</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed short int</td>
<td>INTEGER*2</td>
</tr>
<tr>
<td>signed int, signed long int</td>
<td>INTEGER*4</td>
</tr>
<tr>
<td>float</td>
<td>REAL*4</td>
</tr>
<tr>
<td>double</td>
<td>REAL*8</td>
</tr>
<tr>
<td>long double</td>
<td>REAL*16</td>
</tr>
<tr>
<td>signed char</td>
<td>INTEGER*1</td>
</tr>
<tr>
<td>unsigned char</td>
<td>UNSIGNED<em>1 or CHARACTER</em>1</td>
</tr>
<tr>
<td>char[n]</td>
<td>CHARACTER*’n’</td>
</tr>
</tbody>
</table>

Address of supported data types and aggregates

Examples:
Address of an integer
(...int**...) 
POINTER (X,Y) 
INTEGER*4 Y

Address of an array of integers
(...int[”]8[”]...) 
POINTER (X,Y) 
INTEGER*4 Y(8)

Supported Data Types for Passing by Value

Table 34 lists the data types that can be passed from C++ to Fortran by value.

<table>
<thead>
<tr>
<th>C++</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed int, signed long int</td>
<td>INTEGER*4</td>
</tr>
<tr>
<td>double</td>
<td>REAL*8</td>
</tr>
</tbody>
</table>

statement. Only certain data types, however, can be used as function return values. See Table 35 on page 115 for a list of the supported data types that can be used as function return values.
Table 34. Supported Data Types for Passing by Value from C++ to Fortran (continued)

<table>
<thead>
<tr>
<th>C++</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>long double</td>
<td>REAL*16</td>
</tr>
</tbody>
</table>

Supported Data Types for Passing Function Return Values

Table 35 lists the data types that can be passed as function return values from a C++ function to a Fortran routine.

Table 35. Supported Data Types for Passing as Function Return Values from C++ to Fortran

<table>
<thead>
<tr>
<th>C++</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed short int</td>
<td>INTEGER*2</td>

<tr>
<td>long double</td>
<td>REAL*16</td>
</tr>
<tr>
<td>signed char</td>
<td>INTEGER*1</td>
</tr>
<tr>
<td>unsigned char</td>
<td>UNSIGNED*1</td>
</tr>
</tbody>
</table>

Passing an Alternate Return Code from Fortran to C++

You can pass an alternate return code to a C++ routine from a Fortran subroutine by specifying the called Fortran subroutine in the extern "FORTRAN" linkage specification. The Fortran subroutine will produce an alternate return code when alternate returns are specified as dummy arguments on the SUBROUTINE statement.

In an all-Fortran application, the alternate returns provide a way to return to a point in the calling program other than to the point immediately following the CALL statement. The following example illustrates how a Fortran routine would call a Fortran subroutine to use an alternate return:

CALL FSUB (ARG1, *22, ARG2, *66)

In this example, *22 and *66 specify two labels (22 and 66) to which control can be passed rather than to the point following the CALL statement. The corresponding subroutine would be coded as follows:

SUBROUTINE FSUB (DARG1, DARG2, *, *)

When the FSUB subroutine executes the following RETURN statement, control would pass to the calling program at the second alternate return, at label 66.

RETURN 2

In C++, you can use the fortrc() function and extern "FORTRAN" linkage specification to get the alternate return code from the Fortran RETURN statement of the Fortran call immediately preceeding it. You must not have any other C++ code between the Fortran routine call and fortrc(), otherwise the result is undefined.

In the following example, the C++ routine calls the subroutine FSUB, whose SUBROUTINE and RETURN statements are shown above. The fortrc() function returns an alternate return code of 2.

extern "FORTRAN" {void fsub (float, float);}  
#include <stdlib.h>  
int rc:
You cannot pass return code values from a called C++ function to a calling Fortran routine.

Passing Character Data
Character data can be received by a Fortran routine only when the routine that receives the data declares the data to be of fixed length. Therefore, the Fortran form CHARACTER(*) cannot be used by a Fortran routine to receive character data. An array of characters can be processed in a C++ routine only when the Fortran routine or the C++ routine produces the terminating null character.

Mapping Arrays between C++ and Fortran
Arrays can be passed between C++ and Fortran routines when the array passed has its elements in contiguous storage locations. In addition, in a called Fortran routine, the declaration of the array must indicate a constant number of elements along each dimension.

In C++, arrays of more than one dimension are arranged in storage in row major order, while in Fortran they are arranged in column major order. You need to reference the corresponding element of the other language by reversing the order of the subscripts. For example in an array of floating point integers, the C++ declaration would be float [10] while the Fortran declaration would be REAL*4(20,10).

Another difference in using arrays is that unless specified otherwise, the lower bound (the lowest subscript value) of a Fortran array is 1. In C++, the lowest subscript value is always 0, so you must adjust either the declared lower bound in the Fortran routine or the subscript you are using when you reference the value in C or Fortran.

For example, the two arrays below have the same storage mapping:

C++    float da[10][20];
Fortran    REAL*4 DA(20,10)

The two elements below also represent the same storage:

C++    da[4] [8]
Fortran    DA(9,5)

Data Equivalents
This section describes how C++ and Fortran data types correspond to each other.

Equivalent Data Types for C++ to Fortran
The following examples illustrate how C++ and Fortran routines within a single ILC application might code the same data types. The examples might be clearer to you.
if you first read "Passing Data between C++ and Fortran" on page 114, which describes how a C++ routine can receive parameters that are passed by value and by reference.

**16-Bit Signed Binary Integer**

<table>
<thead>
<tr>
<th>Sample C++ Usage (by Reference)</th>
<th>Fortran Subroutine</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>extern &quot;FORTRAN&quot;</code></td>
<td><code>SUBROUTINE CFORT (ARG)</code></td>
</tr>
<tr>
<td><code>{ void cfort( short int &amp;); }</code></td>
<td><code>INTEGER*2 ARG</code></td>
</tr>
<tr>
<td><code>#include &lt;stdio.h&gt;</code></td>
<td><code>PRINT *, 'FORTRAN ARG VALUE:', ARG</code></td>
</tr>
<tr>
<td><code>main()</code></td>
<td><code>ARG = ARG + 1</code></td>
</tr>
<tr>
<td><code>{ short int x;</code></td>
<td><code>END</code></td>
</tr>
<tr>
<td><code>x=5;</code></td>
<td></td>
</tr>
<tr>
<td><code>cfort(x);</code></td>
<td></td>
</tr>
<tr>
<td><code>printf (&quot;Updated value in C: %d\n&quot;, x);</code></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** Because `short int` is an example of a parameter which must be passed using a C++ explicit pointer, you cannot code `cfort(x)`, passing `x` by value.

</table>
### Long Floating-Point Number

#### Sample C++ Usage (by Value)
```c++
extern "FORTRAN" 
{ double cfort(double); } 
#include <stdio.h> 
main()
{
    double x, y;
    x=12.5;
    y=cfort(x);
    printf("Value returned to C: %f\n", y);
}
```

#### Fortran Function
```fortran
FUNCTION CFORT ( ARG ) 
REAL*8 CFORT 
REAL*8 ARG 
PRINT *, 'FORTRAN ARG VALUE:', ARG 
CFORT = ARG 
END
```

#### Sample C++ Usage (by Reference)
```c++
extern "FORTRAN" 
{ double cfort(double &); } 
#include <stdio.h> 
main()
{
    double x, y;
    x=12.5;
    y=cfort(x);
    printf("Value returned to C: %f\n", y);
}
```

#### Fortran Function
```fortran
FUNCTION CFORT ( ARG ) 
REAL*8 CFORT 
REAL*8 ARG 
PRINT *, 'FORTRAN ARG VALUE:', ARG 
CFORT = ARG 
END
```

### Extended Floating-Point Number

#### Sample C++ Usage (by Value)
```c++
extern "FORTRAN" 
{ long double cfort(long double); } 
#include <stdio.h> 
main()
{
    long double x, y;
    x=12.1L;
    y=cfort(x);
    printf("Value returned to C: %Lf\n", y);
}
```

#### Fortran Function
```fortran
FUNCTION CFORT ( ARG ) 
REAL*16 CFORT 
REAL*16 ARG 
PRINT *, 'FORTRAN ARG VALUE:', ARG 
CFORT = ARG 
END
```

#### Sample C++ Usage (by Reference)
```c++
extern "FORTRAN" 
{ long double cfort(long double &); } 
#include <stdio.h> 
main()
{
    long double x, y;
    x=12.1L;
    y=cfort(x);
    printf("Value returned to C: %Lf\n", y);
}
```

#### Fortran Function
```fortran
FUNCTION CFORT ( ARG ) 
REAL*16 CFORT 
REAL*16 ARG 
PRINT *, 'FORTRAN ARG VALUE:', ARG 
CFORT = ARG 
END
```
### Signed One-Byte Character Data

**Sample C++ Usage (by Reference)**
```c++
extern "FORTRAN"
{ void cfort(signed char &); }
#include <stdio.h>
main()
{
    signed char x, y;
x=-5;
cfort(x);
    printf("Updated value in C: \%d\n", x);
}
```

**Fortran Subroutine**
```fortran
SUBROUTINE CFORT ( ARG )
INTEGER*1 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
ARG = ARG - 1
END
```

### Unsigned One-Byte Character Data

**Sample C++ Usage (by Reference)**
```c++
extern "FORTRAN"
{ void cfort(unsigned char &, unsigned char &); }
#include <stdio.h>
main()
{
    unsigned char x, y;
x='a';
cfort(x,y);
    printf("Value returned to C: \%c\n", y);
}
```

**Fortran Subroutine**
```fortran
SUBROUTINE CFORT ( ARG1, ARG2 )
CHARACTER*1 ARG1, ARG2
PRINT *, 'FORTRAN ARG1 VALUE: ', ARG1
ARG2 = ARG1
END
```

### Fixed-Length Character Data

**Sample C++ Usage**
```c++
extern "FORTRAN"
{ void cfort(char [10], char [10]); }
#include <stdio.h>
main()
{
    char x[10] = "1234567890";
    char y[10];
cfort(x,y);
    printf("Value returned to C: \%10.10s\n", y);
}
```

**Fortran Subroutine**
```fortran
SUBROUTINE CFORT ( ARG1, ARG2 )
CHARACTER*10 ARG1, ARG2
PRINT *, 'FORTRAN ARG1 VALUE: ', ARG1
ARG2 = ARG1
END
```

### Array

**Sample C++ Usage**
```c++
extern "FORTRAN"
{ void cfort(float[]); }
#include <stdio.h>
main()
{
    float matrix[3] = {0.0F, 1.0F, 2.0F};
cfort(matrix);
    printf("Updated values in C: \%f \%f \%f\n",
        matrix[0], matrix[1], matrix[2]);
}
```

**Fortran Subroutine**
```fortran
SUBROUTINE CFORT ( ARG )
REAL*4 ARG(3)
PRINT *, 'FORTRAN ARG VALUES:', ARG
DO J = 1, 3
    ARG(J) = ARG(J) + 1.0
ENDDO
END
```
Address of an Integer

Sample C++ Usage

```c
extern "FORTRAN"
{
    void cfort (int *temp);
}
#include <stdio.h>
main()
{
    int i, *temp;
    i = 5;
    temp = &i;
    cfort(temp);
    printf("Updated integer value in C: %d, i\n", i);
}
```

Fortran Subroutine

```fortran
SUBROUTINE CFORT (ARG)
POINTER*4 (ARG, Y)
INTEGER*4 Y
PRINT *,
1 'FORTRAN INTEGER ARG VALUE:', Y
Y = Y + 1
END
```

Address of an Array

Sample C++ Usage

```c
extern "FORTRAN"
{
    void cfort(int(**)[3]);
}
#include <stdio.h>
main()
{
    int matrix[3] = {0,1,2};
    int (*temp)[3] = &matrix;
    cfort(&temp);
    printf("Updated values in C: %d %d %d\n", matrix[0], matrix[1], matrix[2]);
}
```

Fortran Subroutine

```fortran
SUBROUTINE CFORT (ARG)
POINTER*4 (ARG, Y)
INTEGER*4 Y(3)
PRINT *,
1 'FORTRAN ARRAY ARG VALUES:', Y
DO J = 1, 3
    Y(J) = Y(J) + 1
ENDDO
END
```

Equivalent Data Types for Fortran to C++

The following examples illustrate how C++ and Fortran routines within a single ILC application might code the same data types. The examples might be clearer to you if you first read “Passing Data between C++ and Fortran” on page 114 which describes how a C++ routine can receive parameters that are passed by value and by reference.

16-Bit Signed Binary Integer

Sample Fortran Usage

```fortran
INTEGER*2 X
X = 5
CALL CENTRY(X)
PRINT *,
1 'UPDATED VALUE IN FORTRAN:', X
END
```

C++ Function (by Reference)

```c
extern "FORTRAN"
{
    void centry(short int &);
}
#include <stdio.h>
short int centry(short int &x)
{
    printf("C int arg value: %d, x\n", x);
    x += 1;
}
```

32-Bit Signed Binary Integer

Sample Fortran Usage (by Value)

```fortran
INTEGER*4 X, Y, CENTRY
X = 5
Y = CENTRY(X)
PRINT *,
1 'VALUE RETURNED TO FORTRAN:', Y
END
```

C++ Function (by Value)

```c
extern "FORTRAN"
{
    int centry(int);}
#include <stdio.h>
int centry(int x)
{
    printf("C arg value: %d, x\n", x);
    return(x);
}
**Sample Fortran Usage**

| INTEGER*4 X, Y, CENTRY   | `extern "FORTRAN"
{ int centry(int &); }` |
|-------------------------|----------------------------|
| X = 5                   | `#include <stdio.h>
int centry(int &x)` |
| Y = CENTRY(X)           | `{ }
printf("C int arg value: %d\n",x);
return(x);` |
| PRINT *,                | `Y = CENTRY(X)` |
| 1 'VALUE RETURNED TO FORTRAN: ', Y | `Y = CENTRY(X)` |
| END                     | `Y = CENTRY(X)` |

**Short Floating-Point Number**

| REAL*4 X, Y, CENTRY    | `extern "FORTRAN"
{ float centry(float &); }` |
|-----------------------|----------------------------|
| X = 5.0               | `#include <stdio.h>
float centry(float &x)` |
| Y = CENTRY(X)         | `{ }
printf("C float arg value: %f\n",x);
return(x);` |
| PRINT *,              | `Y = CENTRY(X)` |
| 1 'VALUE RETURNED TO FORTRAN: ', Y | `Y = CENTRY(X)` |
| END                   | `Y = CENTRY(X)` |

**Long Floating-Point Number**

| REAL*8 X, Y, CENTRY   | `extern "FORTRAN"
{ double centry(double &); }` |
|----------------------|----------------------------|
| X = 12.5000          | `#include <stdio.h>
double centry(double &x)` |
| Y = CENTRY((X))      | `{ }
printf("C arg value: %f\n",x);
return(x);` |
| PRINT *,             | `Y = CENTRY((X))` |
| 1 'VALUE RETURNED TO FORTRAN: ', Y | `Y = CENTRY((X))` |
| END                  | `Y = CENTRY((X))` |

**Extended Floating-Point Number**

| REAL*16 X, Y, CENTRY | `extern "FORTRAN"
{ long double centry(long double &); }` |
|----------------------|----------------------------|
| X = 12.1Q00          | `#include <stdio.h>
long double centry(long double &x)` |
| Y = CENTRY((X))      | `{ }
printf("C double arg value: %Lf\n",x);
return(*x);` |
| PRINT *,             | `Y = CENTRY((X))` |
| 1 'VALUE RETURNED TO FORTRAN: ', Y | `Y = CENTRY((X))` |
| END                  | `Y = CENTRY((X))` |
### Sample Fortran Usage

**REAL*16 X, Y, CENTRY**

```fortran
X = 5.0Q0
Y = CENTRY(X)
PRINT *,
 1 'VALUE RETURNED TO FORTRAN:', Y
END```

**C++ Function (by Reference)**

```cpp
extern "FORTRAN"
{ long double centry(long double &); }
#include
long double centry(long double &x)
{
  printf("C long double arg value: \%Lf\n", x);
  return(x);
}
```

### Signed One-Byte Character Data

**Sample Fortran Usage**

```fortran
INTEGER*1 X
X = -5
CALL CENTRY(X)
PRINT *,
 1 'UPDATED VALUE IN FORTRAN:', X
END```

**C++ Function (by Reference)**

```cpp
extern "FORTRAN"
{ void centry(signed char &); }
#include <stdio.h>
void centry(signed char &x)
{
  printf("C char arg value: %d\n", x);
  x -= 1;
}
```

### Unsigned One-Byte Character Data

**Sample Fortran Usage**

```fortran
CHARACTER*1 X, Y
X = 'A'
CALL CENTRY(X, Y)
PRINT *,
 1 'VALUE RETURNED TO FORTRAN: ', Y
END```

**C++ Function (by Reference)**

```cpp
extern "FORTRAN"
{ void centry(unsigned char *, unsigned char &); }
#include <stdio.h>
void centry(unsigned char &x; unsigned char &y)
{
  printf("C char arg value: %c\n", x);
  y = x;
}
```

### Fixed-Length Character Data

**Sample Fortran Usage**

```fortran
CHARACTER*10 X, Y
X = '1234567890'
CALL CENTRY(X, Y)
PRINT *,
 1 'VALUE RETURNED TO FORTRAN: ', Y
END```

**C++ Function (by Reference)**

```cpp
extern "FORTRAN"
{ void centry(char [10],
  char [10]); }
#include <stdio.h>
#include <string.h>
void centry(char x[10],
  char y[10])
{
  printf("C char array arg: %10.10s\n", x);
  memcpy(y, x, 10);
}
```
Array

Sample Fortran Usage
REAL*4 MATRIX(3) / 1.0, 2.0, 3.0 /
CALL CENTRY(MATRIX)
PRINT *,
1 'UPDATED VALUES IN FORTRAN:', MATRIX
END

C++ Function
extern "FORTRAN"
{ void CENTRY(float [3]); }
#include <stdio.h>
void CENTRY(float x[3])
{
    int index;
    printf("C arg values: %f %f %f\n", x[0], x[1], x[2]);
    for (index = 0; index <= 2; index++)
        x[index] -= 1.0F;
}

Address of an Integer

Sample Fortran Usage
POINTER*4 (P, I)
INTEGER*4 I, J
P = LOC(J)
I = 5
CALL CENTRY(P)
PRINT *,
1 'UPDATED VALUE IN FORTRAN:', I
END

C++ Function
extern "FORTRAN"
{ void CENTRY(int **); }
#include <stdio.h>
void CENTRY(int **x)
{
    printf("C int arg value: %d\n", **x);
    **x += 1;
}

Address of an Array

Sample Fortran Usage
POINTER*4 (P, I)
INTEGER*4 I(3)
INTEGER*4 J(3) / 1, 2, 3 /
P = LOC(J)
CALL CENTRY (P)
PRINT *,
1 'UPDATED VALUE IN FORTRAN:', I
END

C++ Function
extern "FORTRAN"
{ void CENTRY(int **)[3]; }
#include <stdio.h>
void CENTRY(int **x)[3]
{
    int index;
    printf("C int array arg values: %d %d %d\n", (**x)[0], (**x)[1], (**x)[2]);
    for (index = 0; index <= 2; index++)
        (**x)[index] -= 1;
}

External Data

External data in a C++ routine can be shared with a common block of the same name in a Fortran routine in the same load module under the following conditions:

- The C++ static data is declared outside of any functions
- The C++ external data is declared NORENT by using #pragma variable(var, NORENT). Otherwise, C++ variables are always RENT.
- The Fortran static common blocks are either used only with one load module in an application or they are declared as private common blocks. A private common block is not shared across load modules and must be created in any of the following ways:
  - Specified or implied by the PC compiler option
  - Referenced by Fortran object code produced by the VS FORTRAN Version 2 Release 4 compiler or earlier
  - In an application that executes with the PC run-time option
Directing Output in ILC Applications

Language Environment does not provide support to coordinate the use of most C++ and Fortran files; however they can share the Language Environment message file which is the ddname specified in the Language Environment MSGFILE run-time option. You must manage all other files to ensure that no conflicts arise. For example, performing output operations on the same ddname is likely to cause unpredictable results.

Under C++, run-time messages and other related output are directed to the default MSGFILE ddname. stderr output is also by default directed to the MSGFILE ddname. stdout is not, by default, directed to the MSGFILE ddname, but can be redirected to do so. Also, output from printf can be interspersed with output from the Fortran PRINT statement and output from Language Environment by redirecting stdout to stderr (for example, passing 1>&2 as a command line parameter).

For more information on how to redirect C++ output, see z/OS XL C/C++ Programming Guide.

Fortran run-time messages, output written to the print unit, and other output (such as output from the SDUMP callable service) are directed to the file specified by the MSGFILE run-time option. To direct this output to the file with the ddname FTnnF001, (where nn is the two-digit error message unit number), specify the run-time option MSGFILE(FTnnF001). If the print unit is different than the error message unit (if the PRTUNIT and the ERRUNIT run-time options have different values), output from a PRINT statement won't be directed to the Language Environment message file.

C++ to Fortran Condition Handling

This section provides two scenarios of condition handling behavior in a C to Fortran ILC application. If an exception occurs in a C routine, the set of possible actions is as described in "Exception Occurs in C" on page 104. If an exception occurs in a Fortran program, the set of possible actions is as described in "Exception Occurs in Fortran" on page 106.

Some conditions can be handled only by the HLL of the routine in which the exception occurred. For example, when an ERR or IOSTAT specifier is present on a Fortran I/O statement and an error is detected while executing that statement, the Fortran semantics take precedence over Language Environment condition handling. In this case, control returns immediately to the Fortran program and no condition is signaled to Language Environment.

C++ exception handling constructs try()/throw()/catch() cannot be used with Language Environment and Fortran condition handling. If you use C exception handling constructs (signal()/raise()) in your C++ routine, condition handling will proceed as described in this section. Otherwise, you will get undefined behavior in your programs if you mix the C++ constructs with the C constructs. For a detailed description of Language Environment condition handling, see z/OS Language Environment Programming Guide.

See z/OS Language Environment Programming Guide for a detailed description of Language Environment condition handling. For information on Fortran condition handling semantics, see VS FORTRAN Version 2 Language and Library Reference.
Enclave-Terminating Language Constructs

Enclaves can be terminated for reasons other than an unhandled condition of severity 2 or greater. HLL constructs that cause the termination of a single language enclave also cause the termination of a C to Fortran enclave. In Language Environment ILC, you can issue the language construct to terminate the enclave from a C++ or Fortran routine.

C Language Constructs Available under C++

Among the C language constructs that terminate an enclave are abort(), exit(), raise(SIGABND), and raise(SIGTERM). When you use a C language construct to terminate an enclave, the T_I_S (Termination Imminent Due to STOP) condition is raised. After T_I_S has been processed and all user code has been removed from the stack, the C atexit list is honored.

Fortran

The Fortran language constructs that cause the enclave to terminate are:
- A STOP statement
- An END statement in the main routine
- A call to EXIT or SYSRCX
- A call to DUMP or CDUMP

All of the constructs listed above except the END statement cause the T_I_S (Termination Imminent due to STOP) condition to be signaled.

Exception Occurs in C++

This scenario describes the behavior of an application that contains a C++ and Fortran routine. In this scenario, a Fortran main routine invokes a C++ subroutine. An exception occurs in the C++ subroutine. Refer to Figure 26 throughout the following discussion.

![Figure 26. Stack Contents When the Exception Occurs](image-url)
The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, C++ determines whether the exception in the C++ routine should be enabled and treated as a condition. If any of the following are true, the exception is ignored, and processing continues at the next sequential instruction after where the exception occurred:
   - You specified SIG_IGN for the exception in a call to signal().

   **Note:** The system or user abend corresponding to the signal(SIGABND) or the Language Environment message 3250 is not ignored. The enclave is terminated.
   - The exception is one of those listed as masked in Table 64 on page 255 and you have not enabled it using the CEE3SPM callable service.
   - You did not specify any action, but the default action for the condition is SIG_IGN (see Table 64 on page 255).

   If you did none of these things, the condition is enabled and processed as a condition.

2. If a user-written condition handler has been registered using CEEHDLR on the C++ stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points.

   In this example, there is not a user-written condition handler registered for the condition, so the condition is percolated.

3. The C global error table is now examined for signal handlers that have been registered for the condition.

   If there is a signal handler registered for the condition, it is given control. If it issues a resume or a call to longjmp(), the condition handling step ends. Processing resumes in the routine to which the resume cursor points.

   In this example no C++ signal handler is registered for the condition, so the condition is percolated.

4. The condition is still unhandled. If C++ does not recognize the condition, or if the C++ default action (listed in Table 64 on page 255) is to terminate, the condition is percolated.

5. There is no user-written condition handler on the Fortran stack frame (because CEEHDLR cannot be called from a Fortran routine), and the condition is percolated.

6. If the condition is of severity 0 or 1, the Language Environment default actions take place, as described in Table 63 on page 255.

7. If the condition is of severity 2 or above, Language Environment default action is to promote the condition to T_I_U (Termination Imminent due to an Unhandled condition) and redrive the stack. Condition handling now enters the termination imminent step.

8. If, on the second pass of the stack, no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

**Exception Occurs in Fortran**

This scenario describes the behavior of an application that contains a Fortran and a C++ routine. In this scenario, a C++ main routine invokes a Fortran subroutine. An exception occurs in the Fortran subroutine. Refer to Figure 27 on page 127 throughout the following discussion.
The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. If an I/O error is detected on a Fortran I/O statement that contains an ERR or IOSTAT specifier, Fortran semantics take precedence. The exception is not signaled to the Language Environment condition handler.

2. In the enablement step, Fortran treats all exceptions as conditions. Processing continues with the condition handling step, described below.

3. There is no user-written condition handler on the Fortran stack frame (because CEEHDLR cannot be called from a Fortran routine), and the condition is percolated.

4. If a user-written condition handler has been registered for the condition (as specified in the C global error table) using CEEHDLR on the C++ stack frame, it is given control. If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points.

   In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

5. If a C signal handler has been registered for the condition, it is given control. If it moves the resume cursor or issues a call to `longjmp()`, the condition handling step ends. Processing resumes in the routine to which the resume cursor points.

   In this example, no C signal handler is registered for the condition, so the condition is percolated.

6. If the condition is of severity 0 or 1, Language Environment default actions take place, as described in Table 63 on page 255.

7. If the condition is of severity 2 or above, Language Environment default action is to promote the condition to T_I_U (Termination Imminent due to an Unhandled condition) and redrive the stack. Condition handling now enters the termination imminent step.
8. If on the second pass of the stack no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

### Sample ILC Applications

Chapter 8. Communicating between C and PL/I

This chapter describes Language Environment’s support for C and PL/I ILC applications. If you are running a C to PL/I ILC application under CICS, you should also consult Chapter 15, “ILC under CICS,” on page 247.

General Facts about C to PL/I ILC

- ILC between C and Enterprise PL/I for z/OS is discussed in Enterprise PL/I for z/OS Programming Guide.
- PL/I routines can run in non-Initial Process Threads (non-IPTs) created by the C routines in z/OS UNIX—conforming C to PL/I applications.
- PL/I Multitasking Facility (MTF) does not support C.
- With Enterprise PL/I for z/OS, a C program that is fetched from a PL/I main must be compiled with the most recent C compiler. If another version of C is desired, specify OPTIONS(ASM).
- Language Environment does not support passing return codes between PL/I and C routines in an ILC application.
- A C NULL is X’00000000’; a PL/I NULL is X’FF000000’; a PL/I SYSNULL is X’00000000’. Comparisons against a NULL value and other uses of the NULL value must therefore be done with care.
- There is no ILC support between AMODE 31 and AMODE 64 applications. PL/I does not support AMODE 64.

Preparing for C to PL/I ILC

This section describes topics you might want to consider before writing an application that uses ILC. For help in determining how different versions of HLLs work together, refer to the migration guides for the HLLs you plan to use.

Language Environment ILC Support

Table 36. Supported Languages for Language Environment ILC

<table>
<thead>
<tr>
<th>HLL Pair</th>
<th>C</th>
<th>PL/I</th>
</tr>
</thead>
<tbody>
<tr>
<td>C–PL/I</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• C/370 Version 1</td>
<td>• OS PL/I Version 2 Release 2 or later</td>
</tr>
<tr>
<td></td>
<td>• C/370 Version 2</td>
<td>• Enterprise PL/I for z/OS</td>
</tr>
<tr>

<tr>
<td></td>
<td>• IBM C/C++ for MVS/ESA</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• z/OS XL C/C++ compilers</td>
<td></td>
</tr>
</tbody>
</table>

Note: In this chapter, C refers to both the pre-Language Environment- and Language Environment-conforming versions of C. PL/I refers to OS PL/I, Enterprise PL/I for z/OS, and PL/I for MVS & VM.

Migrating C to PL/I ILC Applications

Language Environment allows you to run ILC applications that were compiled under previous versions of C and PL/I. In general, you do not need to relink or recompile an existing C to PL/I ILC application in Language Environment.

Determining the Main Routine

In Language Environment, only one routine can be the main routine. If a PL/I routine is identified as a main routine in an ILC application using PROC
OPTIONS(MAIN) and a C main function does not exist, the PL/I main routine is the first to gain control. If a C main function exists, but no PL/I main routine is identified in the ILC application, the C main function gains control first.

If both a PL/I main routine identified by PROC OPTIONS(MAIN) and a C main function exist in the same ILC application, this is a user error. However, the error is not detected by Language Environment.

An entry point is defined for each supported HLL. Table 37 identifies the desired entry point. The table assumes that your code has been compiled using the Language Environment-conforming compilers.

Table 37. Determining the Entry Point

<table>
<thead>
<tr>
<th>HLL</th>
<th>Main Entry Point</th>
<th>Fetched Entry Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>CEESTART</td>
<td>CEESTART or routine name if #pragma linkage(,fetchable) is not used.</td>
</tr>
<tr>
<td>PL/I</td>
<td>CEESTART</td>
<td>CEESTART if OPTIONS(FETCHABLE) is used, or routine name.</td>
</tr>
</tbody>
</table>

When link-editing a PL/I module that is fetched, the name of the routine that is being fetched must be the entry point of the load module, unless the FETCHABLE option is specified on the PROCEDURE statement in the PL/I routine. When link-editing a C module that is fetched, the name of the routine being fetched must be the entry point of the load module, unless #pragma linkage (,fetchable) is specified in the C routine. You cannot have more than one entry point in an ILC application with #pragma linkage (,fetchable) or PL/I FETCHABLE option on the PROCEDURE statement. This error is not detected by Language Environment, but can cause unpredictable results.

Declaring C to PL/I ILC

Declaring a C entry point in a PL/I routine has the same syntax as declaring another PL/I entry point. A C routine can be replaced by a PL/I routine without altering the PL/I code that calls the routine. Likewise, if a C routine calls a PL/I routine, the PL/I procedure contains no explicit declaration indicating control is being passed from the C routine. The declaration is contained within the C routine.

In C, you must declare that the C entry point receives control from a PL/I routine. This declaration is in the form of a #pragma. The body of the C function is the same as if the routine were called from another C function. Calling a PL/I routine and being called by a PL/I routine are handled by the same #pragma preprocessor directive. No special linkage declaration is required for ILC between C and Enterprise PL/I for z/OS.
### Declaration for C Calling PL/I

**C Function**

```c
#include <math.h>

double PLIFUNC( double ); / C prototype /

int main()
{
    double val, result;

    val = 6.2;
    result = PLIFUNC(val);
    printf("val = %f, result = %f\n", val, result);
}
```

**PL/I Routine**

```pli
PROCEDURE PLIFUNC( arg ) OPTIONS(REENTRANT);
    DCL arg FLOAT BINARY(53);
    RETURN (34.0);
END;
```

### Declaration for PL/I Calling C

**PL/I Routine**

```pli
PROCEDURE PLIPROG OPTIONS(MAIN, REENTRANT);
    DCL cfunc EXTERNAL ENTRY
        RETURNS(FIXED BINARY(31));
    DCL arg FIXED BINARY(31);
    DCL a FIXED BINARY(31);
    arg = 10;
    a = cfunc(arg);
END;
```

**C Function**

```c
#include <math.h>

int CFUNC( int parm ) {
    return (5);
}
```

### Building a Reentrant C to PL/I Application

A PL/I to C application can be constructed to be reentrant. You should compile all PL/I routines in an ILC application by using the REENTRANT option of the OPTIONS attribute of the PROCEDURE statement. Compile all your C routines with RENT.

### Calling between C and PL/I

This section describes the types of calls permitted between C and PL/I as well as dynamic call/fetch considerations.

#### Types of Calls Permitted

Table 38 describes the types of calls between C and PL/I that Language Environment allows:

<table>
<thead>
<tr>
<th>ILC Direction</th>
<th>Static Calls</th>
<th>Dynamic Calls Using DLLs</th>
<th>Fetch/Call</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>C to PL/I</td>
<td>Yes</td>
<td>Yes (1)</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>PL/I to C</td>
<td>Yes</td>
<td>Yes (1)</td>
<td>Yes</td>
<td>C must be non-reentrant or naturally reentrant.</td>
</tr>
</tbody>
</table>

**Note:** Enterprise PL/I for z/OS supports calls to a C DLL, and also allows calls from C to a PL/I DLL. In this case, the C code could also optionally be compiled with the XPLINK option.

#### Dynamic Call/Fetch Considerations

Both PL/I and C can specify only one fetchable entry point for an entire load module. In general, target routines need to be recompiled with a Language
Environment-conforming compiler. C fetching PL/I is the only exception. If a PL/I routine is resident in the main load module, the target routine does not need to be recompiled.

If a load module is introduced as a result of the PL/I FETCH statement or the C fetch() function and the load module contains any ILC or the fetching and fetched routines are written in different languages, then the load module cannot be deleted using a corresponding PL/I RELEASE statement or the C release() function.

PL/I fetch can not be used to load a C function that has been compiled with the XPLINK option.

User-written condition handlers registered using CEEHDLR can be fetched, but must be written in the same language as the fetching language.

C Fetching PL/I
The C fetch() function supports fetching a PL/I routine and subsequent invocation using a function pointer. The fetched PL/I routine can make additional calls (either static or dynamic) to other C routines. When a C routine issues the fetch to a load module having a PL/I entry point with statically linked C routines, the C routines might have constructed reentrancy.

When a PL/I routine is dynamically introduced into the enclave as a result of a fetch, the fetch restrictions described in PL/I for MVS & VM Language Reference apply. Enterprise PL/I for z/OS has lifted some of the fetch restrictions. Please see Enterprise PL/I for z/OS Language Reference for more information.

If a PL/I procedure is to be dynamically loaded, you must specify one of the following:

- The routine name as the entry point when you link-edit it (as described in PL/I for MVS & VM Programming Guide or Enterprise PL/I for z/OS Programming Guide).
- OPTIONS(FETCHABLE) on the PROCEDURE statement and recompile.

The declaration of a PL/I fetched routine within a C routine is shown in Figure 30.

typedef int PLIFUNC();
#pragma linkage (PLIFUNC, PLI)

PLIFUNC *fetch_ptr;
fetch_ptr = (PLIFUNC*) fetch("PLIENT"); /* fetch the routine */
fetch_ptr(args); /* call PLIENT */

Figure 30. C Fetching a PL/I Routine

PL/I Fetching C
A PL/I routine can fetch a C function or another PL/I routine that is statically linked to a C function. Any C routine that is either directly or indirectly fetched by PL/I must be either naturally reentrant or be non-reentrant (that is, it cannot have constructed reentrancy via the RENT option and the prelinker).

The declaration of a C fetched routine within a PL/I routine is shown in Figure 31 on page 135.
Passing Data between C and PL/I

There are two sets of data types that you can pass between C and PL/I routines: data types passed by reference using C explicit pointers in the routine, and data types passed by value without using C explicit pointers.

When a parameter is passed by reference, the parameter itself is passed. A copy of the parameter is not made. Any changes to the parameter made by the called routine can alter the original parameter passed by the calling routine. When a parameter is passed by value, a copy of the parameter is passed. Any changes to the parameter made by the called routine cannot alter the original parameter passed by the calling routine.

Passing Pointers from C to PL/I

Pointers can be passed and returned between C and PL/I routines. Because the C #pragma linkage(PLI) specifies that pointers, unlike other parameters, are passed directly, there is one level of indirection less on the PL/I side.

In order for PL/I to receive a pointer to a PL/I data type, C must pass a pointer to a pointer to the C data type. Conversely, if PL/I returns a pointer to a data type, C receives a pointer to a pointer to the data type.

Structures, arrays, and strings should be passed between C and PL/I only by using pointers.

The non-address bits in all fullword pointers declared in PL/I source code should always be zero. If they are not, results are unpredictable.

Passing Pointers from PL/I to C

Pointers to various data objects can be passed from PL/I and accepted by a function written in C.

Because the C #pragma linkage(PLI) specifies that pointers, unlike other parameters, are passed directly, an extra level of indirection is added when passing a pointer value from PL/I to C. If PL/I passes or returns a pointer to a type, C receives a pointer to a pointer to the type.

PL/I parameters that require a locator or descriptor should not be passed directly. This includes parameters that are structures, arrays, or strings. These parameters can be passed indirectly from PL/I by using a pointer to the associated data. For more information on data descriptors, see PL/I for MVS & VM Programming Guide or Enterprise PL/I for z/OS Programming Guide.
The non-address bits in all fullword pointers declared in PL/I source code should always be zero. If they are not, results are unpredictable.

Receiving Value Parameters in C

If you enclose in parentheses the argument you pass from a PL/I routine to a C routine, the argument is passed by value. C should receive the parameter as the equivalent C type. The XL C compiler generates the appropriate addressing code required to access the parameter values.

You can write your PL/I-callable function as if it were in a C-only environment; you can move it to a C-only environment by removing the #pragma directive.

Receiving Reference Parameters in C

If you do not enclose in parentheses the argument you pass from a PL/I routine to a C routine, the argument is passed by reference. C should receive the parameter as a pointer to the equivalent C type.

For example, if a C function named FROMPLI is called from PL/I with an integer argument, the C prototype declaration should be:

```
int FROMPLI(int *);
```

A parameter passed from PL/I by reference is received and used by C as a value parameter provided that its value is not altered. If the value of such a parameter is altered, the effect on the original PL/I variable is undefined.

Data Types Passed Using C Pointers (by Reference)

Table 39 identifies the data types that can be passed as parameters between C and PL/I applications with the use of explicit pointers, or by reference, under C. Conversely, reference parameters passed by PL/I to C are received as pointers to the equivalent data type.

<table>
<thead>
<tr>
<th>C</th>
<th>PL/I</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed short int</td>
<td>REAL FIXED BINARY(15,0)</td>
</tr>
<tr>
<td>signed int</td>
<td>REAL FIXED BINARY(31,0)</td>
</tr>
<tr>
<td>signed long int</td>
<td>REAL FIXED BINARY(31,0)</td>
</tr>
<tr>
<td>float</td>
<td>FLOAT BINARY(21) FLOAT DECIMAL(06)</td>
</tr>
<tr>
<td></td>
<td>FLOAT BINARY (21) is the preferred equivalent for float.</td>
</tr>
<tr>
<td>double</td>
<td>FLOAT BINARY(53) FLOAT DECIMAL(16)</td>
</tr>
<tr>
<td></td>
<td>FLOAT BINARY (53) is the preferred equivalent for double.</td>
</tr>
<tr>
<td>long double</td>
<td>FLOAT BINARY(109) FLOAT DECIMAL(33)</td>
</tr>
<tr>
<td></td>
<td>FLOAT BINARY (109) is the preferred equivalent for long double.</td>
</tr>
<tr>
<td>pointer to . . .</td>
<td>POINTER</td>
</tr>
<tr>
<td>decimal(n,p)</td>
<td>FIXED DECIMAL(n,p)</td>
</tr>
</tbody>
</table>

Note: Data storage alignment must match.

Data Types Passed by Value

Table 40 on page 137 identifies the data types that can be passed as parameters between C and PL/I applications without the use of explicit C pointers. Parameters that are not pointers are passed by value.
In order for a C routine to pass a parameter without using a pointer, the argument should be passed, and the PL/I routine should receive the parameter as the equivalent PL/I data type.

**Table 40. Supported Data Types between C and PL/I without Using C Pointers (by Value)**

<table>
<thead>
<tr>
<th>C</th>
<th>PL/I</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed int</td>
<td>REAL FIXED BINARY(31,0)</td>
</tr>
<tr>
<td>signed long int</td>
<td>REAL FIXED BINARY(31,0)</td>
</tr>
<tr>
<td>double</td>
<td>FLOAT DECIMAL(16)</td>
</tr>
<tr>
<td>double</td>
<td>FLOAT BINARY(53)</td>
</tr>
<tr>
<td>long double</td>
<td>FLOAT DECIMAL(33)</td>
</tr>
<tr>
<td>long double</td>
<td>FLOAT BINARY(109)</td>
</tr>
<tr>
<td>decimal(n,p)</td>
<td>FIXED DECIMAL(n,p)</td>
</tr>
</tbody>
</table>

**Note:** The preferred PL/I data declarations for the C double and long double data types are FLOAT BINARY(53) and FLOAT BINARY(109), respectively. Data storage alignment must match.

**Passing Strings between C and PL/I**

C and PL/I have different string data types:

**C strings**

Logically unbounded length and are terminated by a NULL (the last byte of the string contains X'00').

**PL/I CHAR(n) VARYING**

A halfword-prefixed string of characters with a maximum length of \( n \) characters. The current length is held in the halfword prefix.

**PL/I CHAR(n) VARYINGZ**

A null-terminated string of characters with a maximum length of \( n \) characters.

**PL/I CHAR(n)**

A fixed-length string of characters of length \( n \). There is no halfword prefix indicating the length.

You can pass strings between C and PL/I routines, but you must match what the routine interface demands with what is physically passed.

**Using Aggregates**

Aggregates (arrays, strings, or structures) are mapped differently by C and PL/I and are not automatically mapped. Be sure to completely declare every byte in the aggregate so there are no open fields. Doing so helps ensure that the layouts of aggregates passed between the two languages map to one another correctly. The C and PL/I AGGREGATE compile-time options provide a layout of aggregates to help you perform the mapping.

For more information about PL/I structure mapping, see the appropriate language reference and programming guide.

**Data Equivalents**

This section describes how C and PL/I data types correspond to each other.

Equivalent Data Types for C to PL/I

The following examples illustrate how C and PL/I routines within a single ILC application might code the same data types. The examples might be clearer to you if you first read the section “Passing Data between C and PL/I” on page 135, which describes how a C routine can receive parameters that are passed by value and by reference.

### 16-Bit Signed Binary Integer

<table>
<thead>
<tr>
<th>Sample C Usage</th>
<th>PL/I Subroutine</th>
</tr>
</thead>
</table>
| #pragma linkage (cpli,PLI)  
#include <stdio.h>  
short int cpli( short int*);  
main() {  
    short int x, y;  
x=5;  
y = cpli(&x); /* by reference */  
} | CPLI: PROC(ARG) RETURNS (FIXED BIN(15));  
DCL ARG FIXED BIN (15);  
;  
RETURN (ARG);  
END; |

**Note:** Because short int is an example of a parameter which must be passed using a C explicit pointer, you cannot code `y = cpli(x)`, passing `x` by value.

### 32-bit Signed Binary Integer

<table>
<thead>
<tr>
<th>Sample C Usage</th>
<th>PL/I Subroutine</th>
</tr>
</thead>
</table>
| #pragma linkage (cpli,PLI)  
#include <stdio.h>  
int extern cpli( int );  
main() {  
    int x, y;  
x=5;  
y = cpli(x); /* by value */  
} | CPLI: PROC(ARG) RETURNS (FIXED BIN(31));  
DCL ARG FIXED BIN (31);  
;  
RETURN (ARG);  
END; |

<table>
<thead>
<tr>
<th>Sample C Usage</th>
<th>PL/I Subroutine</th>
</tr>
</thead>
</table>
| #pragma linkage (cpli,PLI)  
#include <stdio.h>  
int extern cpli( int *);  
main() {  
    int x, y;  
x=5;  
y = cpli(&x); /* by reference */  
} | CPLI: PROC(ARG) RETURNS (FIXED BIN(31));  
DCL ARG FIXED BIN (31);  
;  
RETURN (ARG);  
END; |

### Long Floating-Point Number

<table>
<thead>
<tr>
<th>Sample C Usage</th>
<th>PL/I Subroutine</th>
</tr>
</thead>
</table>
| #pragma linkage (cpli,PLI)  
#include <stdio.h>  
main() {  
    void cpli(double);  
double x, y;  
x=12.5;  
cpli(x); /* by value */  
} | CPLI: PROC(ARG)  
RETURNS (FLOAT BIN(53));  
DCL ARG FLOAT BIN(53);  
;  
RETURN (34.0);  
END; |
### Extended Floating-Point Number

#### Sample C Usage
```c
#include <stdio.h>
main()
{
  long double cpli(long double);
  long double x, y;
  x=12.1;
  y=cpli(x); /* by value   */
  cpli(&x);   /* by reference */
}
```

#### PL/I Subroutine
```pli
CPLI: PROC(ARG);
  DCL ARG FLOAT BIN(109);
  RETURN (ARG);
  END;
```

### Pointer to an Integer

#### Sample C Usage
```c
#include <stdio.h>
main()
{
  int i, *temp;
  void cpli (int **);
  i = 5;
  temp=&i;
  cpli(&temp);
}
```

#### PL/I Subroutine
```pli
CPLI: PROC (ARG);
  DCL ARG FIXED BIN(31,0) BASED (ARG);
  END;
```

### Pointer to an Array

**Sample C Usage**

```c
#include <stdio.h>
main()
{  
    int matrix[5];
    int *temp[] = &matrix;
    int i;
    void cpli(int**[]);
    for(i=0;i<5;i++)
        matrix[i] = i;
    cpli(&temp);
}
```

**PL/I Subroutine**

```pli
CPLI: PROC (ARG);
    DCL ARG POINTER;
    DCL I FIXED BIN(31);
    DCL ART(5) FIXED BIN(31,0) BASED(ARG);
    :
    END;
```

### Pointer to a Structure

**Sample C Usage**

```c
#include <stdio.h>
main()
{  
    struct date {  
        int day;
        int month;
        int year  } today;
    struct date *temp = &today;
    void cpli(struct date **);
    int i;
    cpli (&temp);
}
```

**PL/I Subroutine**

```pli
CPLI: PROC (ARG);
    DCL ARG POINTER;
    DCL 1 TODAY BASED (ARG),
        2 DAY FIXED BIN(31),
        2 MONTH FIXED BIN(31),
        2 YEAR FIXED BIN(31);
    :
    END;
```

### Fixed-Length Decimal Data

**Sample C Usage**

```c
#include <stdio.h>
#include <decimal.h>
decimal(5,2) gpd;
main() {  
    decimal(5,2) pd1;
    printf("Packed decimal text\n");
pd1 = 52d;
pdec(pd1);
    if (gpd ! = 57d)
    {  
        printf("Fixed decimal error\n");
        printf("Expect: 57\n");
        printf("Result: \%D(5,2)\n",gpd);
    }
    printf("Value: \%D(5,2)\n", gpd);
    printf("Finished test\n");
}
```

**PL/I Subroutine**

```pli
PDEC: PROC (X);
    DCL X FIXED DEC(5,2);
    DCL GD0 FIXED DEC(5,2) EXTERNAL;
    X = X+5;
    GD0 = X;
    END;
```

### Equivalent Data Types for PL/I to C

The following examples illustrate how C and PL/I routines within a single ILC application might code the same data types. The examples might be clearer to you if you first read [Passing Data between C and PL/I](#) on page 135, which describes how a C routine can receive parameters that are passed by value and by reference.
### 32-Bit Signed Binary Integer

#### Sample PL/I Usage
```pli
MY_PROG: PROC OPTIONS(MAIN);
  DCL CENTRY EXTERNAL ENTRY
    RESULTS (FIXED BIN(31));
  DCL X FIXED BIN(31);
  DCL Y FIXED BIN(31);
  X = 5;
  /* BY VALUE */
  Y=CENTRY((X));
END MY_PROG;
```

#### C Function
```c
#include <stdio.h>

int centry(int x)
{
    printf("x is %d\n",x);
    return(x);
}
```

### Long Floating-Point Number

#### Sample PL/I Usage
```pli
MY_PROG: PROC OPTIONS(MAIN);
  DCL CENTRY EXTERNAL ENTRY
    RESULTS (FLOAT DEC(16));
  DCL X FLOAT DEC(16);
  DCL Y FLOAT DEC(16);
  X = 3.14159265;
  /* BY VALUE */
  Y=CENTRY((X));
END MY_PROG;
```

#### C Function
```c
#include <stdio.h>

double centry(double x)
{
    printf("x is %f\n",x);
    return(x);
}
```

### Extended Floating-Point Number

#### Sample PL/I Usage
```pli
MY_PROG: PROC OPTIONS(MAIN);
  DCL CENTRY EXTERNAL ENTRY
    RESULTS (FLOAT DEC(33));
  DCL X FLOAT DEC(33);
  DCL Y FLOAT DEC(33);
  X = 12.5;
  /* BY VALUE */
  Y=CENTRY((X));
END MY_PROG;
```

#### C Function
```c
#include <stdio.h>

long double centry(long double x)
{
    printf("x is %Lf\n",x);
    return(x);
}
```
### Sample PL/I Usage

**C Function**

```c
#include <stdio.h>
long double centry(long double *x)
{
    printf("*x is %Lf\n",*x);
    return(*x);
}
```

### Pointer to an Integer

**Sample PL/I Usage**

```pli
MY_PROG: PROC OPTIONS(MAIN);
    DCL CENTRY EXTERNAL ENTRY;
    DCL I FIXED BIN(31);
    DCL P POINTER;
    P = ADDR(I);
    I = 5;
    CALL CENTRY (P);
END MY_PROG;
```

**C Function**

```c
#include <stdio.h>
void centry(int **x)
{
    printf("Value is %d\n",**x);
}
```

### Pointer to an Array

**Sample PL/I Usage**

```pli
MY_PROG: PROC OPTIONS(MAIN);
    DCL CENTRY EXTERNAL ENTRY;
    DCL I(5) FIXED BIN(31,0);
    DCL P POINTER;
    P = ADDR(I);
    DO J = 1 TO 5;
        I(J) = J;
    END;
    CALL CENTRY (P);
END MY_PROG;
```

**C Function**

```c
#include <stdio.h>
void centry(int **x)
{
    printf("Value is %d\n",**x);
}
```

### Pointer to a Structure

**Sample PL/I Usage**

```pli
MY_PROG: PROC OPTIONS(MAIN);
    DCL CENTRY EXTERNAL ENTRY;
    DCL 1 TODAY,
        2 DAY FIXED BIN(31),
        2 MONTH FIXED BIN(31),
        2 YEAR FIXED BIN(31);
    DCL P POINTER;
    P = ADDR(TODAY);
    CALL CENTRY (P);
END MY_PROG;
```

**C Function**

```c
#include <stdio.h>
struct date {
    int day;
    int month;
    int year;
};
void centry(struct date **x)
{
    printf("Day is %d\n",(*x)->day);
}
```
Fixed-Length Decimal Data

Sample PL/I Usage

```
PLIPROG: PROC OPTIONS(MAIN, REENTRANT);
  DCL CFUNC EXTERNAL ENTRY
    (FIXED DEC(5,0));
  DCL ARG FIXED DEC(5,0);
  DCL A FIXED DEC(5);
  ARG = 10;
  A = CFUNC(ARG);
END;
```

C Function

```
#include <decimal.h>
#pragma linkage (CFUNC,PLI)
void CFUNC(decimal(5,0));
void CFUNC( decimal(5,0) parm ) {
  if (parm==10d)
    printf("Value is good\n");
  printf("The parm is %D(5,0)\n",parm);
}
```

Name Scope of External Data

In programming languages, the *name scope* is defined as the portion of an application within which a particular declaration applies or is known. The name scope of static external data for PL/I and static variables defined outside of any function for C is the load module. If your application contains PL/I procedures and non-reentrant C routines, PL/I's external data maps to C's external data only within a load module. After you cross a load module boundary, external data does not map. In addition, the external data does not map if any C function in the application is compiled with the XL C RENT compile-time option.

Figure 32 illustrates the name scope of external variables in a PL/I to C enclave, if the C function is non-reentrant. The routine can be a PL/I procedure or C routine. If Routine 3 is a PL/I procedure, however, it cannot have any variables with the EXTERNAL attribute; therefore, the name scope of Routine 3 in the figure refers only to C routines.

![Figure 32](image)

In Figure 32, external data declared in Routine 1 maps to that declared in Routine 2 in the same load module. If the fetch is made to a C Routine 3 in another load module is made, the external data does not map, because the name scope of external data in C is the load module. If the fetch is made to a PL/I Routine 3, the routine is not allowed to have any variables declared with the EXTERNAL attribute.

When the name scopes of PL/I and C are the same, you should not give external data the same name in a PL/I to C application if you cross a load module boundary.
**DLL Considerations**

In DLL code, external variables are mapped across the load module boundary. DLLs are shared at the enclave level. Therefore, a single copy of a DLL applies to all modules in an enclave, regardless of whether the DLL is loaded implicitly (through a reference to a function or variable) or explicitly (through `dllload()`). See [z/OS Language Environment Programming Guide](z/OS Language Environment Programming Guide) for information on building and managing DLL code in your applications.

**Name Space of External Data**

In programming languages, the *name space* is defined as the portion of a load module within which a particular declaration applies or is known. Within the same load module, the name space of external data under both PL/I and C is the same. Therefore, PL/I’s and C’s external data map to each other, provided that the C routine is non-reentrant or naturally reentrant.

![Figure 33. Name Space of External Data in PL/I Static Call to C](image)

Figure 33 illustrates that within the same load module, the name spaces of PL/I and C routines are the same. Therefore you can give external data the same name in a PL/I to C application, if no load module boundary is crossed.

**Using Storage Functions in C to PL/I ILC**

Use the following guidelines when you mix HLL storage constructs and Language Environment storage services:

Storage allocated using the PL/I ALLOCATE statement that:
- Is within a PL/I AREA, or
- Is of the storage class CONTROLLED, or
- Has the REFER option

**must** be released by the PL/I FREE statement. Storage with these characteristics cannot be released by the Language Environment callable service CEEFRST or by an HLL construct such as the C `free()` function.

Storage allocated as a result of the PL/I ALLOCATE statement that is of the storage class BASED can be released by CEEFRST or an HLL construct such as the C `free()` function if the structure:
- Is completely declared,
- Requires no pad bytes to be added automatically by the compiler, and
- Does not contain the REFER option
Directing Output in ILC Applications

Under Language Environment, PL/I run-time output such as run-time messages and ON condition SNAP output is directed to the destination specified in the Language Environment run-time option MSGFILE. The PL/I user-specified output, such as the output of the PUT SKIP LIST statement, remains directed to the PL/I STREAM PRINT file SYSPRINT. You can still have run-time and user-specified output directed to the same destination, as under OS PL/I, by specifying MSGFILE(SYSistar). See PL/I for MVS & VM Programming Guide or Enterprise PL/I for z/OS Programming Guide for details about using the MSGFILE(SYSPRINT) option.

Under Language Environment, C run-time output such as run-time messages is directed to the destination specified in the Language Environment run-time option MSGFILE. stderr output is also directed to the destination of the MSGFILE option. Normally, stdout output is not directed to the destination of the MSGFILE option. You can redirect stdout output to the destination of the MSGFILE option by passing arguments 1>&2 to a C main routine, where 1>&2 associates stdout with stderr, or by placing stdout=stderr in your program. For information on redirecting C output, see z/OS XL C/C++ Programming Guide.

Using SYSPRINT as the Default Stream Output File

SYSPRINT serves as the default stream output file for PL/I and C. In the absence of one language, the other uses SYSPRINT without any problem. If both languages are used in an application, C yields to PL/I’s use of SYSPRINT by redirecting the C stream output to other destinations. However, in the following two cases, the redirection of C's stream output is not possible and the results can be unpredictable:

1. The main load module does not have a PL/I PUT statement and C uses SYSPRINT for its stream output in the main load module. Later, a fetched subroutine load module contains a PL/I PUT statement that PL/I starts to use SYSPRINT for its stream output.

2. When Language Environment preinitialization services are used for a subroutine environment, C uses SYSPRINT for its stream output in the first CEEPPI(callsu,...) then PL/I users SYSPRINT for its PUT statement in the second CEEPPI(callsu).

Directing User-Specified Output to Destination of MSGFILE

You can direct PL/I and C user-specified output to the same destination as the run-time output by specifying MSGFILE(SYSPRINT). In this case, PL/I and C manage their own I/O buffers, line counters, etc., for their own user-specified output. Therefore, MSGFILE(SYSPRINT) must be used carefully because PL/I output from the PUT statement, C output from printf, and run-time output can be interspersed with one another.

C POSIX Multithreading

POSIX-conforming C applications can communicate with PL/I routines in any thread created by C routines. POSIX-conforming C applications can communicate with assembler routines on any thread when the assembler routines use the CEEENTRY/CEETERM macros provided by Language Environment or the EDCPRLG/EDCEPIL macros provided by C/370. If a fork() command is issued, the target of the fork() must be another C routine.
C to PL/I Condition Handling

This section offers two scenarios of condition handling behavior in a C to PL/I ILC application. If an exception occurs in a C routine, the set of possible actions is as described in "Exception Occurs in C." If an exception occurs in a PL/I routine, the set of possible actions is as described in "Exception Occurs in PL/I" on page 148.

Keep in mind that if there is a PL/I routine currently active on the stack, PL/I language semantics can be applied to handle conditions that occur in non-PL/I routines within an ILC application. For example, PL/I semantics apply to Language Environment hardware conditions that map directly to PL/I conditions such as ZERODIVIDE, even if they occur in a non-PL/I routine. Also, PL/I treats any unknown condition of severity 2 or greater as the ERROR condition. In a case in which a C-specific condition of severity 2 or greater is passed to a PL/I stack frame, an ERROR ON-unit can handle it on the first pass of the stack.

Enclave-Terminating Language Constructs

Enclaves might be terminated due to reasons other than an unhandled condition of severity 2 or greater. The language constructs that cause a single language application to be terminated also cause a C to PL/I application to be terminated. Those language constructs of interest are listed below.

C

Typical C language constructs that cause the application to terminate are:

• The abort(), raise(SIGTERM), raise(SIGABRT), kill(), pthread_kill(), and exit() function calls.
  If you call abort(), raise(SIGABRT), or exit(), the T_I_S (Termination Imminent Due to STOP) condition is raised. After T_I_S has been processed and all user code has been removed from the stack, the C atexit list is honored.

PL/I

The PL/I language constructs that cause the application to terminate are:

• A STOP statement, or an EXIT statement
  If you code a STOP or EXIT statement, the T_I_S (Termination Imminent Due to STOP) condition is raised. After T_I_S has been processed and after all user code has been removed from the stack, the C atexit list is honored.

• A call to PLIDUMP with the S or E option
  If you call PLIDUMP with the S or E option, neither termination imminent condition is raised, and the C atexit list is not honored before the enclave is terminated. See z/OS Language Environment Debugging Guide for syntax of the PLIDUMP service.

Exception Occurs in C

This scenario describes the behavior of an application that contains a C and a PL/I routine. Refer to Figure 34 on page 147 throughout the following discussion. In this scenario, a PL/I main routine invokes a C subroutine. An exception occurs in the C subroutine.
The actions taken are the following:

1. In the enablement step, it is determined whether the exception in the C routine should be enabled and treated as a condition. If any of the following are true, the exception is ignored, and processing continues at the next sequential instruction after where the exception occurred:
   - You specified SIG_IGN for the exception in a call to signal().
   - The system or user abend corresponding to the signal(SIGABND) or the Language Environment message 3250 is not ignored. The enclave is terminated.
   - You did not specify any action, but the default action for the condition is SIG_IGN (see Table 64 on page 255).
   - You are running under CICS and a CICS handler is pending.

   If you did none of these things, the condition is enabled and processed as a condition.

2. If a user-written condition handler has been registered on the stack frame using CEEHDLR, it is given control.
   - If it issues a resume, the condition handling step ends. Processing continues in the routine to which the resume cursor points.
   - In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

3. If a signal handler has been registered for the condition on the C stack frame, it is given control. If it successfully issues a resume or a call to longjmp(), the condition handling step ends. Processing resumes in the routine to which the resume cursor points.
   - In this case, there is not a C signal handler registered for the condition.
4. The condition is still unhandled. If C does not recognize the condition, or if the C default action (listed in Table 64 on page 255) is to terminate, the condition is percolated.

5. If a user-written condition handler has been registered on the PL/I stack frame using CEEHDLR, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine at the point where the resume cursor points. In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

6. If an ON-unit has been established for the condition being processed on the PL/I stack frame, it is given control. If it issues a GOTO out-of-block, the condition handling step ends. Execution resumes at the label of the GOTO. In this example, no ON-unit is established for the condition, so the condition is percolated.

7. What happens next depends on whether the condition is promotable to the PL/I ERROR condition. The following can happen:
   • If the condition is not promotable to the PL/I ERROR condition, then the Language Environment default actions take place, as described in Table 63 on page 255. Condition handling ends.
   • If the PL/I default action for the condition is to promote it to the PL/I ERROR condition, the condition is promoted, and another pass is made of the stack to look for ERROR ON-units or user-written condition handlers. If an ERROR ON-unit or user-written condition handler is found, it is invoked.
   • If either of the following occurs:
     – An ERROR ON-unit or user-written condition handler is found, but it does not issue a GOTO out of block or similar construct
     – No ERROR ON-unit or user-written condition handler is found
     then the ERROR condition is promoted to T_I_U (Termination Imminent due to an Unhandled condition). Condition handling now enters the termination imminent step. Because T_I_U maps to the PL/I FINISH condition, a FINISH ON-unit or user-written condition handler is run if the stack frame in which it is established is reached.
   • If no condition handler moves the resume cursor and issued a resume, Language Environment terminates the thread.

Exception Occurs in PL/I

This scenario describes the behavior of an application that contains a PL/I and a C routine. Refer to Figure 35 on page 149 throughout the following discussion. In this example, a C main routine invokes a PL/I subroutine. An exception occurs in the PL/I subroutine.
The actions taken are the following:

1. In the enablement step, PL/I determines if the exception that occurred should be handled as a condition according to the PL/I rules of enablement.
   - If the exception is to be ignored, control is returned to the next sequential instruction after where the exception occurred.
   - If the exception is to be enabled and processed as a condition, the condition handling step, described below, takes place.

2. If a user-written condition handler has been registered on the PL/I stack frame using CEEHDLR, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine at the point where the resume cursor points. In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

3. If an ON-unit has been established for the condition being processed on the PL/I stack frame, it is given control. If it issues a GOTO out-of-block, the condition handling step ends. Execution resumes at the label of the GOTO. In this example, no ON-unit is established for the condition, so the condition is percolated.

4. If a user-written condition handler has been registered using CEEHDLR on the C stack frame, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine to which the resume cursor points.

   **Note:** There are special considerations for resuming from some IBM conditions of severity 2 or greater. See the chapter on coding a user-written condition handler in *z/OS Language Environment Programming Guide* for more information.

In this example, no user-written condition handler is registered for the condition, so the condition is percolated.
5. If a C signal handler has been registered for the condition, it is given control. If it successfully issues a resume or a call to `longjmp()`, the condition handling step ends. Processing resumes in the routine to which the resume cursor points.

In this example no C signal handler is registered for the condition, so the condition is percolated.

6. What happens next depends on whether the condition is promotable to the PL/I ERROR condition. The following can happen:

   - If the condition is not promotable to the PL/I ERROR condition, then the Language Environment default actions take place, as described in Table 63 on page 255. Condition handling ends.
   - If the PL/I default action for the condition is to promote it to the PL/I ERROR condition, the condition is promoted, and another pass of the stack is made to look for ERROR ON-units or user-written condition handlers. If an ERROR ON-unit or user-written condition handler is found, it is invoked.
   - If either of the following occurs:
     - An ERROR ON-unit or user-written condition handler is found, but it does not issue a GOTO out of block or similar construct
     - No ERROR ON-unit or user-written condition handler is found
   
   then the ERROR condition is promoted to T_I_U (Termination Imminent due to an Unhandled condition). Condition handling now enters the termination imminent step. Because T_I_U maps to the PL/I FINISH condition, a FINISH ON-unit is run if the stack frame in which it is established is reached.

   - If no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

**Fixed Point Overflow**

The XL C compiler assumes that fixed point overflow exceptions will be handled by S/390 hardware, while the PL/I compiler assumes the run-time library will process these exceptions. Therefore, if a C to PL/I ILC application incurs a fixed point overflow, Language Environment will try to handle this exception in the run-time library. This will result in increased CPU utilization compared to an application using only C.

Figure 37. C Routine Called by PL/I Main Routine
Chapter 9. Communicating between C++ and PL/I

This chapter describes Language Environment’s support for C++ and PL/I ILC applications. If you are running a C++ to PL/I ILC application under CICS, you should also consult Chapter 15, “ILC under CICS,” on page 247.

General Facts about C++ to PL/I ILC
- ILC between C++ and Enterprise PL/I for z/OS is discussed in Enterprise PL/I for z/OS Programming Guide.
- Language Environment does not support passing return codes between PL/I and C++ routines in an ILC application.
- PL/I Multitasking Facility (MTF) does not support C++.
- A C++ NULL is X'00000000'; a PL/I NULL is X'FF000000'; a PL/I SYNULL is X'00000000'. Comparisons against a NULL value and other uses of the NULL value must therefore be done with care.
- There is no ILC support between AMODE 31 and AMODE 64 applications. PL/I does not support AMODE 64.

Preparing for ILC
This section describes topics you might want to consider before writing an application that uses ILC. For help in determining how different versions of HLLs work together, refer to the migration guides for the HLLs you plan to use.

Language Environment ILC Support
Language Environment supports ILC between the following combinations of C++ and PL/I:

<table>
<thead>
<tr>
<th>HLL Pair</th>
<th>C++</th>
<th>PL/I</th>
</tr>
</thead>
<tbody>
<tr>
<td>C++–PL/I</td>
<td>• IBM C++ for MVS/ESA</td>
<td>• PL/I for MVS &amp; VM</td>
</tr>
<tr>
<td></td>
<td>• z/OS XL C/C++ compilers</td>
<td>• Enterprise PL/I for z/OS</td>
</tr>
</tbody>
</table>

Determining the Main Routine
In Language Environment, only one routine can be the main routine. If a PL/I routine is identified as a main routine in an ILC application by PROC OPTIONS(MAIN), and a C++ main function does not exist, the PL/I main routine is the first to gain control. If a C++ main function exists, but no PL/I main routine is identified in the ILC application, the C++ main function gains control first.

If both a PL/I main routine identified by PROC OPTIONS(MAIN) and a C++ main function exist in the same ILC application, this is a user error. However, the error is not detected by Language Environment.

An entry point is defined for each supported HLL. Table 42 on page 154 identifies the desired entry point. The table assumes that your code has been compiled using the Language Environment-conforming compilers.

Table 42. Determining the Entry Point

<table>
<thead>
<tr>
<th>HLL</th>
<th>Main Entry Point</th>
<th>Fetched Entry Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>C++</td>
<td>CEESTART</td>
<td>Not supported</td>
</tr>
<tr>
<td>PL/I</td>
<td>CEESTART</td>
<td>CEESTART or routine name, if OPTIONS(FETCHABLE) is used.</td>
</tr>
</tbody>
</table>

Declaring C++ to PL/I ILC

Declaring a C++ entry point in a PL/I routine has the same syntax as declaring another PL/I entry point. A C++ routine can be replaced by a PL/I routine without altering the PL/I code that calls the routine. Likewise, if a C++ routine calls a PL/I routine, the PL/I procedure contains no explicit declaration indicating control is being passed from the C++ routine. The declaration is contained within the C++ routine.

In C++, you must declare that the C++ entry point receives control from a PL/I routine. This declaration is in the form of an extern "PLI" linkage specification. The body of the C++ function is the same as if the routine were called from another C++ function. Calling a PL/I routine and being called by a PL/I routine are handled by the same extern "PLI" linkage specification.

Declaration for C++ Calling PL/I

```c++
extern "PLI" {
double PLIFUNC (double );
    / C++ prototype /
}

int main() {
double val,result;
val=7.1;
result=PLIFUNC(val);
printf("val=%f, result=%f\n", val,result);
}
```

Declaration for PL/I Calling C++

```pli
PLIFUNC: Proc(options(reentrant))
        returns(float binary(53));
        Dcl arg float binary(53);
        Return (34.0);
        End;
```

Building a Reentrant C++ to PL/I Application

The XL C++ compiler creates reentrant code by default. To create a reentrant C++ to PL/I application, follow this process:

1. Compile the C++ routines.
2. (Optional) Compile all PL/I routines in the ILC application using the REENTRANT option of the OPTIONS attribute of the PROCEDURE statement.
3. Run the generated C++ and PL/I object code through the Language Environment prelinker to generate a single text deck.

4. Run the text deck provided by the prelinker through the linkage editor to produce a load module.

**Note:** A reentrant C++ to PL/I application has different semantics than a non-reentrant one.

### Calling between C++ and PL/I

Table 43 describes the types of calls between C++ and PL/I that Language Environment allows:

<table>
<thead>
<tr>
<th>ILC Direction</th>
<th>Static Calls</th>
<th>Dynamic Calls Using DLLs</th>
<th>Fetch/Calls</th>
</tr>
</thead>
<tbody>
<tr>
<td>C++ to PL/I</td>
<td>Yes</td>
<td>Yes (1)</td>
<td>C++ does not support fetch() for PL/I</td>
</tr>
<tr>
<td>PL/I to C++</td>
<td>Yes</td>
<td>Yes (1)</td>
<td>No</td>
</tr>
</tbody>
</table>

**Note:** Enterprise PL/I for z/OS supports calls to a C++ DLL, and also allows calls from C++ to a PL/I DLL. In this case, the C++ code could also optionally be compiled with the XPLINK option.

### Passing Data between C++ and PL/I

There are two sets of data types that you can pass between C++ and PL/I routines:
- data types passed by reference using C++ explicit pointers explicitly in the routine,
- data types passed by value without using C++ explicit pointers.

By reference means the parameter itself is passed. A copy of the parameter is not made. Any changes to the parameter made by the called routine can alter the original parameter passed by the calling routine. By value means a copy of the parameter is passed. Any changes to the parameter made by the called routine cannot alter the original parameter passed by the calling routine.

### Passing Pointers from C++ to PL/I

Pointers can be passed and returned between C++ and PL/I routines. Because the C++ extern "PL/I" linkage specifies that pointers, unlike other parameters, are passed directly, there is one level of indirection less on the PL/I side.

In order for PL/I to receive a pointer to a PL/I data type, C++ must pass a pointer to a pointer to the C++ data type. Conversely, if PL/I returns a pointer to a data type, C++ receives a pointer to a pointer to the data type.

Structures, arrays, and strings should be passed between C++ and PL/I only by using pointers.

The non-address bits in all fullword pointers declared in PL/I source code should always be zero. If they are not, results are unpredictable.

### Passing Pointers from PL/I to C++

Pointers to various data objects can be passed from PL/I and accepted by a function written in C++.
An extra level of indirection is added when passing a pointer value from PL/I to C++, because the C++ extern "PLI" linkage specification passes pointers directly. If PL/I passes or returns a pointer to a type, C++ receives a pointer to a pointer to the type.

PL/I parameters that require a locator or descriptor should not be passed directly. This includes parameters that are structures, arrays, or strings. These parameters can be passed indirectly from PL/I by using a pointer to the associated data. For more information on data descriptors, see PL/I for MVS & VM Programming Guide or Enterprise PL/I for z/OS Programming Guide.

The non-address bits in all fullword pointers declared in PL/I source code should always be zero. If they are not, results are unpredictable.

Receiving Value Parameters in C++

If you enclose in parentheses the argument you pass from a PL/I routine to a C++ routine, the argument is passed by value. C++ should receive the parameter as the equivalent C++ type. The XL C++ compiler generates the appropriate addressing code required to access the parameter values.

You can write your PL/I-callable function as if it were in a C++-only environment; you can move it to a C++-only environment simply by removing the extern "PLI" linkage specification.

Receiving Reference Parameters in C++

If a parameter is not enclosed in parentheses a PL/I routine will pass it by reference to a C++ routine. C++ should then receive the parameter as a pointer to the equivalent C++ type.

For example, if a C++ function named FROMPLI is to receive a parameter having the type int, the function prototype declaration looks like this:

```
int FROMPLI(int *i);
```

A parameter passed from PL/I by reference may be received and used by C++ as a value parameter provided that its value is not altered. If the value of such a parameter is altered, the effect on the original PL/I variable is undefined.

Supported Data Types Passed Using C++ Pointers (by Reference)

Table 44 identifies the data types that can be passed as parameters between C++ and PL/I applications with the use of explicit pointers under C++. Parameters that are pointers are passed by reference to PL/I. Conversely, reference parameters passed by PL/I to C++ are received as pointers to the equivalent data type or as a C++ reference variable such as int& i.

Anything that is passed with a pointer can be passed with a reference variable; the effect is the same. Reference variables are generally easier to use.

<table>
<thead>
<tr>
<th>C++ Type</th>
<th>PL/I Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed short int</td>
<td>REAL FIXED BINARY(15,0)</td>
</tr>
<tr>
<td>signed int</td>
<td>REAL FIXED BINARY(31,0)</td>
</tr>
<tr>
<td>signed long int</td>
<td>REAL FIXED BINARY(31,0)</td>
</tr>
</tbody>
</table>

<tr>
<td>long double</td>
<td>FLOAT DECIMAL(33)</td>
</tr>
<tr>
<td></td>
<td>FLOAT BINARY (109) is the preferred equivalent for long double.</td>
</tr>
<tr>
<td>pointer to . . .</td>
<td>POINTER</td>
</tr>
</tbody>
</table>

Note: Data storage alignment must match.

**Supported Data Types Passed by Value**

Table 45 identifies the data types that can be passed by value (without using a C++ pointer) between C++ and PL/I applications.

In order for a C++ routine to pass a parameter without using a pointer, the argument should be passed, and the PL/I routine should receive the parameter as the equivalent PL/I data type.

Table 45. Supported Data Types between C++ and PL/I by Value

<table>
<thead>
<tr>
<th>C++</th>
<th>PL/I</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed int</td>
<td>REAL FIXED BINARY(31,0)</td>
</tr>
<tr>
<td>signed long int</td>
<td>REAL FIXED BINARY(31,0)</td>
</tr>
<tr>
<td>double</td>
<td>FLOAT DECIMAL(16)</td>
</tr>
<tr>
<td>double</td>
<td>FLOAT BINARY(53)</td>
</tr>
<tr>
<td>long double</td>
<td>FLOAT DECIMAL(33)</td>
</tr>
<tr>
<td>long double</td>
<td>FLOAT BINARY(109)</td>
</tr>
</tbody>
</table>

Note: The preferred PL/I data declarations for the C double and long double data types are FLOAT BINARY(53) and FLOAT BINARY(109), respectively. Data storage alignment must match.

**Passing Strings between C++ and PL/I**

C++ and PL/I have different string data types:

**C++ strings**

Logically unbounded length and are terminated by a NULL (the last byte of the string contains X’00’).

**PL/I CHAR(n) VARYING**

A halfword-prefixed string of characters with a maximum length \( n \) characters. The current length is held in the halfword prefix.

**PL/I CHAR(n)**

A fixed-length string of characters of length \( n \). There is no halfword prefix indicating the length.

You can pass strings between C++ and PL/I routines, but you must match what the routine interface demands with what is physically passed.
Using Aggregates

Aggregates (arrays, strings, or structures) are mapped differently by C++ and PL/I and are not automatically mapped. Be sure to completely declare every byte in the aggregate so there are no open fields. Doing so helps ensure that the layouts of aggregates passed between the two languages map to one another correctly. The C++ and PL/I AGGREGATE compiler time options provide a layout of aggregates to help you perform the mapping.

In C++, a structure is a class declared with the struct keyword; its members and base classes are public by default. A C++ class is the same as a C++ structure if the only data is public. If a C++ class that uses features unavailable to PL/I (such as virtual functions, virtual base classes, private data, protected data, static data members, or inheritance) is passed to PL/I, the results are undefined.

For more information about PL/I structure mapping, see PL/I for MVS & VM Language Reference or Enterprise PL/I for z/OS Language Reference.

Data Equivalents

This section describes how C++ and PL/I data types correspond to each other.

Equivalent Data Types for C++ to PL/I

The following examples illustrate how C++ and PL/I routines within a single ILC application might code the same data types.

### 16-Bit Signed Binary Integer

**Sample C++ Usage**

```cpp
#include <stdio.h>

extern "PLI" {
    short int cpli( short int * );
}

main() {
    short int x, y;
    x = 5;
    y = cpli(&x); /* by reference */
}
```

**PL/I Subroutine**

```pli
CPLI: PROC(ARG) RETURNS (FIXED BIN(15));
DCL ARG FIXED BIN (15);
RETURN (ARG);
END;
```

**Note:** Because short int is an example of a parameter which must be passed using an C++ explicit pointer, you cannot code `y = cpli(x)`, passing x by value.

### 32-Bit Signed Binary Integer

**Sample C++ Usage**

```cpp
#include <stdio.h>

extern "PLI" {
    int cpli( int );
}

main() {
    int x, y;
    x = 5;
    y = cpli(x); /* by value */
}
```

**PL/I Subroutine**

```pli
CPLI: PROC(ARG) RETURNS (FIXED BIN(31));
DCL ARG FIXED BIN (31);
RETURN (ARG);
END;
```
Sample C++ Usage

```c
#include <stdio.h>

extern "PLI" {
  int cpli(int *);
}

main() {
  int x, y;
  x=5;
  y = cpli(&x); /* by reference */
}
```

CPLI: PROC(ARG) RETURNS (FIXED BIN(31));
DCL ARG FIXED BIN (31);
RETURN (ARG);
END;

Long Floating-Point Number

Sample C++ Usage

```c
#include <stdio.h>

extern "PLI" {
  double cpli(double);
}

main() {
  double x, y;
  x=12.5;
  cpli(x); /* by value */
}
```

CPLI: PROC(ARG) RETURNS (FLOAT BINARY(53));
DCL ARG FLOAT BINARY(53);
RETURN (ARG);
END;

Extended Floating-Point Number

Sample C++ Usage

```c
#include <stdio.h>

extern "PLI" {
  void double cpli(double *);
}

main() {
  double x;
  x=12.5;
  cpli(&x); /* by reference */
}
```

CPLI: PROC(ARG);
DCL ARG FLOAT BINARY(53);
END;
Sample C++ Usage

```c++
#include <stdio.h>

extern "PLI" {
    long double cpli(long double*);
}

main()
{
    long double x, y;
    x = 12.1;
    y = cpli(&x);  // by reference
}
```

PLI Subroutine

```pli
CPLI: PROC ARG
RETURNS (FLOAT BIN(109));
DCL ARG FLOAT BIN(109);
RETURN (ARG);
END;
```

---

Pointer to an Integer

Sample C++ Usage

```c++
#include <stdio.h>

extern "PLI" {
    void cpli(int **);
}

main()
{
    int i, *temp;
    i = 5;
    temp = &i;
    cpli(&temp);
}
```

PLI Subroutine

```pli
CPLI: PROC ARG;
DCL ARG POINTER;
DCL ART FIXED BIN(31,0) BASED (ARG);
END;
```

---

Pointer to an Array

Sample C++ Usage

```c++
#include <stdio.h>

extern "PLI" {
    int (*temp[] = &matrix);
}

main()
{
    int matrix[5]
    int i;
    void cpli(int**(i++)[]);
    for(i = 0; i < 5; i++)
        matrix[i] = i;
    cpli(&temp);
}
```

PLI Subroutine

```pli
CPLI: PROC ARG;
DCL ARG POINTER;
DCL I FIXED BIN(31)
DCL ART(5) FIXED BIN(31,0) BASED (ARG);
END;
```
Pointer to a Structure

### Sample C++ Usage
```c++
#include <stdio.h>

struct date {
    int day;
    int month;
    int year;
} today;

extern "PLI" {
    void cpli(struct date **);
}

main() {
    struct date *temp = &today;
    int i;
    cpli (&temp);
}
```

### PL/I Subroutine
```pli
CPLI: PROC (ARG);
    DCL ARG POINTER;
    DCL 1 TODAY BASED (ARG),
        2 DAY FIXED BIN(31),
        2 MONTH FIXED BIN(31),
        2 YEAR FIXED BIN(31);
    END;
```

---

Equivalent Data Types for PL/I to C++

This section contains examples that illustrate how C++ and PL/I routines within a single ILC application might code the same data types.

### 32-Bit Signed Binary Integer

#### Sample PL/I Usage
```pli
MY_PROG: PROC OPTIONS(MAIN);
    DCL CENTRY EXTERNAL ENTRY
       RETURNS (FIXED BIN(31));
    DCL X FIXED BIN(31);
    DCL Y FIXED BIN(31);
    X = 5;
    /* BY VALUE */
    Y = CENTRY(X);
END MY_PROG;
```

#### C++ Function
```c++
#include <stdio.h>

extern "PLI" {
    int centry(int x)
    {
        printf("x is %d\n",x);
        return(x);
    }
}
```

---

#### Sample PL/I Usage
```pli
MY_PROG: PROC OPTIONS(MAIN);
    DCL CENTRY EXTERNAL ENTRY
       RETURNS (FIXED BIN(31));
    DCL X FIXED BIN(31);
    DCL Y FIXED BIN(31);
    X = 5;
    /* BY REFERENCE */
    Y = CENTRY(X);
END MY_PROG;
```

#### C++ Function
```c++
#include <stdio.h>

extern "PLI" {
    int centry(int *x)
    {
        printf("x is %d\n",*x);
        return(*x);
    }
}
```
### Long Floating-Point Number

**Sample PL/I Usage**

```pli
MY_PROG: PROC OPTIONS(MAIN);
  DCL CENTRY EXTERNAL ENTRY 
    RETURNS (FLOAT DEC(16));
  DCL X FLOAT DEC(16);
  DCL Y FLOAT DEC(16);
  X = 3.14159265;
  /* BY VALUE */
  Y=CENTRY((X));
END MY_PROG;
```

**C++ Function**

```cpp
#include <stdio.h>
extern "PLI" {

double centry(double x)
{
    printf("x is %f\n",x);
    return(x);
}
```

### Extended Floating-Point Number

**Sample PL/I Usage**

```pli
MY_PROG: PROC OPTIONS(MAIN);
  DCL CENTRY EXTERNAL ENTRY 
    RETURNS (FLOAT DEC(33));
  DCL X FLOAT DEC(33);
  DCL Y FLOAT DEC(33);
  X = 12.5;
  /* BY VALUE */
  Y=CENTRY((X));
END MY_PROG;
```

**C++ Function**

```cpp
#include <stdio.h>
extern "PLI" {

long double centry(long double x)
{
    printf("x is %Lf\n",x);
    return(x);
}
```
**Pointer to an Integer**

**Sample PL/I Usage**

```pli
MY_PROG: PROC OPTIONS(MAIN);
  DCL CENTRY EXTERNAL ENTRY;
  DCL I FIXED BIN(31);
  DCL P POINTER;
  P = ADDR(I);
  I = 5;
  CALL CENTRY (P);
END MY_PROG;
```

**C++ Function**

```c++
#include <stdio.h>

extern "PLI" {

void centry(int **x)
}

void centry(int **x)
{
  printf("Value is %d\n",x);
}
```

**Pointer to an Array**

**Sample PL/I Usage**

```pli
MY_PROG: PROC OPTIONS(MAIN);
  DCL CENTRY EXTERNAL ENTRY;
  DCL I(5) FIXED BIN(31,0);
  DCL J FIXED BIN(31);
  DCL P POINTER;
  P = ADDR(I);
  DO J = 1 TO 5;
    I(J) = J;
  END;
  CALL CENTRY (P);
END MY_PROG;
```

**C++ Function**

```c++
#include <stdio.h>

extern "PLI" {

void centry(**x);
}

void centry(**x)
{
  /* ... */
}
```

**Pointer to a Structure**

**Sample PL/I Usage**

```pli
MY_PROG: PROC OPTIONS(MAIN);
  DCL CENTRY EXTERNAL ENTRY;
  DCL 1 TODAY,
      2 DAY FIXED BIN(31),
      2 MONTH FIXED BIN(31),
      2 YEAR FIXED BIN(31);
  DCL P POINTER;
  P = ADDR(TODAY);
  CALL CENTRY (P);
END MY_PROG;
```

**C++ Function**

```c++
struct date {
  int day;
  int month;
  int year;
};

extern "PLI" {

void centry(struct date **x);
}

void centry(struct date **x)
{
  printf("Day is %d",(x)->day);
}
```

**Name Scope of External Data**

In programming languages, the *name scope* is defined as the portion of an application within which a particular declaration applies or is known. The name scope of static external data for PL/I and static variables defined outside of any function for C++ is the load module.

Because C++ is reentrant, PL/I and C++ external data do not map by default. However, you can map specific variable by using the *pragma variable* directive to specify that a C++ variable is NORENT.

**DLL Considerations**

In DLL code, external variables are mapped across the load module boundary. DLLs are shared at the enclave level. Therefore, a single copy of a DLL applies to all modules in an enclave, regardless of whether the DLL is loaded implicitly.
(through a reference to a function or variable) or explicitly (through dllload()). See z/OS XL C++ Programming Guide for information on building and managing DLL code in your applications.

Name Space of External Data
In programming languages, the name space is defined as the portion of a load module within which a particular declaration applies or is known. With statically linked C++ to PL/I ILC, PL/I external data is not accessible from C++ and C++ external data is not accessible from PL/I unless the #pragma variable directive is used to specify that the specific variable is NORENT.

Using Storage Functions in C++ to PL/I ILC
Use the following guidelines when mixing HLL storage constructs and Language Environment storage services.

The C++ new and delete statements should not be mixed with the C malloc() and free() statements. Storage allocated with new can only be deallocated with delete and vice versa.

Storage allocated using the PL/I ALLOCATE statement that:
• Is within a PL/I AREA, or
• Is of the storage class CONTROLLED, or
• Has the REFER option
must be released by the PL/I FREE statement. Storage with these characteristics cannot be released by the Language Environment callable service CEEFRST or by an HLL construct such as the C++ free() function.

Storage allocated as a result of the PL/I ALLOCATE statement that is of the storage class BASED can be released by CEEFRST or an HLL construct such as the C++ free() function if the structure:
• Is completely declared,
• Requires no pad bytes to be added automatically by the compiler, and
• Does not contain the REFER option

Directing Output in ILC Applications
Under Language Environment, PL/I run-time output such as run-time messages and ON condition SNAP output is directed to the destination specified in the Language Environment run-time option MSGFILE. The PL/I user-specified output, such as the output of the PUT SKIP LIST statement remains directed to the PL/I STREAM PRINT file, SYSPRINT. You can still have the run-time output and the user-specified output directed to the same destination, like under OS PL/I, by specifying MSGFILE(SYSPRINT). See PL/I for MVS & VM Programming Guide or Enterprise PL/I for z/OS Programming Guide for details of using the MSGFILE(SYSPRINT) option.

Under Language Environment, C++ run-time output such as run-time messages is directed to the destination specified in the Language Environment run-time option MSGFILE. stderr output is also directed to the destination of the MSGFILE option. Normally, stdout output is not directed to the destination of the MSGFILE option. You can redirect std output to the destination of the MSGFILE option by passing arguments 1>&2 to a C++ main routine, where 1>&2 associates stdout with stderr, or by placing stdout=stderr in your program. For information on redirecting C++ output, see z/OS XL C/C++ Programming Guide.
Using SYSPRINT as the Default Stream Output File

SYSPRINT serves as the default stream output file for PL/I and C++. In the absence of one language, the other uses SYSPRINT without any problem. If both languages are used in an application, C++ yields to PL/I’s use of SYSPRINT by redirecting the C++ stream output to other destinations. However, in the following two cases, the redirection of C++’s stream output is not possible and the results can be unpredictable:

1. The main load module does not have a PL/I PUT statement and C++ uses SYSPRINT for its stream output in the main load module. Later, a fetched subroutine load module contains a PL/I PUT statement that PL/I starts to use SYSPRINT for its stream output.

2. When Language Environment preinitialization services are used for a subroutine environment, C++ uses SYSPRINT for its stream output in the first CEEPIPI(call_sub,...) then PL/I users SYSPRINT for its PUT statement in the second CEEPIPI(call_sub).

Directing User-Specified Output to Destination of MSGFILE

You can direct PL/I and C++ user-specified output to the same destination as the run-time output by specifying MSGFILE(SYSPRINT). In this case, PL/I and C++ manage their own I/O buffers, line counters, etc., for their own user-specified output. Therefore, MSGFILE(SYSPRINT) must be used carefully because PL/I output from the PUT statement, C++ output from printf, and run-time output can be interspersed with one another.

C++ to PL/I Condition Handling

This section offers two scenarios of condition handling behavior in a C++ to PL/I ILC application. If an exception occurs in a C++ routine, the set of possible actions is as described in "Exception Occurs in C++" on page 166. If an exception occurs in a PL/I routine, the set of possible actions is as described in "Exception Occurs in PL/I" on page 168.

Keep in mind that if there is a PL/I routine currently active on the stack, PL/I language semantics can be applied to handle conditions that occur in non-PL/I routines within an ILC application. For example, PL/I semantics apply to Language Environment hardware conditions that map directly to PL/I conditions such as ZERODIVIDE, even if they occur in a non-PL/I routine. Also, PL/I treats any unknown condition of severity 2 or greater as the ERROR condition. In a case in which a C-specific condition of severity 2 or greater is passed to a PL/I stack frame, an ERROR ON-unit can handle it on the first pass of the stack.

C++ exception handling constructs try/throw/catch cannot be used with Language Environment and PL/I condition handling. If you use C exception handling constructs (signal/raise) in your C++ routine, condition handling will proceed as described in this section. Otherwise, you will get undefined behavior in your programs if you mix the C constructs with the C++ constructs.

For a detailed description of Language Environment condition handling, see z/OS Language Environment Programming Guide.

Enclave-Terminating Language Constructs

Enclaves might be terminated due to reasons other than an unhandled condition of severity 2 or greater. The language constructs that cause a single language
application to be terminated also cause a C++ to PL/I application to be terminated. Those language constructs of interest are listed below.

**C Language Constructs Available under C++**

Among the C language constructs that cause an application to terminate are:

- The `abort()`, `raise(SIGABRT)`, and `exit()` function calls.

  If you call `abort()`, `raise(SIGABRT)`, or `exit()`, the T_I_S (Termination Imminent Due to STOP) condition is raised. After T_I_S has been processed and all user code has been removed from the stack, the C++ atexit list is honored.

**PL/I**

The PL/I language constructs that cause the application to terminate are:

- A STOP statement, or an EXIT statement

  If you code a STOP or EXIT statement, the T_I_S (Termination Imminent Due to STOP) condition is raised. After T_I_S has been processed and all user code has been removed from the stack, the C atexit list is honored.

- A call to PLIDUMP with the S or E option

  If you call PLIDUMP with the S or E option, neither termination imminent condition is raised, and the C++ atexit list is not honored before the enclave is terminated. See [z/OS Language Environment Debugging Guide](z/OS V1R11.0 Language Environment Writing ILC Applications) for syntax of the PLIDUMP service.

**Exception Occurs in C++**

This scenario describes the behavior of an application that contains a C++ and a PL/I routine. Refer to Figure 38 throughout the following discussion. In this scenario, a PL/I main routine invokes a C++ subroutine. An exception occurs in the C++ subroutine.

```
<table>
<thead>
<tr>
<th>C++ subroutine</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception occurs here</td>
</tr>
<tr>
<td>C++ semantics</td>
</tr>
<tr>
<td>PL/I main rtn</td>
</tr>
<tr>
<td>PL/I semantics</td>
</tr>
<tr>
<td>C++ defaults</td>
</tr>
<tr>
<td>PL/I defaults</td>
</tr>
<tr>
<td>Lang. Env. defaults</td>
</tr>
</tbody>
</table>
```

*Figure 38. Stack Contents When the Exception Occurs* 

The actions taken are the following:
1. In the enablement step, it is determined whether the exception in the C++
routine should be enabled and treated as a condition. If any of the following are 
true, the exception is ignored, and processing continues at the next sequential 
instruction after where the exception occurred:

- You specified SIG_Ign for the exception in a call to signal().

Note: The system or user abend corresponding to the signal(SIGABND) or 
the Language Environment message 3250 is not ignored. The enclave 
is terminated.

- The exception is one of those listed as masked in Table 64 on page 255, and 
you have not enabled it using the CEE3SPM callable service.

- You did not specify any action, but the default action for the condition is 
SIG_Ign (see Table 64 on page 255).

- You are running under CICS and a CICS handler is pending.

If you did none of these things, the condition is enabled and processed as a 
condition.

2. If a user-written condition handler has been registered on the stack frame using 
CEEHDLR, it is given control.

If it issues a resume, the condition handling step ends. Processing continues in 
the routine to which the resume cursor points.

In this example, no user-written condition handler is registered for the condition, 
so the condition is percolated.

3. If a C signal handler has been registered for the condition on the C++ stack 
frame, it is given control. If it successfully issues a resume or a call to 
longjmp(), the condition handling step ends. Processing resumes in the routine 
to which the resume cursor points.

In this case, there is not a C signal handler registered for the condition.

4. The condition is still unhandled. If C++ does not recognize the condition, or if 
the C++ default action (listed in Table 64 on page 255) is to terminate, the 
condition is percolated.

5. Is a user-written condition handler has been registered on the PL/I stack frame 
using CEEHDLR, it is given control. If it issues a resume, the condition handling 
step ends. Processing continues in the routine at the point where the resume 
cursor points. In this example, no user-written condition handler is registered for 
the condition, so the condition is percolated.

6. If an ON-unit has been established for the condition being processed on the 
PL/I stack frame, it is given control. If it issues a GOTO out-of-block, the 
condition handling step ends. Execution resumes at the label of the GOTO. In 
this example, no ON-unit is established for the condition, so the condition is 
percolated.

7. What happens next depends on whether the condition is promotable to the PL/I 
ERROR condition. The following can happen:

- If the condition is not promotable to the PL/I ERROR condition, then the 
Language Environment default actions take place, as described in Table 63 
on page 255 Condition handling ends.

- If the PL/I default action for the condition is to promote it to the PL/I ERROR 
condition, the condition is promoted, and another pass is made of the stack 
to look for ERROR ON-units or user-written condition handlers. If an ERROR 
ON-unit or user-written condition handler is found, it is invoked.

- If either of the following occurs:
An ERROR ON-unit or user-written condition handler is found, but it does not issue a GOTO out of block or similar construct.

No ERROR ON-unit or user-written condition handler is found.

Then the ERROR condition is promoted to T_I_U (Termination Imminent due to an Unhandled condition). Condition handling now enters the termination imminent step. Because T_I_U maps to the PL/I FINISH condition, a FINISH ON-unit or user-written condition handler is run if the stack frame in which it is established is reached.

- If no condition handler moves the resume cursor and issued a resume, Language Environment terminates the thread.

**Exception Occurs in PL/I**

This scenario describes the behavior of an application that contains a PL/I and a C++ routine. Refer to Figure 39 throughout the following discussion. In this example, a C++ main routine invokes a PL/I subroutine. An exception occurs in the PL/I subroutine.

![Figure 39. Stack Contents When the Exception Occurs](image)

The actions taken are the following:

1. In the enablement step, PL/I determines if the exception that occurred should be handled as a condition according to the PL/I rules of enablement.
   - If the exception is to be ignored, control is returned to the next sequential instruction after where the exception occurred.
   - If the exception is to be enabled and processed as a condition, the condition handling step, described below, takes place.

2. If a user-written condition handler has been registered on the PL/I stack frame using CEEHDLR, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine at the point where the resume cursor points. In this example, no user-written condition handler is registered for the condition, so the condition is percolated.
3. If an ON-unit has been established for the condition being processed on the PL/I stack frame, it is given control. If it issues a GOTO out-of-block, the condition handling step ends. Execution resumes at the label of the GOTO. In this example, no ON-unit is established for the condition, so the condition is percolated.

4. If a user-written condition handler has been registered using CEEHDLR on the C++ stack frame, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine to which the resume cursor points.

   **Note:** There are special considerations for resuming from some IBM conditions of severity 2 or greater; see the chapter on coding user-written condition handlers in the z/OS Language Environment Programming Guide. In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

5. If a C signal handler has been registered for the condition, it is given control. If it successfully issues a resume or a call to `longjmp()`, the condition handling step ends. Processing resumes in the routine to which the resume cursor points.

   In this example no C signal handler is registered for the condition, so the condition is percolated.

6. What happens next depends on whether the condition is promotable to the PL/I ERROR condition. The following can happen:
   - If the condition is not promotable to the PL/I ERROR condition, then the Language Environment default actions take place, as described in Table 63 on page 253. Condition handling ends.
   - If the PL/I default action for the condition is to promote it to the PL/I ERROR condition, the condition is promoted, and another pass of the stack is made to look for ERROR ON-units or user-written condition handlers. If an ERROR ON-unit or user-written condition handler is found, it is invoked.
   - If either of the following occurs:
     - An ERROR ON-unit or user-written condition handler is found, but it does not issue a GOTO out of block or similar construct
     - No ERROR ON-unit or user-written condition handler is found
     then the ERROR condition is promoted to T_I_U (Termination Imminent due to an Unhandled condition). Condition handling now enters the termination imminent step. Because T_I_U maps to the PL/I FINISH condition, a FINISH ON-unit is run if the stack frame in which it is established is reached.
   - If no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

**Fixed Point Overflow**

The XL C++ compiler assumes that fixed point overflow exceptions will be handled by S/390 hardware, while the PL/I compiler assumes the run-time library will process these exceptions. Therefore, if a C++ to PL/I ILC application incurs a fixed point overflow, Language Environment will try to handle this exception in the run-time library. This will result in increased CPU utilization compared to an application using only C++.
Sample C++ to PL/I ILC Applications

```c
/*COMPILATION UNIT: IBMPCX */
/**Process lc(101),opt(0),s,map,list,stmt,a(f),ag;*/
CEPLI2C: PROC OPTIONS(MAIN);
/***************************************************************/
/* FUNCTION : Interlanguage communications call to */
/* a C++ program. */
/* This example illustrates an interlanguage call from */
/* a PL/I main program to a C++ subroutine. */
/* The parameters passed across the call from PL/I to */
/* C++ have the following declarations: */
/* */
/* PL/I fixed bin(15,0) to C++ short as pointer to BIN */
/* PL/I fixed bin(31,0) to C++ int */
/* PL/I float bin(53) to C++ double */
/* PL/I characters to C++ as pointer to pointer to CHAR */
/***************************************************************/
/***************************************************************/
/* DECLARES FOR THE CALL TO C++ */

Chapter 10. Communicating between COBOL and Fortran

This chapter describes Language Environment's support for COBOL and Fortran ILC applications.

### General Facts about COBOL to Fortran ILC

- A load module consisting of object code compiled with any Fortran compiler link-edited with object code compiled in another language is not reentrant, regardless of whether the Fortran routine was compiled with the RENT compiler option.
- Language Environment does not support passing return codes between COBOL routines and Fortran routines.
- Fortran routines cannot operate under CICS.

### Preparing for ILC

This section describe topics you might want to consider before writing an ILC application. To determine how different versions of HLLs work together, refer to the migration guides for the HLLs you plan to use.

### Language Environment ILC Support

Language Environment provides ILC support between the following combinations of COBOL and Fortran:

<table>
<thead>
<tr>
<th>HLL Pair</th>
<th>COBOL</th>
<th>Fortran</th>
</tr>
</thead>
</table>
| COBOL to Fortran  | • VS COBOL II Version 1 Release 3 (static calls only)  
                   | • COBOL/370                        | • FORTRAN IV G1                                  |
|                   | • COBOL for MVS & VM               | • FORTRAN IV H Extended                         |
|                   | • COBOL for OS/390 & VM            | • VS FORTRAN Version 1, except modules compiled with Release 2.0 or earlier and that either pass character arguments to, or receive character arguments from, subprograms. |
|                   | • Enterprise COBOL for z/OS        | • VS FORTRAN Version 2, except modules compiled with Releases 5 or 6 and whose source contained any parallel language constructs or parallel callable services, or were compiled with either of the compiler options PARALLEL or EC. |

**Note:** Dynamic calls from Fortran are only available from VS FORTRAN Version 2 Release 6.

### Migrating ILC Applications

All COBOL to Fortran ILC applications require a relink except those containing OS/VS COBOL or VS COBOL II programs that were compiled with the NORES compiler option. If an OS/VS COBOL program is relinked, it cannot call or be called by a Fortran routine; the OS/VS COBOL program would need to be upgraded.

Fortran provides a migration tool that replaces old library modules with Language Environment ones. For more information on Fortran's library module replacement tool, see [z/OS Language Environment Programming Guide](#).

### Determining the Main Routine

In Language Environment, only one routine can be the main routine; no other routine in the enclave can use syntax that indicates it is main.
A COBOL program is designated as main if it is the first program to run in an enclave. A Fortran routine is designated as a main routine with a PROGRAM statement, which indicates the name of the main routine. A main routine can also be designated when there are no PROGRAM, SUBROUTINE, or FUNCTION statements, in which case the name of the main routine is the default value of MAIN (or MAIN# for VS FORTRAN Version 2 Releases 5 and 6). The name of the main routine is the entry point into the load module.

Table 47 describes how COBOL and Fortran identify the main routine.

Table 47: How COBOL and Fortran Main Routines Are Determined

<table>
<thead>
<tr>
<th>Language</th>
<th>When Determined</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>COBOL</td>
<td>Run time</td>
<td>Determined dynamically. If it is the first program to run, it is a main program.</td>
</tr>
<tr>
<td>Fortran</td>
<td>Compilation</td>
<td>Determined in the Fortran source by the name on the PROGRAM statement.</td>
</tr>
</tbody>
</table>

An entry point is defined for each supported HLL. Table 48 identifies the main and fetched entry point for each language. The table assumes that your code has been compiled using the Language Environment-conforming compilers.

Table 48: Determining the Entry Point

<table>
<thead>
<tr>
<th>HLL</th>
<th>Main Entry Point</th>
<th>Fetched Entry Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>COBOL</td>
<td>Name of the first object program to get control in the object module</td>
<td>Program name</td>
</tr>
<tr>
<td>Fortran</td>
<td>Name on the PROGRAM statement, or MAIN (or MAIN# for VS FORTRAN Version 2 Releases 5 and 6), if no PROGRAM, SUBROUTINE, or FUNCTION statements are used</td>
<td>Subprogram name</td>
</tr>
</tbody>
</table>

Declaring COBOL to Fortran ILC

There are no special declarations needed in either COBOL or Fortran to use ILC between them.

Calling between COBOL and Fortran

This section describes the types of calls permitted between COBOL and Fortran, and considerations when using dynamic calls and fetch.

Types of Calls Permitted

Table 49 describes the types of calls between COBOL and Fortran that Language Environment allows:

Table 49: Calls Permitted for COBOL and Fortran ILC

<table>
<thead>
<tr>
<th>ILC Direction</th>
<th>Static Calls</th>
<th>Dynamic Calls</th>
</tr>
</thead>
<tbody>
<tr>
<td>COBOL to Fortran</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Fortran to COBOL</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Dynamic Call/Fetch Considerations

This section describes the considerations for using dynamic calls and fetch in COBOL to Fortran ILC.
**COBOL Dynamically Calling Fortran**

Dynamic calls are made in COBOL by either a CALL statement with an identifier whose value is the called routine name, or a CALL statement with a literal in a routine that is compiled with the DYNAM compiler option. The dynamically called routine can be a Fortran routine that can statically call another COBOL program. Or it can be a COBOL program that statically calls a Fortran routine. A routine in the dynamically loaded module can then dynamically call other COBOL or Fortran routines.

You cannot use a COBOL CANCEL statement to delete a dynamically called Fortran routine.

**Restriction:** When a COBOL program dynamically calls a Fortran routine, the dynamically loaded module can contain only routines written in those languages that already exist in a previous load module. (The routine in the previous load module need not be called; it only needs to be present.) For a Fortran routine to be recognized, ensure that at least one of the following is present in a previous load module:

- A Fortran main program
- A Fortran routine that causes one or more Fortran run-time library routines to be link-edited into the load module. If the Fortran routine contains either an I/O statement, a mathematical function reference, or a call to any Fortran callable service (such as CPUTIME), then a library routine is included, and this requirement is satisfied.
- The Fortran signature CSECT, CEESG007. Use the following linkage editor statement to include CEESG007 if neither of the two previous conditions is true:

  ```
  INCLUDE SYSLIB (CEESG007)
  ```

**Fortran Dynamically Calling COBOL**

Dynamic calls are made in Fortran by specifying the name of the routine to be loaded with the DYNAMIC compiler option, and then using the same name in a CALL statement. The dynamically called routine can be either COBOL or Fortran, and it can in turn statically call either a COBOL or Fortran routine. In the dynamically loaded module, a routine can dynamically call other COBOL or Fortran routines.

Neither a COBOL routine nor a Fortran routine can delete a dynamically loaded routine that was dynamically loaded in a Fortran routine.

**Calling Functions**

Only a Fortran subroutine subprogram can be invoked from a COBOL program. A Fortran routine written as a function subprogram cannot be invoked from a COBOL program. Similarly, only Fortran CALL statements can be used to invoke a COBOL program. A COBOL program cannot be invoked with a function reference by a Fortran routine.
Passing Data between COBOL and Fortran

Table 50 lists the data types that can be passed between COBOL and Fortran by reference.

<table>
<thead>
<tr>
<th>COBOL</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>PIC S9(4) USAGE IS COMPUTATIONAL</td>
<td>INTEGER*2</td>
</tr>
<tr>
<td>or</td>
<td></td>
</tr>
<tr>
<td>PIC S9(4) USAGE IS BINARY</td>
<td>INTEGER*2</td>
</tr>
<tr>
<td>PIC S9(9) USAGE IS COMPUTATIONAL</td>
<td>INTEGER*4</td>
</tr>
<tr>
<td>or</td>
<td></td>
</tr>
<tr>
<td>PIC S9(9) USAGE IS BINARY</td>
<td>INTEGER*4</td>
</tr>
<tr>
<td>PIC S9(18) USAGE IS COMPUTATIONAL</td>
<td>INTEGER*8</td>
</tr>
<tr>
<td>or</td>
<td></td>
</tr>
<tr>
<td>PIC S9(18) USAGE IS BINARY</td>
<td>INTEGER*8</td>
</tr>
<tr>
<td>USAGE IS COMPUTATIONAL-1</td>
<td>REAL*4</td>

<tr>
<td>USAGE IS COMPUTATIONAL-2</td>
<td>REAL*8</td>
</tr>
<tr>
<td>PIC X(n) USAGE IS DISPLAY</td>
<td>CHARACTER*n</td>
</tr>
<tr>
<td>USAGE IS POINTER</td>
<td>POINTER</td>
</tr>
</tbody>
</table>

Passing Character Data

Character data can be received by a Fortran routine only when the routine that receives the data declares the data to be of fixed length. Therefore, the following form cannot be used by a Fortran routine to receive character data:

```
CHARACTER*(*)
```

In addition, the `occurs depending on` clause cannot be specified in the COBOL declaration of the character data that is passed to the Fortran routine.

Mapping Arrays

The COBOL equivalent of a Fortran array of one of the data types listed in Table 50 is a fixed-length table that includes one or more `occurs` clauses. A COBOL fixed-length table and Fortran array can be passed between COBOL and Fortran routines only if the number of repeating elements is a constant value and the elements are in contiguous storage locations. COBOL tables containing the `occurs depending on` clause and Fortran assumed-shape or assumed-size arrays cannot, therefore, be passed between COBOL and Fortran routines.

In COBOL, tables of more than one dimension are arranged in row major order, while in Fortran, arrays of more than one dimension are arranged in column major order. You can correspond elements of a Fortran array to a COBOL table simply by reversing the order of the subscripts.
Data Equivalents

This section describes how COBOL and Fortran data types correspond to each other.

Equivalent Data Types for COBOL to Fortran

The following examples illustrate how COBOL and Fortran routines within a single ILC application might code the same data types.

16-Bit Signed Binary Integer

<table>
<thead>
<tr>
<th>Sample COBOL Usage</th>
<th>Fortran Subroutine</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDENTIFICATION DIVISION.</td>
<td>SUBROUTINE CBFF16I( ARG )</td>

</table>
### Short Floating-Point Number

**Sample COBOL Usage**

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. CBFCSFP.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING- STORAGE SECTION.
1 X USAGE IS COMPUTATIONAL-1.
PROCEDURE DIVISION.
  MOVE 5.0E0 TO X.
  CALL "CBFFSFP" USING X.
  DISPLAY "UPDATED VALUE IN COBOL: ", X.
  GOBACK.
END PROGRAM CBFCSFP.
```

**Fortran Subroutine**

```fortran
SUBROUTINE CBFFSFP ( ARG )
REAL*4 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
ARG = ARG + 1.0E0
END
```

### Long Floating-Point Number

**Sample COBOL Usage**

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. CBFCLFP.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING- STORAGE SECTION.
1 X USAGE IS COMPUTATIONAL-2.
PROCEDURE DIVISION.
  MOVE 5.0E0 TO X.
  CALL "CBFFLFP" USING X.
  DISPLAY "UPDATED VALUE IN COBOL: ", X.
  GOBACK.
END PROGRAM CBFCLFP.
```

**Fortran Subroutine**

```fortran
SUBROUTINE CBFFLFP ( ARG )
REAL*8 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
ARG = ARG + 1.0D0
END
```

### Fixed-Length Character Data

**Sample COBOL Usage**

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. CBFCFLC.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING- STORAGE SECTION.
1 X PIC X(10) USAGE IS DISPLAY.
1 Y PIC X(10) USAGE IS DISPLAY.
PROCEDURE DIVISION.
  MOVE "1234567890" TO X.
  CALL "CBFFFLC" USING X, Y.
  DISPLAY "VALUE RETURNED TO COBOL: ", Y.
  GOBACK.
END PROGRAM CBFCFLC.
```

**Fortran Subroutine**

```fortran
SUBROUTINE CBFFFLC ( ARG1, ARG2 )
CHARACTER*10 ARG1, ARG2
PRINT *, 'FORTRAN ARG1 VALUE: ', ARG1
ARG2 = ARG1
END
```
### Array
#### Sample COBOL Usage
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. CBFCAF.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
  1 X.
    2 MATRIX OCCURS 3 TIMES
       USAGE IS COMPUTATIONAL-1.
PROCEDURE DIVISION.
  MOVE 0.0E0 TO MATRIX(1).
  MOVE 1.0E0 TO MATRIX(2).
  MOVE 2.0E0 TO MATRIX(3).
  CALL "CBFFAF" USING X.
  DISPLAY "UPDATED VALUES IN COBOL: ",
        MATRIX(1), MATRIX(2), MATRIX(3).
GOBACK.
END PROGRAM CBFCAF.
```

#### Fortran Subroutine
```fortran
SUBROUTINE CBFFAF ( ARG )
 REAL*4 ARG(3)
 PRINT *, 'FORTRAN ARG VALUES:', ARG
 DO J = 1, 3
    ARG(J) = ARG(J) + 1.0
 ENDDO
END
```

### Address of an Array
#### Sample COBOL Usage
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. CBFCAOA.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
  1 X.
    2 X1 OCCURS 3 TIMES
       PIC S9(9)
       USAGE IS BINARY.
    1 P USAGE IS POINTER.
PROCEDURE DIVISION.

  SET P TO ADDRESS OF X.
  EXIT PROGRAM.
END PROGRAM GETADDR.
END PROGRAM CBFCAOA.
```

#### Fortran Subroutine
```fortran
SUBROUTINE CBFFAOA ( ARG )
 POINTER*4 (ARG, Y)
 INTEGER*4 Y(3)
 PRINT *, 'FORTRAN ARRAY ARG VALUES:', Y
 DO J = 1, 3
    Y(J) = Y(J) + 1
 ENDDO
END
```

### Equivalent Data Types for Fortran to COBOL
The following examples illustrate how COBOL and Fortran routines within a single ILC application might code the same data types.
16-Bit Signed Binary Integer

Sample Fortran Usage

```fortran
INTEGER*2 X
X = 5
CALL FCBC16I(X)
PRINT *,
1 'UPDATED VALUE IN FORTRAN: ', X
END
```

COBOL Subroutine

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. FCBC16I.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
1 X PIC S9(4) USAGE IS BINARY.
PROCEDURE DIVISION USING X.
  DISPLAY "COBOL ARG VALUE: ", X.
  ADD 1 TO X.
  EXIT PROGRAM.
END PROGRAM FCBC16I.
```

32-Bit Signed Binary Integer

Sample Fortran Usage

```fortran
INTEGER*4 X
X = 5
CALL FCBC32I(X)
PRINT *,
1 'UPDATED VALUE IN FORTRAN: ', X
END
```

COBOL Subroutine

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. FCBC32I.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
1 X PIC S9(9) USAGE IS BINARY.
PROCEDURE DIVISION USING X.
  DISPLAY "COBOL ARG VALUE: ", X.
  ADD 1 TO X.
  EXIT PROGRAM.
END PROGRAM FCBC32I.
```

64-Bit Signed Binary Integer

Sample Fortran Usage

```fortran
INTEGER*8 X
X = 5
CALL FCBC64I(X)
PRINT *,
1 'UPDATED VALUE IN FORTRAN: ', X
END
```

COBOL Subroutine

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. FCBC64I.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
1 X PIC S9(18) USAGE IS BINARY.
PROCEDURE DIVISION USING X.
  DISPLAY "COBOL ARG VALUE: ", X.
  ADD 1 TO X.
  EXIT PROGRAM.
END PROGRAM FCBC64I.
```

Short Floating-Point Number

Sample Fortran Usage

```fortran
REAL*4 X
X = 5.0
CALL FCBCSFP(X)
PRINT *,
1 'UPDATED VALUE IN FORTRAN: ', X
END
```

COBOL Subroutine

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. FCBCSFP.
ENVIRONMENT DIVISION.
DATA DIVISION.
LINKAGE SECTION.
1 X USAGE IS COMPUTATIONAL-1.
PROCEDURE DIVISION USING X.
  DISPLAY "COBOL ARG VALUE: ", X.
  ADD 1.0E0 TO X.
  EXIT PROGRAM.
END PROGRAM FCBCSFP.
```
### Long Floating-Point Number

#### Sample Fortran Usage
```
REAL*8 X
X = 5.0D0
CALL FCBCLFP(X)
PRINT *,
1 'UPDATED VALUE IN FORTRAN:', X
END
```

#### COBOL Subroutine
```

  DISPLAY "COBOL ARG VALUES: ", 
  PERFORM VARYING IX 
    FROM 1 BY 1 
    UNTIL IX > 3 
    SUBTRACT 1 FROM M(IX)
END-PERFORM.
EXIT PROGRAM.
END PROGRAM FCBCAOA.
```

External Data

External data in Fortran and COBOL (common block in Fortran and data specified by the EXTERNAL clause in COBOL) cannot be shared among routines.

Directing Output in ILC Applications

COBOL and Fortran do not share files, except the Language Environment message file (the ddname specified in the Language Environment MSGFILE run-time option). You must manage all other files to ensure that no conflicts arise. Performing I/O operations on the same ddname might cause abnormal termination. If directed to the Language Environment message file, output from both COBOL and Fortran programs will be interspersed in the file.

Under COBOL, run-time messages and other related output are directed to the Language Environment message file. For COBOL programs, output from the DISPLAY UPON SYSOUT statement is also directed to the Language Environment message file if the ddname name in the MGSFILE run-time option matches that in the OUTDD compiler option. (The IBM-supplied default value for OUTDD is SYSOUT.)

Fortran run-time messages, output written to the print unit, and other output (such as output from the SDUMP callable service) are directed to the file specified by the MSGFILE run-time option. To direct this output to the file with the ddname FTnnF001, (where nn is the two-digit error message unit number), specify the run-time option MSGFILE(FTnnF001). If the print unit is different than the error message unit (if the PRTUNIT and the ERRUNIT run-time options have different values), output from a PRINT statement won’t be directed to the Language Environment message file.
COBOL to Fortran Condition Handling

This section provides two scenarios of condition handling behavior in a COBOL to Fortran ILC application. If an exception occurs in a COBOL routine, the set of possible actions is as described in "Exception Occurs in COBOL" on page 184. If an exception occurs in a Fortran program, the set of possible actions is as described in "Exception Occurs in Fortran" on page 185.

Keep in mind that some conditions can be handled only by the HLL of the routine in which the exception occurred. Two examples are:

- In a COBOL program, if a statement has a condition handling clause added to a verb (such as ON EXCEPTION), the condition is handled within COBOL. For example, the ON SIZE clause of a COBOL DIVIDE verb (which includes the logical equivalent of the zero divide condition) is handled completely within COBOL.

- When the Fortran ERR or IOSTAT specifier is present on a Fortran I/O statement, and an error is detected while executing that statement, the Fortran language semantics take precedence over Language Environment condition handling. Control returns immediately to the Fortran routine and no condition is signalled to Language Environment.

See z/OS Language Environment Programming Guide for a detailed description of Language Environment condition handling. For information on Fortran condition handling semantics, see VS FORTRAN Version 2 Language and Library Reference.

Enclave-Terminating Language Constructs

Enclaves can be terminated for reasons other than an unhandled condition of severity 2 or greater. HLL constructs that cause the termination of a single language enclave also cause the termination of a COBOL to Fortran enclave. In Language Environment ILC, you can issue the language construct to terminate the enclave from a COBOL or Fortran routine.

COBOL

The COBOL language constructs that cause the enclave to terminate are:

- STOP RUN
  COBOL’s STOP RUN is equivalent to the Fortran stop statement. If you code a COBOL STOP RUN statement, the T_I_S (Termination Imminent Due to STOP) condition is raised.

- Call to ILBOABN0 or CEE3ABD
  Calling ILBOABN0 or CEE3ABD causes T_I_U to be signalled. Condition handlers are given a chance to handle the abend. If the abend remains unhandled, normal Language Environment termination activities occur. For example, the Fortran stop statement is honored and the Language Environment assembler user exit gains control.

User-written condition handlers written in COBOL must be compiled with Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, or COBOL/370.

Fortran

The Fortran language constructs that cause the enclave to terminate are:

- A STOP statement
- An END statement in the main routine
- A call to EXIT or SYSRCX
- A call to DUMP or CDUMP
Except for executing the END statement in a main program all of the constructs listed above cause the T.I.S (termination imminent due to stop) condition to be signaled.

**Exception Occurs in COBOL**

This scenario describes the behavior of an application that contains a COBOL and a Fortran routine. Refer to Figure 42 throughout the following discussion. In this scenario, a Fortran main routine invokes a COBOL subroutine. An exception occurs in the COBOL subroutine.

<td></td>
</tr>
</tbody>
</table>

*Figure 42. Stack Contents When the Exception Occurs*

The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, COBOL determines whether the exception that occurred should be handled as a condition.
   - If the exception is to be ignored, control is returned to the next sequential instruction after where the exception occurred.
   - If the exception is to be enabled and processed as a condition, the condition handling step, described below, takes place.

2. If a user-written condition handler has been registered using CEEHDLR on the COBOL stack frame, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine to which the resume cursor points.

   Two areas to watch out for here are resuming from an IBM condition of severity 2 or greater (see the chapter on coding a user-written condition handler in the Language Environment Programming Guide) and moving the resume cursor in an application that contains a COBOL program (see “GOTO Out-of-Block and Move Resume Cursor” on page 186).

   In this example, no user-written condition handler is registered for the condition, so the condition is percolated.
3. If the condition has a Facility_ID of IGZ, the condition is COBOL-specific. The COBOL default actions occur. If COBOL doesn’t recognize the condition, condition handling continues.

4. There is no user-written condition handler on the Fortran stack frame (because CEEHDLR cannot be called from a Fortran routine), and the condition is percolated.

5. If the condition is of severity 0 or 1, Language Environment default actions take place, as described in Table 63 on page 255.

6. If the condition is of severity 2 or above, Language Environment default actions to promote the condition to T_I_U (Termination Imminent due to an Unhandled condition) and redrive the stack. Condition handling now enters the termination imminent step.

7. If on the second pass of the stack no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

### Exception Occurs in Fortran

This scenario describes the behavior of an application that contains a Fortran and a COBOL routine. Refer to Figure 43 throughout the following discussion. In this scenario, a COBOL main routine invokes a Fortran subroutine. An exception occurs in the Fortran subroutine.

<table>
<thead>
<tr>
<th>Fortran subroutine</th>
<th>Exception occurs here</th>
</tr>
</thead>
<tbody>

<td></td>
</tr>
<tr>
<td>Fortran defaults</td>
<td></td>
</tr>
<tr>
<td>COBOL defaults</td>
<td></td>
</tr>
</tbody>
</table>

**Figure 43. Stack Contents When the Exception Occurs**

The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. If an I/O error is detected on a Fortran I/O statement that contains an ERR or IOSTAT specifier, Fortran semantics take precedence. The exception is not signaled to the Language Environment condition handler.

2. In the enablement step, Fortran treats all exceptions as conditions. Processing continues with the condition handling step, described below.
3. There is no user-written condition handler on the Fortran stack frame (because CEEHDLR cannot be called from a Fortran routine), and the condition is percolated.

4. If a user-written condition handler registered using CEEHDLR is present on the COBOL stack frame, it is given control. (User-written condition handlers written in COBOL must be compiled with COBOL/370 or COBOL for MVS & VM.) If it successfully issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points. Note that you must be careful when moving the resume cursor in an application that contains a COBOL program. See "GOTO Out-of-Block and Move Resume Cursor" for details.

In this example, there is not a user-written condition handler registered for the condition, so the condition is percolated.

5. If the condition is of severity 0 or 1, Language Environment default actions take place, as described in Table 63 on page 255.

6. If the condition is of severity 2 or above, Language Environment default action is to promote the condition to T_I_U (Termination Imminent due to an Unhandled condition) and redrive the stack. Condition handling now enters the termination imminent step.

7. If on the second pass of the stack no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

**GOTO Out-of-Block and Move Resume Cursor**

When a GOTO out-of-block or a call to CEEMRCR causes a routine to be removed from the stack, a “non-return style” termination of the routine occurs. Multiple routines can be terminated by a non-return style termination independent of the number of ILC boundaries that are crossed. If one of the routines that is terminated by the non-return style is a COBOL program, the COBOL program can be re-entered via another call path.

If the terminated program is one of the following, the program is not deactivated. If the COBOL program does not specify RECURSIVE in the PROGRAM-ID, a recursion error is raised if you attempt to enter the routine again.

- A COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, or a VS COBOL II program compiled with the CMPR2 option
- A VS COBOL II program that is compiled with the NOCMPR2 option and contains nested programs
- A COBOL for OS/390 & VM, COBOL for MVS & VM, or COBOL/370 program that is compiled with the NOCMPR2 option and has the combination of the INITIAL attribute, nested programs, and file processing in the same compilation unit.
- An Enterprise COBOL for z/OS program that does not use the combination of the INITIAL attribute, nested routines, and file processing in the same compilation unit.

In addition, if the program is an Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, or a VS COBOL II program with the INITIAL attribute and if it contains files, the files are closed. (COBOL supports VSAM and QSAM files, and these files are closed.)
Sample ILC Applications

    DISPLAY "CBLFFOR ENDED".
    GOBACK.

Figure 45. COBOL Program Dynamically Called by Fortran Program
Chapter 11. Communicating between COBOL and PL/I

This chapter describes Language Environment's support for COBOL and PL/I ILC applications. If you are running a COBOL to PL/I ILC application under CICS, you should also consult [Chapter 15, "ILC under CICS," on page 247.]

General Facts about COBOL to PL/I ILC

- A COBOL program cannot be called as a function.
- The halfword prefix for PL/I varying strings is exposed, so you need to code the COBOL group data item with a halfword in front of the character string.
- PL/I supports access to COBOL files via the COBOL option of the ENVIRONMENT attribute.
- See "Using Storage Functions in C to PL/I ILC" on page 144 for information about how to use PL/I's storage facilities with Language Environment storage services.
- Language Environment supports the passing of return codes between COBOL and PL/I routines within an ILC application.

Preparing for ILC

This section describes topics you might want to consider before writing an application that uses ILC between COBOL and PL/I. For help in determining how different versions of HLLs work together, refer to the migration guides for the HLLs you plan to use.

Language Environment ILC Support

Language Environment supports ILC between the following combinations of COBOL and PL/I:

Table 51. Supported Languages for Language Environment ILC Support

<table>
<thead>
<tr>
<th>HLL Pair</th>
<th>COBOL</th>
<th>PL/I</th>
</tr>
</thead>
</table>
| COBOL to PL/I | • VS COBOL II Release 3 or later  
• COBOL/370 Release 1  
• COBOL for MVS & VM Release 2  
• COBOL for OS/390 & VM  
• Enterprise COBOL for z/OS | • OS PL/I Version 1 Release 3 or later  
• OS PL/I Version 2  
• PL/I for MVS & VM or later  
• Enterprise PL/I for z/OS |

Note: Language Environment does not support ILC between OS/VS COBOL Releases 2.3 or 2.4 and PL/I. It also does not support ILC between COBOL and OS PL/I Version 1 Release 1 or 2.

Migrating ILC Applications

You need to relink pre-Language Environment-conforming ILC applications in order to get Language Environment’s ILC support.

If you link your VS COBOL II to OS PL/I ILC applications to the migration tool provided by OS PL/I Version 2 Release 3, you don’t need to relink your applications to the Language Environment library routines. This migration tool also supports
multitasking applications that contain COBOL. For more information on this migration tool, refer to PL/I for MVS & VM Compiler and Run-Time Migration Guide or Enterprise PL/I for z/OS Migration Guide. The PTF numbers for the PL/I migration tool are:
- On MVS, UN76954 and UN76955

You don’t need to recompile an existing ILC application unless the COBOL programs were compiled with OS/VS COBOL or the PL/I routines were compiled with OS PL/I Version 1 Release 1 or 2. In these cases, you must upgrade the source and compile with a newer version of the compilers.

Determining the Main Routine
In Language Environment, only one routine can be the main routine. The main routine should be presented to the linkage editor first. Because all potential main routines nominate the entry point through the END record, the correct entry point is chosen. If the main routine is not presented first, the entry point must be specified with a link-edit control card.

An entry point is defined for each supported HLL. Table 52 identifies the desired entry point. The table assumes that your code has been compiled using the Language Environment-conforming compilers.

<table>
<thead>
<tr>
<th>HLL</th>
<th>Main Entry Point</th>
<th>Fetched Entry Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>COBOL</td>
<td>Name of the first object program to get control in the object module</td>
<td>Program name</td>
</tr>
<tr>
<td>PL/I</td>
<td>CEESTART</td>
<td>CEESTART or routine name, if OPTIONS(FETCHABLE) is used.</td>
</tr>
</tbody>
</table>

Multitasking with PL/I and COBOL
In a multitasking ILC application, the main program, or target program of a CALL statement that creates a subtask, must be PL/I. Subsequent programs invoked from the first program can be COBOL.

COBOL programs can run in more than one PL/I subtask when all the COBOL programs in the application are Enterprise COBOL programs compiled with the THREAD compiler option. If one or more of the COBOL programs is not Enterprise COBOL compiled with the THREAD compiler option, then when a COBOL program has been invoked in a task (either the main task or a subtask), no other COBOL program can execute in any other task until the task used to invoke the COBOL program ends.

To run Enterprise COBOL for z/OS programs compiled THREAD in a PL/I multitasking application:
1. The COBOL program load modules must be link-edited RENT.
2. If a COBOL program is going to be FETCHed in a subtask, it must be FETCHed in the main task first (even though it may not be called in the main task).
Declaring COBOL to PL/I ILC

If a PL/I routine invokes a COBOL program or a COBOL program invokes a PL/I routine, you must specify entry declarations in the PL/I source code. No special declaration is required within the COBOL program.

When invoking a COBOL program from PL/I, you identify the COBOL entry point by using the OPTIONS attribute in the declaration of the entry in the calling PL/I routine. By specifying OPTIONS(COBOL) when calling a COBOL program, you request that the PL/I compiler generate a parameter list for the COBOL program in the style COBOL accepts.

In a PL/I routine that calls a COBOL program, the declaration of the COBOL entry point looks like the following:

```
DCL COBOLEP ENTRY OPTIONS(COBOL);
```

The entry points in a PL/I routine invoked from a COBOL program must be identified by the appropriate options in the corresponding PL/I PROCEDURE or ENTRY statement, as illustrated here:

```
PLIEP: PROCEDURE (parms) OPTIONS(COBOL);
```

`parms` specifies parameters that are passed from the calling COBOL program.
`OPTIONS(COBOL)` specifies that the entry point can be invoked only by a COBOL program.

For more information on the COBOL option, see PL/I for MVS & VM Language Reference or Enterprise PL/I for z/OS Language Reference.

In addition to the COBOL option, other options suppress remapping of data aggregates. These are described in "Using Aggregates" on page 194.

Only data types common to both languages can be passed or received.

Building a Reentrant COBOL to PL/I Application

**PL/I and COBOL Reentrancy**

In Language Environment, the reentrancy schemes are maintained at their current support for either COBOL and PL/I. However, ILC applications in which PL/I calls COBOL are now reentrant (assuming that all COBOL and PL/I routines in the application are reentrant).

**PL/I Reentrancy**

You should use PROC OPTIONS(REENTRANT) for all external procedures in a multitasking environment.

**Reentrancy for PL/I Multitasking Applications**

COBOL programs running in a PL/I multitasking application should be compiled with the RENT compiler option. COBOL programs compiled with the NORENT compiler option will run in an ILC application; however, once a COBOL NORENT program has run in one task, the same program cannot be used in another task.

Calling between COBOL and PL/I

This section describes the types of calls that are permitted between COBOL and PL/I as well as dynamic call/fetch considerations.
Types of Calls Permitted

Table 53 describes the types of calls between COBOL and PL/I that Language Environment allows:

<table>
<thead>
<tr>
<th>ILC Direction</th>
<th>Static Calls</th>
<th>Dynamic Calls</th>
<th>Fetch/Calls</th>
</tr>
</thead>
<tbody>
<tr>
<td>COBOL to PL/I</td>
<td>Yes</td>
<td>Yes</td>
<td>N/A</td>
</tr>
<tr>
<td>PL/I to COBOL</td>
<td>Yes</td>
<td>N/A</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Dynamic Call/Fetch Considerations

This section describes the call/fetch differences between COBOL to PL/I dynamic CALLs and PL/I to COBOL fetches.

**COBOL Dynamically Calling PL/I**

Dynamically loaded modules that contain ILC cannot be released by using the COBOL CANCEL verb. The dynamically load module is instead released by Language Environment termination processing.

A COBOL program can dynamically CALL a PL/I routine; COBOL programs cannot dynamically CALL PL/I routines that were compiled by compilers previous to Language Environment-conforming version. Fetched PL/I routines must adhere to the restrictions listed in PL/I for MVS & VM Language Reference. Enterprise PL/I for z/OS has lifted some of the fetching restrictions. Please see Enterprise PL/I for z/OS Language Reference for more information.

If a PL/I procedure is to be dynamically loaded, you must do either of the following:
- Specify OPTIONS(COBOL) on the PROC statement of the program that you compile and use the routine name as the entry point when you link-edit it.
- Specify OPTIONS(COBOL FETCHABLE) on the PROC statement of the program that you compile.

In multitasking ILC applications, once a COBOL program is called by PL/I, it can dynamically CALL a PL/I subroutine by using the COBOL CALL identifier statement or the DYNAM compiler option.

**PL/I Fetching COBOL**

PL/I routines can call Language Environment-conforming COBOL programs only. ILC between PL/I and COBOL/370, COBOL for MVS & VM, COBOL for OS/390 & VM, or Enterprise COBOL for z/OS is supported within the fetched load module.

You cannot use the PL/I RELEASE statement to release a COBOL program that was explicitly loaded by FETCH. A COBOL CANCEL statement cannot be issued against any routine dynamically loaded using the PL/I FETCH statement.

Passing Data between COBOL and PL/I

This section lists the data types that are supported between COBOL and PL/I. It also includes information on mapping aggregates across the two languages.
## Supported Data Types between COBOL and PL/I

The data types supported between COBOL and PL/I are listed below.

<table>
<thead>
<tr>
<th>COBOL</th>
<th>PL/I</th>
</tr>
</thead>
<tbody>
<tr>
<td>PIC S9(4) USAGE IS BINARY</td>
<td>REAL FIXED BINARY(15,0)</td>
</tr>
<tr>
<td>PIC S9(9) USAGE IS BINARY</td>
<td>REAL FIXED BINARY(31,0)</td>
</tr>
<tr>
<td>PIC S9(18) USAGE IS BINARY</td>
<td>REAL FIXED BINARY(63,0)</td>
</tr>
<tr>
<td>PIC 9(4) USAGE IS BINARY</td>
<td>REAL FIXED BINARY(16,0) UNSIGNED</td>
</tr>
<tr>
<td>PIC 9(9) USAGE IS BINARY</td>
<td>REAL FIXED BINARY(32,0) UNSIGNED</td>
</tr>
<tr>
<td>PIC 9(18) USAGE IS BINARY</td>
<td>REAL FIXED BINARY(64,0) UNSIGNED</td>
</tr>
<tr>
<td>COMP-1</td>
<td>REAL FLOAT DECIMAL(6)</td>
</tr>
<tr>
<td>COMP-2</td>
<td>REAL FLOAT DECIMAL(16)</td>
</tr>
<tr>
<td>PIC S9(n) USAGE IS PACKED-DECIMAL</td>
<td>FIXED DECIMAL(n)</td>
</tr>
<tr>
<td>PIC S9(n) USAGE IS COMPUTATIONAL-3</td>
<td>FIXED DECIMAL(n)</td>
</tr>
<tr>
<td>PIC X(n) USAGE IS DISPLAY</td>
<td>CHARACTER(n)</td>
</tr>
<tr>
<td>PIC G(n) USAGE IS DISPLAY-1</td>
<td>GRAPHIC(n)</td>
</tr>
<tr>
<td>PIC N(n) USAGE IS DISPLAY-1</td>
<td>GRAPHIC(n)</td>
</tr>
<tr>
<td>PIC N(n) USAGE IS NATIONAL</td>
<td>WIDECHAR(n)</td>
</tr>
<tr>
<td>PIC X(n)</td>
<td>CHAR(n)</td>
</tr>
<tr>
<td>PIC 9(n) USAGE IS DISPLAY</td>
<td>PICTURE ‘(n)9’</td>
</tr>
<tr>
<td>groups</td>
<td>aggregates</td>
</tr>
<tr>
<td>numeric edited</td>
<td>numeric character</td>
</tr>
<tr>
<td>POINTER</td>
<td>POINTER</td>
</tr>
<tr>
<td>FUNCTION-POINTER</td>
<td>POINTER or LIMITED ENTRY</td>
</tr>
</tbody>
</table>

For PL/I double-word binary support (REAL FIXED BINARY(63) or REAL FIXED BINARY(64) UNSIGNED), you must use the LIMITS(FIXEDBIN(31,63)) or the LIMITS(FIXEDBIN(63)) compiler option.

For PL/I 31-digit decimal support, you must use the LIMITS(FIXEDDEC(15,31)) or the LIMITS(FIXEDDEC(31)) compiler option. For COBOL 31-digit decimal support, you must use the ARITHS(EXTEND) compiler option.
PL/I program control data is used to control the execution of your routine. It consists of the area, entry, event, file, label, and locator data types. Program control data can be passed through a COBOL program to a PL/I routine.

COBOL represents the NULL pointer value as X'00000000'. PL/I represents the NULL pointer value as either X'00000000' using the SYSNULL built-in function or as X'FF000000' using the NULL built-in function. You are responsible for managing the different NULL values when passing pointers between COBOL and PL/I.

You must ensure that the physical layout of the data matches when passing data by pointers between PL/I and COBOL. This particularly applies when passing aggregates/groups and strings.

The non-address bits in all fullword pointers declared in PL/I source code should always be zero. If they are not, results are unpredictable.

**Using Aggregates**

PL/I and COBOL map structures differently. In PL/I, the alignment of parameters is determined by the use of the ALIGNED and UNALIGNED attributes. For best results, all parameters passed between PL/I and COBOL routines should be declared using the ALIGNED attribute. The equivalent specification in COBOL is the SYNCHRONIZED clause. See the appropriate language reference and programming guide for details about the ALIGNED attribute.

**COBOL and PL/I Alignment Requirements**

**COBOL Alignment:** COBOL structures are mapped as follows. Working from the beginning, each item is aligned to its required boundary in the order in which it is declared. The structure starts on a doubleword boundary.

If you specify the SYNCHRONIZED phrase, then BINARY and floating-point data items are aligned on halfword, fullword, doubleword boundaries, depending on their length. If SYNCHRONIZED is not specified, then all data items are aligned on a byte boundary only.

**PL/I Alignment:** PL/I structures are mapped by a method that minimizes the unused bytes in the structure. Simply put, the method used is to first align items in pairs, moving the item with the lesser alignment requirement as close as possible to the item with the greater alignment requirement. The method is described in full in PL/I for MVS & VM Language Reference or Enterprise PL/I for z/OS Language Reference.

**Examples of Alignment:** Consider, for example, a structure consisting of a single character and a fullword fixed binary item. The fullword fixed binary item has a fullword alignment requirement; the character has a byte alignment requirement. In PL/I, ALIGNED is the default, and the structure is declared as follows:

```plaintext
DCL A,
  2 B CHAR(1),
  2 C FIXED BINARY(31,0);
```

and is held like this:
In COBOL, using SYNCHRONIZED, the structure would be declared as follows:

```cobol
01 A SYNCHRONIZED.
   02 B PIC X DISPLAY.
   02 C PIC S9(9) BINARY.
```

and is held like this:

![Doubleword boundary](byte markers)

In COBOL, without SYNCHRONIZED, the structure would be declared as follows:

```cobol
01 A.
   02 B PIC X.
   02 C PIC S9(9) USAGE BINARY.
```

and is held like this:

![Doubleword boundary](byte markers)

Mapping Aggregates

When passing aggregates between COBOL and PL/I, you should ensure that the storage layout matches in each HLL. Also, be sure to completely declare every byte in the aggregate so that there are no open fields.

HLL facilities provide listings of the aggregate elements to help you perform the mapping. The COBOL MAP compiler option and PL/I AGGREGATE compiler option provide a layout of aggregates.

Arrays in PL/I map to tables (OCCURS clause) in COBOL.

The options in the entry declaration that inhibit or restrict the remapping of data aggregates in PL/I are listed below:

**NOMAP**

Specifies that a dummy argument is not created by PL/I. The aggregate is passed by reference to the invoked routine.
NOMAPIN
Specifies that if a dummy argument is created by PL/I, it is not initialized with the values of the aggregate.

NOMAPOUT
Specifies that if a dummy argument is created by PL/I, its values are not assigned by the aggregate upon return to the invoking routine.

ARGn
Applies to the NOMAP, NOMAPIN, and NOMAPOUT options. It specifies arguments to which these options apply. If ARGn is omitted, a specified option applies to all arguments.

Data Equivalents
This section describes how PL/I and COBOL data types correspond to each other.

Equivalent Data Types for COBOL to PL/I
The following examples illustrate how COBOL and PL/I routines within a single ILC application might code the same data types.

### Equivalent Data Types for PL/I to COBOL

The following examples illustrate how COBOL and PL/I routines within a single ILC application might code the same data types.

#### 16-Bit Signed Binary Integer

**Sample PL/I Usage**

```
PSFB15: Proc Options(Main);
  Dcl SYSPRINT file;
  Dcl X Fixed Binary(15,0);
  Dcl CTFB15 external entry Options(COBOL);
  X=1;
    Call CTFB15( X );
End;
```

**COBOL Subroutine**

```
IDENTIFICATION DIVISION.
PROGRAM-ID. CTFB15.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING- storage SECTION.
  1 X PIC S9(4) USAGE IS BINARY.
PROCEDURE DIVISION USING X.
  DISPLAY X.
  GOBACK.
END PROGRAM CTFB15.
```
### 32-Bit Signed Binary Integer

**Sample PL/I Usage**
```pli
PSFB31: Proc Options(Main);
Dcl SYSPRINT file;
Dcl X Fixed Binary(31);
Dcl CTFB31 external entry
   Options(COBOL);
   X=1;
   Call CTFB31( X );
End;
```

**COBOL Subroutine**
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. CTFB31.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
LINKAGE SECTION.
    1 X PIC S9(9) USAGE IS BINARY.
PROCEDURE DIVISION USING X.
   DISPLAY X.
   GOBACK.
END PROGRAM CTFB31.
```

### Short Floating-Point Number

**Sample PL/I Usage**
```pli
PSFTD6: Proc Options(Main);
Dcl SYSPRINT file;
Dcl X Float Decimal(6);
Dcl CTFD6 external entry
   Options(COBOL);
   X=1;
   Call CTFD6( X );
End;
```

**COBOL Subroutine**
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. CTFD6.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
LINKAGE SECTION.
    1 X USAGE IS COMP-1.
PROCEDURE DIVISION USING X.
   DISPLAY X.
   GOBACK.
END PROGRAM CTFD6.
```

### Long Floating-Point Number

**Sample PL/I Usage**
```pli
PSFTD16: Proc Options(Main);
Dcl SYSPRINT file;
Dcl X Float Decimal(16);
Dcl CTFD16 external entry
   Options(COBOL);
   X=1;
   Call CTFD16( X );
End;
```

**COBOL Subroutine**
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. CTFD16.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
LINKAGE SECTION.
    1 X USAGE IS COMP-2.
PROCEDURE DIVISION USING X.
   DISPLAY X.
   GOBACK.
END PROGRAM CTFD16.
```

### Fixed-Length Character Data

**Sample PL/I Usage**
```pli
PSFSTR: Proc Options(Main);
Dcl SYSPRINT file;
Dcl Str Char(80);
Dcl CTFSTR external entry
   Options(COBOL);
   Str = 'Test PL/I-COBOL message.';
   Call CTFSTR( Str );
End;
```

**COBOL Subroutine**
```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. CTFSTR.
ENVIRONMENT DIVISION.
DATA DIVISION.
WORKING-STORAGE SECTION.
LINKAGE SECTION.
    80 STR PIC X(80).
PROCEDURE DIVISION USING STR.
   DISPLAY STR.
   GOBACK.
END PROGRAM CTFSTR.
```
Data Type Equivalents when TRUNC(BIN) Is Specified

If you specify the COBOL compiler option TRUNC(BIN), the following data types are equivalent between PL/I and COBOL:

Name Scope of External Data

In programming languages, the name scope is defined as the portion of an application within which a particular declaration applies or is known.

The name scope of external data under COBOL is the enclave. Under PL/I, it is the load module. Figure 46 and Figure 47 on page 200 illustrate these differences.

Due to the difference in name scope for COBOL and PL/I, PL/I external data and COBOL EXTERNAL data—both reentrant and non-reentrant—do not map to each other, regardless of whether you attempt to share the data within the same load module or across different load modules. External variables with the same name are considered separate between COBOL and PL/I.

If your application relies on the separation of external data, however, do not give the data the same name in both languages within a single application. By giving the data in each load module a different name, you can change the language mix in the application later, and your application will still behave as you expect it to.

Figure 46. Name Scope of External Variables for COBOL Dynamic CALL

In Figure 46, COBOL Programs 1, 2, and 3 comprise a COBOL run unit (a Language Environment enclave). EXTERNAL data declared in COBOL Program 1 maps to that declared in COBOL Program 2 in the same load module. When a dynamic call to COBOL Program 3 in another load module is made, the EXTERNAL
data still maps, because the name scope of EXTERNAL data in COBOL is the enclave.

Figure 47. Name Scope of External Variables for PL/I Fetch

The name scope of external data in PL/I is the load module. In Figure 47, external data declared in PL/I Procedure 1 maps to that declared in PL/I Procedure 2 in the same load module. The fetched PL/I Procedure 3 in another load module cannot have any external data in it.

Name Space of External Data

In programming languages, the name space is defined as the portion of a load module within which a particular declaration applies or is known. Figure 48 and Figure 49 on page 201 illustrates that, like the name scope, the name space of external data differs between PL/I and COBOL.

Figure 48. Name Space of External Data for COBOL Static CALL to COBOL
Figure 48 and Figure 49 illustrate that within the same load module, the name space of COBOL programs is the same. However, the name spaces of a COBOL program and a PL/I procedure within the same load module are not the same. If you give external data the same name in both languages, an incompatibility in external data mapping can occur in the future.

**External Data in Multitasking Applications**
External data defined by a COBOL program persists until the enclave terminates. The external data, then, defined in a COBOL subtask, persists even if the subtask terminates; therefore, the same external data can be used by COBOL program in more than one task.

The following example illustrates how you might use external data in a multitasking ILC application:

1. COBOL PGMA is called in subtask 1. COBOL PGMA defines external PIC X data item as EXT1. PGMA sets EXT1 to 'Z'.
2. Subtask 1 terminates.
3. COBOL PGMB is called in subtask 2. PGMB has the same external data item EXT1. The value of EXT1 is 'Z', or the value that was set by PGMA in subtask 1.

**Sharing Data**

This section describes how to share files between COBOL and PL/I, both in a standard environment, and under PL/I multitasking.

**Sharing Files between COBOL and PL/I**

By specifying the COBOL option in the PL/I ENVIRONMENT attributes in a file declaration, files can be shared between COBOL and PL/I. However, if structures are used in a file, mapping can be different, as described in “Using Aggregates” on page 194. When structures are in a file and you don’t know whether the mapping is the same, both COBOL and PL/I structures are mapped. Then the object module transfers the data between structures immediately after reading the data for input and immediately before writing the data for output.

During compilation, the compiler examines the record variable to see if there are any structures. If there are no structures, no further action is taken. If there are structures, the compiler tests to see if the mapping of the structure(s) is the same in
PL/I and COBOL. If the mapping is the same, no action is required. If the compiler cannot determine that the mapping is the same, or if the structure is adjustable, both structures will be mapped.

When the compiler reformats the data, and when a record I/O statement involving a file with the COBOL option is executed, the following actions take place:

**INPUT**  The data is read into a structure that has been mapped using the COBOL mapping algorithm and assigned to a PL/I mapped structure.

**OUTPUT**  Before the output takes place, the data in the PL/I structure is assigned to a structure mapped for COBOL. The output to the file then takes place from the second structure.

### File Sharing under PL/I Multitasking

Files can be opened by COBOL programs that are running in the main task or in a subtask. However, when the task terminates, all open files, external and non-external, defined in COBOL programs within the task, are closed.

### Directing Output in ILC Applications

Under COBOL, run-time messages and other related output are directed to the MSGFILE ddname. The output from DISPLAY goes to the MSGFILE ddname only when the OUTDD compiler option ddname matches the MSGFILE ddname. Output from the COBOL DISPLAY UPON SYSOUT statement is also directed to the default MSGFILE ddname. If you want to intersperse output from COBOL and PL/I, you must compile your COBOL program using OUTDD(SYSPRINT) to override the default OUTDD.

Under PL/I, run-time messages and other related output (such as ON condition SNAP output) are directed to the file specified in the Language Environment MSGFILE run-time option, instead of to the PL/I SYSPRINT STREAM PRINT file. User-specified output is still directed to the PL/I SYSPRINT STREAM PRINT file. To direct this output to the Language Environment MSGFILE file, specify the run-time option MSGFILE(SYSPRINT).

### COBOL to PL/I Condition Handling

This section offers two scenarios of condition handling behavior in a COBOL to PL/I ILC application. If an exception occurs in a COBOL program, the set of possible actions is as described in "Exception Occurs in COBOL" on page 203. If an exception occurs in a PL/I routine, the set of possible actions is as described in "Exception Occurs in PL/I" on page 205.

If a PL/I routine is currently active on the stack, PL/I language semantics can be applied to handle conditions that occur in non-PL/I routines within an ILC application. For example, PL/I semantics apply to Language Environment hardware conditions that map directly to PL/I conditions such as ZERODIVIDE, even if they occur in a non-PL/I routine. Also, PL/I treats any unknown condition of severity 2 or greater as the ERROR condition. In a case in which a COBOL-specific condition of severity 2 or greater is passed to a PL/I stack frame, an ERROR ON-unit can handle it on the first pass of the stack.

However, some conditions can be handled only by the HLL of the routine in which the exception occurred. Two examples are:
• Conditions raised using the PL/I statement SIGNAL are PL/I-specific conditions and can be handled only by PL/I.

• In a COBOL program, if a statement has a condition handling clause added to a verb (such as ON EXCEPTION), the condition is handled within COBOL. For example, the ON SIZE clause of a COBOL DIVIDE verb (which includes the logical equivalent of zero divide condition) is handled completely within COBOL.

Multitasking ILC Consideration
User-written condition handlers registered with the CEEHDLR callable service are not supported in PL/I multitasking applications.

For a detailed description of Language Environment condition handling, see z/OS Language Environment Programming Guide.

Enclave-Terminating Language Constructs
Enclaves might be terminated due to reasons other than an unhandled condition of severity 2 or greater. In Language Environment ILC, you can issue an HLL language construct to terminate a COBOL to PL/I enclave from either COBOL or PL/I.

COBOL
The COBOL language constructs that cause the enclave to terminate are:
• A STOP RUN
COBOL’s STOP RUN is equivalent to the PL/I STOP statement. If you code a COBOL STOP RUN statement, the T_I_S (Termination Imminent Due to STOP) condition is raised.
• A call to ILBOABN0 or CEE3ABD
Calling ILBOABN0 or CEE3ABD causes T_I_U to be signaled. Condition handlers are given a chance to handle the abend. If the abend remains unhandled, normal Language Environment termination activities occur. For example, the Language Environment assembler user exit gains control.
User-written condition handlers written in COBOL must be compiled with Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, or COBOL/370.

PL/I
The PL/I language constructs that cause the enclave to terminate are:
• A STOP or an EXIT statement
If you code a STOP or EXIT statement, the T_I_S (Termination Imminent Due to STOP) condition is raised.
• A call to PLIDUMP with the S or E option
If you call PLIDUMP with the S or E option, neither termination imminent condition is raised before the enclave is terminated. See z/OS Language Environment Debugging Guide for syntax of the PLIDUMP service.

Exception Occurs in COBOL
This scenario describes the behavior of an application that contains a COBOL and a PL/I routine. Refer to Figure 50 on page 204 throughout the following discussion. In this scenario, a PL/I main routine invokes a COBOL subroutine. An exception occurs in the COBOL subroutine.
The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, COBOL determines whether the exception that occurred should be handled as a condition.
   • If the exception is to be ignored, control is returned to the next sequential instruction after where the exception occurred.
   • If the exception is to be enabled and processed as a condition, the condition handling step, described below, takes place.

2. If a user-written condition handler has been registered using CEEHDLR on the COBOL stack frame, it is given control.
   If it issues a resume, the condition handling step ends. Processing continues in the routine to which the resume cursor points.
   Two areas to watch out for here are resuming from an IBM condition of severity 2 or greater (see the chapter on coding a user-written condition handler in z/OS Language Environment Programming Guide) and moving the resume cursor in an application that contains a COBOL program (see “GOTO Out-of-Block and Move Resume Cursor” on page 207).
   In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

3. If an ON-unit has been established for the condition being processed on the PL/I stack frame, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine at the point where the resume cursor points. In this example, no ON-unit is established for the condition, so the condition is percolated.

   Figure 50. Stack Contents When the Exception Occurs

   COBOL subroutine
   COBOL semantics
   PL/I main rtn
   PL/I semantics
   COBOL defaults
   PL/I defaults
   Lang. Env. defaults

   Exception occurs here
5. After all stack frames have been visited, and if the condition is COBOL-specific (with a facility ID of IGZ), the COBOL default action occurs. Otherwise, the Language Environment default actions take place.

6. What happens next depends on whether the condition is promotable to the PL/I ERROR condition. The following can happen:
   - If the condition is not promotable to the PL/I ERROR condition, then the Language Environment default actions take place, as described in Table 63 on page 255. Condition handling ends.
   - If the PL/I default action for the condition is to promote it to the PL/I ERROR condition, the condition is promoted, and another pass of the stack is made to look for ERROR ON-units or user-written condition handlers. If an ERROR ON-unit or user-written condition handler is found, it is invoked.
   - If either of the following occurs:
     - An ERROR ON-unit or user-written condition handler is found, but it does not issue a GOTO out of block or similar construct
     - No ERROR ON-unit or user-written condition handler is found
     then the ERROR condition is promoted to T_I_U (Termination Imminent due to an Unhandled condition). Condition handling now enters the termination imminent step. Because T_I_U maps to the PL/I FINISH condition, both FINISH ON-units and user-written condition handlers can be run if the stack frames in which they are established is reached.
   - If no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

**Exception Occurs in PL/I**

This scenario describes the behavior of an application that contains a PL/I and a COBOL routine. Refer to Figure 51 on page 206 throughout the following discussion. In this scenario, a COBOL main program invokes a PL/I subroutine. An exception occurs in the PL/I subroutine.
The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, PL/I determines if the exception that occurred should be handled as a condition according to the PL/I rules of enablement.
   - If the exception is to be ignored, control is returned to the next sequential instruction after where the exception occurred.
   - If the exception is to be enabled and processed as a condition, the condition handling step, described below, takes place.

2. If a user-written condition handler has been registered on the PL/I stack frame using CEEHDLR, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine at the point where the resume cursor points. In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

3. If an ON-unit has been established for the condition being processed on the PL/I stack frame, it is given control. If it issues a GOTO out-of-block, the condition handling step ends. Execution resumes at the label of the GOTO. In this example, no ON-unit is established for the condition, so the condition is percolated.

4. If a user-written condition handler registered using CEEHDLR is present on the COBOL stack frame, it is given control. (User-written condition handlers written in COBOL must be compiled with COBOL/370, COBOL for MVS & VM, COBOL for OS/390 & VM, or Enterprise COBOL for z/OS.) If it successfully issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points. Note that you must be careful when moving the resume cursor in an application that contains a COBOL program. See "GOTO Out-of-Block and Move Resume Cursor" on page 207 for details.
   In this example, there is not a user-written condition handler registered for the condition, so the condition is percolated.
5. What happens next depends on whether the condition is promotable to the PL/I ERROR condition. The following can happen:

- If the condition is not promotable to the PL/I ERROR condition, then the Language Environment default actions take place, as described in Table 63 on page 255. Condition handling ends.
- If the PL/I default action for the condition is to promote it to the PL/I ERROR condition, then the condition is promoted, and another pass is made of the stack to look for ERROR ON-units or user-written condition handlers. If an ERROR ON-unit or user-written condition handler is found, it is invoked.
- If either of the following occurs:
  - An ERROR ON-unit or user-written condition handler is found, but it does not issue a GOTO out-of-block or similar construct
  - No ERROR ON-unit or user-written condition handler is found

  then the ERROR condition is promoted to T_I_U (Termination Imminent due to an Unhandled condition). Condition handling now enters the termination imminent step. Because T_I_U maps to the PL/I FINISH condition, both FINISH ON-units and user-written condition handlers can be run if the stack frames in which they are established are reached.
- If no condition handler moves the resume cursor and issued a resume, Language Environment terminates the thread.

**GOTO Out-of-Block and Move Resume Cursor**

When a GOTO out-of-block or a call to CEEMRCR causes a routine to be removed from the stack, a “non-return style” termination of the routine occurs. Multiple routines can be terminated by a non-return style termination independent of the number of ILC boundaries that are crossed. If one of the routines that is terminated by the non-return style is a COBOL program, the COBOL program can be re-entered via another call path.

If the terminated program is one of the following, the program is not deactivated. If the COBOL program does not specify RECURSIVE in the PROGRAM-ID, a recursion error is raised if you attempt to enter the routine again.

- An COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, or a VS COBOL II program compiled with the CMPR2 option
- A VS COBOL II program that is compiled with the NOCMPR2 option and contains nested programs
- An COBOL for OS/390 & VM, COBOL for MVS & VM, or COBOL/370 program that is compiled with the NOCMPR2 option and has the combination of the INITIAL attribute, nested programs, and file processing in the same compilation unit.
- An Enterprise COBOL for z/OS program that does not use the combination of the INITIAL attribute, nested routines, and file processing in the same compilation unit.

In addition, if the program is a COBOL program with the INITIAL attribute and if it contains files, the files are closed. (COBOL supports VSAM and QSAM files, and these files are closed.)

*Figure 53. COBOL Program Called by a PL/I Main (Part 3 of 3)*
Chapter 12. Communicating between Fortran and PL/I

This chapter describes Language Environment's support for Fortran and PL/I applications.

**General Facts about Fortran to PL/I ILC**

- Fortran object code link-edited with that of another HLL produces a non-reentrant load module, regardless of whether the Fortran routine was compiled with the RENT compiler option. See "Building a Reentrant Fortran to PL/I Application" on page 215 for more information on reentrancy.
- Language Environment does not support passing return codes between Fortran routines and PL/I routines.
- Fortran routines cannot operate under CICS.
- Support for Fortran on VM is not provided by Language Environment.
- In PL/I multitasking applications, once a Fortran routine is called in a task, no other task can call a Fortran routine until the calling task terminates.

**Preparing for ILC**

This section describes topics you might want to consider before writing an application that uses ILC between Fortran and PL/I. For help in determining how different versions of HLLs work together, refer to the migration guides for the HLLs you plan to use.

**Language Environment ILC Support**

Language Environment supports ILC between the following combinations of Fortran and PL/I:

<table>
<thead>
<tr>
<th>HLL Pair</th>
<th>Fortran</th>
<th>PL/I</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran- to-PL/I static calls</td>
<td>• FORTRAN IV G1</td>
<td>• OS PL/I Version 1 Releases 3.0 through 5.1</td>
</tr>
<tr>
<td></td>
<td>• FORTRAN IV H Extended</td>
<td>• OS PL/I Version 2</td>
</tr>
<tr>
<td></td>
<td>• VS FORTRAN Version 1, except modules compiled with Release 2.0 or earlier and that either pass character arguments to, or receive character arguments from, subprograms.</td>
<td>• PL/I for MVS &amp; VM</td>
</tr>
<tr>
<td></td>
<td>• VS FORTRAN Version 2, except modules compiled with Releases 5 or 6 and whose source contained any parallel language constructs or parallel callable services, or were compiled with either of the compiler options PARALLEL or EC.</td>
<td>• Enterprise PL/I for z/OS</td>
</tr>
</tbody>
</table>

Migrating ILC Applications

You need to relink Fortran to PL/I ILC applications in order to get Language Environment’s ILC support.

Both Fortran and PL/I provide migration tools that replace old library modules with Language Environment ones. For more information on Fortran’s library module replacement tool, see [z/OS Language Environment Programming Guide](#). For more information on the PL/I migration tool, refer to [PL/I for MVS & VM Compiler and Run-Time Migration Guide](#) or [Enterprise PL/I for z/OS Migration Guide](#).

Determining the Main Routine

In Language Environment, only one routine can be the main routine. The main routine should be presented to the linkage editor first.

A Fortran routine is designated as a main routine with a PROGRAM statement, which indicates the name of the main routine. A Fortran routine can also be designated as a main routine in the absence of the PROGRAM, SUBROUTINE, and FUNCTION statements, in which case the name of the main routine has a default value of MAIN (or MAIN# for VS FORTRAN Version 2 Releases 5 and 6).

A PL/I routine is designated as a main routine with the OPTIONS(MAIN) option on the PROCEDURE statement.

An entry point is defined for each supported HLL. Table 57 identifies the desired entry point. The table assumes that your code has been compiled using the Language Environment-conforming compilers.

Table 57. Determining the Entry Point

<table>
<thead>
<tr>
<th>HLL</th>
<th>Main Entry Point</th>
<th>Fetched Entry Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran</td>
<td>Name on the PROGRAM statement or MAIN (or MAIN# for VS FORTRAN Version 2 Releases 5 and 6).</td>
<td>Name on a SUBROUTINE or FUNCTION statement</td>
</tr>
<tr>
<td>PL/I</td>
<td>CEESTART</td>
<td>CEESTART or routine name, if OPTIONS(FETCHABLE) is used.</td>
</tr>
</tbody>
</table>

Declaring Fortran to PL/I ILC

You must specify entry declarations in PL/I source code when a PL/I routine invokes a Fortran routine and when a Fortran routine invokes a PL/I routine. The special declarations causes the PL/I compiler to generate an internal argument list that the Fortran routine accepts. No special declaration is required within the Fortran program.
In the PL/I routine that invokes Fortran, identify the entry point as Fortran in the OPTIONS attribute. The following example illustrates a PL/I routine that identifies a Fortran entry point \texttt{FORTEP}:

```plaintext
DCL FORTEP ENTRY OPTIONS(FORTRAN);
```

In the PL/I routine called by Fortran, declare the entry point in the OPTIONS attribute in the \texttt{PROCEDURE} or \texttt{ENTRY} statement. The following illustrates a PL/I routine \texttt{FORTPLI} that will be called by Fortran:

```plaintext
FORTPLI: PROCEDURE (parms) OPTIONS(FORTRAN);
```

\texttt{parms} specifies the parameters that are passed from the Fortran routine. In previous PL/I compilers, the OPTIONS attribute also needed the INTER keyword to control condition handling between Fortran and PL/I. The INTER keyword is ignored under Language Environment.

**Invoking Functions**

Functions can also be declared as described above. A procedure written in PL/I as a function can be invoked through a function reference in a Fortran routine. Similarly, a routine written in Fortran as a function subprogram can be invoked through a function reference in a PL/I routine.

Character data cannot be used as function return values in functions invoked by either Fortran or PL/I in a Fortran to PL/I ILC application. However, character data can be used as arguments for either functions or subroutines. See "Passing Data between Fortran and PL/I" on page 217 for information on character data in Fortran to PL/I ILC.

### Building a Reentrant Fortran to PL/I Application

Fortran object code link-edited with that of another HLL produces a non-reentrant load module, regardless of whether the Fortran routine was compiled with the \texttt{RENT} compiler option. If you need to call a Fortran routine from a reentrant routine written in another language, link-edit the Fortran routine into a separate load module and invoke it with a dynamic call from another language.

### Calling between Fortran and PL/I

This section describes the types of calls permitted in Fortran to PL/I ILC applications and considerations when using dynamic call/fetch mechanisms.

#### Types of Calls Permitted

Table 58 describes the types of calls between Fortran and PL/I that Language Environment allows:

<table>
<thead>
<tr>
<th>ILC Direction</th>
<th>Static Calls</th>
<th>Dynamic Calls</th>
<th>Fetch/Calls</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran to PL/I</td>
<td>Yes</td>
<td>Yes</td>
<td>N/A</td>
</tr>
<tr>
<td>PL/I to Fortran</td>
<td>Yes</td>
<td>N/A</td>
<td>Yes</td>
</tr>
</tbody>
</table>

See Table 56 on page 213 for exceptions to ILC support.

#### Dynamic Call/Fetch Considerations

This section describes how to perform dynamic calls in Fortran to PL/I ILC applications.
**Fortran Dynamically Calling PL/I**

For Fortran to dynamically call a PL/I routine, the Fortran routine uses the same name in a CALL statement or function reference as is specified on the DYNAMIC compiler option. In the Fortran routine, the dynamically called PL/I routine (FORTPLI in the following example), would be declared as follows:

```fortran
@PROCESS DYNAMIC(FORTPLI)
```

In the PL/I routine, the Fortran calling routine is declared the same as for a Fortran-to-PL/I static call, as follows:

```pli
FORTPLI: PROCEDURE (...) OPTIONS(FORTRAN);
```

The dynamically called routine, whether Fortran or PL/I, can statically call another Fortran or PL/I routine.

The dynamically called routine, whether Fortran or PL/I, can dynamically call another Fortran or PL/I routine. However, only two of the dynamically loaded modules can contain PL/I routines (including the load module dynamically loaded by the operating system or subsystem).

There is no Fortran facility to delete a dynamically loaded routine.

**PL/I Dynamically Calling Fortran**

For PL/I to dynamically call a Fortran routine, the PL/I routine must declare the Fortran entry point, such as in the following example:

```pli
DCL FORTEP ENTRY OPTION(FORTRAN);
```

PL/I could then dynamically call the Fortran routine with the following code:

```pli
FETCH FORTEP;
CALL FORTEP (...);
```

The dynamically called routine, whether Fortran or PL/I, can statically call another Fortran or PL/I routine. However, the dynamically called Fortran routine cannot contain a PL/I routine in the dynamically loaded module unless there was also a PL/I routine in a previously executed load module.

The dynamically called routine, whether Fortran or PL/I, can dynamically call another Fortran or PL/I routine. However, only two of the dynamically loaded modules can contain PL/I routines (including the load module dynamically loaded by the operating system or subsystem).

You cannot use the PL/I RELEASE statement to release a Fortran program.

**Restriction:** When a PL/I routine fetches a Fortran routine, the dynamically loaded module can contain only routines written in those languages that already exist in a previous load module. (The routine in the previous load module need not be called; it only needs to be present.) For a Fortran routine to be recognized, ensure that at least one of the following is present in a previous load module:

- A Fortran main program
- A Fortran routine that causes one or more Fortran run-time library routines to be link-edited into the load module. If the Fortran routine contains either an I/O statement, a mathematical function reference, or a call to any Fortran callable service (such as CPUTIME), then a library routine is included, and this requirement is satisfied.
- The Fortran signature CSECT, CEESG007. Use the following linkage editor statement to include CEESG007 if neither of the two previous conditions is true:
Passing Data between Fortran and PL/I

This section describes the data types that are compatible between Fortran and PL/I. It also includes information on how to map aggregates across the two languages.

Supported Data Types between Fortran and PL/I

The data types supported between Fortran and PL/I are listed below.

<table>
<thead>
<tr>
<th>Fortran</th>
<th>PL/I</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER*2</td>
<td>REAL FIXED BINARY(15,0)</td>
</tr>
<tr>
<td>INTEGER*4</td>
<td>REAL FIXED BINARY(31,0)</td>
</tr>
<tr>
<td>REAL*4</td>
<td>REAL FLOAT DEC(6,0)</td>
</tr>
<tr>
<td>REAL*8</td>
<td>REAL FLOAT DEC(16,0)</td>
</tr>
<tr>
<td>REAL*16</td>
<td>REAL FLOAT DEC(33,0)</td>
</tr>
<tr>
<td>COMPLEX*8</td>
<td>COMPLEX FLOAT DEC(6,0)</td>
</tr>
<tr>
<td>COMPLEX*16</td>
<td>COMPLEX FLOAT DEC(16,0)</td>
</tr>
<tr>
<td>COMPLEX*32</td>
<td>COMPLEX FLOAT DEC(33,0)</td>
</tr>
<tr>
<td>CHARACTER*(n)</td>
<td>CHARACTER((n))</td>
</tr>
<tr>
<td>POINTER</td>
<td>POINTER</td>
</tr>
</tbody>
</table>

Passing Character Data

Character data can be received by a Fortran or PL/I routine only when the routine that receives the data declares the data as fixed length. Therefore, the Fortran form CHARACTER*(*) and the PL/I form CHARACTER(*) cannot be used to receive character data. The VARYING attribute cannot be specified in the PL/I declaration of character data.

Using Aggregates

An array can be passed between Fortran and PL/I routines only when the array has its elements in contiguous storage locations and when the called routine specifies a constant number of elements along each dimension. In Fortran, arrays of more than one dimension are arranged in storage in column major order; in PL/I they are in row major order. Unless you specifically override remapping with the PL/I attributes NOMAP, NOMAPIN, or NOMAPOUT (for overriding remapping in both called and calling Fortran routines), a temporary remapped array is created for the called routine. When an array is remapped, an element can be referenced in both Fortran and PL/I with subscripts in the same order.

Structures are not supported in Fortran to PL/I ILC.

Data Equivalents

This section describes how Fortran and PL/I data types correspond to each other.

Equivalent Data Types for Fortran to PL/I

The following examples illustrate how PL/I and Fortran routines within a single ILC application might code the same data types.
16-Bit Signed Binary Integer

Sample Fortran Usage
INTEGER*2 X, Y, F2PP16I
X = 5
Y = F2PP16I(X)
PRINT *,
1 'VALUE RETURNED TO FORTRAN:', Y
END

PL/I Function
F2PP16I: PROC (X) OPTIONS(FORTRAN)
RETURNS(FIXED BIN(15));
DCL X FIXED BIN(15);
PUT SKIP
LIST('PL/I ARG VALUE:', X);
RETURN (X);
END F2PP16I;

32-Bit Signed Binary Integer

Sample Fortran Usage
INTEGER*4 X, Y, F2PP32I
X = 5
Y = F2PP32I(X)
PRINT *,
1 'VALUE RETURNED TO FORTRAN:', Y
END

PL/I Function
F2PP32I: PROC (X) OPTIONS(FORTRAN)
RETURNS(FIXED BIN(31));
DCL X FIXED BIN(31);
PUT SKIP
LIST('PL/I ARG VALUE:', X);
RETURN (X);
END F2PP32I;

Short Floating-Point Number

Sample Fortran Usage
REAL*4 X, Y, F2PPSFP
X = 5.0
Y = F2PPSFP(X)
PRINT *,
1 'VALUE RETURNED TO FORTRAN:', Y
END

PL/I Function
F2PPSFP: PROC (X) OPTIONS(FORTRAN)
RETURNS(FLOAT DEC(6));
DCL X FLOAT DEC(6);
PUT SKIP
LIST('PL/I ARG VALUE:', X);
RETURN (X);
END F2PPSFP;

Long Floating-Point Number

Sample Fortran Usage
REAL*8 X, Y, F2PPLFP
X = 12.5D0
Y = F2PPLFP(X)
PRINT *,
1 'VALUE RETURNED TO FORTRAN:', Y
END

PL/I Function
F2PPLFP: PROC (X) OPTIONS(FORTRAN)
RETURNS(FLOAT DEC(16));
DCL X FLOAT DEC(16);
PUT SKIP
LIST('PL/I ARG VALUE:', X);
RETURN (X);
END F2PPLFP;

Extended Floating-Point Number

Sample Fortran Usage
REAL*16 X, Y, F2PPEFP
X = 12.1Q0
Y = F2PPEFP(X)
PRINT *,
1 'VALUE RETURNED TO FORTRAN:', Y
END

PL/I Function
F2PPEFP: PROC (X) OPTIONS(FORTRAN)
RETURNS(FLOAT DEC(33));
DCL X FLOAT DEC(33);
PUT SKIP
LIST('PL/I ARG VALUE:', X);
RETURN (X);
END F2PPEFP;
## Complex: Two Adjacent Short Floating-Point Numbers

**Sample Fortran Usage**

```fortran
COMPLEX*8 X, Y, F2PPSCP
X = (5.0, 15.0)
Y = F2PPSCP(X)
PRINT *,
1 'VALUE RETURNED TO FORTRAN:', Y
END
```

**PL/I Function**

```pli
F2PPSCP: PROC (X) OPTIONS(FORTRAN)
RETURNS(COMPLEX FLOAT DEC(6));
DCL X COMPLEX FLOAT DEC(6);
PUT SKIP
LIST('PL/I ARG VALUE:', X);
RETURN (X);
END F2PPSCP;
```

## Complex: Two Adjacent Long Floating-Point Numbers

**Sample Fortran Usage**

```fortran
COMPLEX*16 X, Y, F2PPLCP
X = (5.0D0, 15.0D0)
Y = F2PPLCP(X)
PRINT *,
1 'VALUE RETURNED TO FORTRAN:', Y
END
```

**PL/I Function**

```pli
F2PPLCP: PROC (X) OPTIONS(FORTRAN)
RETURNS(COMPLEX FLOAT DEC(16));
DCL X COMPLEX FLOAT DEC(16);
PUT SKIP
LIST('PL/I ARG VALUE:', X);
RETURN (X);
END F2PPLCP;
```

## Complex: Two Adjacent Extended Floating-Point Numbers

**Sample Fortran Usage**

```fortran
COMPLEX*32 X, Y, F2PPECP
X = (5.0Q0, 15.0Q0)
Y = F2PPECP(X)
PRINT *,
1 'VALUE RETURNED TO FORTRAN:', Y
END
```

**PL/I Function**

```pli
F2PPECP: PROC (X) OPTIONS(FORTRAN)
RETURNS(COMPLEX FLOAT DEC(33));
DCL X COMPLEX FLOAT DEC(33);
PUT SKIP
LIST('PL/I ARG VALUE:', X);
RETURN (X);
END F2PPECP;
```

## Fixed-Length Character Data

**Sample Fortran Usage**

```fortran
X = '1234567890'
CALL F2PPFLC(X, Y)
PRINT *,
1 'VALUE RETURNED TO FORTRAN: ', Y
END
```

**PL/I Subroutine**

```pli
F2PPFLC: PROC (X, Y) OPTIONS(FORTRAN);
DCL X CHARACTER(10);
DCL Y CHARACTER(10);
PUT SKIP
LIST('PL/I ARG VALUE:', X);
Y = X;
RETURN;
END F2PPFLC;
```

## Array

**Sample Fortran Usage**

```fortran
REAL*4 MATRIX(3) / 1.0, 2.0, 3.0 /
CALL F2PPAF(MATRIX)
PRINT *,
1 'UPDATED VALUES IN FORTRAN:', MATRIX
END
```

**PL/I Subroutine**

```pli
F2PPAF: PROC (X) OPTIONS(FORTRAN);
DCL X(3) FLOAT DEC(6);
DCL IX FIXED BIN(31);
PUT SKIP
LIST('PL/I ARG VALUE:', X);
DO IX = 1 TO 3 BY 1;
   X(IX) = X(IX) - 1.0E0;
END;
RETURN;
END F2PPAF;
```
### Address of an Array

**Sample Fortran Usage**

```fortran
POINTER*4 (P, I)
INTEGER*4 I(3)
INTEGER*4 J(3) / 1, 2, 3 /
P = LOC(J)
PRINT *,
1 'UPDATED VALUES IN FORTRAN:', I
END
```

**PL/I Subroutine**

```
F2PPAOA: PROC (X) OPTIONS(FORTRAN);
DCL X POINTER;
DCL Y(3) FIXED BIN(31) BASED(X);
PUT SKIP
LIST('PL/I ARG VALUES:', Y);
DO IX = 1 TO 3 BY 1;
  Y(IX) = Y(IX) - 1;
END;
RETURN;
END F2PPAOA;
```

### Equivalent Data Types for PL/I to Fortran

The following examples illustrate how PL/I and Fortran routines within a single ILC application might code the same data types.

#### 16-Bit Signed Binary Integer

**Sample PL/I Usage**

```
P2FP16I: PROC OPTIONS(MAIN);
DCL PLFF16I ENTRY OPTIONS(FORTRAN) RETURNS(FIXED BIN(15));
DCL X FIXED BIN(15);
DCL Y FIXED BIN(15);
X=5
Y = P2FF16I(X);
PUT SKIP LIST('Value Returned to PL/I:', Y);
END P2FP16I;
```

**Fortran Function**

```
FUNCTION P2FF16I ( ARG )
INTEGER*4 P2FF16I
INTEGER*4 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
P2FF16I = ARG
END
```

#### 32-Bit Signed Binary Integer

**Sample PL/I Usage**

```
P2FP32I: PROC OPTIONS(MAIN);
DCL P2FF32I ENTRY OPTIONS(FORTRAN) RETURNS(FIXED BIN(31));
DCL X FIXED BIN(31);
DCL Y FIXED BIN(31);
X = 5;
Y = P2FF32I(X);
PUT SKIP
LIST('VALUE RETURNED TO PL/I:', Y);
END P2FP32I;
```

**Fortran Function**

```
FUNCTION P2FF32I ( ARG )
REAL*4 P2FF32I
REAL*4 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
P2FF32I = ARG
END
```

#### Short Floating-Point Number

**Sample PL/I Usage**

```
P2FFSFP: PROC OPTIONS(MAIN);
DCL P2FFSFP ENTRY OPTIONS(FORTRAN) RETURNS(FLOAT DEC(6));
DCL X FLOAT DEC(6);
DCL Y FLOAT DEC(6);
X = 5.0E6;
Y = P2FFSFP(X);
PUT SKIP
LIST('VALUE RETURNED TO PL/I:', Y);
END P2FFSFP;
```

**Fortran Function**

```
FUNCTION P2FFSFP ( ARG )
REAL*4 P2FFSFP
REAL*4 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
P2FFSFP = ARG
END
```
Long Floating-Point Number

Sample PL/I Usage
P2FLFP: PROC OPTIONS(MAIN);
DCL P2FLFP ENTRY OPTIONS(FORTRAN)
RETURNS(FLOAT DEC(16));
DCL X FLOAT DEC(16);
DCL Y FLOAT DEC(16);
X = 5.00000000000000E0;
Y = P2FLFP(X);
PUT SKIP
LIST('VALUE RETURNED TO PL/I:', Y);
END P2FLFP;

Fortran Function
FUNCTION P2FLFP ( ARG )
REAL*8 P2FLFP
REAL*8 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
P2FLFP = ARG
END

Extended Floating-Point Number

Sample PL/I Usage
P2FEFP: PROC OPTIONS(MAIN);
DCL P2FEFP ENTRY OPTIONS(FORTRAN)
RETURNS(FLOAT DEC(33));
DCL X FLOAT DEC(33);
DCL Y FLOAT DEC(33);
X = 5.000000000000000000000000E0;
Y = P2FEFP(X);
PUT SKIP
LIST('VALUE RETURNED TO PL/I:', Y);
END P2FEFP;

Fortran Function
FUNCTION P2FEFP ( ARG )
REAL*16 P2FEFP
REAL*16 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
P2FEFP = ARG
END

Complex: Two Adjacent Short Floating-Point Numbers

Sample PL/I Usage
P2FSCP: PROC OPTIONS(MAIN);
DCL P2FSCP ENTRY OPTIONS(FORTRAN)
RETURNS(COMPLEX FLOAT DEC(6));
DCL X COMPLEX FLOAT DEC(6);
DCL Y COMPLEX FLOAT DEC(6);
X = 5.0E0 + 15.0E0I;
Y = P2FSCP(X);
PUT SKIP
LIST('VALUE RETURNED TO PL/I:', Y);
END P2FSCP;

Fortran Function
FUNCTION P2FSCP ( ARG )
COMPLEX*8 P2FSCP
COMPLEX*8 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
P2FSCP = ARG
END

Complex: Two Adjacent Long Floating-Point Numbers

Sample PL/I Usage
P2FLCP: PROC OPTIONS(MAIN);
DCL P2FLCP ENTRY OPTIONS(FORTRAN)
RETURNS(COMPLEX FLOAT DEC(16));
DCL X COMPLEX FLOAT DEC(16);
DCL Y COMPLEX FLOAT DEC(16);
X = 5.000000000000000000000000E0 + 15.000000000000000000000000E0I;
Y = P2FLCP(X);
PUT SKIP
LIST('VALUE RETURNED TO PL/I:', Y);
END P2FLCP;

Fortran Function
FUNCTION P2FLCP ( ARG )
COMPLEX*16 P2FLCP
COMPLEX*16 ARG
PRINT *, 'FORTRAN ARG VALUE:', ARG
P2FLCP = ARG
END
### Complex: Two Adjacent Extended Floating-Point Numbers

**Sample PL/I Usage**

```pli
P2FPECP: PROC OPTIONS(MAIN);
  DCL P2FFECP ENTRY OPTIONS(FORTRAN);
  DCL X COMPLEX FLOAT DEC(33);
  DCL Y COMPLEX FLOAT DEC(33);
  X = 5.0000000000000000000E0 + 15.0000000000000000000D0;
  Y = P2FFECP(X);
  PUT SKIP LIST('VALUE RETURNED TO PL/I:', Y);
END P2FPECP;
```

**Fortran Function**

```fortran
FUNCTION P2FFECP (ARG)
  COMPLEX*32 P2FFECP
  COMPLEX*32 ARG
  PRINT *, 'FORTRAN ARG VALUE:', ARG
  P2FFECP = ARG
END
```

### Fixed-Length Character Data

**Sample PL/I Usage**

```pli
P2FFFLC: PROC OPTIONS(MAIN);
  DCL X CHARACTER(10);
  DCL Y CHARACTER(10);
  X = '1234567890';
  CALL P2FFFLC(X, Y);
  PUT SKIP LIST('VALUE RETURNED TO PL/I:', Y);
END P2FFFLC;
```

**Fortran Subroutine**

```fortran
SUBROUTINE P2FFFLC (ARG1, ARG2)
  CHARACTER*10 ARG1, ARG2
  PRINT *, 'FORTRAN ARG1 VALUE: ', ARG1
  ARG2 = ARG1
END
```

### Array

**Sample PL/I Usage**

```pli
P2FFAF: PROC OPTIONS(MAIN);
  DCL X(3) FLOAT DEC(6);
  X(1) = 0E0;
  X(2) = 1E0;
  X(3) = 2E0;
  CALL P2FFAF(X);
  PUT SKIP LIST('UPDATED VALUES IN PL/I:', X);
END P2FFAF;
```

**Fortran Subroutine**

```fortran
SUBROUTINE P2FFAF (ARG)
  REAL*4 ARG(3)
  DO J=1,3
    ARG(J) = ARG(J) + 1.0
  ENDDO
END
```

### Address of an Array

**Sample PL/I Usage**

```pli
P2FFAOA: PROC OPTIONS(MAIN);
  DCL X(3) FIXED BIN(31);
  DCL Y(3) FIXED BIN(31) BASED(P);
  P = ADDR(X);
  Y(1) = 0;
  Y(2) = 1;
  Y(3) = 2;
  CALL P2FFAOA(P);
  PUT SKIP LIST('UPDATED VALUES IN PL/I:', Y);
END P2FFAOA;
```

**Fortran Subroutine**

```fortran
SUBROUTINE P2FFAOA (ARG)
  POINTER*4 (ARG, Y)
  INTEGER*4 Y(3)
  PRINT *, 'FORTRAN ARRAY ARG VALUES:', Y
  DO J=1,3
    Y(J) = Y(J) + 1
  ENDDO
END
```
External Data

Fortran static common blocks and PL/I static external data of the same name can be shared among routines in a load module under the following conditions:

- The Fortran static common blocks are either used only with one load module in an application or they are declared as private common blocks. A private common block is not shared across load modules and is created in any of the following ways:
  - Specified or implied by the PC compiler option
  - Referenced by Fortran object code produced by the VS FORTRAN Version 2 Release 4 compiler or earlier
  - In an application that executes with the PC run-time option.

Directing Output from ILC Applications

Fortran run-time messages, output written to the print unit, and other output (such as output from the SDUMP callable service) are directed to the file specified by the MSGFILE run-time option. To direct this output to the file with the ddname FTnnF001, (where nn is the two-digit error message unit number), specify the run-time option MSGFILE(FTnnF001). If the print unit is different than the error message unit (if the PRTUNIT and the ERRUNIT run-time options have different values), output from a PRINT statement won’t be directed to the Language Environment message file.

PL/I run-time messages and other related output (such as ON condition SNAP output) are directed to the file specified in the MSGFILE run-time option instead of to the PL/I SYSPRINT STREAM PRINT file. User-written output is still directed to the PL/I SYSPRINT STREAM PRINT file; to direct user-written output to the Language Environment message file, specify the MSGFILE(SYSPRINT) run-time option.

Running Fortran Routines in the PL/I Multitasking Facility

This section describes different considerations and restrictions of running Fortran in the PL/I Multitasking Facility.

In a PL/I multitasking ILC application, Fortran routines can be executed in either the main task or in a subtask. If a Fortran routine has been invoked in a task (either main task or subtask), no other Fortran routine can execute in any other task until the task used to invoke the Fortran routine ends. Therefore, in a multitasking environment, you cannot invoke a Fortran routine in a subtask if a Fortran routine has already been invoked in the main task.

Reentrancy in a Multitasking Application

You need to be careful about calling the routine in a different enclave or in a PL/I subtask, because any load module containing a Fortran routine is non-reentrant. The following restrictions apply:

- Once a Fortran routine in a load module has been invoked, no Fortran routine in the same copy of the load module can be invoked from a different task, even after the first task ends.
- If there are Fortran routines in a load module, then no Fortran routine in the same copy of that load module can be used in an enclave other than in the first enclave in which a Fortran routine is called.
Common Blocks in a PL/I Multitasking Application

In a PL/I multitasking application, Fortran dynamic common blocks are always maintained for the whole enclave, even though subtasks that use them may start and end.

Fortran static common blocks persist only as long as the load module that contains them is in storage. When a load module is loaded from within a subtask, Fortran common blocks persist only within that subtask because the load module is deleted when the task ends. If, in a later subtask, the same load module is loaded, a fresh copy is loaded with fresh contents of the common block.

If, however, the load module is loaded in the main task (with the FETCH statement), and is also specified in a CALL statement to run a subtask, the load module (and the Fortran common blocks) is retained in storage after the subtask ends. The same copy of the load module can be used in another CALL statement to create another subtask, with the same contents of the common block. The following code illustrates this method:

```
FETCH ABC;
CALL ABC (...) TASK;
```

Data-in-Virtual Data Objects in PL/I Multitasking Applications

You can use data objects that are accessed by the data-in-virtual (DIV) callable services in different subtasks. If you want to use the same data object or a different data object in different subtasks, you need to establish their use in the DIVINF or DIVINV callable services. Otherwise, at the end of each subtask, the data object is terminated.

Files and Print Units in a Multitasking Application

Fortran routines running in either the main task or a subtask can open files. However, when the task terminates, all the open files except the Language Environment message file are automatically closed.

If the standard print unit is the same unit number as the error message unit, it is in effect the Language Environment message file, and will stay open when the task terminates. If the standard print unit is different than the error message unit, the print unit will close, along with other Fortran files, at task termination. The unit numbers are set with the PRTUNIT and ERRUNIT run-time options.

Fortran to PL/I Condition Handling

This section offers two scenarios of condition handling behavior in a Fortran to PL/I ILC application. If an exception occurs in a Fortran program, the set of possible actions is as described in "Exception Occurs in Fortran" on page 225. If an exception occurs in a PL/I routine, the set of possible actions is as described in "Exception Occurs in PL/I" on page 227.

Some conditions can be handled only by the HLL of the routine in which the exception occurred. For example, when ERR and IOSTAT specifiers are present on a Fortran I/O statement and an error is detected while executing that statement, Fortran condition handling semantics take precedence over Language Environment condition handling. Control returns immediately to the Fortran program and no condition is signaled to Language Environment.
If there is a PL/I routine currently active on the stack, PL/I language semantics can be applied to handle conditions that occur in non-PL/I routines within an ILC application. For example, PL/I semantics apply to Language Environment hardware conditions that map directly to PL/I conditions such as ZERODIVIDE, even if they occur in a non-PL/I routine. Also, PL/I treats any unknown condition of severity 2 or greater as the ERROR condition. In a case in which a Fortran-specific condition of severity 2 or greater is passed to a PL/I stack frame, an ERROR ON-unit can handle it on the first pass of the stack.

**PL/I Multitasking ILC Considerations**

User-written condition handlers registered with the CEEHDLR callable service are not supported in PL/I multitasking applications.

When a Fortran enclave-terminating construct, such as a STOP statement, is executed from a Fortran routine in a PL/I subtask, the entire enclave is terminated.

**Enclave-Terminating Language Constructs**

Enclaves can be terminated due to reasons other than an unhandled condition of severity 2 or greater. In Language Environment ILC, you can issue an HLL language construct to terminate a Fortran to PL/I enclave from either a Fortran or PL/I routine.

**Fortran**

The Fortran language constructs that cause the enclave to terminate are:
- A STOP statement
- An END statement in the main routine
- A call to EXIT or SYSRCX
- A call to DUMP or CDUMP

**PL/I**

The PL/I language constructs that cause the enclave to terminate are:
- A STOP or EXIT statement
  - If you code a STOP or EXIT statement, the T_I_S (Termination Imminent Due to STOP) condition is raised.
- An END or RETURN statement in the main routine
- A call to PLIDUMP with the S or E option
  - If you call PLIDUMP with the S or E option, neither termination imminent condition is raised before the enclave is terminated. See [z/OS Language Environment Debugging Guide](https://www.ibm.com) for syntax of the PLIDUMP service.

**Exception Occurs in Fortran**

This scenario describes the behavior of an application that contains a Fortran and a PL/I routine. Refer to [Figure 54 on page 226](https://www.ibm.com) throughout the following discussion. In this scenario, a PL/I main routine invokes a Fortran subroutine. An exception occurs in the Fortran subroutine.
The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. If an I/O error is detected on a Fortran I/O statement that contains an ERR or IOSTAT specifier, Fortran semantics take precedence. The exception is not signaled to the Language Environment condition handler.

2. In the enablement step, Fortran treats all exceptions as conditions. Processing continues with the condition handling step, described below.

3. There is no user-written condition handler on the Fortran stack frame (because CEEHDLR cannot be called from a Fortran routine), and the condition is percolated.

4. If a user-written condition handler has been registered on the PL/I stack frame using CEEHDLR, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine at the point where the resume cursor points.

   In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

5. If an ON-unit has been established for the condition being processed on the PL/I stack frame, it is given control. If it issues a GOTO out-of-block, the condition handling step ends. Execution resumes at the label of the GOTO. In this example, no ON-unit is established for the condition, so the condition is percolated.

6. What happens next depends on whether the condition is promotable to the PL/I ERROR condition. The following can happen:

   - If the condition is not promotable to the PL/I ERROR condition, then the Language Environment default actions take place, as described in Table 63 on page 255. Condition handling ends.

   - If the PL/I default action for the condition is to promote it to the PL/I ERROR condition, The condition is promoted, and another pass of the stack is made.

---

Figure 54. Stack Contents When the Exception Occurs

The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. If an I/O error is detected on a Fortran I/O statement that contains an ERR or IOSTAT specifier, Fortran semantics take precedence. The exception is not signaled to the Language Environment condition handler.

2. In the enablement step, Fortran treats all exceptions as conditions. Processing continues with the condition handling step, described below.

3. There is no user-written condition handler on the Fortran stack frame (because CEEHDLR cannot be called from a Fortran routine), and the condition is percolated.

4. If a user-written condition handler has been registered on the PL/I stack frame using CEEHDLR, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine at the point where the resume cursor points.

   In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

5. If an ON-unit has been established for the condition being processed on the PL/I stack frame, it is given control. If it issues a GOTO out-of-block, the condition handling step ends. Execution resumes at the label of the GOTO. In this example, no ON-unit is established for the condition, so the condition is percolated.

6. What happens next depends on whether the condition is promotable to the PL/I ERROR condition. The following can happen:

   - If the condition is not promotable to the PL/I ERROR condition, then the Language Environment default actions take place, as described in Table 63 on page 255. Condition handling ends.

   - If the PL/I default action for the condition is to promote it to the PL/I ERROR condition, The condition is promoted, and another pass of the stack is made.
to look for ERROR ON-units or user-written condition handlers. If an ERROR ON-unit or user-written condition handler is found, it is invoked.

- If either of the following occurs:
  - An ERROR ON-unit or user-written condition handler is found, but it does not issue a GOTO out of block or similar construct
  - No ERROR ON-unit or user-written condition handler is found

then the ERROR condition is promoted to T_I_U (Termination Imminent due to an Unhandled condition). Condition handling now enters the termination imminent step. Because T_I_U maps to the PL/I FINISH condition, both FINISH ON-units and user-written condition handlers can be run if the stack frames in which they are established is reached.

- If no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

**Exception Occurs in PL/I**

This scenario describes the behavior of an application that contains a PL/I and a Fortran routine. Refer to Figure 55 throughout the following discussion. In this scenario, a Fortran main routine invokes a PL/I subroutine. An exception occurs in the PL/I subroutine.

The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, PL/I determines if the exception that occurred should be handled as a condition according to the PL/I rules of enablement.
   - If the exception is to be ignored, control is returned to the next sequential instruction after where the exception occurred.
   - If the exception is to be enabled and processed as a condition, the condition handling step, described below, takes place.

---

**Figure 55. Stack Contents When the Exception Occurs**

The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, PL/I determines if the exception that occurred should be handled as a condition according to the PL/I rules of enablement.
   - If the exception is to be ignored, control is returned to the next sequential instruction after where the exception occurred.
   - If the exception is to be enabled and processed as a condition, the condition handling step, described below, takes place.
2. If a user-written condition handler has been registered on the PL/I stack frame using CEEHDLR, it is given control. If it issues a resume, the condition handling step ends. Processing continues in the routine at the point where the resume cursor points. In this example, no user-written condition handler is registered for the condition, so the condition is percolated.

3. If an ON-unit has been established for the condition being processed on the PL/I stack frame, it is given control. If it issues a GOTO out-of-block, the condition handling step ends. Execution resumes at the label of the GOTO. In this example, no ON-unit is established for the condition, so the condition is percolated.

4. This is no user-written condition handler on the Fortran stack frame (because CEEHDLR cannot be called from a Fortran routine), and the condition is percolated.

5. What happens next depends on whether the condition is promotable to the PL/I ERROR condition. The following can happen:
   - If the condition is not promotable to the PL/I ERROR condition, then the Language Environment default actions take place, as described in Table 63 on page 255. Condition handling ends.
   - If the PL/I default action for the condition is to promote it to the PL/I ERROR condition, the condition is promoted, and another pass is made of the stack to look for ERROR ON-units or user-written condition handlers. If an ERROR ON-unit or user-written condition handler is found, it is invoked.
   - If either of the following occurs:
     - An ERROR ON-unit or user-written condition handler is found, but it does not issue a GOTO out of block or similar construct
     - No ERROR ON-unit or user-written condition handler is found
     then the ERROR condition is promoted to T_I_U (Termination Imminent due to an Unhandled condition). Condition handling now enters the termination imminent step. Because T_I_U maps to the PL/I FINISH condition, both FINISH ON-units and user-written condition handlers can be run if the stack frames in which they are established are reached.
   - If no condition handler moves the resume cursor and issued a resume, Language Environment terminates the thread.

Figure 57. PL/I Routine Called by Fortran
Chapter 13. Communicating between Multiple HLLs

This section describes considerations for writing ILC applications comprised of three or more languages. One approach to writing an n-way ILC application is to treat it as several pairwise ILC groupings within a single application. For any call between routines written in two different HLLs, you must, at a minimum, adhere to the restrictions described for that pair, as documented in the pairwise ILC descriptions.

The considerations in this section apply to any combination of supported languages within an ILC application. These common considerations are summarized here to provide a convenient overview of writing an n-way ILC application. For specific details, refer to the appropriate pairwise considerations described previously.

If you are running any ILC application under CICS, you should also consult Chapter 15, “ILC under CICS,” on page 247.

Supported Data Types across HLLs

Table 60 lists those data types that are common across all supported HLLs when passed without using a pointer. There are, in addition to those listed in this table, additional data types supported across specific ILC pairs; these are listed in the applicable pairwise ILC descriptions.

<table>
<thead>
<tr>
<th>C</th>
<th>C++</th>
<th>COBOL</th>
<th>PL/I</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed long int</td>
<td>signed long int</td>
<td>PIC S9(9) USAGE IS BINARY</td>
<td>Real Fixed Bin(31,0)</td>
</tr>
<tr>
<td>double</td>
<td>double</td>
<td>COMP-2</td>
<td>Real Float Dec(16)</td>
</tr>
</tbody>
</table>

External Data

The following list describes how external data maps across the languages, as well as how mapping is restricted:

- **C to C++**
  
  External variables map if: 1) C has constructed reentrancy, or 2) C++ uses `#pragma variable(...,norent)` to make the specific variable non-reentrant.

- **C to COBOL**
  
  C and COBOL static external variables do not map to each other.

- **C to PL/I**
  
  If C is non-reentrant, then C and PL/I static external variables map by name. If the C routine has constructed reentrancy, the C and PL/I static external variables will map if the C routine uses `#pragma variable(...,norent)` to make the specific variable non-reentrant.

- **C++ to COBOL**
  
  C++ and COBOL static external variables do not map to each other.

- **C++ to PL/I**
  
  External variables map if C++ uses `#pragma variable(...,norent)` to make specific variable non-reentrant.

- **COBOL to PL/I**
  
  COBOL and PL/I static external variables do not map to each other.
Thread Management

POSIX-conforming C/C++ applications can communicate with Enterprise COBOL for z/OS programs compiled THREAD on any thread.

POSIX-conforming C/C++ applications can communicate with the following COBOL programs on only one thread:
- Enterprise COBOL for z/OS (compiled NOTHREAD)
- COBOL for OS/390 & VM
- COBOL for MVS & VM
- COBOL/370
- VS COBOL II

POSIX-conforming C/370 applications can communicate with assembler routines on any thread when the assembler routines use the CEEENTRY/CEETERM macros or the EDCPRLG/EDCEPIL macros provided by C/C++.

OS/390-conforming C applications can communicate with PL/I on any thread created by C routines. PL/I routines, however, must follow the rules described in z/OS Language Environment Programming Guide.

If an asynchronous signal is being delivered to a thread, the thread is interrupted for the signal only when the execution is:
- In a user C routine,
- Just prior to a return to a C routine
- In an Enterprise COBOL for z/OS program compiled with the THREAD option
- Just prior to return to Enterprise COBOL for z/OS program compiled with the THREAD option, or
- Just prior to an invocation of a Language Environment library from a user routine

C routines or COBOL routines compiled with the THREAD compiler option may need to protect against asynchronous signals based on the application logic including the possible use of the POSIX signal-blocking function that is available. For all other routines, it does not have to be concerned about being interrupted during its execution for an asynchronous signal.

Condition Handling

This section describes what happens during Language Environment condition handling and enclave termination.

C++ exception handling constructs `try/throw/catch` cannot be used with Language Environment and HLL condition handling. If you use C exception handling constructs (`signal/raise`) in your C++ routine, condition handling will proceed as described in this section and in the other C chapters. Otherwise, you will get undefined behavior in your programs if you mix the C constructs with the C++ constructs.

Enclave-Terminating Constructs

Enclave termination can occur due to reasons other than an unhandled condition of severity 2, 3, or 4. These include:
A language STOP-like construct such as a C abort(), raise(SIGABRT), exit() function call, COBOL STOP RUN, or PL/ISTOP or EXIT statement. When one of these statements is encountered, the T_I_S (Termination Imminent Due to STOP) condition is signaled.

- A return from the main routine
- A Language Environment-initiated abend
- A user-requested abend (call to CEE3ABD or ILBOABN0)

You can call CEE3ABD to request an abend either with or without clean-up. If the abend is issued without clean-up, T_I_U (Termination Imminent due to an Unhandled condition) is not raised. See z/OS Language Environment Programming Reference for more information about the CEE3ABD callable service.

If you call CEE3ABD and request an abend with clean-up, or you call ILBOABN0 from a COBOL program, T_I_U is signaled. Condition handlers are given a chance to handle the abend. If the abend remains unhandled, normal Language Environment termination activities occur. For example, the C atexit list is honored if a C routine is present on the stack, and the Language Environment assembler user exit gains control.

### C, COBOL, and PL/I Scenario: Exception Occurs in C

This scenario describes the behavior of an application that contains C, COBOL, and PL/I. Refer to Figure 58 throughout the following discussion.

![Figure 58. Stack Contents When the Exception Occurs](image)
In this example, X.COBOL invokes Y.PLI, which invokes Z.C. A condition is raised in Z.C. The stack contains what is shown in Figure 58 on page 233. No user-written condition handlers have been registered using CEEHDLR for any stack frame, and no PL/I ON-units have been established.

The actions taken follow the three Language Environment condition handling steps: enablement, condition, and termination imminent.

1. In the enablement step, it is determined whether the exception in the C routine should be enabled and treated as a condition. If any of the following are true, the exception is ignored, and processing continues at the next sequential instruction after where the exception occurred:
   - You specified SIG_IGN for the exception in a call to signal().
     However, the system or user abend represented by the Language Environment message 3250 and the signal(SIGABND) is not ignored. The enclave is terminated.
   - The exception is one of those listed as masked in Table 64 on page 255.
   - You do not specify any action, but the default action for the condition is SIG_IGN (see Table 64 on page 255).
   - You are running under CICS and a CICS handler is pending.

   If you do none of these things, the condition is enabled and processed as a condition.

2. If a user-written condition handler is registered using CEEHDLR on the Z.C stack frame, it receives control. If it issues a resume, the condition handling step ends. Processing continues in the routine to which the resume cursor points. In this example, there is no user-written condition handler registered, so the condition is percolated.

3. If a C signal handler has been registered for the condition on the Z.C stack frame, it is given control. If it issues a resume or a call to longjmp(), the condition handling step ends. Processing resumes in the routine to which the resume cursor points.

   In this example, no signal handler is registered, so the condition is percolated.

4. The condition is still unhandled. If C does not recognize the condition, or if the C default action (listed in Table 64 on page 255) is to terminate, the condition is percolated.

5. No user-written condition handlers can be registered using CEEHDLR on the Y.PLI stack frame, because they cannot be written in PL/I. If an ON-unit that corresponds to the condition being processed exists on the Y.PLI stack frame, however, it is given control. If it issues a GOTO out of block, the condition handling step ends. Execution resumes at the label of the GOTO.

   In this example, no ON-unit has been established for the condition on the Y.PLI stack frame, so the condition is percolated.

6. If a user-written condition handler has been registered using CEEHDLR on the X.COBOL stack frame, it is given control. (User-written condition handlers written in COBOL must be compiled with COBOL/370, COBOL for MVS & VM, or COBOL for OS/390 & VM.) If it issues a resume, with or without moving the resume cursor, the condition handling step ends. Processing continues in the routine to which the resume cursor points.

   7. What happens next depends on whether the condition is promotable to the PL/I ERROR condition. The following can happen:
• If the condition is not promotable to the PL/I ERROR condition, then Language Environment default actions take place, as described in Table 63 on page 255. Condition handling ends.
• If the PL/I default action for the condition is to promote it to the PL/I ERROR condition, the condition is promoted, and another pass of the stack is made to look for ERROR ON-units or user-written condition handlers. If an ERROR ON-unit or user-written condition handler is found, it is invoked.
• If either of the following occurs:
  – An ERROR ON-unit or user-written condition handler is found, but it does not issue a GOTO out of block or similar construct
  – No ERROR ON-unit or user-written condition handler is found
then the ERROR condition is promoted to T_I_U (Termination Imminent due to an Unhandled condition). Condition handling now enters the termination imminent step. Because T_I_U maps to the PL/I FINISH condition, a FINISH ON-unit or user-written condition handler is run if the stack frame in which it is established is reached.
• If no condition handler moves the resume cursor and issues a resume, Language Environment terminates the thread.

User handlers that you register using CEEHDLR must be written in the same language you are using to do the registration.

Chapter 14. Communicating between Assembler and HLLs

This chapter describes Language Environment’s support for assembler–HLL ILC applications. For more information on using assembler under Language Environment, see \textit{z/OS Language Environment Programming Guide}.

Calling between Assembler and an HLL

Language Environment-conforming assembler routines can be dynamically called/fetched from any Language Environment-conforming HLL. In addition, Language Environment-conforming assembler routines can dynamically load another routine by using the Language Environment CEEFETCH macro or CEELOAD macro. Using CEEFETCH to load the routine allows the routine to be deleted using CEERELES.

\textbf{Note:} CEEFETCH/CEERELES and CEELOAD should \textbf{not} be used for DLLs.

Using the CEEFETCH Macro

CEEFETCH dynamically loads a routine and is preferred over CEELOAD for loading routines. However, it does not create a nested enclave. CEEFETCH is the only supported method for loading a routine that was created using the DFSMS Binder when omitting the use of the Language Environment Prelinker Utility. The Language Environment Prelinker Utility function is provided in the DFSMS Binder eliminating the requirement for the prelink step to create the routine.

System services should not be used to delete modules loaded with CEEFETCH; instead, the CEERELES macro should be used to delete routines loaded with CEEFETCH. During thread (if SCOPE=THREAD) or enclave (if SCOPE=ENCLAVE) termination, Language Environment deletes modules loaded by CEEFETCH.

If CEEFETCH completes successfully, the address of the loaded routine is found in R15. The routine can then be invoked using BALR 14,15 (or BASSM 14,15). The syntax of CEEFETCH is described in \textit{z/OS Language Environment Programming Guide}.

CEEFETCH can be used to dynamically load a routine that has been compiled XPLINK, as long as the entry point has been defined using \texttt{#pragma linkage (..., fetchable)}.

Using the CEERELES Macro

CEERELES dynamically deletes a Language Environment-conforming routine. The syntax of CEERELES is described in \textit{z/OS Language Environment Programming Guide}.

Using the CEELOAD Macro

CEELOAD is used to dynamically load a Language Environment-conforming routine. It does not create a nested enclave, so the target of CEELOAD must be a subroutine.

Some restrictions apply when using CEELOAD to call, fetch, or dynamic load:

- You cannot fetch or dynamically call a routine that has been fetched by or dynamically called by another language, or has been dynamically loaded by CEELOAD.
• You cannot dynamically load a routine with CEELOAD that has already been
dynamically loaded by CEELOAD, or has been fetched or dynamically called by
another language.
• You cannot dynamically load a routine with CEELOAD that has been compiled
XPLINK.
• The loading of a DFSMS program object with Deferred Load Classes is not
supported by CEELOAD.

The syntax of CEELOAD is described in [z/OS Language Environment Programming
Guide](#).

While CEELOAD supports dynamic loading, in order to provide for loading and
deleting a module, the CEEFETCH and CEERELES macros should be used.

**Passing Arguments between HLL and Assembler Routines**

Arguments are passed between HLL and assembler routines in a list of addresses. Each
address in a parameter list occupies a fullword in storage. The last fullword in
the list must have its high-order bit turned on for the last parameter address to be
recognized. Each address in a parameter list is either the address of a data item or
the address of a control block that describes a data item.

**POSIX**

With POSIX(ON), calls to assembler can occur on any thread as long as the
assembler routines use:

- The CEEENTRY/CEETERM macros provided by Language Environment, or
- The EDCPRLG/EDCEPIL macros provided by C/370

**C and C++**

To facilitate calls between assembler and C or C++, you should include the
following directives in your C or C++ code:

**In C**

```c
#pragma linkage(OS)
```

**In C++**

```c++
extern "OS"
```

Using either of these directives will result in the compiler generating code that uses
the OS linkage convention. In this case, register 1 will contain the address of a list
of addresses of the actual arguments. The last address in this list has its high order
bit set. For more information, refer to the descriptions of these directives in [z/OS XL
C/C++ Language Reference](#).

**COBOL**

For COBOL to use z/OS parameter passing, use the USING BY REFERENCE
phrase for CALL and PROCEDURE DIVISION statements:

```cobol
77 X PIC S9(9) BINARY VALUE 32767.
77 Y PIC X(4) VALUE 'PRM2'.
77 Z POINTER.
SET Z TO ADDRESS OF Y.
CALL 'SUB1' USING BY REFERENCE X,Y,Z
```

---

240 z/OS V1R11.0 Language Environment Writing ILC Applications
To pass a pointer to a copy of the parameters in COBOL, use the USING BY CONTENT phrase.

```
77 X PIC S9(9) BINARY VALUE 32767.
77 Y PIC X(4)   VALUE 'PRM2'.
77 Z POINTER.
SET Z TO ADDRESS OF Y.
CALL 'SUB1' USING BY CONTENT X,Y,Z
```

**Figure 62. Parameter passing by reference**

To pass a parameter value directly in the parameter list in COBOL, as C does, use the USING BY VALUE phrase.

```
77 X PIC S9(9) BINARY VALUE 32767.
77 Y PIC X(4)   VALUE 'PRM2'.
77 Z POINTER.
SET Z TO ADDRESS OF Y.
CALL 'SUB1' USING BY VALUE X,Y,Z
```

**Figure 63. Parameter passing by content**

To pass a parameter value directly in the parameter list in COBOL, as C does, use the USING BY VALUE phrase.

```
77 X PIC S9(9) BINARY VALUE 32767.
77 Y PIC X(4)   VALUE 'PRM2'.
77 Z POINTER.
SET Z TO ADDRESS OF Y.
CALL 'SUB1' USING BY VALUE X,Y,Z
```

**Figure 64. Parameter passing by value**

To pass and/or receive a function value in COBOL, as C does, use the RETURNING phrase. The returned function value is accessed using register 15, so the COBOL RETURN-CODE special register cannot be used.

```
77 X PIC S9(9) BINARY VALUE 32767.
77 Y PIC X(4)   VALUE 'PRM2'.
77 Z POINTER.
SET Z TO ADDRESS OF Y.
CALL 'SUB1' USING BY VALUE X,Y RETURNING R
```
For an Assembler program to call PL/I, specify OPTIONS(ASM) on the PROC statement of the PL/I routine to be called. For PL/I to call an Assembler program, your PL/I program should have an ENTRY declaration for the Assembler routine it calls, and OPTIONS(ASM) should usually be specified on the ENTRY declaration.

How the parameters are passed should match. Generally, Assembler routines pass and receive parameters using a list of addresses. This corresponds to passing parameters BYADDR in PL/I. For details on how to pass parameters in PL/I, see *Enterprise PL/I for z/OS Programming Guide*.

**Fortran**

Assembler programs that initialized the Fortran run-time environment to call Fortran subroutines may need to be restructured to initialize Language Environment.

**Cancelling or Releasing Assembler**

An assembler routine must be released using the same language that fetched it. An ILC module which has been loaded using CEELOAD cannot be deleted. An ILC module which has been fetched using CEEFETCH can be released using CEERELES. COBOL, C, C++, and PL/I can only CANCEL or release the assembler routine if there is no ILC with PL/I and Fortran in the target load modules.

**Calling COBOL from Assembler**

**AMODE Considerations**

When a called COBOL program returns control to a calling assembler program, the AMODE won’t be reset to the AMODE of the calling program. Upon return to the calling assembler program, the AMODE will be the same as when the COBOL program was invoked. Therefore, when an assembler program calls a COBOL program that has a different AMODE, the calling program must save its own AMODE before calling. When control returns from the COBOL program, the calling assembler program must then restore its own AMODE.

The following instruction sequence illustrates the previous discussion:

```
LA 2,RESET  SAVE BRANCH ADDRESS AND CURRENT
BSM 2,0  AMODE IN REGISTER 2
BASSM 14,15  CALL COBOL PROGRAM
BSM 0,2  BRANCH AND RESTORE AMODE FROM REG. 2
RESET DS  OH
```

If an assembler program that is AMODE 31 calls a COBOL program that is AMODE 24, the assembler program must also be RMODE 24 in order for COBOL to return...
to the assembler program. If the assembler program is AMODE ANY, in this case, an abend may result from the COBOL program as a result of branching to an invalid address since R14 will contain a 31-bit address from the assembler program's save area, but COBOL will return to the assembler program in AMODE 24.

When you have an application with COBOL subprograms, some of the COBOL subprograms can be AMODE(31) and some can be AMODE(24). If your application consists of only COBOL programs and you are only using static and dynamic calls, each COBOL subprogram will always be entered in the proper AMODE. For example, if you are using a COBOL dynamic call from an AMODE(31) COBOL program to an AMODE(24) COBOL program, automatic AMODE switching is done.

However, if you are using Assembler programs along with other HLL programs that call COBOL subprograms, you must ensure that when a COBOL subprogram is called more than once in an enclave, it is entered in the same AMODE each time it is called.

**Cancelling COBOL Programs**

Any COBOL subprograms compiled with the RENT compiler option that have been loaded by assembler routines must not be deleted by assembler routines. (This restriction does not apply to COBOL main programs loaded and deleted by assembler drivers.)

NOTE TO REVIEWERS: Should “subroutine” be changed to “routine” here?

A COBOL subroutine that has been fetched using CEEFETCH can be deleted using CEERELES.

**Non-Language Environment-Conforming Assembler Invoking an HLL Main Routine**

When a C, C++, COBOL, or PL/I main routine is called from a non-Language Environment-conforming assembler program, the actions in Table 61 take place.

<table>
<thead>
<tr>
<th>Type of Assembler Invocation</th>

</tbody>
</table>

**Language Environment-Conforming Assembler Invoking an HLL Main Routine**

When a C, C++, or PL/I main routine is called from a Language Environment-conforming assembler, the actions in Table 62 on page 244 take place.
Note: Unlike C, C++, and PL/I, COBOL has no mechanism to statically declare a program “main”; rather, a “main” program is determined dynamically when a COBOL program is the first program in an enclave. Therefore, it is meaningful to call a COBOL “main”, only in the context of creating a new enclave in which a COBOL program is the first to run. Only parts of the following tables apply to a COBOL main.

Table 62. What Occurs When Language Environment-Conforming Assembler Invokes an HLL Main

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Note: See [z/OS Language Environment Programming Guide](#) for information on nested enclaves.

### Assembler Main Calling HLL Subroutines for Better Performance

To improve performance of a C, C++, COBOL, or PL/I routine called repeatedly from assembler, use a Language Environment-conforming assembler routine, because the Language Environment environment is maintained across calls. If the assembler routine is not Language Environment-conforming, the Language Environment environment is initialized and terminated at every call. To improve the performance for an assembler routine that is not Language Environment-conforming, use preinitialization services. (See [z/OS Language Environment Programming Guide](#) for information on using preinitialization services.)

The call can be either a static call (the HLL routine is linked with the assembler routine) or a dynamic load (using the CEELOAD or the CEEFETCH macro). The assembler routine is a main routine and the called HLL program is a subroutine.

For example, see [Figure 66 on page 245](#), which demonstrates a Language Environment-conforming assembler routine statically calling a COBOL program.
**Compilation Unit: LEASMCB**

* Bring up the LE/370 environment

Chapter 15. ILC under CICS

In general, Language Environment provides the same ILC support for applications running under CICS as for those running in a non-CICS environment. If there is any ILC within a run unit under CICS, each compile unit must be compiled with a Language Environment-conforming compiler.

If you are using ILC in CICS DL/I applications, EXEC CICS DLI and CALL xxxTDLI can only be used in programs with the same language as the main program. CEETDLI is not supported on CICS.

XPLINK-compiled functions cannot run under CICS Transaction Server prior to CICS TS 3.1.

Fortran cannot run under CICS.

Language Pairs Supported in ILC under CICS

To understand what support Language Environment offers your ILC application, see the description for the specific language pair below, and the applicable ILC chapter. If your ILC application involves multiple HLLs, see Chapter 13, “Communicating between Multiple HLLs,” on page 231.

Note: In this chapter the term ILC refers to the ILC that occurs within a Language Environment enclave.

Description of an Enclave

A key feature of the program management model is the enclave, which consists of one or more load modules, each containing one or more separately compiled, bound routines. A load module can include HLL routines, assembler routines, and Language Environment routines.

By definition, the scope of a language statement is that portion of code in which it has semantic effect. The enclave defines the scope of the language semantics for its component routines.

The Enclave Defines the Scope of the Definition of the Main Routine and Subroutines: The enclave boundary defines whether a routine is a main routine or a subroutine. The first routine to run in the enclave is known as the main routine in Language Environment. All others are designated subroutines of the main routine. The first routine invoked in the enclave must be capable of being designated main according to the rules of the language of the routine. All other routines invoked in the enclave must be capable of being a subroutine according to the rules of the languages of the routines.

If a routine is capable of being invoked as either a main or subroutine, and recursive invocations are allowed according to the rules of the language, the routine can be invoked multiple times within the enclave. The first of these invocations could be as a main routine and the others as subroutines.

Program Mask Conventions

The maskable program exceptions are enabled for all member languages represented in the root or main load module during Language Environment.
Initialization. Each member language informs Language Environment of its program mask requirements, and Language Environment ORs all of the requirements together and sets the program mask during initialization. During termination, the program mask is reset by Language Environment to its value upon entry to Language Environment initialization.

When running an ILC application, the subroutines may involve multiple HLLs. The characteristics of these HLLs, such as program mask attributes, will be shared across the enclave.

Language Environment neither saves nor restores the program mask setting across calls to Language Environment services or calls within the Language Environment environment.

The run-time option XUFLOW indicates the initial setting of the mask for exponent underflow. You can alter this setting by using the callable service CEE3SPM.

In summary, the program mask’s initial setting is determined by the requirements of the members within the main load module and by the setting of the XUFLOW run-time option.

While the enclave is running, the program mask is influenced by the callable service, CEE3SPM, and by members’ requirements that are newly added as a result of a dynamic call or fetch.

**C/C++ and COBOL**

Language Environment supports ILC between routines written in C/C++ and COBOL under CICS as follows:

- Calls supported as documented in the sections “Calling between C++ and COBOL” and “Calling between C and COBOL” with the exception that there is no support for ILC calls to or from routines written in pre-Language Environment-conforming versions of C or COBOL.
- There is no support for ILC calls to or from routines written in pre-Language Environment-conforming versions of C or COBOL.

All components of your C/C++ to COBOL ILC application must be reentrant.

If there is any ILC with a run unit under CICS, each compile unit must be compiled with a Language Environment-conforming compiler.

For more information on ILC between C/C++ and COBOL, see [Chapter 4, “Communicating between C and COBOL”](#) on page 27 and “Communicating between C++ and COBOL” on page 53.

**z/OS XL C/C++ and PL/I**

Language Environment supports ILC between routines written in z/OS XL C/C++ and PL/I for MVS & VM or Enterprise PL/I for z/OS under CICS as follows:

- z/OS XL C/C++ routines can statically call PL/I routines.
- PL/I routines can statically call z/OS XL C/C++ routines.
- z/OS XL C/C++ routines can fetch() PL/I routines that have OPTIONS(FETCHABLE) specified.
- PL/I routines can FETCH only those z/OS XL C/C++ routines that have not been run through the CICS translator. A PL/I routine cannot dynamically call an z/OS
XL C/C++ routine that has been translated because the CICS translator introduces writable static data elements that are not capable of being initialized when the dynamic call is made.

In addition, during the FETCH of z/OS XL C/C++ from PL/I, the static read/write pointer is not swapped.

- z/OS XL C/C++ routines calling PL/I routines must pass the EIB and COMMAREA as the first two parameters if the called routine contains any EXEC CICS commands.
- There is no support under CICS for ILC calls to or from routines written in pre-Language Environment-conforming versions of C or PL/I.

All components of your z/OS XL C/C++ to PL/I ILC application must be reentrant.

If there is any ILC with a run unit under CICS, each compile unit must be compiled with a Language Environment-conforming compiler.

For more information on ILC between PL/I and C, see Chapter 8, “Communicating between C and PL/I,” on page 131.

**COBOL and PL/I**

Language Environment supports ILC between routines compiled with Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, or PL/I for MVS & VM or Enterprise PL/I for z/OS under CICS as follows:

- Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, and COBOL/370 programs can statically call PL/I routines.
- PL/I routines can statically call Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, and COBOL/370 programs.
- Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, and COBOL/370 programs can dynamically CALL PL/I routines that have OPTIONS(FETCHABLE) specified.
- PL/I routines can FETCH Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, and COBOL/370 programs.
- COBOL routines calling PL/I routines must pass EIB and COMMAREA as the first two parameters if the called routine contains any EXEC CICS commands.
- PL/I routines calling Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, or COBOL/370 programs must pass the EIB and COMMAREA as the first two parameters if the called program contains any EXEC CICS commands.

For more information on ILC between COBOL and PL/I, see Chapter 11, “Communicating between COBOL and PL/I,” on page 189.

If there is any ILC with a run unit under CICS, each compile unit must be compiled with a Language Environment-conforming compiler.

**Assembler**

There is no support for Language Environment-conforming assembler main routines under CICS prior to z/OS V1R4, or prior to CICS Transaction Server for z/OS Version 3.1.
COBOL Considerations
Static and dynamic calls are allowed in VS COBOL II, COBOL/370, COBOL for MVS & VM, COBOL for OS/390 & VM, and Enterprise COBOL for z/OS to but not from routines written in non-Language Environment-conforming assembler routines.

Calls are allowed from Language Environment-conforming assembler subprograms to COBOL/370, COBOL for MVS & VM, COBOL for OS/390 & VM, and Enterprise COBOL for z/OS.

Calls are allowed from COBOL/370, COBOL for MVS & VM, COBOL for OS/390 & VM, and Enterprise COBOL for z/OS to Language Environment-conforming assembler routines.

Calls are allowed from VS COBOL II programs to Language Environment-conforming assembler routines if the NAB=NO option is used on the CEEENTRY macro.

PL/I Considerations
PL/I routines can statically call assembler routines declared with OPTIONS(ASSEMBLER). When you declare a routine with OPTIONS(ASSEMBLER), arguments are passed according to standard linking conventions.

Called assembler subroutines can invoke CICS services if they were passed the appropriate CICS control blocks.

See the CICS documentation for information on the use of CICS commands in an assembler language subroutine.

Link-Editing ILC Applications under CICS
You must link ILC applications with the CICS stub, DFHELII, in order to get ILC support under Language Environment.

ILC applications in which C/C++ is one of the participating languages must be link-edited AMODE(31).

CICS ILC Application

The following examples illustrate how you can use ILC under CICS. A COBOL main program, COBCICS, dynamically CALLs a PL/I routine, PLICICS, which does the following:
- Writes a message to the operator
- Establishes a ZERODIVIDE ON-unit
- Generates a divide-by-zero
- Writes another message to the operator
- Returns to the COBOL main program

COBCICS then calls CUCICS, a statically linked C routine, and passes a message character string and a length field to the subroutine. This routine then calls the Language Environment service CEEMOUT to write the message to the CESE transient data queue.
A CICS COBOL main dynamically calls a PL/I subroutine, and statically calls a C subroutine. COBCICS passes a message to the C subroutine to output to the transient data queue.

Appendix B. Using Nested Enclaves

An enclave is a logical run-time structure that supports the execution of a collection of routines.

z/OS Language Environment explicitly supports the execution of a single enclave within a Language Environment process. However, by using the system services and language constructs described in this chapter, you can create an additional, or nested, enclave and initiate its execution within the same process.

The enclave that issues a call to system services or language constructs to create a nested enclave is called the parent enclave. The nested enclave that is created is called the child enclave. The child must be a main routine; a link to a subroutine by commands and language constructs is not supported under Language Environment.

If a process contains nested enclaves, none or only one enclave can be running with POSIX(ON).

Understanding the Basics

In Language Environment, you can use the following methods to create a child enclave:

- Under CICS, the EXEC CICS LINK and EXEC CICS XCTL commands (see CICS Application Programming Guide for more information about these commands).
- Under z/OS, the SVC LINK command.
- Under z/OS, the C system() function (see z/OS Language Environment Programming Guide for more information about system()).
- Under z/OS, the PL/I FETCH and CALL to any of the following PL/I routines with PROC OPTIONS(MAIN) specified:
  - Enterprise PL/I for z/OS
  - PL/I for MVS & VM
  - OS PL/I Version 2
  - OS PL/I Version 1 Release 5.1
  - Relinked OS PL/I Version 1 Release 3.0–5.1

Such a routine, called a fetchable main in this book, can only be introduced by a FETCH and CALL from a PL/I routine.

The routine performing the FETCH and CALL must be compiled with the PL/I for MVS & VM or Enterprise PL/I compiler or be a relinked OS PL/I routine.

If the target routine of any of these commands is not written in a Language Environment-conforming HLL or Language Environment-conforming assembler, no nested enclave is created.

COBOL Considerations

In a non-CICS environment, OS/VS COBOL routines are supported in a single enclave only.

PL/I Considerations

PL/I MTF is supported in the initial enclave only. If PL/I MTF is found in a nested enclave, Language Environment diagnoses it as an error. If a PL/I MTF application contains nested enclaves, the initial enclave must contain a single task. Violation of this rule is not diagnosed and is likely to cause unpredictable results.
Determing the Behavior of Child Enclaves

If you want to create a child enclave, you need to consider the following factors:

- The language of the main routine in the child enclave
- The sources from which each type of child enclave gets run-time options
- The default condition handling behavior of each type of child enclave
- The setting of the TRAP run-time option in the parent and the child enclave

All of these interrelated factors affect the behavior, particularly the condition handling, of the created enclave. The sections that follow describe how the child enclaves created by each method (EXEC CICS LINK, EXEC CICS XCTL, SVC LINK, CMSCALL, C system() function, and PL/I FETCH and CALL of a fetchable main) will behave.

Creating Child Enclaves Using EXEC CICS LINK or EXEC CICS XCTL

If your C, C++, COBOL, or PL/I application uses EXEC CICS commands, you must also link-edit the EXEC CICS interface stub, DFHELII, with your application. To be link-edited with your application, DFHELII must be available in the link-edit SYSLIB concatenation.

See CICS Application Programming Guide for more information about the EXEC CICS LINK and EXEC CICS XCTL commands.

How Run-Time Options Affect Child Enclaves

The child enclave gets its run-time options from one of the sources discussed in z/OS Language Environment Programming Guide. The run-time options are completely independent of the creating enclave, and can be set on an enclave-by-enclave basis.

Some of the methods for setting run-time options might slow down your transaction. Follow these suggestions to improve performance:

- If you need to specify options in CEEUOPT, specify only those options that are different from system defaults.
- Before putting transactions into production, request a storage report (using the RPTSTG run-time option) to minimize the number of GETMAINs and FREEMAINs required by the transactions.
- Ensure that VS COBOL II transactions are not link-edited with IGZETUN, which is no longer supported and which causes an informational message to be logged. Logging this message for every transaction inhibits system performance.

How Conditions Arising in Child Enclaves Are Handled

This section describes the default condition handling for child enclaves created by EXEC CICS LINK or EXEC CICS XCTL.

Condition handling varies depending on the source of the condition, and whether or not an EXEC CICS HANDLE ABEND is active:

- If a Language Environment or CEEBXITA-initiated (generated by setting the CEEAUE_ABND field of CEEBXITA) abend occurs, the CICS thread is terminated. This occurs even if a CICS HANDLE ABEND is active, because CICS HANDLE ABEND does not gain control in the event of a Language Environment abend.
- If a software condition of severity 2 or greater occurs, Language Environment condition handling takes place. If the condition remains unhandled, the problem is not percolated to the parent enclave. The CICS thread is terminated with an
abend. These actions take place even if a CICS HANDLE ABEND is active, because CICS HANDLE ABEND does not gain control in the event of a Language Environment software condition.

- If a user abend or program check occurs, the following actions take place:
  - If no EXEC CICS HANDLE ABEND is active, and TRAP(ON) is set in the child enclave, Language Environment condition handling takes place. If the abend or program check remains unhandled, the problem is not propagated to the parent enclave. The CICS thread is terminated with an abend.
  - An active EXEC CICS HANDLE ABEND overrides the setting of TRAP. The action defined by the EXEC CICS HANDLE ABEND takes place.

Creating Child Enclaves by Calling a Second Main Without an RB Crossing

The behavior of a child enclave created by an calling a second main program is determined by the language of its main routine: C, C++, COBOL, Fortran, PL/I, or Language Environment-conforming assembler (generated by use of the CEEENTRY and associated macros).

How Run-Time Options Affect Child Enclaves
Run-time options will be processed in the normal manner for enclaves created because of a call to a second main, that is, programmer defaults present in the load module will be merged, options in the command line equivalent will also be processed, as will options passed by the assembler user exit if present.

How Conditions Arising in Child Enclaves Are Handled
The command-line equivalent is determined in the same manner as for a SVC LINK for both VM and MVS.

Creating Child Enclaves Using SVC LINK or CMSCALL

The behavior of a child enclave created by an SVC LINK or CMSCALL is determined by the language of its main routine: C, C++, COBOL, Fortran, PL/I, or Language Environment-conforming assembler (generated by use of the CEEENTRY and associated macros).

MVS Considerations: When issuing a LINK to a routine, the high-order bit must be set on for the last word of the parameter list. To do this, set VL=1 on the LINK assembler macro.

How Run-Time Options Affect Child Enclaves
Child enclaves created by an SVC LINK or CMSCALL get run-time options differently, depending on the language that the main routine of the child enclave is written in.

Child Enclave Has a C, C++, Fortran, PL/I, or Language Environment-Conforming Assembler Main Routine: If the main routine of the child enclave is written in C, C++, Fortran, PL/I, or in Language Environment-conforming assembler, the child enclave gets its run-time options through a merge from the usual sources. Therefore, you can set run-time options on an enclave-by-enclave basis. However, you cannot pass command-line parameters to nested enclaves.

Child Enclave Has a COBOL Main Routine: If the main routine of the child enclave is written in COBOL, the child enclave inherits the run-time options of the creating enclave. Therefore, you cannot set run-time options on an enclave-by-enclave basis.
How Conditions Arising in Child Enclaves Are Handled

If a Language Environment or CEEBXITA-initiated (generated by setting the CEEAUE_ABND field of CEEBXITA) abend occurs in a child enclave created by SVC LINK or CMSCALL, regardless of the language of its main, the entire process is terminated.

Condition handling in child enclaves created by SVC LINK or CMSCALL varies, depending on the language of the child’s main routine, the setting of the TRAP run-time option in the parent and child enclaves, the type of condition, and whether the routine is running under MVS. Refer to one of the following tables to see what happens when a condition remains unhandled in a child enclave.

Table 65. Handling Conditions in Child Enclaves

<table>
<thead>
<tr>
<th>If the Child Enclave Was Created By:</th>
<th>See:</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Child Enclave Has a COBOL Main Routine: Child enclaves created by SVC LINK or CMSCALL that have a COBOL main program inherit the run-time options of the parent enclave that created them. Therefore, the TRAP setting of the parent and child enclaves is always the same.

Table 68. Unhandled Condition Behavior in a COBOL Child Enclave, under MVS

</tr>
</tbody>
</table>
Creating Child Enclaves Using the C system() Function

Child enclaves created by the C system() function get run-time options through a merge from the usual sources (see z/OS Language Environment Programming Guide for more information). Therefore, you can set run-time options on an enclave-by-enclave basis. See z/OS XL C/C++ Run-Time Library Reference for information on the system() function when running with POSIX(ON).

Under MVS, when you perform a system() function to a COBOL program, in the form:

```
system("PGM=program_name,PARM='...'")
```

the run-time options specified in the PARM= portion of the system() function are ignored. However, run-time options are merged from CEEDOPT, CEEUOPT, and the CEEAUE_OPTIONS from the assembler user exit.

z/OS UNIX Considerations

In order to create a nested enclave under z/OS UNIX, you must either:

- Be running with POSIX(OFF) and issue system(), or
- Be running with POSIX(ON) and have set the environment variables to signal that you want to establish a nested enclave. You can use the __POSIX_SYSTEM environment variable to cause a system() to establish a nested enclave instead of performing a fork()/exec(). __POSIX_SYSTEM can be set to NO, No, or no.

In a multiple enclave environment, the first enclave must be running with POSIX(ON) and all other nested enclaves must be running with POSIX(OFF).

How Conditions Arising in Child Enclaves Are Handled

If a Language Environment- or CEEBXITA-initiated (generated by setting the CEEAUE_ABND field of CEEBXITA) abend occurs in a child enclave created by a call to system(), the entire process is terminated.

Depending on what the settings of the TRAP run-time option are in the parent and child enclave, the following might cause the child enclave to terminate:

- Unhandled user abend
- Unhandled program check

TRAP(ON | OFF) Effects for Enclaves Created by system()

</tbody>
</table>
Creating Child Enclaves That Contain a PL/I Fetchable Main

Under VM, the target load module can only be a member of a LOADLIB or be in a saved segment or relocatable load module. The target load module cannot be on a text deck or be a member of a TXTLIB.

Additional fetch and call considerations of PL/I fetchable mains are discussed in "Special Fetch and Call Considerations."

How Run-Time Options Affect Child Enclaves

Child enclaves created when you issue a FETCH and CALL of a fetchable main get run-time options through a merge from the usual sources. Therefore, you can set run-time options on an enclave-by-enclave basis.

How Conditions Arising in Child Enclaves Are Handled

If a Language Environment or CEEBXITA-initiated (generated by setting the CEEAUE_ABND field of CEEBXITA) abend occurs in a child enclave that contains a fetchable main, the entire process is terminated.

Depending on what the settings of the TRAP run-time option are in the parent and child enclave, the following might cause the child enclave to terminate:

- Unhandled user abend
- Unhandled program check
- Unhandled condition severity 2 or above
- Non-Language Environment abend

Table 71. Unhandled Condition Behavior in a Child Enclave That Contains a PL/I Fetchable Main, under MVS

<td>Process terminated with abend U4036, Reason code=2</td>
<td>Process terminated with abend SOCx</td>
</tr>
</tbody>
</table>

Special Fetch and Call Considerations

You should not recursively fetch and call the fetchable main from within the child enclave; results are unpredictable if you do.

The load module that is the target of the FETCH and CALL is reentrant if all routines in the load module are reentrant.

Language Environment relies on the underlying operating system for the management of load module attributes. In general, multiple calls of the same load module are supported for load modules that are any of the following:

- Reentrant
  - It is recommended that your target load module be reentrant.
- Nonreentrant but serially reusable
You should ensure that the main procedure of a nonreentrant but serially reusable load module is self-initializing. Results are unpredictable otherwise.

- Nonreentrant and non-serially reusable

If a nonreentrant and non-serially reusable load module is called multiple times, each new call brings in a fresh copy of the load module. That is, there are two copies of the load module in storage: one from FETCH and one from CALL. Even though there are two copies of the load module in storage, you need only one PL/I RELEASE statement because upon return from the created enclave the load module loaded by CALL is deleted by the operating system. You need only release the load module loaded by FETCH.

**Other Nested Enclave Considerations**

The following sections contain other information you might need to know when creating nested enclaves. The topics include:

- The string that CEE3PRM returns for each type of child enclave (see [z/OS Language Environment Programming Reference](https://www.ibm.com) for more information about the CEE3PRM callable service)
- The return and reason codes that are returned on termination of the child enclave
- How the assembler user exit handles nested enclaves
- Whether or not the message file is closed on return from a child enclave
- z/OS UNIX considerations
- AMODE considerations

**What the Enclave Returns from CEE3PRM**

CEE3PRM returns to the calling routine the user parameter string that was specified at program invocation. Only program arguments are returned.

See [Table 72](#) to determine whether a user parameter string was passed to your routine, and where the user parameter string is found. This depends on the method you used to create the child enclave, the language of the routine in the child enclave, and the PLIST, TARGET, or SYSTEM setting of the main routine in the child enclave. If a user parameter string was passed to your routine, the user parameter string is extracted from the command-line equivalent for your routine (shown in [Table 73](#) on page 265) and returned to you.

**Note:** Under CICS, CEE3PRM always returns a blank string.

**Table 72. Determining the Command-Line Equivalent**

</tbody>
</table>

If Table 72 on page 264 indicates that a parameter string was passed to your routine at invocation, the string is extracted from the command-line equivalent listed in the right-hand column of Table 77. The command-line equivalent depends on the language of your routine and the run-time options specified for it.

## Table 73. Determining the Order of Run-Time Options and Program Arguments

### Finding the Return and Reason Code from the Enclave

The following list tells where to look for the return and reason codes that are returned to the parent enclave when a child enclaves terminates:

- EXEC CICS LINK or EXEC CICS XCTL

If the CICS thread was not terminated, the return code is placed in the optional RESP2 field of EXEC CICS LINK or EXEC CICS XCTL. The reason code is discarded.
• SVC LINK or CMSCALL to a child enclave with a main routine written in any Language Environment-conforming language
  If the process was not terminated, the return code is reported in R15. The reason code is discarded.
• C’s system() function
  Under MVS, if the target command or program of system() cannot be started, “-1” is returned as the function value of system(). Otherwise, the return code of the child enclave is reported as the function value of system(), and the reason code is discarded. (See z/OS XL C/C++ Programming Guide for more information about the system() function.)
• FETCH and CALL of a fetchable main
  Normally, the enclave return code and reason code are discarded when control returns to a parent enclave from a child enclave. However, in the parent enclave, you can specify the OPTIONS(ASSEMBLER RETCODE) option of the entry constant for the main procedure of the child enclave. This causes the enclave return code of the child enclave to be saved in R15 as the PL/I return code. You can then interrogate that value by using the PLIRETV built-in function in the parent enclave.

Assembler User Exit

An assembler user exit (CEEBXITA) is driven for enclave initialization and enclave termination regardless of whether the enclave is the first enclave created in the process or a nested enclave. The assembler user exit differentiates between first and nested enclave initialization.

Message File

Under MVS, the message file is not closed when control returns from a child enclave.

AMODE Considerations

ALL31 should have the same setting for all enclaves within a process. You cannot invoke a nested enclave that requires ALL31(OFF) from an enclave running with ALL31(ON).
Appendix C. Accessibility

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use software products successfully. The major accessibility features in z/OS enable users to:

- Use assistive technologies such as screen readers and screen magnifier software
- Operate specific or equivalent features using only the keyboard
- Customize display attributes such as color, contrast, and font size

Using assistive technologies

Assistive technology products, such as screen readers, function with the user interfaces found in z/OS. Consult the assistive technology documentation for specific information when using such products to access z/OS interfaces.

Keyboard navigation of the user interface

Users can access z/OS user interfaces using TSO/E or ISPF. Refer to z/OS TSO/E Primer, z/OS TSO/E User's Guide, and z/OS ISPF User's Guide Vol I for information about accessing TSO/E and ISPF interfaces. These guides describe how to use TSO/E and ISPF, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

z/OS information

z/OS information is accessible using screen readers with the BookServer/Library Server versions of z/OS books in the Internet library at:

http://www.ibm.com/systems/z/os/zos/bkserv/
Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

---

**Policy for unsupported hardware**

Various z/OS elements, such as DFSMS™, HCD, JES2, JES3, and MVS, contain code that supports specific hardware servers or devices. In some cases, this device-related element support remains in the product even after the hardware devices pass their announced End of Service date. z/OS may continue to service element code; however, it will not provide service related to unsupported hardware devices. Software problems related to these devices will not be accepted for service, and current service activity will cease if a problem is determined to be associated with out-of-support devices. In such cases, fixes will not be issued.

---

**Programming Interface Information**

This publication documents intended Programming Interfaces that allow the customer to write programs to obtain the services of Language Environment in z/OS.

---

**Trademarks**

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies.

A current list of IBM trademarks is available on the Web at [Copyright and trademark information](http://www.ibm.com/legal/copytrade.shtml).

UNIX is a registered trademark of The Open Group in the United States and other countries.

Java and all Java-based trademarks are trademarks of Sun Microsystems, Inc. in the United States, other countries, or both.

Other company, product, and service names may be trademarks or service marks of others.
Bibliography

This section lists the books in the Language Environment library and other publications that may be helpful when using Language Environment.
