Chapter 2. Managing the Volume Table of Contents ........................................ 141
Creating the VTOC and VTOC Index .......................................................... 141
Protecting the VTOC and VTOC Index ....................................................... 141
RACF ........................................................................................................ 141
APF ........................................................................................................ 141
Password Protection ................................................................................. 143
Copying/Restoring/Initializing the VTOC ............................................... 143
Volumes Containing a Nonindexed VTOC .............................................. 143
Volumes Containing an Indexed VTOC .................................................... 143
Deleting a Data Set from the VTOC ......................................................... 143
Specifying the Volumes Affected .............................................................. 144
Erasing Sensitive Data ............................................................................ 144
System-Managed-Storage Considerations ............................................ 144
General Considerations and Restrictions ............................................. 145
SCRATCH and CAMLST Macro Specification ........................................ 146
Example ................................................................................................... 146
SCRATCH Parameter List ......................................................................... 147
Return Codes from SCRATCH ................................................................. 148
Status Codes from SCRATCH ................................................................. 149
Renaming a Data Set in the VTOC ............................................................. 149
Specifying the Volumes Affected .............................................................. 150
System-Managed-Storage Considerations ............................................ 150
General Considerations and Restrictions ............................................. 150
RENAME and CAMLST Macro Specification ........................................ 152
Example ................................................................................................... 152
RENAME Parameter List ......................................................................... 153
Return Codes from RENAME ................................................................. 153
Status Codes from RENAME ................................................................. 154

Chapter 3. Using Catalog Management Macros ........................................ 157
Application Program Considerations ...................................................... 157
Catalog Search Order ............................................................................. 157
Retrieving Information from a Catalog .................................................. 158
Retrieving Information by Data Set Name (LOCATE and CAMLST NAME) 158
Retrieving Information by Generation Data Set Name (LOCATE and CAMLST NAME) 160
Retrieving Information by Alias (LOCATE and CAMLST NAME) .......... 162
Reading a Block by Relative Block Address (LOCATE and CAMLST BLOCK) 163
Return Codes from LOCATE ................................................................. 163
Using Non-VSAM Data Set Catalog Entries .......................................... 163
Cataloging a Non-VSAM Data Set (CATALOG and CAMLST CAT) ........ 163
Uncataloging a Non-VSAM Data Set (CATALOG and CAMLST UNCAT) 165
Recataloging a Non-VSAM Data Set (CATALOG and CAMLST RECAT) 166
Return Codes from CATALOG ............................................................... 168

Chapter 4. Executing Your Own Channel Programs .................................. 169
Using EXCP ............................................................................................. 169
IDAW Requirements .............................................................................. 170
EXCP Requirements ............................................................................. 171

**Chapter 6. Using Password Protected Data Sets**

- Providing Data Set Security ........................................ 233
- PASSWORD Data Set Characteristics .............................. 234
- Creating Protected Data Sets ...................................... 235
- Protection Feature Operating Characteristics .................. 236
- Maintaining the PASSWORD Data Set Using PROTECT ......... 238
- Record Format .......................................................... 238
- Protection-Mode Indicator .......................................... 238
- PROTECT Macro Specification .............................. 239

**Chapter 7. Using System Macro Instructions**

- Ensuring Data Security by Validating the Data Extent Block (DEBCHK macro) 247
  - DEBCHK Macro Specification .................................. 248
- Obtaining I/O Device Characteristics (DEVTYPE macro) ........ 252
  - DEVTYPE Macro Specification ................................. 252
- IHADVA Mapping macro ............................................. 270
- Reading and Modifying a Job File Control Block (RDJFCB Macro) ... 273
  - RDJFCB Macro Specification ................................... 276
- DEQ at Demount Facility for Tape Volumes ....................... 288
- High-Speed Cartridge Tape Positioning .......................... 290
- OPEN - Initialize Data Control Block for Processing the JFCB .... 291
- Purging and Restoring I/O Requests .............................. 293
  - PURGE Macro Specification ..................................... 293
  - RESTORE Macro Specification ................................ 296
- Performing Track Calculations (TRKCALC macro) .............. 297
  - Using TRKCALC ................................................... 297
  - Restrictions .................................................... 298
  - TRKCALC Macro Specification ................................. 298
- Perform calculations and conversions with 28-bit cylinder addresses (TRKADDR macro) .... 306
  - Calculate the relative track number on the volume (TRKADDR ABSTOREL) .... 307
  - Compare two track addresses (TRKADDR COMPARE) ........... 307
  - Extract 28-bit cylinder number (TRKADDR EXTRACTCYL) ........ 308
  - Extract 4-bit track number (TRKADDR EXTRACTTRK) ........... 308
  - Increment track address (TRKADDR NEXTTRACK) .................. 309
  - Normalize cylinder number (TRKADDR NORMALIZE) ............. 309
  - Convert a relative track number to a 28-bit cylinder address (TRKADDR RELTOABS) .... 310
  - Set cylinder number from register (TRKADDR SETCYL) ........ 310
  - Convert normalized track address into an absolute 28-bit track address (TRKADDR NORMTOABS) .................. 311
- Determining Level and Name of DFSMS ................................ 311
- Determining Version, Release, and Modification Level of DFSMS .... 311
- Determining Name of DFSMS ....................................... 312
- Determining DFARELS During Assembler Macro Phase ........... 312

**Chapter 8. Displaying Messages on Cartridge Magnetic Tape Subsystems**

- MSGDISP—Displaying a Mount Message .......................... 315
- MSGDISP—Displaying a Verify Message .......................... 316
- MSGDISP—Displaying a Ready Message ........................... 318
- MSGDISP—Displaying a Demount Message ......................... 320
- MSGDISP—Reseting the Message Display .......................... 321
- MSGDISP—Providing the Full Range of Display Options ........ 324
- Return Codes from MSGDISP ....................................... 326
Chapter 11. Managing Hierarchical File System Data Sets ........................................ 395
Creating Hierarchical File System Data Sets .................................................. 395
   Defining the Root File System ................................................................. 395
   Creating and Mounting the Root File System ......................................... 396
   Creating Additional File Systems and Directories .................................. 396
      Adding and Mounting File Systems to the Root File System ............... 396
Managing File System Size ........................................................................... 397
Managing File System Activity ..................................................................... 398
Accessing HFS Data Set Attributes .............................................................. 398
Transporting a File System ........................................................................ 398
Removing (Deleting) a File System ............................................................... 399
Migrating a File System ................................................................................ 399
Backing Up File Systems ............................................................................ 399
Recovering a Backed-Up File System ......................................................... 400
HFS Deferred File System Synchronization .................................................. 400
   How to specify a SYNC value .................................................................... 401
Using pfsctl (BPX1PCT) Physical File System Control for HFS ..................... 401
   DisplayBufferLimits Command ............................................................... 402
   ChangeBufferLimits Command ............................................................... 403
   DisplayGlobalStats Command ................................................................. 403
   DisplayFSStats Command ..................................................................... 404
   ExtendFS Command ............................................................................. 405
   BPX1PCT Return and Reason Codes ......................................................... 406

Chapter 12. User Access to Subsystem Statistics, Status, and Counts
 Information ........................................................................................................ 411
Register 1 Parameter List ............................................................................... 411
Passed Argument List -- SSGARGL ............................................................. 411

Control Blocks ............................................................................................... 433
Data Extent Block (DEB) Fields ..................................................................... 433
Data Facilities Area (DFA) Fields ................................................................ 439

Maintaining the System Image Library .......................................................... 443
UCS Images in SYS1.IMAGELIB ..................................................................... 445
   Examples of UCS Image Coding ............................................................... 446
   UCS Image Alias Names ........................................................................ 450
   UCS Image Tables in SYS1.IMAGELIB ..................................................... 450
   Alias Names in UCS Image Tables .......................................................... 450
   Adding or Modifying a UCS Image Table Entry ..................................... 454
   Verifying the UCS Image ....................................................................... 458
FCB Images in SYS1.IMAGELIB ..................................................................... 459
   Adding an FCB Image to the Image Library ......................................... 461
   Modifying an FCB Image ..................................................................... 463
JES Support for the 3211 Indexing Feature .................................................... 464

Using the extended address volume (EAV) migration assistance tracker ........ 467
Information conventions for the EAV migration assistance tracker ............... 468
   Tracking information ............................................................................. 468
   Tracking value ....................................................................................... 468
DFSMS instances tracked by the EAV migration assistance tracker ............... 469

About This Document

This document is intended to help system programmers modify and extend the data management capabilities of the operating system and for programmers to write advanced application programs.

For information about the accessibility features of z/OS, for users who have a physical disability, see Accessibility on page 483.

Required product knowledge

To use this document effectively, you should be familiar with:

- Assembler language
- Standard program linkage conventions
- The utility programs IEHLIST and IEHPROGM
- Data management access methods and macro instructions
- The storage management functions provided by DFSMSdss™ and DFSMShsm™. DFSMSdss moves data from one device to another, backs up and recovers data sets, and reduces free-space fragmentation on DASD volumes. DFSMShsm manages storage by migrating and recalling data sets through a hierarchy of storage devices.

To learn about physical storage administration, see z/OS DFSMSdfp Storage Administration, SC26-7402.

Accessing z/OS DFSMS information on the Internet

In addition to making softcopy information available on CD-ROM, IBM provides access to z/OS softcopy information on the Internet. To view, search, and print z/OS information, go to the z/OS Internet Library:

http://www.ibm.com/systems/z/os/zos/bkserv/

How to Read Syntax Diagrams

Throughout this library, diagrams are used to illustrate the programming syntax. Keyword parameters are parameters that follow the positional parameters. Unless otherwise stated, keyword parameters can be coded in any order. The following list tells you how to interpret the syntax diagrams:

- Read the diagrams from left-to-right, top-to-bottom, following the main path line. Each diagram begins on the left with double arrowheads and ends on the right with two arrowheads facing each other.

  Syntax Diagram

- If a diagram is longer than one line, each line to be continued ends with a single arrowhead and the next line begins with a single arrowhead.

  First Line

  Second Line

  Last Line

- Required keywords and values appear on the main path line. You must code required keywords and values.

  REQUIRED_KEYW

If several mutually exclusive required keywords or values exist, they are stacked vertically in alphanumeric order.

  REQUIRED_KEYW_OR_VALUE_1
  REQUIRED_KEYW_OR_VALUE_2

- Optional keywords and values appear below the main path line. You can choose not to code optional keywords and values.
If several mutually exclusive optional keywords or values exist, they are stacked vertically in alphanumeric order below the main path line.

- An arrow returning to the left above a keyword or value on the main path line means that the keyword or value can be repeated. The comma means that each keyword or value must be separated from the next by a comma.

- An arrow returning to the left above a group of keywords or values means more than one can be selected, or a single one can be repeated.

- A word in all uppercase is a keyword or value you must spell exactly as shown. In this example, you must code `KEYWORD`.

If a keyword or value can be abbreviated, the abbreviation is discussed in the text associated with the syntax diagram.

- If a diagram shows a character that is not alphanumeric (such as parentheses, periods, commas, and equal signs), you must code the character as part of the syntax. In this example, you must code `KEYWORD=(001,0.001)`.

- If a diagram shows a blank space, you must code the blank space as part of the syntax. In this example, you must code `KEYWORD=(001 FIXED)`.

- Default keywords and values appear above the main path line. If you omit the keyword or value entirely, the default is used.
• A word in all lowercase italics is a variable. Where you see a variable in the syntax, you must replace it with one of its allowable names or values, as defined in the text.

• References to syntax notes appear as numbers enclosed in parentheses above the line. Do not code the parentheses or the number.

Notes:
1 An example of a syntax note.

• Some diagrams contain syntax fragments, which serve to break up diagrams that are too long, too complex, or too repetitious. Syntax fragment names are in mixed case and are shown in the diagram and in the heading of the fragment. The fragment is placed below the main diagram.

Syntax Fragment:

Address and Register Conventions

The notation used to code an operand appears in the following format:

symbol
  The operand can be any valid assembler-language symbol.

(0)
  General register 0 can be used as an operand. When used as an operand in a macro instruction, the register must be specified as the decimal number 0 enclosed in parentheses as shown.

(1)
  General register 1 can be used as an operand. When used as an operand in a macro instruction, the register must be specified as the decimal number 1 enclosed in parentheses as shown. When you use register 1, the instruction that loads it is not included in the macro expansion.

(2-12)
  The operand specified can be any of the general registers 2 through 12. All registers as operands must be coded in parentheses; for example, if register 3 is coded, it is coded as (3). A register from 2 through 12 can be coded as a decimal number, symbol (equated to a decimal number), or an expression that results in a value of 2 through 12.

RX-Type Address
  The operand can be specified as any valid assembler-language RX-type address as shown in the following examples:
<table>
<thead>
<tr>
<th>Name</th>
<th>Operation</th>
<th>Operand</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALPHA1</td>
<td>L</td>
<td>REG1,39(4,TEN)</td>
</tr>
<tr>
<td>ALPHA2</td>
<td>L</td>
<td>2,ZETA(4)</td>
</tr>
<tr>
<td>BETA1</td>
<td>L</td>
<td>REG2,ZETA(REG4)</td>
</tr>
<tr>
<td>BETA2</td>
<td>L</td>
<td>2,ZETA</td>
</tr>
<tr>
<td>GAMMA1</td>
<td>L</td>
<td>2,ZETA</td>
</tr>
<tr>
<td>GAMMA2</td>
<td>L</td>
<td>REG2,ZETA</td>
</tr>
<tr>
<td>GAMMA3</td>
<td>L</td>
<td>2,=<code>'1000</code></td>
</tr>
<tr>
<td>LAMBDA1</td>
<td>L</td>
<td>3,20(,5)</td>
</tr>
</tbody>
</table>

Both ALPHA instructions specify explicit addresses; REG1 and TEN have been defined as absolute symbols. Both BETA instructions specify implied addresses, and both use index registers. ZETA is a relocatable symbol. Indexing is omitted from the GAMMA instructions. GAMMA1 and GAMMA2 specify implied addresses. The second operand of GAMMA3 is a literal. LAMBDA1 specifies an explicit address with no indexing.

**A-Type Address**

The operand can be specified as any address that can be written as a valid assembler-language A-type address constant. An A-type address constant can be written as an absolute value, a relocatable symbol, or relocatable expression. Operands requiring an A-type address are inserted into an A-type address constant during the macro expansion process. For more details about A-type address constants, see *High Level Assembler/MVS & VM & VSE Language Reference*.

**absexp**

The operand can be an absolute value or expression. An absolute expression can be an absolute term or an arithmetic combination of absolute terms. An absolute term can be a nonrelocatable symbol, a self-defining term, or the length attribute reference. For more details about absolute expressions, see *High Level Assembler/MVS & VM & VSE Language Reference*.

**relexp**

The operand can be a relocatable symbol or expression. If the program containing a relocatable symbol or expression is relocated n bytes away from its originally assigned area of storage, the value of a relocatable symbol or expression changes by n. For more details about relocatable symbols and expressions, see *High Level Assembler/MVS & VM & VSE Language Reference*.
How to send your comments to IBM

We appreciate your input on this publication. Feel free to comment on the clarity, accuracy, and completeness of the information or give us any other feedback that you might have.

Use one of the following methods to send us your comments:
1. Send an email to mhvrdfs@us.ibm.com
3. Mail the comments to the following address:
   IBM Corporation
   Attention: MHVRCFS Reader Comments
   Department H6MA, Building 707
   2455 South Road
   Poughkeepsie, NY 12601-5400
   U.S.A.
4. Fax the comments to us as follows:
   - From the United States and Canada: 1+845+432-9405
   - From all other countries: Your international access code +1+845+432-9405

Include the following information:
- Your name and address
- Your email address
- Your telephone or fax number
- The publication title and order number:
  - z/OS V1R13.0 DFSMSdfp Advanced Services
  - SC26-7400-14
- The topic and page number related to your comment
- The text of your comment.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you.

IBM or any other organizations will only use the personal information that you supply to contact you about the issues that you submit.

If you have a technical problem

Do not use the feedback methods listed above. Instead, do one of the following:
- Contact your IBM service representative
- Call IBM technical support
- Visit the IBM support portal at [http://www.ibm.com/systems/z/support/](http://www.ibm.com/systems/z/support/)
Summary of Changes

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

Changes made in z/OS Version 1 Release 13 as updated September 2012

This document contains information previously presented in z/OS DFSMSdfp Advanced Services, SC26-7400 13.

New and Changed Information

This following sections summarize new information that is included in this document.

• Chapter 4, “Executing Your Own Channel Programs,” on page 169 has been updated with new information about EXCP virtual support for High Performance FICON (zHPF) channel programs.

Changes made in z/OS Version 1 Release 13 as updated April 2012

This document contains information previously presented in z/OS DFSMSdfp Advanced Services, SC26-7400 12.

New and Changed Information

This following sections summarize new information that is included in this document.

• Chapter 4, “Executing Your Own Channel Programs,” on page 169 has been updated with new information about the execute-channel-program-virtual-real (EXCPVR) macro instruction and High Performance FICON (zHPF) channel programs.

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

Changes made in z/OS Version 1 Release 13

This document contains information previously presented in z/OS DFSMSdfp Advanced Services, SC26-7400 11.

The following sections summarize the changes to that information.

New and Changed Information

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.
Changes made in z/OS Version 1 Release 12

This document contains information previously presented in z/OS DFSMSdfp Advanced Services, SC26-7400-10.

The following sections summarize the changes to that information.

New and Changed Information

This following sections summarize new information that is included in this document.

- Chapter 4, “Executing Your Own Channel Programs,” on page 169 has been updated to say that OPEN will capture the UCB if the application program does not specify the new option and CLOSE will uncapture it.
- “Data Extent Block (DEB) Fields” on page 433 has been updated to include the new four-byte UCB address and the moved device modifier byte.

This following sections summarize changed information that is included in this document.

- The EXCP and EXCPVR appendages have been changed with new information about register contents. See “EXCP and EXCPVR Appendages” on page 208.
- The XDAP macro has been updated with new information for the bkref_ addr parameter. See “Executing Direct Access Programs” on page 227.
- The INFO=AMCAP option of DEVTYPE has been updated for the new bits. For more information, see “IHADVA Mapping macro” on page 270.
- The RDJFCB macro description has been updated to say that it supports the XTIOT option of dynamic allocation. For more information see, “Reading and Modifying a Job File Control Block (RDJFCB Macro)” on page 273.

The "Readers' Comments - We'd Like to Hear from You" section at the back of this publication has been replaced with a new section "How to send your comments to IBM" on page xxi. The hardcopy mail-in form has been replaced with a page that provides information appropriate for submitting comments to IBM.

Changes made in z/OS Version 1 Release 11

This document contains information previously presented in z/OS DFSMSdfp Advanced Services, SC26-7400-09.

Changes made in z/OS Version 1 Release 11

This document contains information previously presented in z/OS DFSMSdfp Advanced Services, SC26-7400-08.

The following sections summarize the changes to that information.

New and Changed Information

This following sections summarize new information that is included in this document.

- Chapter 1, “Using the Volume Table of Contents,” on page 1 includes the following changes in support of EAV enhancements:
  - “Format-9 DSCB” on page 14 contains new and changed fields.
  - Updates to “REALLOC Parameter List” on page 52.
– Updates to “Serializing and Updating” on page 55 CVAF requests.

• Chapter 4, “Executing Your Own Channel Programs,” on page 169 contains a release update to section “Converting a Relative Track Address to an Actual Track Address” on page 219.

• Chapter 6, “Using Password Protected Data Sets,” on page 233 contains a release update.

• Chapter 7, “Using System Macro Instructions,” on page 247 contains the following updates to DEVINFO for solid state device support and EAV enhancements:
  – “DEVTYPE—Info Form” on page 258
  – “Device Characteristics Information” on page 262
  – “IHADVA Mapping macro” on page 270

• “Control Blocks” on page 433 contains new and changed fields in “Data Facilities Area (DFA) Fields” on page 439 in support of EAV.

• “Using the extended address volume (EAV) migration assistance tracker” on page 467 contains new tracking info in “DCB Open of EAS eligible data set” on page 480 in support of EAV.
Chapter 1. Using the Volume Table of Contents

This information is intended to help you to use system macros to access and modify the volume table of contents (VTOC) and VTOC index. The direct access device storage management (DADSM) routines control space allocation on direct access volumes through the VTOC for a volume and through the VTOC index if one exists. A storage administrator uses the ICKDSF utility to build these structures. See “Creating the VTOC and VTOC Index” on page 141.

VTOC Components

The VTOC is a data set that describes the contents of the direct access volume on which it resides. It is a contiguous data set; that is, it resides in a single extent on the volume and starts after cylinder 0, track 0 and before track 65,535. A VTOC’s address is located in the VOLVTOC field of the standard volume label (see Figure 1). The volume label is described in z/OS DFSMS Using Data Sets. A VTOC consists of complete tracks.

1. The 140 bytes are divided into a 44-byte key portion followed by a 96-byte data portion. You can refer to the logical 140-byte DSCB or to either of its parts.

Figure 1. Locating the volume table of contents

The VTOC is composed of 140-byte\(^1\) data set control blocks (DSCBs) that correspond either to a data set currently residing on the volume, or to contiguous, unassigned tracks on the volume.

A special type of data is in a hierarchical file system (HFS) data set. Each one contains a UNIX type of file system that is compliant with the IEEE POSIX standard and OSF XPG4.2 standard. Certain linear data sets contain z/OS file system (zFS) file systems. They also meet these standards. Each data set containing an HFS or zFS file system can contain UNIX files and directories belonging to multiple users.
Using the VTOC

You can access the files through z/OS UNIX System Services, BSAM, QSAM, and VSAM. See [z/OS DFSMS Using Data Sets](#). DSCBs for data sets describe their characteristics and location. DSCBs for contiguous, unassigned tracks indicate their location.

Data Set Control Block (DSCB) Types

The VTOC contains several kinds of DSCBs. This section describes what the DSCBs are used for, how many exist on a volume, and how to locate them. The DSCB layouts are shown in [Table 2 on page 5](#) through [Table 5 on page 13](#).

The first record in every VTOC is the VTOC DSCB (format-4). The record describes the device the volume resides on, the volume attributes, and the size and contents of the VTOC data set. The next DSCB in the VTOC data set is a free-space DSCB (format-5) even if the free space is described by format-7 DSCBs. The third and subsequent DSCBs in the VTOC can occur in any order.

One or more DSCBs in the VTOC define a data set on each volume on which the data set resides. The number of DSCBs needed to define a data set is determined by the number of extents that the data set occupies and by whether it has a format 9 DSCB. One or more format-3 DSCBs are required for data sets with more than three extents.

[Figure 2 on page 3](#) shows a VTOC and the DSCBs needed to define four data sets. Data set A (in Figure 2) has 29 extents, so it cannot be a basic format, direct or partitioned (PDS) data set. Because it has so many extents, it requires a format-1 DSCB and two format-3 DSCBs. Data set B has 16 extents and therefore requires both a format-1 and a format-3 DSCB. Data sets C and D have three or fewer extents and need only a format-1 DSCB. Data sets B, C, and D could be any type of data set.
Figure 3 on page 4 shows a VTOC and the DSCBs needed to define four data sets on an extended address volume. Data set W (in Figure 3) has 29 extents, so it cannot be a basic format, direct or partitioned (PDS) data set. Because it has so many extents, it requires a format-1 DSCB and two format-3 DSCBs. Data set X has 16 extents and since it is an EAS eligible data set it requires a format-8 and a format-9 DSCB, plus an additional format-3 DSCB. Data sets Y and Z have three or fewer extents and need only a format-1 DSCB. Data sets X, Y, and Z could be any type of data set.
The mapping macro for the format-1, format-2, format-3, format-4, format-5, format-8, and format-9 DSCBs is IECSDSL1. Code positional parameters to specify which formats of DSCB to map. For example, the following maps format-1 and format-3:

```
IECSDSL1 1,3
```

The macro does not generate a DSECT statement. This makes it easier to embed it in your own DSECT or CSECT. You can use a technique such as the following to get separate DSECT statements:

```
F1AREA DSECT
  IECSDSL1 1
F3AREA DSECT
  IECSDSL1 3
```

The first symbol generated for each format is of the form IECSDSLn, where n is the number of the format.

---

**Figure 3. Contents of VTOC on an extended address volume - DSCBs Describing Data Sets on Volume That Has No VTOC Index**

The mapping macro for the format-1, format-2, format-3, format-4, format-5, format-8, and format-9 DSCBs is IECSDSL1. Code positional parameters to specify which formats of DSCB to map. For example, the following maps format-1 and format-3:

```
IECSDSL1 1,3
```

The macro does not generate a DSECT statement. This makes it easier to embed it in your own DSECT or CSECT. You can use a technique such as the following to get separate DSECT statements:

```
F1AREA DSECT
  IECSDSL1 1
F3AREA DSECT
  IECSDSL1 3
```

The first symbol generated for each format is of the form IECSDSLn, where n is the number of the format.
Using the VTOC

Format-0 DSCB

Name: Free VTOC Record

Function: Describes an unused record in the VTOC (contains 140 bytes of binary zeros). To delete a DSCB from the VTOC, a format-0 DSCB is written over it.

How Many: One for every unused 140-byte record on the VTOC. The DS4DSREC field of the format-4 DSCB is a count of the number of format-0 DSCBs on the VTOC. This field is not maintained for an indexed VTOC.

How Found: Search on key equal to X'00'.

Format-1 and Format-8 DSCBs

Note: The fields in the format 1 DSCB and the format 8 DSCB are almost identical. The small differences are noted in the field descriptions.

Name: Identifier

Function: Describes the first three extents and other information about a data set.

How Many: One for each data set on the volume, except the VTOC.

How Found: Use the OBTAIN macro or a CVAF macro.

Table 2 shows the contents of a format-1 or format-8 DSCB.

Notes on DS1REFD field:
1. For a VSAM data set, if the date in the FMT-1 DSCB's DS1REFD field is earlier than the current date, OPEN updates the field with the current date.
2. For a multivolume VSAM data set, OPEN updates the DS1REFD field only for the first volume of the data component of the base cluster.
3. For a non-VSAM multivolume data set that is not SMS managed, OPEN updates the DS1REFD field on the first volume OPEN selected to use.
4. For a non-VSAM multivolume SMS-managed data set that is not extended format, OPEN updates the DS1REFD field on the first volume OPEN selected to use, as well as the first volume of the data set.
5. For an extended format single-striped non-VSAM data set, OPEN updates the DS1REFD field on the first volume OPEN selected to use, as well as the first volume of the data set.
6. For an extended format multi-striped non-VSAM data set, OPEN updates the DS1REFD fields on all volumes of the data set.

</tbody>
</table>

**Format-2 DSCB**

This format applied only to ISAM data sets, which can no longer be created or opened.
Using the VTOC

Format-3 DSCB

Name: Extension

Function: Describes extents after the third extent of a non-VSAM data set or a VSAM data space.

How Many: One for each data set or VSAM data space on the volume that has more than three extents. There can be as many as 10 for a PDSE, HFS, extended format data set, or a VSAM data set cataloged in an integrated catalog facility catalog. PDSEs, HFS, and extended format data sets can have up to 123 extents. Each component of a VSAM data set cataloged in an integrated catalog facility catalog can have up to 123 extents per volume. All other data sets are restricted to 16 extents per volume.

How Found: Chained from a format 1, format 2 or format 9 DSCB that represents the data set. In the case of a PDSE, HFS data set, sequential extended-format data set, or VSAM data set, the chain also can be from a preceding format-3 DSCB.

Table 3 shows the contents of a format-3 DSCB.

<table>
<thead>
<tr>
<th>Offset Dec Type</th>

<td>-</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format-4 DSCB

Name: VTOC

Function: Describes the extent and contents of the VTOC and provides volume and device characteristics. This DSCB contains a flag indicating whether the volume is SMS managed.

How Many: One on each volume.

How Found: The VOLVTOC field of the standard volume label contains the format-4 address. The format-4 DSCB is always the first record in the VTOC.

Table 4 on page 11 shows the contents of a format-4 DSCB.

Table 4 on page 11 shows the contents of a format-4 DSCB.

Exception: The format-4 DSCB has a 44-byte key of X'04' bytes not shown in Table 4 on page 11.

Format-5 DSCB

**Name:** Free Space

**Function:** On a nonindexed VTOC, describes the space on a volume that has not been allocated to a data set (available space). For an indexed VTOC, a single empty format-5 DSCB resides in the VTOC; free space is described in the index and DS4IVTOC is normally on.

**How Many:** One for every 26 noncontiguous extents of available space on the volume for a nonindexed VTOC; for an indexed VTOC, there is only one.

**How Found:** The first format-5 DSCB on the volume is always the second DSCB of the VTOC. If there is more than one format-5 DSCB, it is chained from the previous format-5 DSCB using the DS5PTRDS field.

Table 5 shows the contents of a format-5 DSCB.

Format-7 DSCB

**Name:** Free space for certain devices
Only one field in the format-7 DSCB is an intended interface. This field indicates whether the DSCB is a format-7 DSCB. You can reference that field as DS1FMTID or DS5FMTID. A character 7 indicates that the DSCB is a format-7 DSCB, and your program should not modify it.

If you are diagnosing a problem, see [z/OS DFSMSdfp Diagnosis](#) for the layout of the Format-7 DSCB.

### Format-9 DSCB

**Name:** Metadata and DSCB pointers.

**Function:** Contains metadata about the data set and pointers to all format 3 DSCBs for the data set.

**How Many:** One for each format 8 DSCB.

**How Found:** Chained from a format-8 DSCB that represents the data set. Data sets that have a format 1 DSCB do not have a format 9 DSCB.

Table 6 shows the contents of a format-9 DSCB.

#### Vendor fields in DS9ATRV1 in the format 9 DSCB

z/OS does not enforce any rules on the content of the DS9ATRV1 field. It is available for vendor products to set. IBM provides the following recommendations:

Each vendor should store subfields in the following format beginning at the leftmost byte:

<table>
<thead>
<tr>
<th>Offset X'0'</th>
<th>Length</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'0')</td>
<td>Character</td>
<td>1</td>

</tr>
<tr>
<td>2 (X'2')</td>
<td>Character</td>
<td></td>
<td>Beginning of variable-length field up to 15 bytes.</td>
</tr>
</tbody>
</table>

### Allocating and Releasing DASD Space

DADSM allocate and extend routines assign tracks and cylinders on direct access volumes for data sets. The DADSM extend routine gets additional space for a data set that has exceeded its primary allocation. The DADSM scratch and partial release routines release space that is no longer needed on a direct access volume.

The DADSM routines allocate and release space by adding, deleting, and modifying the DSCBs and updating the VTOC index. When space is released, the scratch routines free the DSCBs of the deleted data set or data space.

Every data set occupies an integral number of tracks. Unused space on a track cannot be used for another data set unless the whole track is released. The minimum amount of space allocated to a data set is zero tracks but a PDS with no tracks can never contain a member.
After a certain place on the volume, the system rounds up each primary or secondary space request so it is a multiple of 21 cylinders. Currently that place is after the first 65520 cylinders. The space within the first 65520 cylinders is called the track-managed space, even if data sets are allocated in units of cylinders. The space after the first 65520 cylinders is called the cylinder-managed space. If the volume capacity is 65520 cylinders or less, then all of the space is track-managed.

**Note:** When a user program needs to determine the characteristics of a given volume, it must separately check each of the following characteristics and not assume that the value obtained for one characteristic implies the values for the other three:
- Whether space beyond a certain place on the volume is managed in multicylinder units.
- The location on the volume where the multicylinder units begin.
- The number of cylinders in a multicylinder unit.
- Whether the VTOC contains format 8 and 9 DSCBs.

### The VTOC Index

The VTOC index enhances the performance of VTOC access. The VTOC index is a physical-sequential data set on the same volume as the related VTOC. It consists of an index of data set names in format-1 DSCBs contained in the VTOC and volume free space information.

An SMS-managed volume requires an indexed VTOC; otherwise, the VTOC index is highly recommended. For additional information about SMS-managed volumes, see [z/OS DFSMS Implementing System-Managed Storage](#).

**Note:** You can use the ICKDSF REFORMAT REFVTOC command to rebuild a VTOC index to reclaim any no longer needed index space and to possibly improve access times.

z/OS does support sharing a non-SMS-managed volume that contains a VTOC index with a non-z/OS system. If the other system updates the VTOC and turns on the DS4DOSBT, then later when z/OS is used to modify the VTOC, DADSM can detect that the index is no longer valid. The z/VSE operating system sets this bit on.

Device Support Facilities (ICKDSF) initializes a VTOC index into 2048-byte physical blocks, or 8192-byte physical blocks on an extended address volume, named VTOC index records (VIRs). The DEVTYPE INFO=DASD macro can be used to return the actual block size or it can be determined from examining the format-1 DSCB of the index data set. VIRs are used in several ways. A VTOC index contains the following kinds of VIRs:

- **VTOC index entry record (VIER)** identifies the location of format-1 and format-8 DSCBs and the format-4 DSCB.
- **VTOC pack space map (VPSM)** identifies the free and allocated space on a volume.
- **VTOC index map (VIXM)** identifies the VIRs that have been allocated in the VTOC index.
- **VTOC map of DSCBs (VMDS)** identifies the DSCBs that have been allocated in the VTOC.

A format-1 DSCB in the VTOC contains the name and extent information of the VTOC index. The name of the index must be 'SYS1.VTOCIX.volser', where 'volser'
Using the VTOC

is the serial number of the volume containing the VTOC and its index. The name must be unique within the system to avoid ENQ contention and must conform to standard data set naming conventions.

Notes:
1. If first character of volser is numeric, you must either precede or replace the first character with the letter "V" (for example, if volser is 12345, then you should use either V12345 or V2345).
2. RMF statistics on the VTOC index will always show the data set name as SYS1.VTOCIX.Vvolser regardless of what the actual name is on the volume.

You can only create (allocate) one data set whose name begins with 'SYS1.VTOCIX.' on a volume. To rename a VTOC index data set when the VTOC index is active, use a name beginning with 'SYS1.VTOCIX.' If a 'SYS1.VTOCIX.' data set already exists on a volume, you cannot rename another data set on the volume to a name with those qualifiers. If the VTOC index is active, you cannot scratch the VTOC index data set.

The relationship of a VTOC to its index is shown in Figure 4.

![Figure 4. Example of the Relationship of a VTOC to Its Index](image-url)
Using the VTOC

VTOC Index Records

VTOC index records consist of the following types:

VTOC Index Entry Record
The first level-one VIER is created with the VTOC index. Subsequent VIERs are created whenever a VIER is too full to allow a data set name to be added to the VTOC index. VIERs have the following characteristics:

- A VIER uses one VIR and contains variable-length index entries. The number of VIERs in an index depends upon the number of data sets on the volume.
- All index entries within a VIER are at the same index level. VIERs in a VTOC index can be on several levels and have a hierarchic relationship. Index entries in higher-level VIERs point to lower-level VIERs. Index entries in level-one VIERs (those at the lowest level) point to format-1 or format-8 DSCBs for data sets on the volume.
- Whenever a fourth VIER is created on the same level, a VIER at a higher level is created. Once a higher-level VIER is filled with pointers to lower-level VIERs, another VIER at the same level is created.

VTOC Pack Space Map
The VPSM shows the allocated space on a volume and the space that remains free. The space within the first 65,520 cylinders is called the track-managed space. The VPSMs for this area contains bit maps of the cylinders and tracks on the volume. A value of one indicates that the cylinder or track has been allocated; zero, that it is unallocated. The space after the first 65,520 cylinders is called the cylinder-managed space. The VPSMs for this area contains bit maps of only multicylinder units. Individual cylinders and tracks are not mapped in this type of VPSM. A value of one indicates that the multicylinder unit is allocated; zero, that it is unallocated.

VTOC Index Map
The VIXM contains a bit map in which each bit represents one VTOC index record. The status of the bit indicates whether the VIR is allocated (1), or unallocated (0). On an extended address volume, the VIXM record header is enlarged to accommodate the volume size, free space statistics for the VTOC and index, free space statistics for the entire volume and from track-managed space. Fields in this expanded header define the RBA of the first VPSM record that maps multicylinder units, along with the minimum allocation unit in cylinders for the VPSMs that map cylinder-managed space.

An area of the VIXM is reserved for VTOC recording facility (VRF) data. (This facility allows detection of and recovery from some errors in an indexed VTOC.)

VTOC map of DSCBs
The VMDS shows the DSCBs that have been allocated in the VTOC. The map contains a bit map of DSCBs corresponding the relative DSCB record in the VTOC. A value of one indicates that the DSCB has been has been allocated; zero indicates that it is unallocated.

Structure of an Indexed VTOC
Indexed and nonindexed VTOCs have similar structures with the following differences for an indexed VTOC:

- Only a single, empty format-5 DSCB exists.
- Some format-4 DSCB data (the number of format-0 DSCBs and the CCHHR of the highest format-1 DSCB) is not maintained by DADSM. The VSE bit (bit 0 in field DS4VTOCI), set to 1 in the format-4 DSCB, indicates that the contents of
these fields (and the format-5 DSCB) are not valid. The index bit (bit 7 in field DS4VTOCI) is set in the format-4 DSCB; it indicates that a VTOC index exists.

---

**Accessing the VTOC with DADSM Macros**

You can use either DADSM or common VTOC access facility (CVAF) macros to access a VTOC and its index. (CVAF access is described in “Accessing the VTOC with CVAF Macros” on page 55.) The DADSM macros and tasks covered here include:

- **LSPACE** provides information on volume size, free space on the volume, free space on the VTOC and INDEX, volume fragmentation, and VTOC status. Also provided is information on the size of the track-managed space and its free space statistics.
- **OBTAIN** reads one or more DSCBs from the VTOC.
- **PARTREL** releases unused space from a sequential or partitioned data set or a PDSE.
- **REALLOC** allocates DASD space.

To read one or more DSCBs into virtual storage, use the OBTAIN and CAMLST macro instructions. Identify the DSCB to be read using the name of the data set associated with the DSCB, or the absolute track address of the DSCB. Provide a 140-byte data area in virtual storage to contain the DSCB. On a request to read multiple DSCBs specify the NUMBERDSCB= parameter on the OBTAIN or CAMLST macro and provide consecutive 140-byte return areas in virtual storage to contain this number of DSCBs. When you specify the name of the data set, an identifier (format-1, format-4, or format-8) DSCB is read into virtual storage. To read a DSCB other than a format-1, format-4, or format-8 DSCB, specify an absolute track address (see the example on page "Example" on page 40). Code the EADSCB=OK on the OBTAIN or CAMLST macro when your program supports DSCBs that describe data sets with format-8 and format-9 DSCBs. The extent descriptors in DSCBs for a data set described with these formats may have 28-bit cylinder track addresses. Use the TRKADDR macro or IECTRKAD service to manipulate 16-bit or 28-bit cylinder track addresses.

**Restriction:** You cannot use the OBTAIN macro instruction with either a SYSIN or SYSOUT data set.

To release unused space from a sequential, partitioned, or key sequenced data set or a PDSE, use the PARTREL macro instruction. Your program must be APF authorized.

Another way is to code the RLSE option on the SPACE keyword on the DD statement or the dynamic allocation equivalent. This technique does not require APF authorization. It requires that your program open the data set with the OUTPUT, EXTEND, OUTIN, OUTINX or INOUT option and the last operation before closing the data set not be a read or POINT macro.

The following macro instruction descriptions include coding examples, programming notes, and exception return code descriptions.

**Requesting DASD Volume Information Using LSPACE**

LSPACE provides information on volume size, free space on the volume, free space on the VTOC and INDEX, volume fragmentation, and VTOC status. Also provided is information on the size of the track-managed space and its free space statistics.
Using the VTOC

The LSPACE macro returns status information (such as LSPACE subfunction, return code, and reason code) in the parameter list. The LSPACE macro also returns the return code in register 15. For volumes that are configured with more than 9999 cylinders, you can use the EXPMSG option to create an expanded message return area that the LSPACE macro needs. For volumes that are configured with cylinder-managed space, you can use the XEXPMSG option to create an extended expanded message return area that the LSPACE macro needs. The use of XEXPMSG is recommended for all requests to return message data. The expanded data return area (EXPDATA) will return binary data of free space and total volume space information for volumes. For volumes with cylinder-managed space, this will be returned as free space for the entire volume and free space for the track-managed space. The two sets of free space data will be the same for a volume that does not have cylinder-managed space. The use of EXPDATA is recommended for all requests to return binary data. You can have LSPACE return additional information such as the format 4 DSCB, the total number of free extents on the volume or the fragmentation index. This information can be returned in the:

- Message return area
- Expanded message return area
- Extended expanded message return area
- Data return area
- Expanded data return area
- Format-4 DSCB return area

The calling program must ensure that the volume to be processed remains mounted during LSPACE processing. The volume need not be allocated.

If the device is not ready when you issue LSPACE and remains not ready, LSPACE eventually gives return code 4 with a timeout message. (See Table 8 on page 32.) In the current level of the system, LSPACE defaults to waiting as long as 240 seconds. You can change this amount of time by setting the byte at offset 7 in the parameter list. (See Table 7 on page 29.) You must use the list and execute forms of the macro because the macro has no parameter for this.
**LSPACE—Standard Form**

The format of the standard form of the LSPACE macro is:

```
label LSPACE MF=I UCB=addr(reg), MSG=addr(reg), EXPMSG=addr(reg), DATA=addr(reg), XEXPMSG=addr(reg), EXPDATA=addr(reg)
```

The keywords are the same as described in the execute form of the LSPACE macro. See the execute form of the LSPACE macro for the descriptions.

**MF=I**

Specifies the standard form of the LSPACE macro.

- **I** Specifies the standard form of the macro. This generates a standard parameter list containing the required variables, loads the address of the parameter list in register 1, and issues a supervisor call. The standard form is the default.

**Requirement:** UCB must be specified when MF=I is used.

**PLISTVER=plistver | IMPLIED_VERSION | MAX**

This keyword defines the version of the LSPACE parameter list that should be generated for the MF=I form of the LSPACE macro.

PLISTVER=plistver specifies the version of the LSPACE parameter list that should be generated, where plistver is either 1 or 2. This PLISTVER= keyword is required for any macro keys associated with version 2 or larger to be specified. The macro keys associated with each supported version of the macro are listed below:

**PLISTVER=1**

PLISTVER=1 is associated with the following macro keys:

- DATA
- EXPMSG
- F4DSCB
- MSG
Using the VTOC

SMF

PLISTVER=2

PLISTVER=2 is associated with the following macro keys:
- XEXPMSG
- EXPDATA
- DATATYPE

When PLISTVER= IMPLIED_VERSION is specified the generated parameter list is the lowest version that allows all of the parameters on the invocation to be processed. When PLISTVER is omitted, the default is the lowest version of the parameter list, which is version 1.

When PLISTVER= MAX is specified, the generated parameter list is the largest size currently supported. This size may grow from release to release thus possibly affecting the amount of storage needed by your program. If your program can tolerate this, IBM recommends that you always specify MAX when creating the list form parameter list as that will ensure that the list form parameter list is always long enough to hold whatever parameters might be specified on the execute form.

LSPACE-Execute Form

The format of the execute form of the LSPACE macro is:

```
LSPACE

MF=(E, addr) or (E, (reg))

Specifies the execute form of the LSPACE macro.

The MF=L form is usually issued before the execute form to create the parameter list.

(E, addr) Loads the address of the parameter list specified by addr into register 1 and then issues a supervisor call.
```
(E, (reg)) Loads the address of the parameter list specified by (reg) into register 1 and then issues a supervisor call.

UCB=addr or (reg)
Specifies the address of the UCB for the volume whose free space information you are requesting. The address can be for a captured UCB, or for an actual UCB above or below the 16MB line. For 31-bit callers, the high-order byte is part of the UCB address and must be cleared to zeros if a 24-bit UCB address is being passed.

addr—RX-type address
Specifies the address of a fullword containing the UCB address.

(reg)—(2-12)
Specifies a register containing the UCB address for the device. Note that this differs from the addr form of the parameter.

When using the standard (MF=I) form of the macro, you must provide a UCB address.

Restrictions:
1. The LSPACE macro will accept the address of a UCB or UCB copy. Unauthorized programs can get a copy of the UCB by using the UCBSCAN macro and specifying the COPY and UCBAREA keywords. The UCB copy can be above or below the 16MB line and on a word boundary. Refer to z/OS HCD Planning for details.
2. LSPACE does not support VIO UCBs.

MSG=addr or (reg) or 0 or EXPMSG=addr or (reg) or 0 or DATA= addr or (reg) or 0
Specifies the way LSPACE is to return free space information. (optional)

Restriction: The MSG, EXPMSG, and DATA parameters are mutually exclusive.

MSG=addr or (2-12) or 0
Specifies the address of a caller-provided 30-byte message return area into which LSPACE returns either a free space message or, for unsuccessful requests, status information. For a description of this area, see "Message Return Area" on page 31.

addr—RX-type address
Specifies the address of the message return area.

(reg)—(2-12)
Specifies a register containing the address of the message return area.

0 Specifies that you do not want the free space message. This is the default for all forms of the macro except execute.

EXPMSG=addr or (reg) or 0
Specifies the address of a caller-provided 40-byte expanded message return area into which LSPACE returns either a free space message or, for unsuccessful requests, status information. For a description of this area, see "Expanded Message Return Area" on page 33.

addr—RX-type address
Specifies the address of the message return area.

(reg)—(2-12)
Specifies a register containing the address of the message return area.
Using the VTOC

0     Specifies that you do not want the free space message. This is the default for all forms of the macro except execute.

DATA=addr or (reg) or 0
Specifies the address of a caller-provided data return area into which LSPACE returns free space and volume information. For a description of this area, see "Data Return Area" on page 33.

addr—RX-type address
Specifies the address of the data return area.

(reg)–(2-12)  Specifies a register containing the address of the data return area.

0  Specifies that you do not want the free space and volume information.

SMF=TEST or YES or NONE
Specifies the type of SMF processing.

TEST  Specifies that LSPACE is to test for an active SMF system and whether SMF volume information is desired. If these conditions are met, an SMF record is written. Only programs executing in supervisor state, protect key 0-7, or APF authorized can specify this operand.

YES  Specifies that you want an SMF record containing volume information to be written. Only programs executing in supervisor state, protect key 0-7, or APF authorized can specify this operand.

NONE  Specifies that you do not want an SMF record containing volume information to be written. This is the default for all forms of the macro except execute.

F4DSCB=addr or (reg) or 0
Specifies the address of a 96-byte DSCB return area provided by the calling program, into which LSPACE returns the volume's format-4 DSCB. For a description of the format-4 DSCB fields, see Table 4 on page 11.

addr—RX-type address
Specifies the address of the format-4 DSCB return area.

(reg)–(2-12)
Specifies a register containing the address of the format-4 DSCB return area.

0  Specifies that you do not want the data portion of the format-4 DSCB for the volume. This is the default for all forms of the macro except execute.

XEXPMSG=addr or (reg) or 0
Specifies the address of a caller-provided 95-byte extended expanded message return area into which LSPACE returns either a free space message or, for unsuccessful requests, status information. Specify this keyword if you wish to obtain free space information in the message return area for volumes that are configured with cylinder-managed space. The returned free space will include space for the total volume and space from the track-managed space on a volume. The two sets of free space message data will be the same for a volume that does not have cylinder-managed space. The use of XEXPMSG is recommended for all requests to return message data. See "LSPACE Information Return Areas" on page 31 for a description of the message return area.
**Using the VTOC**

\(addr\)– RX-type address

Specifies the address of the message return area.

\((reg)\)– (2-12)

Specifies a register containing the address of the message return area.

0  Specifies that you do not want the free space message. This is the default for all forms of the macro except execute.

**EXPDATA=addr or (reg) or 0**

Specifies the address of a caller-provided EXPANDED data return area into which LSPACE returns expanded free space and volume information. Specify this keyword if you wish to obtain free space information and total volume space in the LSPACE data return area for volumes. The returned free space will include space for the total volume and space from the track managed space on a volume. For volumes with cylinder-managed space this data will be returned as free space for the entire volume and free space for the track-managed space. The two sets of free space data will be the same for a volume that does not have cylinder-managed space. The use of EXPDATA is recommended for all requests to return binary data. See Table 9 on page 33 for a description of the expanded data return area.

\(addr\)– RX-type address

Specifies the address of the expanded data return area.

\((reg)\)– (2-12)

Specifies a register containing the address of the expanded data return area.

0  Specifies that you do not want the expanded free space and volume information.

**DATATYPE= ALL or FRAGINDEX or INDEX or VOLUME or VTOC**

This keyword is allowed only when the DATA or EXPDATA keyword is specified. Only the information specified will be returned to the caller. DATATYPE is valid for both non-EAV and EAV. This keyword will eliminate unnecessary I/O required to retrieve free space information that is not be required by the caller. DATATYPE=ALL is the default.

**ALL**  Provide all available LSPACE statistics. This is the default

**FRAGINDEX**  Provide the fragmentation index

**INDEX**  Provide free space information related to the VTOC INDEX

**VOLUME**  Provide free space information for the VOLUME

**VTOC**  Provide free space information related to the VTOC

**PLISTVER**

This keyword, if specified on the MF=E form of the LSPACE macro, will generate an MNOTE.

**LSPACE—List Form**

The format of the list form of the LSPACE macro is:
Using the VTOC

```
MF=L or (L,MSG) or (L,EXPMSG) or (L,EXPMSG) or (L,DATA) or (L,EXPDATA)
```

Specifies the list form of the LSPACE macro.

- **L**
  Generates the required constants in the calling program. You can then issue the execute form of the macro, which uses these constants.

- **(L,MSG)**
  Generates the required message return area constants in the calling program. No other parameters are allowed.

- **(L,EXPMSG)**
  Generates the required expanded message return area constants in the calling program. No other parameters are allowed.

- **(L,XEXPMSG)**
  Generates the required extended expanded message return area constants (95-bytes) in the calling program. No other parameters are allowed. Use this keyword to obtain the message data area for all volume sizes including ones with cylinder-managed space.

- **(L,DATA)**
  Generates the required data return area constants in the calling program. No other parameters are allowed.

- **(L,EXPDATA)**
  Generates the required expanded data return area constants in the calling program. No other parameters are allowed. Use the keyword to obtain the data area for all volume sizes including ones with cylinder-managed space.

```
DATATYPE=ALL or FRAGINDEX or INDEX or VOLUME or VTOC
```

This keyword is allowed only when the DATA or EXPDATA keyword is specified. Only the information specified will be returned to the caller. DATATYPE is valid for both non-EAV and EAV. This keyword
Using the VTOC

will eliminate unnecessary I/O required to retrieve free space information that is not be required by the caller. DATATYPE=ALL is the default.

ALL       Provide all available LSPACE statistics. This is the default
FRAGINDEX Provide the fragmentation index
INDEX     Provide free space information related to the VTOC INDEX
VOLUME    Provide free space information for the VOLUME
VTOC      Provide free space information related to the VTOC

PLISTVER=plistver | IMPLIED_VERSION | MAX
This keyword defines the version of the LSPACE parameter list that should be generated for the MF=I form of the LSPACE macro.

PLISTVER=plistver specifies the version of the LSPACE parameter list that should be generated, where plistver is either 1 or 2. This PLISTVER= keyword is required for any macro keys associated with version 2 or larger to be specified. The macro keys associated with each supported version of the macro are listed below:

PLISTVER=1
   PLISTVER=1 is associated with the following macro keys:
       DATA
       EXPMSG
       F4DSCB
       MSG
       SMF

PLISTVER=2
   PLISTVER=2 is associated with the following macro keys:
       XEXPMSG
       EXPDATA
       DATATYPE

When PLISTVER= IMPLIED_VERSION is specified the generated parameter list is the lowest version that allows all of the parameters on the invocation to be processed. When PLISTVER is omitted, the default is the lowest version of the parameter list, which is version 1.

When PLISTVER= MAX is specified, the generated parameter list is the largest size currently supported. This size may grow from release to release thus possibly affecting the amount of storage needed by your program. If your program can tolerate this, IBM recommends that you always specify MAX when creating the list form parameter list as that will ensure that the list form parameter list is always long enough to hold whatever parameters might be specified on the execute form.

LSPACE–DSECT Form
The format of the DSECT form of the LSPACE macro is:
Using the VTOC

MF=D or \((D,\text{MSG})\) or \((D,\text{EXPMSG})\) or \((D,\text{XEXPMSG})\) or \((D,\text{DATA})\) or \((D,\text{EXPDATA})\)

Specifies the DSECT form of the LSPACE macro.

- \(D\) Generates a DSECT that maps the LSPACE parameter list. No other parameters are allowed. See Table 7 on page 29 for the format of the LSPACE parameter list.
- \((D,\text{MSG})\) Generates a DSECT that maps the message return area. No other parameters are allowed. For the format of the area, see “Message Return Area” on page 31.
- \((D,\text{EXPMSG})\) Generates a DSECT that maps the expanded message return area. No other parameters are allowed. For the format of the area, see “Expanded Message Return Area” on page 33.
- \((D,\text{XEXPMSG})\) Generates a DSECT that maps the extended expanded message return area (95-bytes). No other parameters are allowed. Use this keyword to obtain the message data area for all volume sizes including ones with cylinder-managed space. For the format of the area, see “Expanded Message Return Area” on page 33.
- \((D,\text{DATA})\) Generates a DSECT that maps the data return area. No other parameters are allowed. For the format of the area, see “Data Return Area” on page 33.
- \((D,\text{EXPDATA})\) Generates a DSECT that maps the base and expanded data return area. No other parameters are allowed. Use the keyword to obtain the data area for all volume sizes including ones with cylinder-managed space. For the format of the area, see “Data Return Area” on page 33.

PLISTVER=plistver | MAX

This keyword defines the version of the LSPACE parameter list that should be generated for the MF=D form of the LSPACE macro.

PLISTVER=plistver specifies the version of the LSPACE parameter list that should be generated, where plistver is either 1 or 2. This PLISTVER= keyword is required for any macro keys associated with version 2 or larger to be specified. The macro keys associated with each supported version of the macro are listed below:

PLISTVER=1

PLISTVER=1 is associated with the following macro keys:

- DATA
- EXPMSG
- F4DSCB
- MSG
SMF

PLISTVER=2

PLISTVER=2 is associated with the following macro keys:

- XEXPMSG
- EXPDATA
- DATATYPE

When PLISTVER= MAX is specified, the generated parameter list is the largest size currently supported. This size may grow from release to release thus possibly affecting the amount of storage needed by your program. If your program can tolerate this, IBM recommends that you always specify MAX when creating the list form parameter list as that will ensure that the list form parameter list is always long enough to hold whatever parameters might be specified on the execute form.

When PLISTVER is omitted, the default is the lowest version of the parameter list mapping.

The next five flags pertain to the DATATYPE keyword values:

- **LSPAFRSI**: Volume is specified, the return of volume free space information is requested
- **LSPAFRVT**: Vtoc is specified, the return of vtoc free space information is requested
- **LSPAFRVX**: Index is specified, the return of index free space information is requested
- **LSPAFRFI**: Fragindex is specified, the return of the fragmentation index is requested
- **LSPAFALL**: All is specified or defaulted. The return of all free space information is requested, including the frag index

| LSPARES2  | 25(X'19') | 3    | Reserved                                                                     |
| LSPARES3  | 26(X'1A') | 20   | Reserved                                                                     |

For more information about the LSPACE return code, subfunction code, and the subfunction return and reason codes, see Table 8 on page 32 and **z/OS DFSMSdfp Diagnosis**.
Return Codes from LSPACE
Control returns to the instruction following the instructions generated by the LSPACE macro.

See Table 8 on page 32 for a description of the LSPACE return codes.

LSPACE returns four bytes of diagnostic information in register 0. See the “DADSM/CVAF Diagnostic Aids” section of z/OS DFSMSdfp Diagnosis for a description of this information.

LSPACE Information Return Areas
The LSPACE macro returns status information to the parameter list and, optionally, returns volume information to any of the four following caller requested return areas.

Requests for the MSG, EXPMSG, XEXPMSG, DATA, and EXPDATA areas are mutually exclusive. LSPACE checks to ensure that the storage key of each information return area is equal to the caller's key or that the caller is authorized prior to its use.

Message Return Area: LSPACE returns information to a 30-byte message return area (Figure 5). If you provide a message return area with the MSG option, LSPACE returns EBCDIC text, qualified by return codes as shown in Table 8 on page 32.

<tbody>
<tr>
<td>16(X'10')</td>
<td>No text returned (invalid parameter list or SMF indicator). This return code indicates a parameter list error, which can be a bad parameter list storage key, parameter list ID is invalid (not set to ‘LSPA’), or the parameter list size is not sufficient.</td>
</tr>
<tr>
<td>20 (X'14')</td>
<td>No text returned (processing error in LSPACE)</td>
</tr>
</tbody>
</table>

**Expanded Message Return Area:** LSPACE returns information to a 40-byte expanded message return area (Figure 6). By providing an expanded message return area with the EXPMSG option, LSPACE returns EBCDIC text, qualified by return codes as shown in Table 8 on page 32.

Even though the expanded message return area displays the same return code information as the standard message return area, the space information provided for return code zero consists of six-digit values (aaaaaa instead of aaaa).

</table>

Beginning of the base data return area: For DATA and EXPDATA requests, the following 32 bytes if requested or defaulted by the DATATYPE keyword will be returned. They represent statistics that describe the entire volume. LSPDFO and LSPDVIRS are not applicable to volume statistics.

**LSPDEVFS:** Free space statistics from the entire volume. For volumes with cylinder-managed space (LSPDCYLM = '1') these statistics represent space from both the track and cylinder-managed space on the volume. See LSPDTMFS for statistics from the track-managed space on the volume.

**Format-4 DSCB Return Area**: If you provide a format-4 DSCB return area with the F4DSCB option, LSPACE returns information to it as described in Table 4 on page 11.

**LSPACE Examples**

The following example returns free space information in the message return area.

LSPAMFIM LSPACE MSG=MYMSG, UCB=(R10), MF=I

The following example returns free space information in the data return area.

LSPAMFID LSPACE DATA=MYDATA, UCB=(R10), MF=I

The following example uses the list form of the macro to define the parameter list, and the execute form to refer to the same parameter list.
Reading DSCBs from the VTOC Using OBTAIN

The following section discusses using the OBTAIN routine to read a DSCB. You can specify either the data set name or the absolute device address.

OBTAIN does not support z/OS UNIX files. You will receive unpredictable results if you issue OBTAIN for an z/OS UNIX file.

Reading a DSCB by Data Set Name

If you specify a data set name using OBTAIN and the CAMLST SEARCH option, the OBTAIN routine reads the 96-byte data portion of the format-1 DSCB and the absolute track address of the DSCB into virtual storage. The absolute track address is a 5-byte field in the form CCHHR that contains zeros VIO data sets.

The format of the OBTAIN and CAMLST macros is:

```
label OBTAIN-listname_addrx

NUMBERDSCB=number_dscbs

NOTOK
EADSCB= OK
```

```
listname CAMLST-SEARCH-,dsname_relexp-,vol_relexp-,wkarea_relexp-

NUMBERDSCB=number_dscbs

EADSCB= OK
```

- **listname_addrx**
  - Points to the parameter list (labeled listname) set up by the CAMLST macro instruction.

- **SEARCH**
  - Code this operand as shown.

- **dsname_relexp**
  - Specifies the virtual storage location of a fully-qualified data set name. The area that contains the name must be 44 bytes long.

  **Tip:** A DSNAME of 44 bytes of X'04' (X'040404...04') can be used to read a format-4 DSCB.

- **vol_relexp**
  - Specifies the virtual storage location of the 6-byte volume serial number on which the DSCB is located.
Using the VTOC

**wkarea_relexp**
Specifies the virtual storage location of a 140-byte work area that you must define.

**NUMBERDSCB**
Specifies a value between 0 and 255 that designates the number of consecutive 140-byte return areas that are provided in wkarea_relexp. The system treats a value of 0 as a 1. Currently the system does not support a chain of more than 12 DSCBs for one data set, but it is valid for you to provide an area that is longer than currently needed. The system verifies that the provided area is valid. When you provide an area that is long enough to contain more than one DSCB, obtain processing will return DSCBs for the requested data set name in logical VTOC order until all the 140-byte return areas are used. The logical VTOC order is a format-1 DSCB, followed by zero or more format-3 DSCBs or a format-8 DSCB, followed by one or more format-9 DSCBs, followed by zero or more format-3 DSCBs. No absolute maximum number of DSCBs for a data set should be assumed. The actual number of DSCBs are returned in a field located in the first 140-byte return area.

On the OBTAIN macro you can code a register number or symbol for a register number in parentheses. It means that the specified register contains the number of DSCBs that can fit in the return area. If you code the NUMBERDSCB parameter on OBTAIN, the macro execution stores the value in the CAMLST area. You cannot code a register on the CAMLST macro.

Note that for programs run on a pre-z/OS R10 system that do not support this keyword, the NUMBERDSCB value will be treated as if it were 1.

**EADSCB**
Specifies whether this program supports data sets with format-8 and format-9 DSCBs. Such data sets can appear on extended address volumes.

**EADSCB=OK**
Code **EADSCB=OK** when your program does not support data sets that have format-8 and format-9 DSCBs. The extent descriptors in DSCBs for a data set described with these formats may have track addresses that contain cylinder addresses 65,520 or larger. **EADSCB=OK** is accepted for data sets described by all DSCB types, including format-1 DSCBs, regardless of the volume size where the data set resides. Your program can also run on an older level of the system that does not support this keyword. In these cases, **EADSCB=OK** is ignored. **EADSCB=OK** sets byte 2 bit 4 in the OBTAIN parameter list to on.

**EADSCB=NOTOK**
Code **EADSCB=NOTOK** when your program does **not** support DSCBs that describe data sets with format-8 and format-9 DSCBs. **EADSCB=NOTOK** is the default when the EADSCB keyword is not specified.

When **EADSCB=NOTOK** is coded or assumed by default, OBTAIN will set return code 24 if the target of the OBTAIN request has a format-8 DSCB.
Using the VTOC

**EADSCB=NOTOK** sets byte 2 bit 4 in the OBTAIN parameter list to zero.

**Example:** In the following example, the format-1 DSCB for data set A.B.C is read into virtual storage using the SEARCH option. The serial number of the volume containing the DSCB is 770655.

```
  OBTAIN DSCBABC READ DSCB FOR DATA
  * SET A.B.C INTO DATA
  * AREA NAMED WORKAREA
```

```
DSCBABC DC CL44 'A.B.C' DATA SET NAME
DSABC DC CL44 'A.B.C' DATA SET NAME
VOLNUM DC CL6 '770655' VOLUME SERIAL NUMBER
WORKAREA DS 140C 140-BYTE WORK AREA
```

**Recommendation:** Check the return codes.

The OBTAIN macro instruction points to the CAMLST parameter list. SEARCH, the first operand of CAMLST, specifies that a DSCB be read into virtual storage using the data set name at the address indicated in the second operand. DSABC specifies the virtual storage location of a 44-byte area containing the fully-qualified name of the data set whose format-1 DSCB is to be read. VOLNUM specifies the virtual storage location of a 6-byte area in which you have placed the serial number of the volume containing the required DSCB. WORKAREA specifies the virtual storage location of a 140-byte work area into which the DSCB is to be returned.

Control is returned to your program at the next executable instruction following the OBTAIN macro instruction. If the DSCB has been successfully read into your work area, register 15 contains zeros. Otherwise, register 15 contains one of the return codes shown in Table 10.

**Return Codes from OBTAIN (Reading by Data Set Name)**

*Table 10. DADSM OBTAIN Return Codes*

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0(X'00')</td>
<td>Successful completion of OBTAIN routine.</td>
</tr>
<tr>
<td>4(X'04')</td>
<td>The required volume was not mounted.</td>
</tr>
<tr>
<td>8(X'08')</td>
<td>The format-1 DSCB was not found in the VTOC of the specified volume.</td>
</tr>
<tr>
<td>12(X'0C')</td>
<td>A permanent I/O error was encountered, or an invalid format-1 DSCB was found when processing the specified volume, or an unexpected error return code was received from CVAF (common VTOC access facility).</td>
</tr>
<tr>
<td>16(X'10')</td>
<td>Invalid work area pointer.</td>
</tr>
<tr>
<td>24(X'18')</td>
<td>Data set has a format-8 DSCB and EADSCB=NOTOK is in effect</td>
</tr>
<tr>
<td>24(X'1C')</td>
<td>Internal error with EADSCB=NOTOK in effect.</td>
</tr>
</tbody>
</table>

On return from SEARCH requests, the first 103 bytes of the first 140 byte return area will contain:

- The 96 byte data portion of the format-1, format-4, or format-8 DSCB
- Followed by 5 bytes that contain the absolute track address (CCHHR) of this DSCB. For VSAM object names that appear in the catalog, but not in the VTOC or VIO data sets, these 5 bytes contain zeros.
- Followed by a 2 byte count of the total number of DSCBs associated with the data set DSCB, even if there are insufficient return areas into which to read them.
Using the VTOC

all. This count includes all DSCB types that could describe a data set. Set to zero for DSCBs constructed from catalog when DSCBs are not present in the VTOC.

- If the request specified multiple DSCBs, only the format-1 or format-8 pseudo DSCB will be returned when the DSCB was not found in the VTOC and had to be constructed from Catalog. No forward chain pointer to the next DSCB will be present in this returned DSCB. The remaining 140 byte return areas will contain the entire 140 byte key and data portions of the associated DSCB.

If the request did not specify multiple DSCBs, a format-1 or format-8 pseudo DSCB will be returned when the DSCB was not found in the VTOC and had to be constructed from Catalog. No forward chain pointer to the next DSCB will be present in this returned DSCB. After executing these macro instructions, the first 96 bytes of the work area contain the data portion of the format-1 or format-4 DSCB; the next 5 bytes contain the absolute track address (CCHHR) of the DSCB. For VSAM or VIO data sets, these 5 bytes contain zeros.

Reading a DSCB by Absolute Device Address

You can read a DSCB from a VTOC using OBTAIN and the CAMLST SEEK option. Specify the SEEK option by coding SEEK as the first operand of the CAMLST macro and by providing the absolute device address of the DSCB you want to read, unless the DSCB is for a VIO data set. Only the SEARCH option can be used to read the DSCB of a VIO data set.

The format of the OBTAIN and CAMLST macros is:

```
label
OBTAIN listname_addrx NUMBERDSCB=number_dscbs

EADSCB= NOTOK OK
```

```
lstname CAMLST SEEK,dsname_relexp,,cchhr_relexp,,vol_relexp,,
-wkarea_relexp NUMBERDSCB=number_dscbs

EADSCB= NOTOK OK
```

- **listname**
  
  Label of the CAMLST macro instruction.

- **SEARCH**
  
  Code this operand as shown when calling obtain to read by the passed data set name.

- **SEEK**
  
  Code this operand as shown when calling obtain to read by the passed CCHHR device address.

- **dsname_relexp**
  
  For SEARCH requests, specifies the virtual storage location of a fully-qualified data set name. The area that contains the name must be 44-bytes long.
For SEEK requests, specifies the virtual storage location of the 5-byte absolute device address (CCHHR) of a DSCB.

Specifies the virtual storage location of the 6-byte volume serial number on which the DSCB is located.

For all requests, specifies the virtual storage location of a 140-byte work area, or larger, that must be defined.

Specifies a value between 0 and 255 that designates the number of consecutive 140-byte return areas that are provided in wkarea_relexp. The system treats a value of 0 as a 1. Currently the system does not support a chain of more than 12 DSCBs for one data set, but it is valid for you to provide an area that is longer than currently needed. The system verifies that the provided area is valid. When you provide an area that is long enough to contain more than one DSCB, OBtain processing will return DSCBs for the requested data set name in logical VTOC order until all the 140-byte return areas are used. The logical VTOC order is a format-1 DSCB, followed by zero or more format-3 DSCBs or a format-8 DSCB, followed by one or more format-9 DSCBs, followed by zero or more format-3 DSCBs. No absolute maximum number of DSCBs for a data set should be assumed. When the target of the seek operation is not a format-1 or format-8 DSCB, the NUMBERDSCB value is treated as if it were 1 and only that single DSCB will be returned.

On the OBTAIN macro, you can code a register number or symbol for a register number in parentheses. This means that the specified register contains the number of DSCBs that can fit in the return area. If you code the NUMBERDSCB parameter on OBTAIN, the macro execution stores the value in the CAMLST area. You cannot code a register on the CAMLST macro.

Note that for programs run on a pre-z/OS R10 system that do not support this keyword, the NUMBERDSCB value will be treated as if it were 1.

Specifies whether this program supports data sets with format-8 and format-9 DSCBs. Such data sets can appear on extended address volumes.

Code EADSCB=NOTOK when your program does not support data sets that have format-8 and format-9 DSCBs. The extent descriptors in DSCBs for a data set described with these formats may have track addresses that contain 28-bit cylinder numbers. EADSCB=OK is accepted for data sets described by all DSCB types, including format-1 DSCBs, regardless of the volume size where the data set resides. Your program can also run on an older level of the system that does not support this keyword. In these cases, EADSCB=OK is ignored.

EADSCB=OK sets byte 2 bit 4 in the OBTAIN parameter list to on.

Code EADSCB=NOTOK when your program does not support
Using the VTOC

DSCBs that describe data sets with format-8 and format-9 DSCBs. **EADSCB=NOTOK** is the default when the EADSCB keyword is not specified.

When **EADSCB=NOTOK** is coded or assumed by default, OBTAIN will set return code 24 if the target of the OBTAIN request has a format-8 or format-9 DSCB. OBTAIN will not check format-3 DSCB extent ranges for track addresses that contain 28-bit cylinder numbers.

**EADSCB=NOTOK** sets byte 2 bit 4 in the OBTAIN parameter list to zero.

**Example:** In the following example, the DSCB at actual-device address X'00 00 00 01 07' is returned in the virtual storage location READAREA, using the SEEK option. The DSCB resides on the volume with the volume serial number 108745.

```
OBTAIN ACTADDR READ DSCB FROM
  * LOCATION SHOWN IN CCHHR
  * INTO STORAGE AT LOCATION
  * NAMED READAREA

ACTADDR CAMLST SEEK,CCHHR,VOLSER,READAREA
CCHHR DC XL5'0000000107' ABSOLUTE TRACK ADDRESS
VOLSER DC CL6'108745' VOLUME SERIAL NUMBER
READAREA DS 140C 140-BYTE WORK AREA
```

**Recommendation:** Check the return codes.

The OBTAIN macro points to the CAMLST parameter list. SEEK, the first operand of CAMLST, specifies that a DSCB be read into virtual storage. CCHHR specifies the storage location containing the 5-byte actual-device address of the DSCB. VOLSER specifies the storage location containing the serial number of the volume where the DSCB resides. READAREA specifies the storage location to which the 140-byte DSCB is to be returned.

Control is returned to your program at the next executable instruction following the OBTAIN macro instruction. If the DSCB has been read into your work area, register 15 contains zeros. Otherwise, register 15 contains one of the return codes shown in Table 11.

**Return Codes from OBTAIN (Reading by Absolute Device Address)**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0(X'00')</td>
<td>Successful completion of OBTAIN routine.</td>
</tr>
<tr>
<td>4(X'04')</td>
<td>The required volume was not mounted.</td>
</tr>
<tr>
<td>8(X'08')</td>
<td>The format-1 DSCB was not found in the VTOC of the specified volume or an &quot;alien&quot; (non-VSAM) request was returned from Catalog.</td>
</tr>
<tr>
<td>12(X'0C')</td>
<td>A permanent I/O error was encountered or an unexpected error return code was received from CVAF.</td>
</tr>
<tr>
<td>16(X'10')</td>
<td>Invalid work area pointer.</td>
</tr>
<tr>
<td>20(X'14')</td>
<td>The SEEK option was specified and the absolute track address (CCHHR) is not within the boundaries of the VTOC.</td>
</tr>
<tr>
<td>24(X'18')</td>
<td>Data set has a format-8 or format-9 DSCB and <strong>EADSCB=NOTOK</strong> is in effect</td>
</tr>
<tr>
<td>28(X'1C')</td>
<td>Internal error with EADSCB=NOTOK in effect.</td>
</tr>
</tbody>
</table>
On return from SEEK requests with multiple DSCBs requested, the entire 140 bytes of the first return area will contain the 140 byte key and data portions of the DSCBs read from the volume. The remaining 140 byte return areas will contain the entire 140 byte key and data portions of the DSCBs chained from this first DSCB until the chain of DSCBs has ended or until the 140 byte return areas are exhausted.

On return from SEEK requests without multiple DSCBs specified, the first return area will contain the entire 140 byte key and data portions of the DSCB read from the user's passed device address.

Releasing Unused Space from a DASD Data Set Using PARTREL

DADSM supports the release of unused space that is allocated to sequential or partitioned data sets, PDSEs, sequential extended-format data sets, and VSAM extended format data sets. The partial release function is called when:

- The data set is closed (if the RLSE subparameter of SPACE was specified on its DD statement or the storage administrator specified an appropriate value for the partial release option in the management class definition).
- A restart is processing from a checkpoint taken before the data set was extended.
- DFSMShsm performs a space management cycle and an appropriate value is specified in the management class definition.
- A PARTREL macro is issued.

For an extended address volume, partial release processing will release space on multicylinder unit boundaries when the last used track is in an extent in cylinder-managed space. For VSAM striped data sets where at least one stripe is on an extended address volume, partial release processing will ensure the stripes remain the same size. For these reasons, it is possible that the high allocated track after the release may be larger than the last used track or that no space could be released.

The PARTREL Macro

The PARTREL macro supports sequential and partitioned data sets on volumes with or without indexed VTOCs. It supports PDSEs and extended format data sets on SMS-managed volumes for which indexed VTOCs are required. PARTREL does not support z/OS UNIX files. You will receive unpredictable results if you issue PARTREL for z/OS UNIX files.

PARTREL can be coded in the execute, DSECT, and list forms, but not the standard form. The calling program:

- Must be APF authorized.
- Must have allocated the volume to this task and must ensure it stays mounted during the PARTREL function.
- Must ensure that the data set is not open.
- Must not hold any locks or an ENQ on the VTOC.
- Must provide the address of an available standard register save area in general register 13.
- Can provide the associated parameter list and parameters in storage either above or below 16MB virtual.
- Can be in any storage key.
- Can run in either supervisor or problem program state.
Using the VTOC

- Can be in either 24 or 31-bit addressing mode.
- Requires the address of a UCB, not a UCB copy.

**PARTREL—Execute Form**

The format of the execute form of the PARTREL macro is:

```
PARTREL -label- -MF-(E,-addr or (E,(reg)))-
             -DSN-(addr or (reg))-
             -ERASE-Y or N or T-
             -MODE-S or U or P-
             -TIOT-NOE or NO-
             -UCB-(reg) or (0-12)-

VSAMTYPE-K or V or R or S or A-
VSAMFMT-S or E or T or D-
VSAMCLSR-SE or LE or E or N-
VSAMTRKS-(addr or (reg))-
VSAMSEC-B or N or Y or N-
```

Except for MODE, all parameters default to the current contents of the parameter list. The MODE parameter defaults to PGM.

Descriptions of these parameters include information about DADSM processing. The descriptions use the term value to designate the parameter value passed to DADSM. The value can be:
- Specified as a parameter on the PARTREL macro
- Provided as the parameter's associated value in the parameter list
- Defined by DADSM from the information provided in the request.

**MF=(E,-addr) or (E,(reg))**
- Specifies the execute form of the macro and the address of an existing PARTREL parameter list.
  
  *addr*—RX-type address, *(reg)*—(0-12)
- Specifies the PARTREL parameter list address.

**DSN=addr or (reg)**
- Specifies the address of a 44-byte area that contains the data set name. The name must be left-justified, with any unused bytes defined as blanks. For a VSAM file, you must specify the component name, not the cluster name.
  
  *addr*—RX-type address, *(reg)*—(0), (2-12)
- You must provide a value for DSN.

**ERASE=** YES or NO or TEST
- Specifies a residual data erase attribute (see "Deleting a Data Set from the VTOC" on page 143 for a description of erase attributes).
- ERASE=YES and ERASE=NO are mutually exclusive. The default is ERASE=TEST. If you specify VSAMTYPE, ERASE is ignored.
- **ERASE=** YES
  - Specifies that the area being released should be
erased (overwritten with zeros) before it is made available for new allocations.

**ERASE=NO**  Specifies that the area should not be erased. This specification overrides the RACF erase attribute.

**ERASE=TEST**  Specifies that the associated RACF erase attribute is to be used.

**MODE=PGM or SUP**  Specifies that PARTREL is requested by a caller in problem program state (MODE=PGM) or in supervisor state (MODE=SUP). MODE=PGM is the default.

If the calling program is in supervisor state (and wants control returned in supervisor state), the value of MODE must be SUP. If the calling program is in problem program state, the value of MODE must be PGM.

**TIOT=ENQ or NOENQ**  Specifies the desired SYSZTIOT and SYSDSN ENQ processing within partial release. The default is ENQ. If you specify VSAMTYPE, TIOT is ignored.

**TIOT=ENQ**  Specifies that partial release is to do its normal, exclusive ENQ on SYSZTIOT and SYSDSN. If either of these ENQ requests fails, PARTREL terminates the request with a return code of X'08'.

**TIOT=NOENQ**  Specifies that the caller has provided the necessary serialization. If partial release finds that the caller does not have exclusive use of SYSDSN, PARTREL terminates the request with a return code of X'24'.

When TIOT=NOENQ is specified and flag PRLTIOTX is set on, the ENQ TEST is not executed. This is a dangerous option and can cause data corruption. IBM recommends that you not set PRLTIOTX.

**UCB=(reg)**  Specifies the address of the UCB for the volume on which the subject data set resides. The UCB address can be for a captured UCB, or for an actual UCB above or below the 16MB line. For 31-bit callers, the high-order byte is part of the UCB address and must be cleared to zeros if a 24-bit UCB address is being passed. The volume must be mounted, and you must ensure that it remains mounted. Use the address of a UCB, not a UCB copy.

(reg)-(0), (2-12)  specifies a register containing the UCB address for the device.

**VSAMTYPE=KSDS or ESDS or RRDS or LDS or VRRDS**  Specifies the type of VSAM data set.

Currently, only extended format VSAM data sets are supported.

If you specify VSAMTYPE, you must also specify VSAMFMT, VSAMCLLR, VSAMSEC, and VSAMTRKS.

If you specify VSAMTYPE, the ERASE= parameter is ignored.
Using the VTOC

VSAMTYPE=KSDS
Specifies a VSAM key-sequenced data set.

VSAMTYPE=ESDS
Specifies a VSAM entry-sequenced data set.

VSAMTYPE=RRDS
Specifies a VSAM fixed-length relative record data set.

VSAMTYPE=LDS
Specifies a VSAM linear data set.

VSAMTYPE=VRRDS
Specifies a VSAM variable-length relative record data set.

VSAMFMT=EXTD or STD
Specifies the format of the data set.

VSAMFMT=EXTD
Specifies that this is an extended format data set.

VSAMFMT=STD
Specifies that this is not an extended format data set. If you specify STD catalog services returns an error to partial release.

VSAMCLLR=VSAMCLSE or NOTVSAM
Specifies the caller.

VSAMCLLR=VSAMCLSE
Specifies that the caller is VSAM CLOSE.

VSAMCLLR=NOTVSAM
Specifies that the caller is other than VSAM CLOSE.

VSAMSEC=BYPASS or NOBYPASS
Specifies if security checking is to be performed

VSAMSEC=BYPASS
Specifies that security checking is not to be performed.

VSAMSEC=NOBYPASS
Specifies that security checking is to be performed.

VSAMTRKS=addr or (reg)
Specifies the address of a 4-byte area that is used to contain the number of tracks released for this data set.

You must provide an address for VSAMTRKS only if you code VSAMTYPE.

addr—RX-type address, (reg)-(0), (2-12)
For a VSAM extended format data set, PARTREL returns a value which is the sum of all the space released for all the parts of the data set.

PARTREL—List Form
The format of the list form of the PARTREL macro is:
Restrictions:
1. The execute form of the UCB parameter cannot be specified on the list form.
2. The list form MODE parameter is for documentation only. The value of MODE is as specified or defaulted on the execute form.

For an explanation of the parameters, see the execute form.

PARTREL–DSECT Form

The format of the DSECT form of the PARTREL macro is:

```
PARTREL  MF=D
```

Description: The following example provides a description of the parameter list:
```
++PRPLID DS  CL4 EBCDIC 'PREL' FOR PARTREL
+PRLENGTH DS  AL2 LENGTH OF PARAMETER LIST
+PRRCDE DS  H ERROR CODE RETURNED FROM
++ PARTIAL RELEASE
+PRFLAG DS  XL1 PARAMETER FLAG BYTE
+PRPGM EQU X'00' MODE=PGM (PROBLEM PROGRAM)
+PRLSUP EQU X'80' MODE=SUP (SUPERVISOR STATE)

```
Return Codes From PARTREL

Control returns to the instruction following the last instruction generated by the PARTREL macro. Register 15 contains the applicable PARTREL return code.

If an error occurs, PARTREL issues message IEC614I, consisting of failure-related status information.

- If an error results from a CVAF function, the subfunction return code field contains the CVAF return code, and the subfunction reason code field contains the CVAF status code (CVSTAT).
- If an error results from the execution of an EXCP channel program, the subfunction return code and reason code fields contain either:
  - The ECB completion code and the CSW channel status, if the ECB completion code is not X'41' and the channel status is not zero.
  - The sense bytes (two) from the IOB, if the ECB completion code is X'41' and there is no channel status.
- If an error results from an RACF invocation, the subfunction return code and reason code fields contain the RACF return code and reason code.

Table 12 describes the conditions indicated by the PARTREL return code.

Exception: This is a cumulative list of DADSM partial release return codes. Some of these codes might not apply to the PARTREL macro.

**Table 12. DADSM PARTREL Return Codes**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>

</tr>
</tbody>
</table>
Creating (Allocating) a DASD Data Set Using REALLOC

The REALLOC macro builds a parameter list to allocate a new data set. You can code the macro in the execute, DSECT, and list forms, but not in the standard form. The calling program includes the following requirements and options:

- Must be APF authorized
- Must allocate the volume to this address space and must ensure it stays mounted during the REALLOC function
- Must not hold any locks
- Can provide the associated parameter list and parameters in storage either above or below 16MB
- Can use any storage key
- Can run in either supervisor or problem program state
- Can be in either 24 or 31-bit addressing mode
- Must note that REALLOC does not call RACF or catalog management
- Must note that REALLOC cannot create data sets on SMS-managed volumes (SMS-managed data sets can be created through JCL or dynamic allocation)
- Must note that REALLOC cannot create PDSEs, HFS data sets, or extended format data sets
- Requires the address of a UCB, not a UCB copy.
Using the VTOC

In addition, the calling program must provide the REALLOC macro with one or more model DSCBs. You can use the OBTAIN macro to get the DSCBs from other data sets and modify them for the request. DADSM uses these model DSCBs to validate the allocation request, and to construct the DSCBs written to the VTOC for the requested allocation.

The ALLOC parameter for the REALLOC macro defines the allocation request as either absolute (ABS) or movable (MOV).

The requested data set's allocation is not sensitive to its placement on the volume. This is not a reference to the format-1 DSCB bit DS1DSGU (unmovable bit), that can be either on or off in an ALLOC=MOV request's partial DSCB. That is, the data set can subsequently contain location-dependent information.

An absolute request is limited to a single volume with indexed VTOC support. An absolute request provides a set of allocation parameters, a full format-1 or format-8 DSCB, and an optional format-3 DSCB, that describe the space and attributes of the desired data set. An optional format-9 DSCBs can also be provided to pass additional attributes:

- Support is provided for, but not limited to, data sets with a user label extent.
- The number of extents to be allocated, and their absolute placement on the volume, are defined by the format-1 or format-8 DSCB and one (optional) format-3 DSCB.

For an absolute request, the following checks are performed prior to writing the passed DSCBs. The type of checks depend on the volume for which the REALLOC macro is issued.

- For any volume, a passed DSCB format must not describe a format that is not supported. The supported formats in REALLOC processing are 1, 3, 8, or 9.
- For an extended address volume, a passed format-1 DSCB must not describe extents that contain cylinder addresses larger than 65,519.
- A passed format-1, format-3, or format-8 DSCB must not describe extents that contain cylinder addresses larger than the highest cylinder address of the volume.
- For an extended address volume, a passed format-8 DSCB must not describe a data set organization that is not EAS eligible.
- For an extended address volume, a passed format-3 or format-8 DSCB must not describe an extent that begins on cylinder address 65519 or lower and that ends on cylinder address 65520 or higher.
- For a volume that is not an extended address volume, a passed format-8 or format-9 DSCB is not allowed.

The partial DSCB (mapped by the IECPDSCB macro) consists of the first 106 bytes of a format-1 DSCB followed by 10 bytes in which the primary space request and number of directory blocks are specified.

A movable request is limited to a single volume with or without indexed VTOC support. A movable request provides a set of allocation parameters and a partial DSCB that describe the attributes of the desired data set:

- Absolute track allocated data sets are not supported.
- The maximum number of extents that can be allocated is determined by the data set organization (PD1DSORG) and the system managed storage indicators.
Using the VTOC

(PD1SMSFG) bytes in the partial DSCB. If PD1DSORG indicates a VSAM data set organization, the maximum number of extents is 7257 across multiple volumes, 123 on a single volume.

REALLOC—Execute Form

The format of the execute form of the REALLOC macro is:

```
label REALLOC MF=(E,addr) (E,(reg))

,ALLOC=MOV

,DSSIZE=addr (reg)

,F3DSCB=addr (reg)

,F9DSCB=addr (reg)

,MNUF9=number_dscbs (reg)

,PDSCB=addr (reg)

,PSDIR=addr (reg)

,UCB=(reg)

```

All parameters except ALLOC default to the current contents of the referenced parameter list. The ALLOC parameter defaults to MOV.

**MF=(E,addr) or (E,(reg))**

Specifies the execute form of the macro and the address of a REALLOC parameter list.

\textit{addr}—RX-type address, \textit{(reg)}—(0-12)

Specifies the address of the REALLOC parameter list.

**ALLOC=ABS or MOV or NON**

Specifies one of the following:

**ALLOC=ABS**

Specifies that the REALLOC request is for absolute extents.

**ALLOC=MOV**

Specifies that the REALLOC request is for a movable allocation.

ALLOC=MOV is the default.

**ALLOC=NON**

Specifies that the REALLOC request is to rebuild the free space chain on an unindexed VTOC without allocating a data set. Expect a DADSM create return code X'3D'.

**DSSIZE=addr or (reg)**

Specifies the size of the data set to be allocated in tracks. The DSSIZE parameter is invalid for an ALLOC=ABS request.

\textit{addr}—RX-type address

Specifies the address of a word that contains the data set size.

\textit{(reg)}—(0), (2-12)

Specifies a register that contains the size of the data set.
Using the VTOC

Provide a value for DSSIZE for an ALLOC=MOV request. The PDPIPQTY field of the partial DSCB is ignored.

REALLOC assumes that you have provided the value of DSSIZE in tracks even if the PD1SCALO flag byte of the partial DSCB indicates a cylinder request (X'C0'), or an average block request, (X'40').

If the PD1SCALO flag byte of the partial DSCB indicates a cylinder request (X'C0'), or an average block with round request (X'41'), the value of DSSIZE is rounded up to the next full cylinder.

F2DSCB
This parameter still is supported for assembly purposes, but the system no longer supports it when your program executes. This because you can no longer create indexed sequential data sets

F3DSCB=addr or (reg)
Specifies the in-storage address of a format-3 DSCB. This DSCB is used as a model to construct the allocated data set's format-3 DSCB.

The F3DSCB parameter is invalid for an ALLOC=MOV request.

addr–RX-type address, (reg)–(0), (2-12)
Provide a value for F3DSCB in an ALLOC=ABS request when the DS1NOEPV byte of the format-1 DSCB indicates more than three extents (or when the DS1NOEPV byte indicates more than two extents and the DS1EXT1 extent type indicator is X'40', a user label extent).

The REALLOC request is limited to a maximum of 16 extents when the F3DSCB keyword is specified. No more than one format-3 DSCB can be specified.

Enter a value of zero for the F3DSCB in an ALLOC=ABS request when the DS1NOEPV byte of the format-1 DSCB indicates that there are less than four extents (or when the DS1NOEPV byte indicates that there are less than three extents and the DS1EXT1 extent type indicator is X'40', a user label extent).

F9DSCB=addr or (reg) or 0
Specifies the address of a caller-provided contiguous partial format-9 DSCB data area where attribute information from it is to be used when creating a format-9 DSCB. Specify this keyword if you wish to pass format-9 DSCB attribute information to REALLOC processing. Only attribute information in the format-9 DSCB will be processed. Format-9 DSCBs with a subtype field with a value other than 1 will be ignored. See mapping macro, IECSDSL1.

The number of contiguous partial format-9 DSCBs defined in this data area is defined in the NUMF9=number_dscb keyword or is defaulted to one.

addr–RX-type address
Specifies the address of the partial format-9 DSCB data area.

(reg)–(2-12)
Specifies a register containing the address of the partial format-9 DSCB data area.

0 Specifies that you do not want to pass a partial format-9 DSCB data area.

MINAU=addr or (reg)
Specifies the size of the minimum allocation unit in tracks. All primary extents for this data set are in multiples of this minimum allocation unit. This minimum does not apply to subsequent extensions of the data set.

The MINAU parameter is invalid on an ALLOC=ABS request.
Using the VTOC

addr—RX-type address
  Specifies the address of a word containing the minimum allocation unit.

(reg)–(0), (2-12)
  Specifies a register containing the minimum allocation unit.

The MINAU parameter has no effect on the requested allocation if:

- You provide a value of zero.
- The PD1SCALO flag byte of the partial DSCB indicates either a cylinder request (X'C0') or an average block with round request (X'41').

Otherwise, the value of DSSIZE must be a multiple of the value of MINAU.

NUMF9=number_dscbs or (reg)
  For REALLOC with F9DSCB requests, number_dscbs is an absolute expression or (register) with a value between 0 and 255 that designates the number of consecutive 140-byte partial format-9 DSCB areas that are provided in the F9DSCB=addr. The system treats a value of 0 as a 1 when F9DSCB=addr is specified. Format-9 DSCBs with a subtype field with a value other than 1 are ignored.

PDSCB=addr or (reg)
  Specifies the address of a partial DSCB (for ALLOC=MOV) or the in-storage address of a full format-1 or format-8 DSCB (for ALLOC=ABS). This DSCB is used as a model to construct the allocated data set's format-1 or format-8 DSCB.

addr—RX-type address, (reg)–(0), (2-12)
  Provide a value for the PDSCB parameter and initialize the PD1FMTID field to X'F1' for a format-1 DSCB or to X'F8' for a format-8 DSCB. However, the PDSCB attribute information determines EAS eligibility and whether the actual allocated DSCB allocated is a format-1 or format-8 DSCB.

PDSDIR=addr or (reg)
  Specifies the number of 256-byte directory blocks for a partitioned data set (PDS).

addr—RX-type address
  Specifies an in-storage address of a full word containing the number of 256-byte PDS directory blocks.

(reg)–(0), (2-12)
  Specifies a register containing the number of 256-byte PDS directory blocks.

Provide a value for PDSDIR when partitioned organization is indicated:
- The DS1DSORG flag byte of the format-1 DSCB is X'02' (ALLOC=ABS).
- The PD1DSORG flag byte of the partial DSCB is X'02' (ALLOC=MOV).

For an ALLOC=MOV request, you can specify the value of PDSDIR in the PDDIRQTY field of the partial DSCB. The PDDIRQTY field is used only if the REALLOC parameter list value of PDSDIR is zero.

Do not specify a value for PDSDIR if a PDS is not indicated.

UCB=(reg)
  Specifies the address of the UCB for the volume on which the data set is to be allocated. The UCB address can be for a captured UCB, or for an actual UCB above or below the 16MB line. For 31-bit callers, the high-order byte is part of the UCB address and must be cleared to zeros if a 24-bit UCB.
address is being passed. The volume must be mounted, and remain mounted. Use the address of a UCB, not a UCB copy.

\( (\text{reg})-\{0\}, \ (2-12) \)

Specifies a register containing the UCB address for the device.

**REALLOC–List Form**

The format of the list form of the REALLOC macro follows. See the execute form for an explanation of the parameters.

<table>
<thead>
<tr>
<th>REALLOC–List Form</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
</tr>
<tr>
<td>( \text{MOV} )</td>
</tr>
<tr>
<td>( \text{F3DSCB}=\text{addr} )</td>
</tr>
<tr>
<td>( \text{F9DSCB}=\text{addr} )</td>
</tr>
<tr>
<td>( \text{NUMF9}=\text{number_dscbs} )</td>
</tr>
<tr>
<td>( \text{PDSCB}=\text{addr} )</td>
</tr>
</tbody>
</table>

**Restrictions:**

1. The execute form parameters DSSIZE, MINAU, PDSDIR, and UCB cannot be specified on the list form.
2. The list form's ALLOC parameter affects the tests made by the REALLOC macro during assembly, and the contents of the parameter list.
3. The value of ALLOC is as specified or defaulted on the execute form.

**REALLOC–DSECT Form**

The format of the DSECT form of the REALLOC macro is:

<table>
<thead>
<tr>
<th>REALLOC–DSECT Form</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
</tr>
</tbody>
</table>

**REALLOC Parameter List**

The parameter list for the DSECT form expansion is:

<table>
<thead>
<tr>
<th>Table 13. REALLOC Parameter List</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offset</td>
</tr>
<tr>
<td>--------</td>
</tr>
<tr>
<td>0(X’00’)</td>
</tr>
<tr>
<td>0(X’00’)</td>
</tr>
<tr>
<td>4(X’04’)</td>
</tr>
<tr>
<td>6(X’06’)</td>
</tr>
<tr>
<td>8(X’08’)</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>9(X’09’)</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>...</td>
</tr>
</tbody>
</table>

### Return Codes from REALLOC

Control returns to the instruction following the instructions generated by the REALLOC macro. Register 15 contains the applicable REALLOC return code as shown in [Table 14 on page 54](#).

REALLOC returns 4 bytes of diagnostic information in register 0. See [z/OS DFSMSdfp Diagnosis](#).

If an error occurs, REALLOC issues message IEC614I, consisting of failure-related status information. See [Table 14 on page 54](#) for descriptions of the conditions indicated by the REALLOC return code.

**Exception:** This is a cumulative list of DADSM create return codes. Some of these codes might not apply to the REALLOC macro.
### Table 14. DADSM CREATE Return Codes

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00(X'00')</td>
<td>If the 4 bytes of diagnostic information returned in register 0 are all zeros, this indicates successful data set creation. If they are nonzero, see the DADSM/CVAF Diagnostic Aids section of <a href="#">z/OS DFSMSdfp Diagnosis</a> to determine the failure-related conditions.</td>

### Accessing the VTOC with CVAF Macros

The common VTOC access facility (CVAF) macros and tasks discussed in this section consist of the following:

- CVAFDIR directly accesses one or more DSCBs.
- CVAFDSM obtains volume free space information.
- CVAFFILT reads sets of DSCBs for one or more DASD data sets.
- CVAFSEQ retrieves the following:
  - Data set names from an active VTOC index
  - DSCBs in physical-sequential order
  - DSCBs in data set name order (index required).
- CVAFSTST determines if a DASD volume has an active VTOC index.

["Coding CVAF VTOC Access Macros" on page 73](#) contains descriptions of these macros and examples of their use.

When calling CVAF, your program can be in either 24-bit or 31-bit addressing mode. If it is in 31-bit mode, the control blocks shown in Figure 7 on page 68 might reside above the 16 MB line. All these areas must be accessible in your program's storage key.

**Note:** You must supply a UCB address that matches the caller's AMODE. That is, AMODE=24 requires a 24 bit UCB address, while AMODE=31 requires a 31 bit UCB address.

### Serializing and Updating

CVAF requires that you provide all necessary system resource serialization for your request. You can ensure the integrity of multiple data elements (sets of DSCBs or VIRs) returned by CVAF only if you adequately serialize system resources and avoid multiple CVAFFILT requests for a set of DSCBs or VIRs. Weigh possible system performance loss because of serialization against the potential loss of data integrity.

Updating without adequate serialization might compromise the integrity of the volume's VTOC, the VTOC index, or any associated data set.

CVAF only complies with requests to modify the volume's VTOC or index from authorized programs.

CVAF assumes that an authorized program holds an exclusive RESERVE (or ENQ) on the *qname* (major name) of SYSVTOC, and the *rname* (minor name) of the volume's serial number, with the scope of SYSTEMS. This RESERVE can be made more efficient if Global Resource Serialization or a functional equivalent is active.
Using the VTOC

The SYSVTOC qname does not serialize access to the format-1 or the format-8 DSCB for a data set. You can provide serialization by allocating the data set with disposition OLD, MOD, or NEW (not SHR). This causes the proper ENQ, ensuring that no other job can update that data set's format-1 or format-8 DSCB.

If your program holds the enqueue for the SYSVTOC resource, then no other program can later start and complete a DADSM request. This includes extending or creating a data set on that volume in your own address space. If you try to extend a data set under the same task that holds SYSVTOC, it will be abnormally terminated. If a different task requests SYSVTOC, that task will wait. If your program then requests a resource that is held by that task, the two tasks will be in a deadlock. To prevent deadlocks between tasks in the same address space when either of the tasks has previously enqueued on SYSVTOC, the secondary caller of CVAF must ensure the enqueue bit is on (CV3ENQD) in the CVPL. Other options to get around this limitation are either:

- Allocating a data set so that it does not require secondary extents.
- Requesting that the output data set be on a volume other than the one where the application holds enqueue for the SYSVTOC resource.

Identifying the Volume

If authorized, you can identify the volume to the CVAFDIR, CVAFDSM, CVAFFILT, and CVAFSEQ macros by specifying the address of the UCB. These macros do not accept the address of a UCB copy. If your program is not authorized, specify the address of a SAM or EXCP DEB opened to the volume's VTOC.

The data extent block (DEB) can be obtained by opening a DCB for INPUT, using the RDJFCB and OPEN TYPE=J macros. (After issuing an OPEN TYPE=J macro, the DCB's DCBDEBA field contains the DEB's address.) The DCB's DDNAME must identify a DD statement allocated to the unit whose VTOC is to be accessed. Once your program issues the RDJFCB macro, it must initialize the JFCBDSNM field with the data set name of the format-4 DSCB: 44 bytes of X'04'. The RDJFCB macro is described under "RDJFCB Macro Specification" on page 278; the OPEN macro is described under "OPEN - Initialize Data Control Block for Processing the JFCB" on page 291. For an extended address volume the DCB macro must point to a DCBE where the EADSCB=OK keyword is specified. If you do not code this option, the OPEN function will issue ABEND 113-48 and message IEC142I.

If a CVAF macro call specifies IOAREA=KEEP, a subsequent CVAF call using a different CVAF parameter list (CVPL) might omit the UCB and DEB keywords and supply the IOAREA address from the other CVPL by using the IOAREA keyword.

Generating a CVPL (CVAF Parameter List)

The CVAFDIR, CVAFDSM, CVAFFILT, and CVAFSEQ macros use the CVPL to pass parameters to CVAF. The CVAFTST macro expands to provide its only parameter (UCB address) in register 1, and calls the applicable CVAF module. CVAF returns information related to the CVAF request in the CVPL. The CVAFTST macro will accept the address of a UCB or UCB copy. Unauthorized programs can get a copy of the UCB by using the UCBSCAN macro and specifying the COPY, UCBAREA, CMXTAREA, and DCEAREA keywords. The UCB copy, including the extension, must be below the 16MB line and on a word boundary. Data accessed with the DCEAREA can be above the 16MB line. Refer to z/OS HCD Planning for details.
Using the VTOC

Specifying the CVAFDIR, CVAFDSM, CVAFFILT, or CVAFSEQ macro with MF=L or MF=I (the default) as a subparameter generates a CVPL. Upon return the CV1IVT bit in the CVPL indicates whether the accessed VTOC was indexed or nonindexed. If an error occurs, the CVSTAT field contains feedback data. The CVAF I/O area address is returned in the CVIOAR field and the CVAF filter save area address is returned in the CVFSA field. To use the generated CVPL to execute a different function than was originally specified, use the MF=E keyword.

To specify a CVAF filter request, use a CVPL generated by the CVAFFILT macro. The CVAFFILT macro generates a CVPL 4 bytes longer (total length = X'44') than that generated by the other CVAF macros (total length = X'40'). CVAFFILT request need a longer parm list to accommodate one extra file.

- To get the longer parameter list (X'44' bytes), specify CVPLFSA=YES on the inclusion of the ICVAFPL mapping macro.
- To get the shorter parameter list (X'40' bytes), specify the CVPLX=YES on the inclusion of the ICVAFPL mapping macro.

The ICVAFPL macro maps the CVPL. The format of the CVPL is shown in Table 15.

**Note:** The area starting at CVCTAR5 is generated only when the CVPLX=YES macro variable is specified on the invocation of ICVAFPL.

Using Buffer Lists

A buffer list consists of one or more chained control blocks, each with a header and buffer list entries, obtained and initialized by your program before calling CVAF. The header indicates whether the buffer list is for DSCBs. The entries point to and describe the buffers. You can create buffer lists in two ways:

- Directly, when you fill in the arguments and buffer addresses of DSCBs to be read or written
- Indirectly (by CVAF), when you code the IXRCDS=KEEP and/or MAPRCDS=YES keywords.

The ICVAFBFL macro maps CVAF buffer lists. Table 17 shows the format of a buffer list header. Table 18 on page 60 shows the format of a buffer list entry.

### Buffer List Header

The buffer list header indicates whether the buffer list describes buffers for DSCBs. The DSCB bit must be set to 1 and the VIR bit to zero for CVAF to process a request to read or write a DSCB. Provide buffer lists and buffers in your program's protect key. CVAF uses the protect key and subpool fields in the buffer list header only if you code ACCESS=RLSE.

Each buffer list header contains a count of the number of entries in the buffer list that directly follows the header.

The forward chain address chains buffer lists together. The format of the buffer list header is shown in Table 17.

</tbody>
</table>

Buffer List Entry

A buffer list contains one or more entries in contiguous storage. Each entry provides the buffer address, the length of the DSCB buffer, the argument, and indicates whether the argument is an RBA, a TTR, or a CCHHR. The fields and bit uses are listed below.

- For a DSCB buffer, the RBA bit must be 0, and either the TTR or CCHHR bits must be set to 1 (they must not both be 1).
- The BFLESKIP bit causes an entry to be ignored.
- The BFLEIOER bit is an output indicator from CVAF that indicates an I/O error occurred during reading or writing of the DSCB.
- The BFLELTH field is the length of the buffer; for a DSCB buffer, the length must be 96 or 140.
- The BFLEARG field is the argument (address) of the DSCB. Specify the format of the 5-byte field by setting the BFLECHR, BFLETTR, or BFLERBA bit to 1. The respective BFLEARG values and formats are as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>CCHHR</td>
<td>5-byte CCHHR</td>
</tr>
<tr>
<td>TTR</td>
<td>0TTR0</td>
</tr>
<tr>
<td>RBA</td>
<td>1 byte of 0 followed by a 4-byte relative byte address.</td>
</tr>
</tbody>
</table>

The values for BFLEARG depend on the variables associated with a given request. These are described in the following request-oriented topics.

The format of the buffer list entry is shown in Table 18.

Table 18. Format of a Buffer List Entry

Using the VTOC
Accessing the DSCB Directly

The CVAFDIR macro can be used to read or write one or more DSCBs and is described in "CVAFDIR Macro Overview and Specification" on page 73. After a CVAFDIR call, you can test the CV1IVT bit in the CVPL to determine whether the VTOC is indexed or nonindexed.

If the first buffer is 96 bytes, CVAF issues a channel program to verify that the key in the DSCB matches the 44-byte data set name you entered, unless the operation is a write and the BFLENOVR bit is on.

If the first buffer is for a 96-byte write and the BFLENOVR bit in the BFLEFL is set to 1, CVAF skips the key verification, improving performance. If you are not certain that the data set name you provide is correct, set the BFLENOVR bit to 0. If the BFLENOVR bit is set to 0, CVAF does not execute the write unless the keys match.

If CVAF is performing key verification, and the DSCB key does not match the data set name you supply, CVAF ignores any specified BFLEARG and writes the first DSCB using the rules described in the following section, "Specifying a Data Set Name to Read or Write a DSCB."

Specifying a Data Set Name to Read or Write a DSCB

To read or write one or more DSCBs by specifying only the data set name (that is, BFLEARG is zero), specify either ACCESS=READ or ACCESS=WRITE.

Specify the address of the data set name in the DSN keyword. Specify the address of the buffer list in the BUFLIST keyword. Each of these areas and the associated buffers must be in your program’s protect key.

The buffer list must contain at least one buffer list entry with the skip bit off and a pointer to a 96-byte first buffer. Do not use a 140-byte buffer as the first buffer. You can chain buffer list headers together, but at this time, CVAF only uses the first buffer list.

For an indexed VTOC, CVAF searches the index for the data set name. If the data set name is found, the DSCB argument is put into the buffer list entry and used to read or write the DSCB. If the data set name cannot be found in the index, CVAF performs a key search of the VTOC.

For a nonindexed VTOC, CVAF uses a channel program to perform a key search of the VTOC to locate the data set name and read or write the DSCBs. If the data set name is found, CVAF puts the DSCB argument into the buffer list entry.

The DSCB argument returned in the buffer list entry is in the format determined by the BFLECHR or BFLETTR bits in the buffer list entry.

If CVAF does not find the data set name in the VTOC, a return code of 4 is indicated in register 15, and an error code of 1 in the CVSTAT field.

For CVAF calls that pass a data set name, a CVAFDIR request will fail if the EADSCB=OK indicator is not set and the DSCB associated with this data set name is a format-8 DSCB. CVAF return code of 4 with a CVAF status code (CVSTAT) of STAT082 will be set.

If you use CVAFDIR MULTIPLEDSCBS=YES ACCESS=READ, all DSCBs associated with this data set name are read and returned in the buffer list buffer (BFLEBUF) for entries without the skip bit on in logical VTOC order. The associated
address of each DSCB is put in the corresponding BFLEARG field. The total number of DSCBs associated with this data set name is also returned in the BFLHNOEN field of the buffer list header. If there are not enough buffers to house all the DSCBs associated with this data set name, only those DSCBs that have BFLEs are processed. The buffer list header field BFLHNOEN will then have a number greater than the BFLHNOE field.

If you use CVAFDIR MULTIPLEDSCBS=YES ACCESS=WRITE, all BFLEs without the skip bit are used to write all DSCBs with one call. BFLEARG must be correct for all entries (except the first 96-byte DSCB) and BFLEBUF must point to the correct corresponding DSCB to be written.

**Specifying the DSCB Location**

To read or write one or more DSCBs by specifying the DSCB’s location (that is, BFLEARG), specify either ACCESS=READ or ACCESS=WRITE.

Specify the address of the data set name in the DSN keyword and the address of the buffer list in the BUFLIST keyword. Each of these areas and the associated buffers must be in your program’s protect key.

The buffer list must have at least one buffer list entry with the skip bit off and a pointer to a 96-byte or 140-byte buffer. You can chain buffer lists together, but at this time CVAF uses only the first buffer list.

If the first buffer is for a 140-byte read or write, CVAF issues a channel program to read or write the DSCB at the location specified in the buffer list entry. CVAF ignores the specified data set name. If you specify VERIFY=YES, CVAF verifies that the designated DSCB is a format-0 DSCB before issuing the write channel program.

For CVAF calls that specify the DSCB location, a CVAFDIR request will fail if the EADSCB=OK indicator is not set and the DSCB associated with this location is a format-8 DSCB. CVAF return code of 4 with a CVAF status code (CVSTAT) of STAT082 will be set.

If you use CVAFDIR MULTIPLEDSCBS=YES ACCESS=READ, all DSCBs associated with the data set whose format-1 or format-8 DSCB is pointed to by the BFLEARG of the first BFLE entry are read and returned in the buffer list buffer (BFLEBUF) for entries without the skip bit on in logical VTOC order. The associated address of each DSCB is put in the corresponding BFLEARG field. The total number of DSCBs associated with this data set is also returned in the BFLHNOEN field of the buffer list header. If there are not enough buffers to house all the DSCBs associated with this data set name, only those DSCBs that have BFLEs are processed. The buffer list header field BFLHNOEN will then have a number greater than the BFLHNOE field.

If you use CVAFDIR MULTIPLEDSCBS=YES ACCESS=WRITE, all BFLEs without the skip bit are used to write all DSCBs with one call. BFLEARG must be correct for all entries and BFLEBUF must point to the correct corresponding DSCB to be written.

**Releasing Buffers and Buffer Lists Obtained by CVAF**

You can release buffers and buffer lists acquired by CVAF in the following ways:

- Issue a CVAF call with ACCESS=RLSE, and specify a buffer list address with the BUFLIST keyword.
Using the VTOC

- Free a MAP records buffer list by coding MAPRCD=NO or MAPRCD=(NO,addr) and specifying any ACCESS.
- Free an index records buffer list by coding IXRCD=NOKEEP or IXRCD=(NOKEEP,addr) and specifying any ACCESS.

CVAF frees all eligible buffers and any buffer lists that become empty. Eligible buffers are those pointed to by buffer list entries with the skip bit off. CVAF frees a buffer list if none of its buffer list entries have the skip bit on. If buffer lists are chained together, CVAF checks and frees all appropriate buffer lists. Do not request CVAF to release the same buffer list twice by specifying its address in more than one place.
Accessing DSNs or DSCBs in Sequential Order

You can use the CVAFSEQ macro to request the return of information about the data sets:

- DSCBs in indexed (data set name) order (either format-1 and format-8 DSCBs or a format-4 DSCB)
- One or more DSCBs in physical-sequential order. (If you are unauthorized, you can request only one DSCB.)
- The next data set name in the index.

CVAF reads the DSCBs into buffers identified by the BUFLIST keyword. See "CVAFSEQ Macro Overview and Specification" on page 119 for additional information about the macro.

Use the buffer list to specify the argument of each DSCB to be read. For indexed access, request 96-byte DSCBs in the buffer list. For physical-sequential access, request 140-byte DSCBs.

If you select indexed order, CVAF returns each format-1, format-4, or format-8 DSCB pointed to by the index. To return only the data set names in the index (not the DSCBs), specify DSNONLY=YES. CVAF updates the DSN area specified in the CVAFSEQ macro with the data set name of each DSCB read, every time you issue CVAFSEQ. CVAF also returns the CCHHR of the DSCB in the argument area supplied with the ARG keyword.

Note: The returned DSCB from CVAFSEQ always includes the key portion of the DSCB when the supplied length is 140 bytes for the buffer (field BFLELTH). The mapping for structure IECSDSF4 in macro IECSDSL1, however, does not include the key portion of the DSCB. Therefore, if you use the format-4 DSCB fields defined in this structure (all fields starting with DS4), you must adjust the starting point of the first field in the IECSDSF4 structure to correspond to 44 bytes into the returned buffer.

For indexed access, a CVAFSEQ request will fail if the EADSCB=OK indicator is not set and the DSCB attempted to be read is a format-8 DSCB. CVAF return code of 4 with a CVAF status code (CVSTAT) of STAT082 will be set.

Initiating Indexed Access (DSN Order)

To initiate indexed access (DSN order), either supply 44 bytes of binary zeros in the DSN area (to indicate the first data set name in the index) or specify the data set name that is the starting point for the index search.

The name returned in the DSN area is equal to or greater than the DSN supplied, depending on the ACCESS keyword selection.

If you specify DSNONLY=NO, CVAF returns the DSCB and argument using the buffer list provided with the BUFLIST keyword. CVAF uses the first entry in the buffer list with the skip bit set to 0 and a nonzero buffer address. You can specify the argument format by setting either the TTR or CCHHR bit in the buffer list entry to 1. If neither bit is set, CVAF returns a CCHHR argument. For indexed access, the DSCB size in the buffer list entry must be 96 bytes.

If you specify DSNONLY=YES, specify the CCHHR argument in the ARG area.
Using the VTOC

The data set name of the format-4 DSCB is in the index and CVAF might return its name (44 bytes of X'04'). The format-4 DSCB's name is likely to be the first data set name in the VTOC index.

Initiating Physical-Sequential Access

To initiate physical-sequential access, either specify DSN=0, or do not specify the DSN parameter at all. To begin the read, initialize the argument field in the first buffer list entry to zero or to the argument of the DSCB. If the argument is zero, CVAF uses the argument of the start of the VTOC.

The ACCESS keyword determines whether CVAF reads the DSCB whose argument is supplied or the DSCB following it. For example, to read the first DSCB (the format-4 DSCB) in the VTOC, you can set the BFLEARG in the first buffer list entry to zero and specify ACCESS=GTEQ in the CVAFSEQ macro. If you subsequently specify ACCESS=GT, CVAF reads the second DSCB (the first format-5 DSCB). Set the DSCB size to 140 in buffer list entries.

If your program is authorized, CVAF reads as many DSCBs as there are entries in the buffer list for a single CVAF call; if it is not authorized, CVAF reads only one DSCB.

CVAF uses one buffer list and does not inspect a second buffer list chained from the first. If your program is authorized, CVAF uses all entries in the buffer list; if it is not authorized, CVAF uses only the first entry. CVAF does not inspect the skip bit. Each entry must contain a buffer address and have the length field set to 140. CVAF updates the argument field of each buffer list entry with the argument of the DSCB. You can specify the argument format by setting either the TTR or CCHHR bit in the buffer list entry to 1. If neither bit is set, CVAF returns a CCHHR argument.

CVAF uses only the argument in the first entry to begin the search and does not inspect arguments in subsequent entries. If you specify a nonzero argument value in the first entry, there must be a DSCB with that argument.

CVAF indicates an end-of-data condition by providing return code 4 in register 15, and a value of X'20' in the CVSTAT field. CVAF sets the argument fields of all buffer list entries following the last DSCB read, to zero (the first entry is zero if CVAF does not read any DSCBs).

CVAF reads all DSCBs, including format-0 DSCBs. You cannot be certain that you have read all DSCBs until CVAF has read the entire VTOC. For a nonindexed VTOC, the DS4HPCHR field of the format-4 DSCB contains the CCHHR of the last format-1 DSCB. DSCBs other than format-1 can reside beyond that location. For an indexed VTOC, the VMDS contains information about which DSCBs are format-0 DSCBs.

For physical-sequential access, a CVAFSEQ request to an extended address volume will fail if the EADSCB=OK indicator is not set. CVAF return code of 4 with a CVAF status code (CVSTAT) of STAT082 will be set.

Reading Sets of DSCBs with CVAF Filter

You can use the CVAFFILT macro to retrieve sets of DSCBs into buffers provided by the calling program. CVAF filter service supports both indexed and nonindexed VTOCs. "CVAFFILT Macro Overview and Specification" on page 99 describes the macro's format and parameters. The following section summarizes this service and its requirements.
Using the VTOC

- Request DSCBs by specifying either one or more fully-qualified data set names, or one partially-qualified name. See "Filter Criteria List (FCL)" on page 68 and "Partially-Qualified Names for CVAFFILT" on page 104 for further information.

- Identify a single DASD volume in the CVPL.

- For each data set that has a format-1 DSCB, the VTOC order returned by CVAFFILT is the format-1 DSCB, followed by any format 3 DSCBs.
  
  For each data set that has a format-8 DSCB, the VTOC order returned by CVAFFILT is the format-8 DSCB, one or more format-9 DSCBs, followed by any format-3 DSCBs. Currently, the minimum buffer list entry size needed to read all DSCBs associated with a data set is 12. This is one format-8 DSCB, one format-9 DSCB, and 10 format-3 DSCBs to reach the 123-extent limit.

- CVAF filter service returns DSCB information for one or more qualifying data sets into caller-provided buffers. See "Example of CVAFFILT Macro Sequences" on page 71 and "Example of Using the CVAFFILT Macro" on page 105 for further information. CVAF filter service does not return a partial DSCB chain in the following cases:
  - If you do not provide enough buffers to hold the requested DSCBs, CVAF filter service returns one or more complete DSCB chains and/or a status code (CVSTAT in the CVPL). The status code indicates if a RESUME CVAF call can be used to retrieve the rest (or more) of the DSCBs. See "RESUME Capability" for specific information.
  - If the total number of buffers is insufficient to contain a data set's complete DSCB chain, CVAF filter service sets the FCLDSNST byte in the FCL, ignores the data set, and processes the next qualifying data set. To avoid this situation, provide a minimum of eleven DSCB buffers (enough for a data set at the 123 extent limit).

- For fully qualified data set names in the Filter Criteria List, a CVAFFILT request issued to an extended address volume will fail if the EADSCB=OK indicator is not set and the DSCB associated with the fully qualified data set name is described by a format-8 DSCB. For partially qualified data set names in the Filter Criteria List, a CVAFFILT request issued to an extended address volume will fail if the EADSCB=OK indicator is not set and a DSCB associated with a data set that matches the Filter Criteria List is described by a format-8 DSCB. In both these cases, the data set name status in the FCL (FCLDSNST) will be set to a status value of (x'06'). This status code indicates that a data set name is described by a format-8 DSCB and the caller did not specify support for it with the EADSCB=OK keyword. It will be set only when other data set name status codes are not applicable. CVAF status code (CVSTAT) of STAT086 (x'56') will be set with these errors. This status code indicates all of the user FCL entries were processed, a resume is not required, one or more errors were found.

**RESUME Capability**

If CVAF filter service terminates because you failed to provide sufficient buffers, the information necessary for a RESUME function is saved in the filter save area. (Specifying FLTAREA=KEEP on the initial CVAFFILT allocates the filter save area.)

To allow RESUME processing to execute correctly, you must maintain the relationship between the requested volume (identified by CVDEB, CVUCB, or a kept IOAREA), your FCL, and CVAF's FSA. If you observe this requirement, you can initiate and resume multiple CVAF filter service operations asynchronously on one or more DASD volumes. You can ensure this relationship by providing a unique CVPL and FCL for the duration of the READ/RESUME/RELEASE sequence associated with each logical request.
Using the VTOC

Issuing an ACCESS=RESUME without having previously specified FLTAREA=KEEP causes CVAF filter service to produce return code 4 in register 15 and 66 (decimal) in the CVSTAT field.

If you specify FLTAREA=KEEP, issue a subsequent CVAFFILT call with the ACCESS=RLSE keyword to release filter save area storage.

Filter Criteria List (FCL)

The filter criteria list (FCL) consists of a list header and a variable number of list entries. The list entries follow the header, and each entry represents a data set name to be processed by CVAF filter. The header and entries, shown in Table 20 and Table 21 on page 70, are mapped by the I CVFCL macro. The format of the FCL header is shown in Table 20.

</tr>
</tbody>
</table>

- **FCLID**  
  Must be a 4-character EBCDIC constant of 'FCLbb'. (bb here represents a blank.)

- **FCLCOUNT**  
  Specifies the number of data set name entries (FCLDSN) supplied in the list. Do not change this parameter between the initial CVAFFILT call and any subsequent RESUME operations.
  - If you specify a partially-qualified data set name, specify FCLCOUNT = 1. See the format of partially-qualified data set names on page 104.
  - If you specify a list of fully-qualified names, CVAFFILT processes only the number of names specified in FCLCOUNT.

- **FCLDSCBR**  
  Indicates the total number of DSCB entries (including format-1, format-2, and format-3) returned to the caller's buffers by a single CVAFFILT call.

  If CVAF encounters an error after successfully processing a data set, you can:
  1. Initialize FCLDSCBR to 0 before each READ and RESUME call.
  2. Upon return from CVAF filter service, process the number of DSCBs indicated by FCLDSCBR.
  3. Then, interpret the CVAF return code and CVSTAT.

- **FCL1FLAG**  
  Define your request for ACCESS=READ with this flag byte. Any subsequent RESUME requests refer to a copy of these bits in the filter save area (FSA).

- **FCL1LIST**  
  If you specify a list of fully-qualified data set names, set this bit to 1. If you specify a single partially-qualified data set name, set this bit to 0.

- **FCL1ORDR**  
  If you specify that CVAF is to return DSCB chains in the data set name sequence implied by the placement of the FCLDSN elements, set this bit to 1.

**Notes:**

1. It can improve performance to allow CVAF to determine the sequence of return for format-1 DSCBs.
2. CVAF returns DSCBs for a given data set in format-1, format-3 order. For an extended address volume, the data set order for EAS eligible data sets is a format-1, one or more format-9, and any format-3 DSCBs.
3. If you specify a single partially-qualified data set name, this field is not used.

- **FCL1EQF1**  
  To have CVAF return only the format-1 or format-8 DSCBs for the data set names, set this bit to 1.
Using the VTOC

**FCL1EQF9**  To have CVAF return only the format-1 or format-8 and format-9 DSCBs for the data set names, set this bit to 1.

**FCL2FLAG**  CVAF filter indicates the following status conditions in this byte.

**FCL2SEQ**  This bit is set to 1 if a sequential VTOC access path is most efficient. If CVAF filter selects the direct VTOC access path, it sets this field to 0.

**FCL2DIR**  This bit is set to 1 if storage limitations within the sequential VTOC access path require direct DSCB reads. CVAF initializes this bit to 0 on each ACCESS=READ and ACCESS=RESUME request. Testing this bit when CVAF filter returns control can indicate if you need to change the storage limitation.

The format of the FCL entry is shown in Table 21.

</tbody>
</table>

**FCLDSN**  Contains data set name information. This and the following fields are repeated in the FCL as a set as many times as indicated by the value in FCLCOUNT.

**FCLDSNST**  Indicates DSCB retrieval status.

- CVAF filter initializes this byte to 0 for ACCESS=READ requests.
- After processing the data set name for either ACCESS=READ or ACCESS=RESUME, CVAF filter updates this byte.
Using the VTOC

- ACCESS=RESUME requests do not process data set names whose FCLDSNST field is nonzero; therefore, results can be unpredictable if you alter this field.
- For partially-qualified data set name requests, CVAF filter does not post the FCLDSNST field until it has returned all DSCB chains for all qualifying data sets. CVAF filter posts the highest numeric value that applied during its processing.
- For fully-qualified data set name requests, CVAF filter returns a FCLDSNST byte for each data set name. If the value is greater than 1, CVAF filter has not returned any DSCBs for the associated data set name.

See Table 21 on page 70 for an explanation of the values in this field.

FCLDSNLG Indicates the length of the data set name. This value is required.

FCL3FLAG The status flag byte associated with the data set name pointed to by FCLDSNA.

FCL3UPDT This bit indicates that CVAF filter processed the associated data set name during the current invocation of CVAFFILT.
  - When initializing for either a READ or RESUME request, CVAF filter sets this bit to 0.
  - When CVAF filter has completed processing for the associated data set name, it sets this bit to 1.

FCL3DSNRV Reserved, unused.

FCLDSNA Specifies the address of a fully-qualified data set name, or, if this is the only data set name and FCL1LIST is 0, a partially-qualified data set name. You must provide both this address and the storage area to which it points.

Example of CVAFFILT Macro Sequences

The example below demonstrates the order that you might issue CVAFFILT macro calls to complete the following tasks:
- Request the DSCBs for a list of data sets.
- Resume CVAFFILT processing interrupted because of insufficient user buffers.
- Release the kept filter save area.

The example assumes the following conditions:
- You are an authorized caller (that is, you are specifying a UCB address and IOAREA=KEEP).
- You have initialized a CVAF buffer list with the following characteristics:
  - Four buffers
  - The buffer list address in your program has the label BUFADDR.
Using the VTOC

- The same buffer list is used for ACCESS=READ and ACCESS=RESUME processing.
- You have initialized a filter criteria list as follows:
  - FCLCOUNT = 6 (You are requesting DSCB chains for six data set names.)
  - FCL1LIST = '1'B (The data set names are fully qualified.)
  - FCL1ORDR = '1'B (You want the DSCB chains returned in the order implied by data set name elements in the FCL.)
  - The first five data sets have DSCB chain lengths or 1, 5, 2, 3, and 1, respectively, on the volume.
  - The sixth data set (SYS6.F) is not defined on the volume.

To obtain an initialized CVPL, you could issue the following CVAFFILT macro (list form—does not call CVAF). This example requests the branch entry to CVAF and specifies that the caller is in supervisor state.

CVPLIST CVAFFILT BRANCH=(YES,SUP),MF=L

To obtain the first set of DSCB chains, you could issue the following CVAFFILT macro (execute form—calls CVAF). This example specifies that the filter save area is to be kept to allow for ACCESS=RESUME calls. The IOAREA is to be kept for improved efficiency.

CVAFFILT ACCESS=READ,BUFLIST=bufaddr,FCL=fcladdr,
    UCB=ucbaddr,FLTAREA=KEEP,IOAREA=KEEP,
    MF=(E,CVPLIST)

This CVAFFILT call returns the following DSCBs:

<table>
<thead>
<tr>
<th>Buffer</th>
<th>Contents of Buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Format-1 DSCB, SYS1.A</td>
</tr>
<tr>
<td>2</td>
<td>Format-1 DSCB, SYS3.C</td>
</tr>
<tr>
<td>3</td>
<td>Format-3 DSCB, SYS3.C</td>
</tr>
<tr>
<td>4</td>
<td>Undefined (unused)</td>
</tr>
</tbody>
</table>

CVAF filter produces return code = 4, CVSTAT = X'40' (RESUME recommended), and FCLDSCBR = 3. (CVAF returns a total of three DSCBs for the two data sets.) CVAF would not return DSCBs for data set SYS2.B because its chain contains more DSCBs than the total number of buffers provided. To retrieve the DSCBs for SYS2.B, you need to specify at least five buffers and execute another ACCESS=READ. (Even though CVAF allows you to specify a different buffer list for each READ or RESUME, or to modify the existing list between READ and RESUME calls, modifying the FCL would cause unpredictable results.) Buffer entry 4 does not have any DSCBs returned, because SYS4.D's DSCB chain size is larger than the number of remaining buffers. The FCL status information would be as follows:

<table>
<thead>
<tr>
<th>DSN</th>
<th>FCLDSNST</th>
<th>FCL3UPDT</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYS1.A</td>
<td>1</td>
<td>1</td>
<td>DSCBs returned from this call</td>
</tr>
<tr>
<td>SYS2.B</td>
<td>5</td>
<td>1</td>
<td>DSCB chain exceeds total buffers</td>
</tr>
<tr>
<td>SYS3.C</td>
<td>1</td>
<td>1</td>
<td>DSCBs returned from this call</td>
</tr>
<tr>
<td>SYS4.D</td>
<td>0</td>
<td>0</td>
<td>DSCBs can be returned by RESUME</td>
</tr>
<tr>
<td>SYS5.E</td>
<td>0</td>
<td>0</td>
<td>DSCBs can be returned by RESUME</td>
</tr>
<tr>
<td>SYS6.F</td>
<td>0</td>
<td>0</td>
<td>DSCBs can be returned by RESUME</td>
</tr>
</tbody>
</table>

Because this CVAFFILT invocation recommends RESUME, and you specified FLTAREA=KEEP, you could use the following execute form of CVAFFILT to obtain more DSCB chains:
This CVAFFILT call returns DSCBs as follows:

<table>
<thead>
<tr>
<th>Buffer</th>
<th>Contents of Buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Format-1 DSCB, SYS4.D</td>
</tr>
<tr>
<td>2</td>
<td>Format-2 DSCB, SYS4.D</td>
</tr>
<tr>
<td>3</td>
<td>Format-3 DSCB, SYS4.D</td>
</tr>
<tr>
<td>4</td>
<td>Format-1 DSCB, SYS5.E</td>
</tr>
</tbody>
</table>

CVAF filter produces return code = 0, CVSTAT = 0 (request completed), and updates the FCL status as follows:

<table>
<thead>
<tr>
<th>DSN</th>
<th>FCLDSNST</th>
<th>FCL3UPDT</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYS1.A</td>
<td>1</td>
<td>0</td>

</tbody>
</table>

FCLDSCBR would contain 4. (This CVAFFILT call returns a total of four DSCBs.) CVAF filter does not return any DSCBs for SYS6.F, because its format-1 DSCB cannot be found on the volume (FCLDSNST = '2').

Because this status indicates that CVAF filter has returned all requested DSCBs, and you requested FLTAREA=KEEP and IOAREA=KEEP on the previous call, request the RLSE function as follows:

```cvaflilt ACCESS=RLSE,FLTAREA=NOKEEP,IOAREA=NOKEEP, MF=(E,CVPLIST)```

---

**Coding CVAF VTOC Access Macros**

This section includes VTOC index information that depends on internal system logic. It is intended to help you to use CVAF macro instructions to modify the VTOC

- **CVAFDIR Macro Overview and Specification**
- **CVAFDSM Macro Overview and Specification** on page 92
- **CVAFFILT Macro Overview and Specification** on page 99
- **CVAFSEQ Macro Overview and Specification** on page 119
- **CVAFSTST Macro Overview and Specification** on page 137
- **VTOC Index Error Message and Associated Codes** on page 138

---

**CVAFDIR Macro Overview and Specification**

For an indexed or nonindexed VTOC, you can use the CVAFDIR macro to perform the following functions:

- Read or write one or more DSCBs by specifying the name of the data set they represent.
- Read or write one or more DSCBs by specifying their addresses.

In addition, for an indexed VTOC, you can use the CVAFDIR macro to perform the following functions:

- Read or write VTOC index records. (This allows calling programs to modify the VTOC index.)
- Read and retain in virtual storage the first high-level VIER, and VIERs used during an index search.
- Read and retain in virtual storage the space map VIRs.
CVAF Macros

- Free VIRs retained in virtual storage.

See "Accessing the DSCB Directly" on page 62 for additional information.

The format of the CVAFDIR macro is:

```
LABEL
CVAFDIR ACCESS=READ
   ,DSN=addr
   ,BUFLIST=addr

   ,ACCESS=WRITE
   ,DSN=addr
   ,BUFLIST=addr

Notes:
1. If YES is coded, the default is SUP.

ACCESS: Read or Write a DSCB or VIRs, or Release Buffer Lists

When ACCESS is READ or WRITE, a single DSCB is accessed for an indexed or nonindexed VTOC, or one or more VIRs are accessed for an indexed VTOC.

ACCESS=READ

Specifies that a single DSCB or one or more VIRs are to be read into a buffer whose address is in a buffer list.

If the buffer list is for a DSCB, only one entry is used in the buffer list. The first entry with the skip bit set to zero and a nonzero buffer address is used.

All VIRs whose buffer list entry has the skip bit off are read into a buffer.

DSN and BUFLIST are required if ACCESS=READ for a DSCB buffer list.

ACCESS=WRITE

Specifies that a single DSCB or one or more VIRs are to be written from buffers whose address is in a buffer list.

ACCESS=WRITE is permitted with BRANCH=NO only if the caller is authorized by APF.

DSN and BUFLIST are required if ACCESS=WRITE for a DSCB buffer list.
If any buffer list entry has its modified bit set, only those entries with the modified bit set are written. If no modify bits are on, all VIRs are written.

ACCESS=RLSE
Applies only to VIR buffer lists. It requests the release of one or more buffers in the VIR buffer list chain identified in the BUFLIST keyword, and the release of each buffer list for which all buffers are released.

DSN and BUFLIST are not required if ACCESS=RLSE.

Only buffers in the buffer list with the skip bit set to zero and with a nonzero buffer address are released. The buffer list is not released if any entry has the skip bit set to one.

For an indexed VTOC, if ACCESS=RLSE is coded, buffer lists and buffers pointed to by the BUFLIST keyword are released, along with buffer lists supplied in the CVAF parameter list CVMRCDS and CVIRCDS fields. If the CVMRCDS or the CVIRCDS buffers are supplied in the BUFLIST field, either directly or indirectly through chaining, the keyword MAPRCDS=YES, IXRCS=KEEP, or MAPRCDS=(NO,0), IXRCS=(NOKEEP,0) must be coded to prevent CVAF from freeing the buffers more than once. If buffers are released, the CVAF parameter list field pointing to the buffer list is updated.

**DSN: Specify the Name of the DSCB**

DSN=addr
Supplies the address of a 44-byte data set name of the DSCB to be accessed.

DSN is required if ACCESS=READ or WRITE and the request is to read or write a DSCB. If a 140-byte DSCB is specified:
- CVAF validity checks the storage location, but ignores the contents of the location.
- Specify an argument that points to an extent within the VTOC.

**BUFLIST: Specify One or More Buffer Lists**

BUFLIST=addr
Supplies the address of a buffer list used to read or write a DSCB or VIRs.

**VERIFY: Verify that a DSCB is a Format-0 DSCB**

VERIFY=YES
CVAF verifies that the DSCB is a format-0 DSCB before writing the DSCB. The first four bytes of the key are compared with binary zeros. If the key does not start with 4 bytes of zeros, the DSCB is not written and an error code is returned.

VERIFY=NO
CVAF does not test the key of the DSCB. This is the default.

Restriction: VERIFY applies only when writing a 140-byte DSCB. VERIFY is ignored when a VIR is written.

**UCB or DEB: Specify the VTOC to Be Accessed**

UCB= rs-type or (2-12) standard form UCB= rx-type or (2-12) execute form
Specifies the address of the UCB for the VTOC to be accessed. The UCB address can be for a captured UCB, or for an actual UCB above or below the 16MB line. Use the address of a UCB, not a UCB copy. An unauthorized caller must not use this parameter. If your program is in 31-bit mode, this address must be in 31-bit.
address; the high order byte is part of the address. You should not code the UCB parameter with MF=L.

**Recommendation:** Code the address of the UCB parameter as register (2-12). Coding an RX-Type address gives unpredictable results.

**Note:** You must supply a UCB address that matches the caller's AMODE. That is, AMODE=24 requires a 24 bit UCB address, while AMODE=31 requires a 31 bit UCB address.

DEB=addr Supplies the address of a DEB opened to the volume table of contents (VTOC) you want to access. CVAF does not allow output requests to the VTOC or VTOC index if you specify the DEB subparameter. If you are not authorized (neither APF nor in a system key), you cannot perform any asynchronous activity (such as EXCP, CLOSE, EOV) against the data set represented by the DEB because CVAF removes the DEB from the DEB table for the duration of the CVAF call. If you are not authorized, (neither APF authorized nor in a system key), specify a DEB address, not a UCB, to CVAFDIR. See “Identifying the Volume” on page 56 for further details.

If you supply a previously obtained I/O area through the IOAREA keyword, neither UCB nor DEB need be supplied. Otherwise, supply either a UCB or DEB. If you supply a UCB address, it is overlaid in the CVPL by the UCB address in the I/O area. If you supply both the DEB and UCB addresses in the CVPL, the DEB address is used and the UCB address in the CVPL is overlaid by the UCB address in the DEB.

**IOAREA: Keep or Free the I/O Work Area**

**IOAREA=KEEP**

Specifies that, upon completion of the CVAF request, the program should keep the CVAF I/O area associated with the CVAF parameter list. You can code IOAREA=KEEP with BRANCH=NO only if the caller is authorized (APF or system key).

If IOAREA=KEEP is coded, the caller must call CVAF with IOAREA=NOKEEP specified at some future time, whether or not any further VTOC access is required. An example of such a caller is the recovery routine of the routine that calls CVAF.

When you code IOAREA=KEEP, it allows subsequent CVAF requests to be more efficient, because the program can bypass certain initialization functions. You do not need to specify either DEB or UCB when a previously obtained CVAF I/O area is supplied; you also cannot change those values.

When IOAREA=KEEP is first issued, CVAF returns the CVAF I/O area in the CVAF parameter list (CVIOAR). Subsequent calls of CVAF can use that same parameter list, and CVAF obtains its I/O area from the CVIOAR.

When processing on the current volume is finished, release all areas that were kept.

**IOAREA=(KEEP, addr)**

Supplies the address of a previously obtained I/O area. If a different CVAF parameter list is used, the previously obtained I/O area can be passed to CVAF by coding its address as the second parameter of the IOAREA keyword.
CVAF Macros

IOAREA=NOKEEP
Causes the work area to be freed upon completion of the CVAF request.

IOAREA=(NOKEEP, addr)
Causes a previously obtained work area to be freed upon completion of the CVAF request.

MAPRCDS: Keep or Free MAPRCDS Buffer List and Buffers
This keyword applies to an indexed VTOC only and specifies the disposition of the MAPRCDS buffer list and buffers.

MAPRCDS=YES
Specifies that the buffer list and buffers are to be retained at the end of processing.

If no buffer list address is in the CVAF parameter list, CVAF reads the MAP VIRs into buffers it obtains. The buffer list that contains the address and RBAs of the VIRs can be accessed after processing from the CVAF parameter list field, CVMRCDS. The buffer list and VIR buffers are in your protect key: subpool 0 if you are not authorized; subpool 229 if you are.

When processing on the current volume is finished, release all areas that were kept.

MAPRCDS=(YES, addr)
If MAPRCDS=YES is coded and the buffer list address (CVMRCDS in CVAF parameter list) is supplied, VIRs are not read.

The CVMRCDS buffer list used in CVAFDIR macro can be passed to another CVAF macro call through the MAPRCDS keyword.

If MAPRCDS=YES is coded for a nonindexed VTOC, the function is performed, but an error code is returned.

MAPRCDS=NO
If MAPRCDS=NO is coded, all the buffers without the skip bit on in the buffer list whose address is in the CVMRCDS field of the CVPL are freed. If all the buffers are freed, the buffer list is also freed.

MAPRCDS=(NO, addr)
Frees buffer lists and buffers previously obtained by CVAF.

You must free buffer lists and buffers obtained by CVAF. This can be done in one of three ways:
- By coding MAPRCDS=NO on the CVAFDIR macro that obtained the buffers
- By coding MAPRCDS=NO on a subsequent CVAF macro
- By coding CVAFDIR ACCESS=RLSE and providing the address of the buffer list in the BUFLIST keyword.

Requirement: You must enqueue the VTOC and reserve the unit to maintain the integrity of MAP records read.

IXRCDS: Retain VIERS in Virtual Storage
This keyword applies to indexed VTOCs only.

IXRCDS=KEEP
Specifies that VIERS read into storage are to be kept in virtual storage. The VIERS are retained even if processing cannot complete successfully. The CVAF parameter list in field CVIRCDS contains the address of a buffer list with the VIR buffer addresses and RBAs of the VIERS read.
CVAF Macros

The index search function dynamically updates the buffer list and, when necessary, obtains additional buffer lists and chains them together.

If IXRCDS=KEEP is specified and no buffer list is supplied to CVAF in the CVPL, CVAF obtains a buffer list and buffers and reads the first high-level VIER. The address of the buffer list is placed in the CVMICDS field of the CVPL.

The buffer list and VIR buffers are in your protect key. The subpool is 0 if you are not authorized; it is subpool 229 if you are.

If IXRCDS=KEEP is coded for a nonindexed VTOC, a request to read or write a DSCB is performed, but an error code is returned.

When processing on the current volume is finished, release all areas that were kept.

**IXRCDS=(KEEP,addr)**

The index records buffer list address from one CVAF request is being passed to this CVAF parameter list by specifying its address as the second parameter in the IXRCDS keyword.

**IXRCDS=NOKEEP**

If IXRCDS=NOKEEP is coded, the VIERs that are accessed (if any) are not retained. Furthermore, the buffer list supplied in the CVIRCDS field in the CVAF parameter list is released, as are all buffers found in the buffer list. If the skip bit is set in any entry in the buffer list, the buffer and buffer list are not freed. This is the default.

**IXRCDS=(NOKEEP,addr)**

Specifies that previously accessed VIERs are not to be retained.

You must free buffer lists and buffers obtained by CVAF. This can be done in one of three ways:

- By coding IXRCDS=NOKEEP on the CVAFDIR macro that obtained the buffers
- By coding IXRCDS=NOKEEP on a subsequent CVAF macro
- By coding CVAFDIR ACCESS=RLSE and providing the address of the buffer list in the BUFLIST keyword.

**Requirement:** You must enqueue the VTOC and reserve the unit to maintain the integrity of the VIERs read.

**BRANCH: Specify the Entry to the Macro**

**BRANCH=(YES,SUP)**

Requests the branch entry. Your program be in supervisor state. Protect key checking is bypassed.

If BRANCH=YES is coded, an 18-word save area must be supplied. No lock can be held on entry to CVAF. SRB mode is not allowed.

**BRANCH=YES**

Equivalent to BRANCH=(YES,SUP), because SUP is the default when YES is coded. Protect key checking is bypassed.

**BRANCH=(YES,PGM)**

Requests the branch entry. Your program be authorized by APF and be in problem state. Protect key checking is bypassed.
BRANCH=NO
Requests the SVC entry. If any output operations are requested, your program must be authorized by APF. Protect key checking is performed. This is the default.

EADSCB: Specify the support level for extended attribute DSCBs

EADSCB=OK
This specification indicates that the calling program supports extended attribute DSCBs. An extended address volume may have these DSCBs allocated to it. The returned DSCBs (format-3, format-8) may contain extent descriptors described by 28-bit cylinder addresses or DSCBs (format-9) that contain additional attribute information.

For search calls where the data set name is passed (CVAFDIR ACCESS=READ,BFLEARG=0), a CVAFDIR request will fail if the EADSCB=OK indicator is not set and the DSCB associated with this data set name is a format-8 DSCB.

For seek calls where the record address is passed (CVAFDIR ACCESS=READ,BFLEARG=cccc), a CVAFDIR request issued to an EAV volume will be failed if the EADSCB=OK indicator is not set and the DSCB associated with this address is a format-8 DSCB.

For seek calls where the record address is passed (CVAFDIR ACCESS=READ,BFLEARG=cccc), and MULTIPLEDSCBS=NO is specified or defaulted to NO, a CVAFDIR request will fail if the EADSCB=OK indicator is not set and the DSCB associated with this address is a format-3 DSCB that contain track addresses above 65,520 cylinders.

The failing error code for these cases will be reflected as follows:
- CVAF status code (CVSTAT) set to STAT082.
- Return code 4.

EADSCB=OK will set the CV4EADOK indicator in the CVPL.

For all other calls, the EADSCB=OK keyword is ignored.

EADSCB=NOTOK
Indicates a calling program does not support extended attribute DSCBs. The specification of this will resolve to the CV4EADOK indicator in the CVPL to be set off. This is the default.

MULTIPLEDSCBS: Specify whether multiple DSCBs should be processed

MULTIPLEDSCBS=NO
This specification indicates that the calling program requests that only one DSCB should be processed. This is the default for MF=L and MF=I forms of the CVAFDIR macro. When the MULTIPLEDSCBS keyword is not specified on the MF=E form, the existing setting of CV4MULTD is left unchanged. When MULTIPLEDSCBS=NO is specified or defaulted, only the first available buffer list entry is processed.

MULTIPLEDSCBS=YES
This specification indicates that the calling program requests to read/write multiple DSCBs to/from a buffer list that contains more than one buffer list entry. This parameter causes an indicator in the CVPL, CV4MULTD, to be set on. Multiple DSCB processing for reads and writes is requested by specifying the MULTIPLEDSCBS=YES keyword and providing a buffer list that contains more than one buffer list entry (BFLHNOE>1).
MF: Specify the Form of the Macro
This keyword specifies whether the list, execute, or normal form of the macro is requested.

MF=I  If I is coded or if neither L nor E is coded, the CVAF parameter list is generated and CVAF is called. This is the normal form of the macro.

MF=L  Indicates the list form of the macro. A parameter list is generated, but CVAF is not called.

MF=(E, addr)  Indicates the execute form of the macro. The CVAF parameter list whose address is in addr can be modified by this form of the macro.

Return Codes from CVAFDIR
On return from CVAF, register 1 contains the address of the CVPL (CVAF parameter list), and register 15 contains one of the following return codes:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>The request was successful. However, if the CVAFDIR request is to read or write a DSCB and a VTOC index structure error is encountered, the CVSTAT field indicates the structure error that was encountered. (CVSTAT code descriptions are in z/OS DFSMSdfp Diagnosis, GY27-7618)</td>
</tr>
<tr>
<td>4 (X'04')</td>
<td>An error occurred. The CVSTAT field in the CVPL contains an indication of the cause of the error. (CVSTAT code descriptions are in z/OS DFSMSdfp Diagnosis, GY27-7618)</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>Invalid VTOC index structure while processing a request to read or write a VTOC index record. The CVSTAT field in the CVPL contains an indication of the cause of the error. (CVSTAT code descriptions are in z/OS DFSMSdfp Diagnosis, GY27-7618)</td>
</tr>
<tr>
<td>12 (X'0C')</td>
<td>The CVAF parameter list is not in your protect key or is not valid (the ID is not valid, or the length field is incorrect, or the CVFCTN (function code) field is not valid or is not supported in this release). The CVPL has not been modified.</td>
</tr>
<tr>
<td>16 (X'10')</td>
<td>An I/O error was encountered.</td>
</tr>
</tbody>
</table>

Example of Using the CVAFDIR Macro with a VTOC
This example uses the CVAFDIR macro to read a DSCB of a given data set name and determines whether the DSCB is for a partitioned data set. The address of the 44-byte data set name is supplied to the program in register 5 (labeled RDSN in the example). The address of a DEB open to the VTOC is supplied to the program in register 4 (labeled RDEB in the example).

The buffer list is in the program and is generated by the ICVAFBFL macro. The DSCB buffer is in the program and is generated by the IECSDSL1 macro.

Figure 8. Example of CVAFDIR Macro with VTOC (Part 1 of 2)
Example of Using the CVAFDIR Macro with an Indexed VTOC

This example uses the CVAFDIR macro to read one or more DSCBs from a VTOC. The UCB is supplied to the program in register 4 (labeled RUCB). The TTR of each DSCB read is to be returned to the caller as well as the return code received back from CVAFDIR. This program must be APF authorized.

The address of a parameter list is supplied to the program in register 5 (labeled RLIST). The parameter list contains one or more 4-word entries. The format of each 4-word entry is mapped by the LISTMAP DSECT. The first word contains the address of the data set name of the DSCB to be read. The second word contains the address of the 96-byte buffer into which the DSCB is to be read. The third word contains the address of the 3-byte TTR of the DSCB read. The fourth word contains the return code received back from CVAFDIR for the DSCB read.

Figure 8. Example of CVAFDIR Macro with VTOC (Part 2 of 2)
The CVPL is generated by a list form of the CVAFDIR macro at label CVPL. The BUFLIST, IXRCDS, IOAREA, and BRANCH keywords are coded on the list form of the macro. IXRCDS=KEEP and IOAREA=KEEP are coded to avoid overhead if two or more DSCBs are to be read. BRANCH=(YES,PGM) is coded in the list form of the CVAFDIR macro to cause the CVPL to have the CV1PGM bit set to one; this indicates to CVAF that the caller is authorized by APF and not in supervisor state. The execute forms of the CVAFDIR macro then specify BRANCH=YES, and not BRANCH=(YES,PGM), because the CV1PGM bit is set in the list form of the macro.

The CVAFDIR macro with ACCESS=RLSE is coded before the program exits to release the CVAF I/O area and the index records buffer list. BUFLIST=0 is coded because no user-supplied buffer list is to be released; BUFLIST was coded on the list form of the CVAFDIR macro and, therefore, is in the CVBUFL field of the CVPL. This field must be set to zero for the release function.

Example of Using the CVAFDIR macro to read multiple DSCBs

This example uses the CVAFDIR macro to read multiple DSCBs for a VSAM data set that has 123 extents using the MULTIPLESCBS=YES parameter. Refer to the documentation within the sample source for program logic and expected output.

The following is the sample JCL used to execute the sample source module below.

```bash
//*
//******************************
//* JCL TO EXECUTE CVDIR027 MODULE *
//******************************
//*
```
The following is the CVAFDIR sample source to read multiple DSCBs.

```assembly
CVDIR027 CSECT
CVDIR027 AMODE 31
CVDIR027 RMODE 24

***********************************************************************
**
** CVDIR027 - MODULE THAT ISSUES THE CVAFDIR MACRO WHICH RETURNS
** THE DSCBS FOR A GIVEN DATASET USING THE KEYWORDS
** MULTIPLEDSCBS=YES AND EADSCB=OK.
**
** THIS MODULE USES A PASSED DSN (SEARCH) AND ISSUES THE
** CVAFDIR MACRO TO PERFORM A READ OF ALL DSCBS FOR THE
** DATASET. THE DATASET PROCESSED IS VSAM AND HAS 123
** EXTENTS. THE DSN IS CVAFDIR1.VSAM01.DATA.
**
** THE CVAFDIR MACRO CALL WILL USE THE FOLLOWING:
** EADSCB=OK CODED
** MULTIPLEDSCBS=YES CODED
**
** THIS MODULE HAS BEEN WRITTEN TO RUN AT THE Z/OS 1.10
** LEVEL AND WILL CREATE A SLIGHTLY DIFFERENT OUTPUT
** REPORT DEPENDENT UPON DEVICE TYPE (EAV OR NON EAV).
** THE NUMBER OF BUFFER LIST ENTRIES NEEDED WILL BE 11
** FOR A NON EAV DEVICE AND THE NUMBER OF BUFFER LIST
** ENTRIES NEEDED WILL BE 12 FOR AN EAV DEVICE TO
** ACCOUNT FOR THE FORMAT 9 DSCB.
**
** THIS MODULE WILL CREATE AN OUTPUT REPORT DIRECTED TO
** THE OUTDD DD THAT SHOULD LOOK LIKE THE FOLLOWING:

-------------------------------
**
** NON EAV VOLUME
**
** CVDIR027 START OF OUTPUT MESSAGES
**
** PROCESSING DSN: CVAFDIR1.VSAM01.DATA
** CVAFDIR CALL: EADSCB=OK AND MULTIPLEDSCBS=YES CODED
** CV4EADOK BIT SET / EADSCB=OK
** CV4MULTD BIT SET / MULTIPLEDSCBS=YES
** RC00 VERIFIED - THE REQUEST WAS SUCCESSFUL
** X"00" DECOO00000000 CVSTAX CODE VERIFIED
** BUFFER LIST ENTRIES PROVIDED: 12
** BUFFER LIST ENTRIES NEEDED : 11
**
** CVDIR027 END OF OUTPUT MESSAGES

**
** EAV VOLUME
**
** CVDIR027 START OF OUTPUT MESSAGES
**
** PROCESSING DSN: CVAFDIR1.VSAM01.DATA
```

Chapter 1. Using the Volume Table of Contents  85
CVAF Macros

* CVAFDIR CALL: EADSCB=OK AND MULTIPLEDSCBS=YES CODED *

CVAFDSM Macro Overview and Specification

The CVAFDSM macro is used to obtain volume information for an indexed or nonindexed VTOC.
The CVAFDSM macro can be used for an indexed VTOC to obtain:
- One or more extents that describe unallocated space on the volume
- A count of free DSCBs on the VTOC
- A count of free VTOC index records in the VTOC index.
- A value that represents the highest allocated DSCB as determined by the VTOC INDEX.

The CVAFDSM macro can be used for a non-indexed VTOC to obtain:
- One or more extents that describe unallocated space on the volume

The format of the CVAFDSM macro is:

```
CVAFDSM label ACCESS=MAPDATA,MAP=INDEX VOLUME VTOC,EXTENTS=addr
```

- `RTA4BYTE`: YES or NO
- `MAPRCD`: YES or NO
- `UCB`: (YES, addr) or (NO, addr)
- `DEB`: addr
- `INDEX`: NO or RTA4BYTE= YES
- `MAPRCDS`: YES or NO
- `MAPRCDS`: YES or NO
- `RTA4BYTE`: YES or NO
- `UARTanggal`: NO or RTA4BYTE= YES
- `DEB`: addr
- `UCB`: (YES, addr) or (NO, addr)
- `COUNT`: YES or NO
- `CTAREA`: addr
- `HADSCB`: addr
- `KEEP`: KEEP or NOKEEP
- `IODELAY`: NO or IODELAY= KEEP
- `BRANCH`: YES or NO
- `EADSCB`: OK or NOTOK
- `MF`: (E, addr)

**Notes:**
1. Default if MF=I.
2. Default if MF=L or MF=(E, addr).
3. If YES is coded, the default is SUP.

**ACCESS**: Request Information from Index Space Maps or the VTOC

**ACCESS=MAPDATA**

Obtains data from index space maps or free space DSCBs.

The following data is available from the index space maps:
- The number of format-0 DSCBs (the data is obtained from the VTOC map of DSCBs)
- The number of unallocated VIRs in the index (the data is obtained from the VTOC index map)
The number (and location) of extents of unallocated pack space (the data is obtained from the VTOC pack space map).

The following data is available from nonindexed VTOCs:
• The number (and location) of extents of unallocated pack space.

**MAP: Identify the Map to Be Accessed**

**MAP=INDEX**
Specifies that the VTOC index map (VIXM) is to be accessed and a count of unallocated VIRs returned. COUNT=YES must also be coded.

**MAP=VOLUME**
For indexed VTOCs, specifies that the VTOC pack space map (VPSM) is to be accessed and information on unallocated extents of pack space returned.

For nonindexed VTOCs, specifies that the information from the free space DSCBs on unallocated extents is to be returned.

For indexed and nonindexed VTOCs, EXTENTS=addr and COUNT=NO must also be coded.

**MAP=VTOC**
Specifies that the VTOC map of DSCBs (VMDS) is to be accessed and a count of format-0 DSCBs returned. COUNT=YES must also be coded.

**EXTENTS: Storage Area Where Extents Are Returned**

**EXTENTS=addr**
Specifies the address where extent information is to be returned. You specify this parameter only when you also specify MAP=VOLUME to request that unallocated space information from the volume is to be returned.

When RTA4BYTE=YES is specified the following occurs:
• Information about free extents uses mapping macro ICVEDT02 (see "Using Macro ICVEDT02 to Map the Extents Area" on page 61 for ICVEDT02 format).

• EXTENTS= specifies the address of a control block (ICVEDT02) used to pass 4 byte relative track addresses of the unallocated space. You provide this storage, and you must use this mapping macro to initialize it.

Prior to calling CVAF, initialize the ICVEDT02 control block as follows:
– Place “ICVEDT02” in the first 8 bytes (DT2X7EYE).
– Place the total area length, in bytes, in DT2X7LEN. This value is 36 + (8 * the value in DT2X7ENT).
– Set the control block level number to “1” (DT2X7LEV). (Note that this value can be different in a possible future release, if IBM makes changes that effect the control block.)
– Set the remaining fields in the control block static area DT2X7FLG through DT2X7RE2 to zero prior to calling CVAF for the first time. Leave these fields unchanged from the way the previous call returned them, when calling for additional extents.
– Set DT2X7ENT to the total number of extent descriptor entries that will fit in the storage you provide.
– Place the relative track address (RTA) at which CVAF should start the search into the first four bytes of the first extent area DT2RTAST(1). CVAF updates the first extent entry with information about the next free extent found that has a higher starting RTA than that provided.
CVAF Macros

Each subsequent extent entry is filled in with information about additional free space extents (in ascending RTA order).

For all calls, if all the unallocated extents from the volume are returned before the provided storage area is filled, the remaining entries are set to zero. CVAF will now set return code 4 in register 15, and will set the CVSTAT field to X'20' to indicate end of data.

If End Of Data is reached before the provided storage area is filled with unallocated extents, CVAF will set return code 4 in register 15. If return code 0 is set in register 15, you can call CVAF again to get the remaining unallocated space information if there is any. Do NOT modify ANY header information in ICVEDT02, as CVAF can have saved internal use restart information there. Instead, copy the last ending RTA+1 (DT2RTAED) returned from the previous CVAF search into DT2RTAST.

When RTA4BYTE=NO is specified or defaulted the following occurs:

- Information about free extents has the format of XXYYZ (see "RTA4BYTE: Specify the Type of Extent Area Used" for XXYYZ format).
- EXTENTS= is the address of a 1-byte count field containing the number of 5-byte entries that follow. You provide this storage area. The length of the area, in bytes, is $1 + (\text{count} \times 5)$, where count is the value of the first byte of the area. The first two bytes ("XX") of the first 5-byte extent area entry, is the relative track address (RTA) at which CVAF will start the search. CVAF updates the first entry with information about the next free extent found that has a higher starting RTA than that supplied. Each subsequent entry is filled in with information about additional free extents (in ascending track address order).
- CVAF can be called multiple times, as needed, to retrieve more extents than the area can hold in a single call. The first extent returned is the first free extent after the relative track address ("XX") recorded in the first extent (XXYYZ) in the area.
- To retrieve the first free extent on the volume, set "XX" in the first entry to zero. When calling additional times, set "XX" in the first entry to the LAST relative track address returned by the previous call.

Recommendation: If you use larger volumes, specify RTA4BYTE=YES when you request extent information. If an extent is beyond the 64x1024 tracks boundary when the program specifies RTA4BYTE=NO or allows the default, the CVAF request fails with a CVSTAT of STAT075.

RTA4BYTE: Specify the Type of Extent Area Used

RTA4BYTE=YES

Specifies that the extents area contains pairs of addresses in the format RTA RTA+1, where RTA is the four byte relative address of the first track of the extent, and RTA+1 is the four byte relative address of the last track of the extent plus 1.

You must use the macro ICVEDT02 to map the extent area if you specify RTA4BYTE=YES. See table 19 on page 61 for a description.

RTA4BYTE=YES is a required parameter for a nonindexed VTOC, and optional for an indexed VTOC.

RTA4BYTE=NO

Specifies that the extents area is in the format XXYYZ where:

XX The relative track address of the first track of the extent
CVAF Macros

YY The number of whole cylinders in the extent
Z The number of additional tracks in the extent.

If you do not specify the RTA4BYTE parameter, the default is RTA4BYTE=NO.

MAPRCDS: Keep or Free MAPRCDS Buffer List and Buffers

MAPRCDS=YES

Specifies that the buffer list and buffers are to be retained at the end of the function.

If MAPRCDS=YES is specified and no buffer list is supplied through the CVAF parameter list, CVAF reads the VIRs into buffers obtained by CVAF. The buffer list that contains the address and RBAs of the VIRs can be accessed after the CVAF call from the CVAF parameter list field, CVMRCDS. The buffer list and VIR buffers are in the caller's protect key: subpool 0 if the caller is not authorized; subpool 229 if the caller is authorized.

MAPRCDS=YES is the default if MF=I is specified or defaulted.

When processing on the current volume is finished, release all areas that were kept.

MAPRCDS=(YES, addr)

If MAPRCDS=YES is coded, but the buffer list address (CVMRCDS in CVAF parameter list) is supplied, the VIRs are not read.

The CVMRCDS buffer list from one CVAF call can be passed to another CVAF macro call through the MAPRCDS keyword.

MAPRCDS=NO

Specifies that the MAP records buffers and buffer list are freed upon completion of the CVAFDSM function.

NO is the default if MF=L is specified.

MAPRCDS=(NO, addr)

Frees buffer lists and buffers previously obtained by CVAF.

Buffer lists and buffers obtained by CVAF must be freed by the caller. This can be done in one of the following ways:

• By coding MAPRCDS=NO on the call that obtained the buffers
• By coding MAPRCDS=NO on a subsequent CVAF call
• By coding CVAFDIR ACCESS=RLSE and providing the buffer list in the BUFLIST keyword.

If MF=(E, addr) is coded and MAPRCDS is not coded, the parameter list value of MAPRCDS is not changed.

Requirement: You must enqueue the VTOC and reserve the unit to maintain the integrity of the MAP records read.

UCB or DEB: Specify the VTOC to Be Accessed

UCB= rs-type or (2-12) standard form UCB= rx-type or (2-12) execute form

Specifies the address of the UCB for the VTOC to be accessed. The UCB address can be for a captured UCB, or for an actual UCB above or below the 16MB line. Use the address of a UCB, not a UCB copy. An unauthorized caller
can not use this parameter. If your program is in 31-bit mode, this address must be in 31-bit address; the high order byte is part of the address. You should not code the UCB parameter with MF=L.

**DEB=addr**
Supplies the address of a DEB opened to the VTOC you want to access. CVAF does not allow output requests to the VTOC or VTOC index if you specify the DEB subparameter. Without authorization, you cannot perform any asynchronous activity (such as EXCP, CLOSE, EOV) against the data set represented by the DEB because CVAF removes the DEB from the DEB table for the duration of the CVAF call. If you are not authorized (neither APF authorized nor in a system key), specify a DEB address, not a UCB, to CVAFDSM. See "Identifying the Volume" on page 56 for further details.

If you supply a previously obtained I/O area through the IOAREA keyword, neither UCB nor DEB need be supplied. Otherwise, supply either a UCB or DEB. If you supply a UCB address, it is overlaid in the CVPL by the UCB address in the I/O area. If you supply both the UCB and the DEB addresses in the CVPL, the DEB address is used and the UCB address in the CVPL is overlaid by the UCB address in the DEB.

**COUNT: Obtain a Count of Unallocated DSCBs or VIRs**

- **COUNT=YES** Indicates that a count of unallocated DSCBs or VIRs in the designated space map is requested. MAP=VTOC or MAP=INDEX must be specified if COUNT=YES is coded.
- **COUNT=NO** Indicates that a count of unallocated DSCBs or VIRs is not desired but, rather, information on free space on the pack is desired. MAP=VOLUME must be coded if COUNT=NO is coded or the default.

**CTAREA: Supply a Field to Contain the Number of Format-0 DSCBs**

- **CTAREA=addr** Supplies the address of a 4-byte field to contain the number of format-0 DSCBs when COUNT=YES, MAP=VTOC is specified; or the number of unallocated VIRs in the VTOC index when COUNT=YES, MAP=INDEX is specified.

**HADSCB: Supply a Field to Contain the CCHHR of the Highest Allocated DSCB**

- **HADSCB=addr** Supplies the address of a 5-byte field to contain the CCHHR of the highest allocated DSCB in the VTOC when COUNT=YES and MAP=VTOC are specified.

**IOAREA: Keep or Free the I/O Work Area**

- **IOAREA=KEEP** Specifies that the CVAF I/O area associated with the CVAF parameter list is to be kept upon completion of the CVAF request. IOAREA=KEEP can be coded with BRANCH=NO only if the caller is authorized (APF or system key).

If IOAREA=KEEP is coded, the caller must call CVAF with IOAREA=NOKEEP specified at some future time, whether or not any further VTOC access is required. An example of such a caller is the recovery routine of the caller of CVAF.
CVAF Macros

Coding IOAREA=KEEP allows subsequent CVAF requests to be more efficient, as certain initialization functions can be bypassed. Neither DEB nor UCB need be specified when a previously obtained CVAF I/O area is supplied; neither can they be changed.

When IOAREA=KEEP is first issued, CVAF returns the CVAF I/O area in the CVAF parameter list (CVIOAR). Subsequent calls of CVAF can use that same parameter list, and CVAF obtains its I/O area from the CVIOAR.

When processing on the current volume is finished, release all areas that were kept.

IOAREA=(KEEP,addr)
Supplies the address of a previously obtained I/O area. If a different CVAF parameter list is used, the previously obtained CVAF I/O area can be passed to CVAF by coding its address as the second parameter of the IOAREA keyword.

IOAREA=NOKEEP
Causes the work area to be freed upon completion of the CVAF request. This is the default.

IOAREA=(NOKEEP,addr)
Causes a previously obtained work area to be freed upon completion of the CVAF request.

BRANCH: Specify the Entry to the Macro

BRANCH=(YES,SUP)
Requests the branch entry. The caller must be in supervisor state. Protect key checking is bypassed.

If BRANCH=YES is coded, an 18-word save area must be supplied. No lock can be held on entry to CVAF. SRB mode is not allowed.

BRANCH=YES
Equivalent to BRANCH=(YES,SUP), because SUP is the default when YES is coded. Protect key checking is bypassed.

BRANCH=(YES,PGM)
Requests the branch entry. The caller must be APF authorized and in problem state. Protect key checking is bypassed.

BRANCH=NO
Requests the SVC entry. The caller must be APF authorized if any output operations are requested. Protect key checking is performed. This is the default.

EADSCB: Specify the support level for extended attribute DSCBs

EADSCB=OK
This specification indicates that the calling program supports RTAs that could contain tracks an extended address volume.

For calls that request unallocated space (ACCESS=MAPDATA, MAP=VOLUME, RTA4BYTE=YES and EXTENTS=address), a CVAFDSM request issued to an EAV volume will be failed if the EADSCB=OK indicator is not set.

The failing error code for these cases will be reflected as follows:
• CVAF status code (CVSTAT) set to STAT082.
• Return code 4.

EADSCB=OK will set the CV4EADOK indicator in the CVPL. All other calls to CVAFDSM are allowed and EADSCB=OK will be ignored.
CVAF Macros

EADSCB=NOTOK
Indicates a calling program does not support extended attribute DSCBs.
EADSCB=NOTOK will set the CV4EADOK indicator in the CVPL to off. This is
the default.

MF: Specify the Form of the Macro
This keyword specifies whether the list, execute, or normal form of the macro is
requested.

MF=I
If I is coded or if neither L nor E is coded, the CVAF parameter list
is generated, as is code, to call CVAF. This is the default.

MF=L
Indicates the list form of the macro. A parameter list is generated,
but code to call CVAF is not generated.

MF=(E, addr)
Indicates the execute form of the macro. The remote CVAF
parameter list supplied as addr is used in, and can be modified by,
the execute form of the macro.

Return Codes from CVAFDSM
On return from CVAF, register 1 contains the address of the CVPL (CVAF
parameter list), and register 15 contains one of the following return codes:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>The request was successful.</td>
</tr>
</tbody>
</table>
| 4 (X'04')  | End of data (CVSTAT is set to decimal 32), or an error was
          | encountered. The CVSTAT field in the CVPL contains an
          | indication of the cause of the error. (CVSTAT code
          | descriptions are in z/OS DFSMSdfp Diagnosis, GY27-7618) |
| 8 (X'08')  | Invalid VTOC index structure. CVSTAT contains an indication of
          | the cause of the error. (CVSTAT code descriptions are in z/OS
          | DFSMSdfp Diagnosis, GY27-7618) |
| 12 (X'0C') | One of the following
          | • The CVAF parameter list is not in your protect key.
          | • The CVAF parameter list protect key is invalid.
          | • The CVAF parameter list ID is invalid.
          | • The CVAF parameter list length is incorrect.
          | • The CVAF parameter list has not been modified.
          | • The function code (CVFCTN) field is not valid.
          | • The function code (CVFCTN) field is not supported by this
          | release. |
| 16 (X'10') | An I/O error was encountered. |

CVAFFILT Macro Overview and Specification
You can use the CVAFFILT macro to invoke the CVAF filter service. You can also
use it to map or initialize the CVAF parameter list (CVPL). CVAF filter retrieves data
set DSCB chains from an indexed or nonindexed VTOC and places them in buffers
you provide. You can request the DSCBs for a single partially-qualified data set
name or for a list of fully-qualified data set names.

Identify a specific DASD device and provide both a filter criteria list (FCL) defining
the request, and a CVAF buffer list (with buffers) for DSCB return. The format of the
two elements of the FCL is shown in Table 20 on page 68 and Table 21 on page 70
The format of the buffer list is shown in “Using Buffer Lists” on page 59. CVAFFILT
returns a complete set of DSCBs in the order that they are chained in the VTOC
(format-1, format-2, then format-3).
Keywords coded on the list form of the macro need not be coded on the execute form. Keywords coded on one CVAFFILT call remain in effect for subsequent calls unless overridden, if you use the same CVAFFILT parameter list.

See "Reading Sets of DSCBs with CVAF Filter" on page 66 for additional information.

The format of the CVAFFILT macro is:

```
CVAFFILT
  label

  ,ACCESS=READ

  ,BUFLIST=addr

  ,UCB=(ucbaddr)

  ,DEB=addr

  ,FCL=addr

  ,FLTAREA=addr

  ,NOKEEP

  ,IOAREA=KEEP

  ,EADSCB=OK

  ,MF=D

  ,L=(E,addr)

  ,PGM=Sup
```

**Restriction:** For the first operand following CVAFFILT, do not code the leading comma.

**Control Block Address Resolution:**

Keyword=addr or (reg)

You, as the caller, either define or reference the control blocks needed by CVAF filter. Caller-defined control blocks are: BUFLIST, CVPL, and FCL. Caller-referenced control blocks are: DEB, FLTAREA, IOAREA, and UCB. The CVAFFILT macro generates different instructions for keyword=addr and keyword=(reg) depending upon whether you are specifying a defined or referenced control block.

- When you specify any control block's address as (reg), the CVAFFILT macro assumes that the register specified contains that address.
- When you specify a "defined" control block's address as addr, the CVAFFILT macro assumes that the specified location is that of the control block itself. The macro generates a load address instruction (LA) to obtain the control block's address.
- When you specify a "referenced" control block's address as addr, the CVAFFILT macro assumes that the specified location is that of a word containing the address of the control block. The macro generates a load instruction (L) to obtain the control block's address.
CVAF Macros

ACCESS: Retrieve a DSCB, or Release FLTAREA and/or IOAREA

ACCESS=READ
Retrieves all DSCBs associated with the data set names specified in the filter criteria list (FCL), placing them in your buffers. You can select (filter) the retrieved DSCBs by providing either a list of one or more fully-qualified names, or a single partially-qualified name, using single or double asterisk notation. (See the example of partially-qualified names in "Partially-Qualified Names for CVAFFILT" on page 104.)

If the number of buffers is not large enough to hold all the requested DSCBs, CVAFFILT indicates this in the CVSTAT status byte of the CVAF parameter list (CVPL). You can resume the READ function by issuing a call with ACCESS=RESUME. See "Codes Put in the CVSTAT Field" on page 139.

When selecting DSCBs by partially-qualified name, CVAFFILT uses only the first data set name in the FCL list. Set the FCLCOUNT count field in the FCL to 1 or CVAFFILT returns error code 63 in the CVSTAT status byte of the CVPL. The DSCBs returned by CVAFFILT might not be in sequence by data set name; however, the DSCBs for each data set are always in order (format-1, format-2, format-3).

When selecting DSCBs by fully-qualified names, you can request that CVAF filter return the DSCBs for the selected data set names in the data set name order implied by the FCL. See the FCL1ORDR flag in Table 20 on page 68.

Always test the status byte of each data set name in the FCL list to ensure successful completion. (Some error conditions result in failure to return a data set's DSCBs.) See the FCLDSNST byte in Table 21 on page 70.

ACCESS=RESUME
Resumes a previously initiated READ or RESUME function that was terminated because you did not provide enough buffers to contain all the requested DSCBs. For the RESUME function to execute correctly, the keyword FLTAREA=KEEP must be coded in each of the previous READ and RESUME function calls.

ACCESS=RLSE
Releases the previously kept filter save area (FLTAREA) and/or CVAF I/O work area (IOAREA).

BUFLIST: Specify a Buffer List

BUFLIST=addr or (reg)
Supplies the address of a buffer list used to read DSCBs. When you specify ACCESS=RLSE, the BUFLIST keyword is required for the standard form of the macro. See the format of the buffer list header and buffer list entry in Table 17 on page 59 and Table 18 on page 60, respectively.

UCB or DEB: Specify the VTOC to Be Accessed

UCB= rs-type or (2-12) standard form UCB= rx-type or (2-12) execute form
Specifies the address of the UCB for the VTOC to be accessed. The UCB address might be for a captured UCB, or for an actual UCB above or below the 16 MB line. Use the address of a UCB, not a UCB copy. An unauthorized caller must not use this parameter. If your program is in 31-bit mode, this address must be in 31-bit address; the high order byte is part of the address. You should not code the UCB parameter with MF=L.

DEB=addr or (reg)
Supplies the address of a DEB opened to the VTOC you want to access. If you
CVAF Macros

are not authorized, specify a DEB address, not a UCB, to CVAFFILT; also, without authorization, you cannot perform any asynchronous activity against the data set represented by the DEB (such as EXCP, CLOSE, EOV), because CVAF removes the DEB from the DEB table for the duration of the CVAF call. See "Identifying the Volume" on page 56 for further details.

If you supply a previously obtained I/O area through the IOAREA keyword, neither UCB nor DEB is needed. Otherwise, supply either a UCB or DEB. If you supply a UCB address, it is overlaid in the CVPL by the UCB address in the I/O area. If you supply both the UCB and the DEB addresses in the CVPL, the DEB address is used and the UCB address in the CVPL is overlaid by the UCB address in the DEB.

FCL: Specify a Filter Criteria List

\[ FCL=addr \text{ or } \text{(reg)} \]

Supplies the address of a filter criteria list. It is required when ACCESS=READ is specified on the standard form of the macro. The format of the two elements of the filter criteria list is shown in Table 20 on page 68 and Table 21 on page 70.

FLTAREA: Keep or Free the Filter Save Area

\[ FLTAREA=\text{KEEP} \]

Specifies keeping the filter save area. Code this operand if the RESUME function might be called later (to resume processing prematurely terminated because the number of caller-supplied buffers is not enough to contain all the returned DSCBs).

CVAFFILT returns the address of the kept filter save area in the CVAFFILT parameter list (CVFSA field). If you specify the same parameter list in subsequent RESUME calls, CVAFFILT reuses the same filter save area.

Tip: If you code this operand, you must subsequently issue CVAFFILT with ACCESS=RLSE to release the filter save area.

\[ FLTAREA=(\text{KEEP}, addr \text{ or } \text{(reg)}) \]

Supplies the address of a previously obtained filter save area. See the description of FLTAREA=KEEP operand for additional concerns.

\[ FLTAREA=\text{NOKEEP} \]

Frees the filter save area upon completion of the CVAF request.

\[ FLTAREA=(\text{NOKEEP}, addr \text{ or } \text{(reg)}) \]

Frees a previously obtained filter save area upon completion of the CVAF request.

IOAREA: Keep or Free the I/O Work Area

\[ IOAREA=\text{KEEP} \]

Specifies keeping the CVAF I/O work area. For authorized callers, CVAFFILT returns the address of the kept I/O work area in the CVAFFILT parameter list (CVIOAR). If you specify the same parameter list in subsequent calls, CVAFFILT reuses the same I/O work area.

Tip: If you code this operand, you must subsequently issue CVAFFILT with ACCESS=RLSE to release the I/O work area.

\[ IOAREA=(\text{KEEP}, addr \text{ or } \text{(reg)}) \]

Supplies the address of a previously obtained filter save area. See the description of IOAREA=KEEP operand for additional concerns.
CVAF Macros

IOAREA=NOKEEP
Frees the filter save area upon completion of the CVAF request.

IOAREA=(NOKEEP, addr or (reg))
Frees a previously obtained CVAF I/O work area upon completion of the CVAF request.

BRANCH: Specify the Entry to the Macro

BRANCH=NO
Requests the SVC (default) entry. Protect key checking is performed.

BRANCH=YES
Equivalent to BRANCH=(YES,SUP), because SUP is the default when you code YES. You must be in supervisor state. Protect key checking is bypassed.

BRANCH=(YES,SUP)
Requests the branch entry. You must be in supervisor state. Protect key checking is bypassed. If you specify BRANCH=YES, supply an 18-word save area. You cannot hold a lock at entry to CVAF. You cannot be in SRB mode.

BRANCH=(YES,PGM)
Requests the branch entry. You must be APF authorized and be in problem state. Protect key checking is bypassed.

EADSCB=value: Specify the support level for extended attribute DSCBs.

EADSCB=OK
This specification indicates that the calling program supports extended attribute DSCBs. An extended address volume may have these DSCBs allocated to it. The returned DSCBs (format-3, format-8) may contain extent descriptors described by 28-bit cylinder addresses or DSCBs (format-9) that contain additional attribute information.

For fully qualified data set names in the Filter Criteria List, a CVAFFILT request fails if the EADSCB=OK, indicator is not set and the DSCB associated with the fully qualified data set name is a format-8 DSCB.

For partially qualified data set names in the Filter Criteria List, a CVAFFILT request fails if the EADSCB=OK, indicator is not set and a DSCB associated with a data set that matches the Filter Criteria List is a format-8 DSCB.

The failing error code for these cases will be reflected as follows:
• Data set name status in the FCL (FCLDSNST) is set to a status value of (X'06'). This status code indicates that a data set name is described by a format-8 DSCB and the caller did not specify support for an EAV with the EADSCB=OK keyword.
• Set the no resume CVAF status code (CVSTAT) of STAT072
• Return code 4.

EADSCB=OK will set the CV4EADOK indicator in the CVPL.

EADSCB=NOTOK
Indicates a calling program does not support extended attribute DSCBs. EADSCB=NOTOK will set the CV4EADOK indicator in the CVPL to off. This is the default.

MF: Specify the Form of the Macro
Specifies whether the DSECT, list, execute, or normal form of the macro is requested. You can be in either 24-bit or 31-bit addressing mode. If you are not
**CVAF Macros**

authorized, you must pass the address of a DEB built by OPEN. If you are
authorized, you can pass either the DEB address or the UCB address. You must
ensure that the volume is allocated and will remain mounted (for example, by
dynamic allocation).

**MF=I**  Specifies the standard form of the macro. The CVAF parameter list is
generated and CVAF is called. The default is MF=I.

**MF=D**  Specifies the DSECT form of the macro. The macro generates a request for
the ICVAFLP macro to map the unique CVAF filter CVPL (4-bytes longer
than standard CVPL).

**MF=L**  Specifies the list form of the macro. The CVAF parameter list is generated,
but CVAF is not called.

**MF=(E, addr or (reg))**  Specifies the execute form of the macro. The CVAF parameter list whose
address is in addr or reg is used. You can modify the parameter list with
this form of the macro.

**Return Codes from CVAFFILT**

CVAF filter service does not issue any messages. Upon return from CVAF, register
1 contains the address of the CVAF parameter list and register 15 contains one of
the following return codes:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>The request was successful.</td>
</tr>
<tr>
<td>4 (X'04')</td>
<td>Logical error; status information in CVSTAT.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>Invalid VTOC structure.</td>
</tr>
<tr>
<td>12 (X'0C')</td>
<td>CVAFFILT parameter list in wrong key, or not valid.</td>
</tr>
<tr>
<td>16 (X'10')</td>
<td>I/O error.</td>
</tr>
</tbody>
</table>

CVSTAT in the CVAF parameter list contains the status code. See "Codes Put in
the CVSTAT Field" on page 139 for a list of the status codes.

**Partially-Qualified Names for CVAFFILT**

CVAFFILT supports partially-qualified data set names using single or double
asterisk notation and the percent sign as shown in the following text:

- You can use a single asterisk to represent a single qualifier. For example,
  SYS1.*.LOAD designates any data set with three qualifiers, the first being SYS1,
  the second being any qualifier, and the third being LOAD.

- You can also use a single asterisk to represent zero or more unspecified
  characters. For example, LOAD.*LIB designates any data set having only two
  qualifiers, with LOAD being the first, and the second qualifier ending with the
  character string LIB (for example, LINKLIB). The asterisk can appear anywhere
  within the qualifier. You can use two single asterisks in the following way:
  LOAD.A*B*.LIB. CVAFFILT does not support the use of two or more single
  asterisks with any other character within a single qualifier (for example,
  LOAD.A**.LIB is not valid).

- A double asterisk represents a place holder for zero or more qualifiers. For
  example, SYS1.* designates any data set having SYS1 as its first or only
  qualifier.

- You can specify a percent sign (%) as part of a partially-qualified name. The
  percent sign designates any data set whose name matches the partially-qualified
  name, except for the single character in the position indicated by the percent
  sign. For example, SYS%.*LOAD% designates any data set with three qualifiers,
CVAF Macros

the first being any 4-character qualifier beginning with SYS, the second being any qualifier, and the third being any five character qualifier beginning with LOAD.

Example of Using the CVAFFILT Macro
This example uses the CVAFFILT macro to read all format-1 and format-3 DSCBs for specific data sets within a given VTOC as well as for all data sets within a given VTOC. It will also calculate the number of DSCBs and print the totals and appropriate messages to an output file. Refer to the documentation within the example source in "CVAFFILT Macro Overview and Specification" on page 99 for setup requirements, program logic, and expected output.

The CVAF parameter list, buffer list, and filter criteria list are defined in the sample source. The ICVAFPL macro generates the CVAF parameter list, the ICVAFBFL macro generates the buffer list, and the ICVFCL macro generates the filter criteria list.

Sample JCL for the CVAFFILT macro: The following is the sample JCL used to Assemble, Link, and Execute the example source. Changes will have to be made to this JCL as appropriate for each customer environment.

```
//CVAFFEXP JOB ,MSGCLASS=X,TIME=(,10),
// NOTIFY=$SYSUID
//*
//STEP01 EXEC PROC=ASMACLG
//SYSIN DD *
//   (INCLUDE EXAMPLE SOURCE HERE)
//*/
//*
//L.SYSLMOD DD DSN=YOUR.AUTH.LINKLIB(CVAFFEXP),DISP=SHR
//L.SYSIN DD *
//   SETCODE AC(1)
//   ENTRY CVAFFEXP
//*/
//*
//G.SYSABEND DD SYSOUT=*  
//SYSPRINT DD SYSOUT=*  
//*
//G.CVAFFDD DD DISP=SHR,UNIT=3390,VOL=SER=339L62
//G.OUTDD DD DSN=CVAFFLT1.OUTPUT,  
//   DISP=(NEW,CATLG),  
//   UNI)”
1) 2 SEQUENTIAL DATASETS WITH 5 EXTENTS. (1 FMT1/1 FMT3 EACH)
DSCBS RETURNED WILL BE COMBINED TO TOTAL 2 FMT1 / 2 FMT3'S
DSN: CVAFFLT1.DATA01
DSN: CVAFFLT1.DATA02
CREATE ON THE VOLUME ASSOCIATED WITH THE CVAFDD DD

2) PDSE DATASET WITH 122 EXTENTS. (1 FMT1/10 FMT3'S)
DSN: CVAFFLT1.PDSE01
CREATE ON THE VOLUME ASSOCIATED WITH THE CVAFDD DD

3) 1 SEQUENTIAL DATASET WITH 5 EXTENTS (1 FMT1/1 FMT3)
DSN: CVAFFLT1.DATA01
CREATE ON THE VOLUME ASSOCIATED WITH THE CVAFDD DD

4) RETURN DSCB COUNT FOR ENTIRE VOLUME USING CVAFFILT RESUME
PROCESING.
DSN'S ON THE VOLUME: (IN SEQUENCE ORDER)
SYS1.VTOCIX.V39L62  (VTOC INDEX - 1 FMT1)
CVAFFLT1.DATA01   (5 EXTENTS - 1 FMT1/1 FMT3)
CVAFFLT1.DATA02   (5 EXTENTS - 1 FMT1/1 FMT3)
CVAFFLT1.PDSE01   (122 EXTENTS - 1 FMT1/10 FMT3'S)
DSN'S CREATED ON THE VOLUME ASSOCIATED WITH THE CVAFDD DD

OUTPUT IN OUTDD DATASET SHOULD BE THE FOLLOWING:

---------------------------------------------------------------------

CVAFFEXP START OF OUTPUT MESSAGES

RC00 VERIFIED - THE REQUEST WAS SUCCESSFUL
CVAFFILT RETURNED THE FOLLOWING DSCBS FOR DSN: CVAFFLT1.DATA01
AND FOR DSN: CVAFFLT1.DATA02
NUMBER OF FORMAT 1 DSCBS - 0000002
NUMBER OF FORMAT 3 DSCBS - 0000002

RC00 VERIFIED - THE REQUEST WAS SUCCESSFUL
CVAFFILT RETURNED THE FOLLOWING DSCBS FOR DSN: CVAFFLT1.PDSE01
NUMBER OF FORMAT 1 DSCBS - 0000001
NUMBER OF FORMAT 3 DSCBS - 0000010

RC00 VERIFIED - THE REQUEST WAS SUCCESSFUL
CVAFFILT RETURNED THE FOLLOWING DSCBS FOR DSN: CVAFFLT1.DATA01
NUMBER OF FORMAT 1 DSCBS - 0000001
NUMBER OF FORMAT 3 DSCBS - 0000001

RC04 VERIFIED - CVSTAT 064 RESUME IS NECESSARY
CVAFFILT (INITIAL) RETURNED THE FOLLOWING DSCBS FOR THE VOLUME:
NUMBER OF FORMAT 1 DSCBS - 0000003
NUMBER OF FORMAT 3 DSCBS - 0000002
CVAFFILT (RESUME) RETURNED THE FOLLOWING DSCBS FOR THE VOLUME:
NUMBER OF FORMAT 1 DSCBS - 0000001
NUMBER OF FORMAT 3 DSCBS - 0000010
CVAFFILT RESUME OPERATION COMPLETE - ALL DSCBS RETURNED

CVAFFEXP END OF OUTPUT MESSAGES

---------------------------------------------------------------------

NOTE: THE NUMBER OF DSCBS RETURNED WILL VARY IF THE DATASET DOES
NOT EXIST ON THE VOLUME OR IF THE DATASET EXTENT IS NOT AS
LISTED ABOVE OR IF THERE IS NO VTOC INDEX ON THE VOLUME.

NOTE: WHEN CREATING A PDSE ON A SMS MANAGED VOLUME A VVDS
WILL ALSO BE CREATED AND THE FMT1 COUNT WILL BE
*** INCREASED BY ONE. ***

**********************************************************************
**
* CVAFFEXP - LOGIC NOTES *
* THIS EXAMPLE WILL PERFORM THE FOLLOWING: *
* INITIALIZATION *
* - OBTAIN THE NECESSARY INFORMATION FROM THE DASD VOLUME *
* - OPEN AN OUTPUT FILE AND WRITE THE NECESSARY OUTPUT MESSAGES *
* - INITIALIZE THE NECESSARY BUFFER LIST FOR CVAFFILT *
** MAINLINE *
* - INITIALIZE A FCL TO READ FOR TWO SPECIFIC SEQ DATASETS *
* - ISSUE CVAFFILT READ TO READ THE DSCBS FOR THE TWO DATASETS *
* - CHECK THE RETURN CODE AND CVSTAT CODE FROM CVAFFILT *
* - COUNT THE NUMBER OF FMT1 AND FMT3 DSCBS FOR THE REQUEST *
* - FORMAT THE DSCB COUNTS AND WRITE TO THE OUTPUT DATASET *
* - ISSUE CVAFFILT RLSE TO RELEASE THE WORK AREAS USED *
* - INITIALIZE A FCL TO READ FOR ONE SPECIFIC PDSE DATASET *
* - ISSUE CVAFFILT READ TO READ THE DSCBS FOR THE PDSE DATASET *
* - CHECK THE RETURN CODE AND CVSTAT CODE FROM CVAFFILT *
* - COUNT THE NUMBER OF FMT1 AND FMT3 DSCBS FOR THE REQUEST *
* - FORMAT THE DSCB COUNTS AND WRITE TO THE OUTPUT DATASET *
* - ISSUE CVAFFILT RLSE TO RELEASE THE WORK AREAS USED *
* - INITIALIZE A FCL TO READ FOR ONE SPECIFIC SEQ DATASET *
* - ISSUE CVAFFILT READ TO READ THE DSCBS FOR THE ONE DATASET *
* - CHECK THE RETURN CODE AND CVSTAT CODE FROM CVAFFILT *
* - COUNT THE NUMBER OF FMT1 AND FMT3 DSCBS FOR THE REQUEST *
* - FORMAT THE DSCB COUNTS AND WRITE TO THE OUTPUT DATASET *
* - ISSUE CVAFFILT RLSE TO RELEASE THE WORK AREAS USED *
* - INITIALIZE A FCL TO READ THE DSCBS ON THE ENTIRE VOLUME *
* - ISSUE CVAFFILT READ TO READ THE DSCBS FOR THE VOLUME *
* - CHECK THE RETURN CODE AND CVSTAT CODE FROM CVAFFILT *
* - PROCESS ALL DSCBS USING CVAFFILT RESUME AS NECESSARY *
* - COUNT THE NUMBER OF FMT1 AND FMT3 DSCBS FOR THE REQUEST *
* - FORMAT THE DSCB COUNTS AND WRITE TO THE OUTPUT DATASET *
* - ISSUE CVAFFILT RLSE TO RELEASE THE WORK AREAS USED *
** FINALIZATION *
* - CLOSE THE OUTPUT FILE *
* - EXIT *

* CVAFFEXP - JOB INFORMATION *
* NORMAL END OF JOB: *
* - RC=00 AND OUTDD OUTPUT AS DETAILED ABOVE *

* ABNORMAL END OF JOB: *
* - ABEND 100 - ERROR OPENING VTOC ON THE DASD VOLUME THAT IS *
*   ASSOCIATED WITH THE CVAFDD DD STATEMENT *
* - ABEND 101 - ERROR OPENING THE OUTDD DATASET *
* - ABEND 102 - ERROR CLOSING THE OUTDD DATASET *

*DASD VOLUMES USED IN THIS EXAMPLE: *
* - 339L61 - 3390 WHERE OUTDD DATASET IS DEFINED *
* - 339L62 - 3390 WHERE TEST DATASETS DETAILED ABOVE ARE DEFINED*

CVAFSEQ Macro Overview and Specification

The CVAFSEQ macro can be used to:
- Read an indexed VTOC sequentially in data-set-name (DSN) order
- Read an indexed VTOC or a nonindexed VTOC in physical-sequential order.

See "Accessing DSNs or DSCBs in Sequential Order" on page 65 for additional information.

The format of the CVAFSEQ macro is:
CVAF Macros

**ACCESS**: Specify Relationship between Supplied and Returned DSN

**ACCESS=GT**

Specifies that the DSN or argument value is to be used to return a DSCB whose DSN or argument is greater than that supplied.

**ACCESS=GTEQ**

Specifies that the DSN or argument value is to be used to return a DSCB whose DSN or argument is greater than or equal to that supplied.

**Recommendation**: A CVAF call specifying ACCESS=GTEQ should be followed by an ACCESS=GT request, or the same DSCB or name is returned.

**BUFLIST**: Specify One or More Buffer Lists

**BUFLIST=addr**

Supplies the address of a buffer list used to read or write DSCBs and VIRs.

**DSN**: Specify Access by DSN Order or by Physical-Sequential Order

**DSN=addr**

Supplies the address of a 44-byte area containing either zeros or a data set name. Specifying the DSN keyword causes access of an indexed VTOC by DSN order. BUFLIST is required if DSNONLY=NO is coded or the default.

**DSN omitted**

If you omit the DSN keyword, access of an indexed or nonindexed VTOC is by physical-sequential order. BUFLIST is required.

If the order is physical-sequential, initialize the argument field in the first buffer list entry to zero or to the argument of the DSCB. If the argument is zero (BFLEARG=00), the read begins at the start of the VTOC. You must be authorized (APF or system key) to read multiple DSCBs with a single invocation of the CVAFSEQ macro. See "Initiating Physical-Sequential Access" on page 66 for more information.

---

Notes:

1. If YES is coded, the default is SUP.
UCB or DEB: Specify the VTOC to Be Accessed

**UCB=** \textit{rs-type} or (2-12) \textit{standard form} \textbf{UCB= rx-type} or (2-12) \textit{execute form}

Specifies the address of the UCB for the VTOC to be accessed. The UCB address can be for a captured UCB, or for an actual UCB above or below the 16MB line. Use the address of a UCB, not a UCB copy. An unauthorized caller must not use this parameter. If your program is in 31-bit mode, this address must be in 31-bit address; the high order byte is part of the address. You should not code the UCB parameter with MF=L.

**Recommendations:**

- Code the address of the UCB parameter only as register (2-12). Coding an RX-type address gives you unpredictable results.
- Do not use the UCB address passed back in the CVPL from a previous CVAFSEQ request, particularly in AMODE=24, as it may be invalid (because it is a captured and then uncaptured address). The recommendation is to use IOAREA=KEEP.

**DEB=**\textit{addr}

Supplies the address of a DEB opened to the VTOC you want to access. CVAF does not allow output requests to the VTOC or VTOC index if you specify the DEB subparameter. If you are not authorized, you cannot perform any asynchronous activity (such as EXCP, CLOSE, EOV), against the data set represented by the DEB because CVAF removes the DEB from the DEB table for the duration of the CVAF call. If you are not authorized (neither APF authorized nor in a system key), specify a DEB address, not a UCB, to CVAFSEQ. See [Identifying the Volume](#) on page 56 for further details.

If you supply a previously obtained I/O area through the IOAREA keyword, neither UCB nor DEB need be supplied. Otherwise, supply either a UCB or DEB. If you supply a UCB address, it is overlaid in the CVPL by the UCB address in the I/O area. If you supply both the UCB and the DEB addresses in the CVPL, the DEB address is used and the UCB address in the CVPL is overlaid by the UCB address in the DEB.

**DSNONLY: Specify That Only the Data Set Name Is Read**

This keyword is applicable only to accessing an indexed VTOC in DSN order.

**DSNONLY=NO**

Requests that the data set name be obtained from the VTOC index and the DSCB be read into a buffer supplied through the BUFLIST keyword.

BUFLIST is required.

**DSNONLY=YES**

Requests that only the data set name be obtained from the VTOC index. If the ARG keyword is coded, the argument of the DSCB is returned.

**ARG: Specify Where the Argument of the DSCB Is to Be Returned**

This keyword is applicable only to accessing an indexed VTOC in DSN order with DSNONLY=YES coded.

**ARG=**\textit{addr}

Supplies the address of the 5-byte area where the CCHHR of each data set name in the VTOC index is returned when DSNONLY=YES is coded.
CVAF Macros

IOAREA: Keep or Free the I/O Work Area

**IOAREA=KEEP**

Specifies that the CVAF I/O area associated with the CVAF parameter list is to be kept upon completion of the CVAF request. IOAREA=KEEP can be coded with BRANCH=NO only if the caller is authorized (APF, or system key).

If IOAREA=KEEP is coded, the caller must call CVAF with IOAREA=NOKEEP specified at some future time, whether or not any further VTOC access is required: for example, the recovery routine of the caller of CVAF.

Coding IOAREA=KEEP allows subsequent CVAF requests to be more efficient, because certain initialization functions can be bypassed. Neither DEB nor UCB need be specified when a previously obtained CVAF I/O area is supplied; nor can they be changed.

When IOAREA=KEEP is first issued, CVAF returns the CVAF I/O area in the CVAF parameter list (CVIOAR). Subsequent calls of CVAF can use that same parameter list, and CVAF obtains its I/O area from the CVIOAR.

When processing on the current volume is finished, release all areas that were kept.

**Note:** Do not switch back and forth between AMODE=24 and AMODE=31 during a succession of CVAFSEQ requests while IOAREA=KEEP is active. This can cause problems such as ABENDS in CVAF.

**IOAREA=(KEEP, addr)**

Supplies the address of a previously obtained I/O area. If a different CVAF parameter list is used, the previously obtained CVAF I/O area can be passed to CVAF by coding its address as the second parameter of the IOAREA keyword.

**IOAREA=NOKEEP**

Causes the work area to be freed upon completion of the CVAF request.

**IOAREA=(NOKEEP, addr)**

Causes a previously obtained work area to be freed upon completion of the CVAF request.

IXRCDS: Retain VIERs in Virtual Storage

This keyword applies to an indexed VTOC only.

**IXRCDS=KEEP**

Specifies that the VIERs read into storage during the CVAF function are to be kept in virtual storage. The VIERs are retained even if the index function is unsuccessful. The VIERs are accessed from the CVAF parameter list (CVIRCDS). CVIRCDS is the address of a buffer list containing the VIR buffer addresses and RBAs of the VIERs read.

Index search function dynamically updates the buffer list and, when necessary, obtains additional buffer lists and chains them together.

If IXRCDS=KEEP is specified and no buffer list is supplied to CVAF in the CVPL, CVAF obtains a buffer list and buffers and reads the first high-level VIER. The address of the buffer list is placed in the CVIRCDS field of the CVPL.

The buffer list and VIR buffers are in the caller's protect key. The subpool is 0 if the caller is not authorized; subpool 229 if the caller is authorized.

If IXRCDS=KEEP for an nonindexed VTOC, a request to read a DSCB can be performed, but an error code is returned.
When processing on the current volume is finished, release all areas that were kept.

**IXRCS=(KEEP,addr)**

The CVIRCDS from one CVAF call can be passed to another CVAF parameter list by specifying the address as the second parameter in the IXRCS keyword.

**IXRCS=NOKEEP**

If IXRCS=NOKEEP is coded, the VIERs that are accessed (if any) are not retained. Furthermore, the buffer list supplied in the CVIRCDS field in the CVAF parameter list is released, as are all buffers found in the buffer list. If the skip bit is set in any entry in the buffer list, the buffer and buffer list are not freed.

**IXRCS=(NOKEEP,addr)**

specifies that previously accessed VIERs are not to be retained.

You must free buffer lists and buffers obtained by CVAF. This can be done in one of three ways:

- By coding IXRCS=NOKEEP on the CVAFSEQ macro that obtained the buffers
- By coding IXRCS=NOKEEP on a subsequent CVAF macro
- By coding CVAFDIR ACCESS=RLSE and providing the address of the buffer list in the BUFLIST keyword.

**Requirement:** You must enqueue the VTOC and reserve the unit to maintain the integrity of the VIERs read.

**BRANCH: Specify the Entry to the Macro**

**BRANCH=(YES,SUP)**

Requests the branch entry. The caller must be in supervisor state. Protect key checking is bypassed.

If BRANCH=YES is coded, an 18-word save area must be supplied. No lock can be held on entry to CVAF. SRB mode is not allowed.

**BRANCH=NO**

requests the SVC entry. The caller must be APF authorized if any output operations are requested. Protect key checking is performed. This is the default.

**EADSCB=value:** Specify the support level for extended attribute DSCBs.

**EADSCB=0K**

This specification indicates that the calling program supports extended attribute DSCBs. An extended address volume may have these DSCBs allocated to it. The returned DSCBs (format-3, format-8) may contain extent descriptors described by 28-bit cylinder addresses or DSCBs (format-9) that contain additional attribute information.

For calls that initiate physical sequential access (DSN=0 or omitted), a CVAFSEQ request issued to an EAV volume will be failed if this new, EADSCB=0K, indicator is not set.
CVAF Macros

For calls that initiate index order (DSN=address) where the BUFLIST=address keyword is specified, a CVAFSEQ request issued to an EAV volume will be failed if the EADSCB=OK indicator is not set and the DSCB associated with this address is a format-8 DSCB.

The failing error code for these cases will be reflected as follows:
- CVAF status code (CVSTAT) set to STAT082.
- Return code 4

EADSCB=OK will set the CV4EADOK indicator in the CVPL. All other calls to CVAFSEQ are allowed and EADSCB=OK will be ignored. That is CVAFSEQ calls with DSNONLY=YES and ARG=address specified.

EADSCB=NOTOK
Indicates a calling program does not support extended attribute DSCBs. EADSCB=NOTOK will turn off the CV4EADOK indicator in the CVPL. This is the default.

MF: Specify the Form of the Macro
This keyword specifies whether the list, execute, or normal form of the macro is requested.

MF=I
If I is coded, or neither L nor E is coded, the CVAF parameter list is generated, as is code, to call CVAF. This is the normal form of the macro.

MF=L
Indicates the list form of the macro. A parameter list is generated, but code to call CVAF is not generated.

MF=(E,addr)
Indicates the execute form of the macro. The remote CVAF parameter list supplied as addr is used in and can be modified by the execute form of the macro.

Return Codes from CVAFSEQ
On return from CVAF, register 1 contains the address of the CVPL (CVAF parameter list), and register 15 contains one of the following return codes:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>The request was successful.</td>
</tr>
<tr>
<td>4 (X'04')</td>
<td>End of data (CVSTAT is set to decimal 32), or an error was encountered. The CVSTAT field in the CVPL contains an indication of the cause of the error. Error descriptions are in &quot;VTOC Index Error Message and Associated Codes&quot; on page 138.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>Invalid VTOC index structure. CVSTAT contains an indication of the cause of the error. Error descriptions are in &quot;VTOC Index Error Message and Associated Codes&quot; on page 138.</td>
</tr>
<tr>
<td>12 (X'0C')</td>
<td>The CVPL (CVAF parameter list) is not in your protect key, or is not valid (the ID is not valid, or the length field is incorrect, or the CVFCTN field is not valid). The CVPL has not been modified.</td>
</tr>
<tr>
<td>16 (X'10')</td>
<td>An I/O error was encountered.</td>
</tr>
</tbody>
</table>

Example of using the CVAFSEQ macro with an indexed VTOC
This example uses the CVAFSEQ macro to count the number of VSAM data sets whose data set names are within the range defined by two supplied data set names. The addresses of the two data set names are supplied to the program in
registers 6 and 7, labeled RDSN1 and RDSN2, respectively. The address of a DEB open to the VTOC is supplied in register 4, labeled RDEB.

The CVAF parameter list is expanded by a list form of the CVAFSEQ macro. ACCESS=GTEQ is specified on the list form of macro and is, therefore, not coded in the first execution of the CVPL. Subsequent executions of the CVPL (at label RELOOP) specify ACCESS=GT.

End of data is tested by comparing the CVSTAT field to the value of STAT032, which is an equate in the ICVAFPL mapping macro.

The count of VSAM DSCBs matching the data set name criterion is returned in register 15, unless an error is encountered, in which case a negative 1 is returned in register 15.

Example of using the CVAFSEQ macro to process a volume in physical sequential order

This example will use the CVAFSEQ macro to read through the DSCBs in physical sequential order. Although CVAFSEQ can be used to process both an indexed and non-indexed volume in physical sequential order, this example uses a non-indexed volume. The CVAFSEQ call will return DSCBs where BFLEARG is set to a starting CCHHR. This value is initially set to zero and the CVAFSEQ call uses ACCESS=GT. A buffer list with five buffer list entries is contained within the program and is used to read up to five DSCBs at a time.

Output from this program will be to OUTDD. It will be a list of all the datasets on the volume and their corresponding CCHHRs. The output from this program is based on the volume and dataset information detailed within the source code example. If the output received is different, it can be verified using the IEHLLIST utility.

This program must be APF authorized because it uses the UCB= and BRANCH=(YES,PGM) parameters. It is bad programming practice to give a program APF authorization unnecessarily. In this case, these two options just give a slight performance improvement. To remove APF authorization from this example, perform these steps:

- Remove the SETCODE and ENTRY statements for the binder.
- Replace the UCB parameter with DEB=(reg). Precede the CVAFSEQ macro with an instruction to load the specified register from DEBADD.
- Remove the BRANCH parameter on CVAFSEQ.

Sample JCL for CVAFSEQ macro to process a volume in sequential order:
The following is the sample JCL used to Assemble, Link, and Execute the example source. Changes will have to be made to this JCL, as appropriate, for each customer environment.

```
//SEQXMP2 JOB ,MSGCLASS=X,TIME=(,10),
   NOTIFY=&SYSUID
/*
//STEP01 EXEC PROC=ASMCLG
//SYSIN DD *
   (INCLUDE EXAMPLE SOURCE HERE)
/*
//L.SYSLMOD DD DSN=YOUR.AUTH.LINKLIB(SEQXMP2),DISP=SHR
//L.SYSIN DD *
   SETCODE AC(1)
   ENTRY SEQXMP2
/*
//G.SYSABEND DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
/*
//G.CVAFFDD DD DISP=SHR,UNIT=3390,Vol=SER=339003
//G.OUTDD DD DSN=CVAFSEQ1.OUTPUT,
   DISP=(NEW,CATLG),
   UNIT=3390,Vol=SER=339001,
   SPACE=(TRK,(2,2)),
   DCB=(RECFM=FBA,LRECL=133,BLKSIZ=1330)
/*
```

Code example of the CVAFSEQ macro to process a volume in sequential order:
SEQXMP2 TITLE 'CVAF CVAFSEQ - SEQXMP2 EXAMPLE'
SEQXMP2 CSECT
SEQXMP2 AMODE 24
SEQXMP2 RMODE 24
*
******************************************************************************
**
** SEQXMP2 - THIS MODULE WILL READ THROUGH THE DSCBS ON A
** NONINDEXED VOLUME. IT WILL USE THE CVAFSEQ MACRO
** TO READ UP TO 5 DSCBS AT A TIME IN PHYSICAL
** SEQUENTIAL ORDER.
** OUTPUT FROM THIS MODULE WILL BE TO OUTDD. IT WILL
** LIST ALL OF THE DATASETS ON THE VOLUME AND THEIR
** CORRESPONDING CCHHR'S. THE FMT4, FMT5, AND FMT7 DSCBS
** AND THEIR CORRESPONDING CCHHRS WILL NOT BE LISTED.
**
** THE FOLLOWING DATASETS WERE ALLOCATED IN THE FOLLOWING
** ORDER ON A NONINDEXED VOLUME.
** 10 SEQUENTIAL DATASETS: CVAFSEQ1.SEQ01-CVAFSEQ1.SEQ10
** 5 PDS DATASETS: CVAFSEQ1.PDS01-CVAFSEQ1.PDS05
** 5 PDSE DATASETS: CVAFSEQ1.PDSE01-CVAFSEQ1.PDSE05
** 2 VSAM DATASETS: CVAFSEQ1.VSAM01-CVAFSEQ1.VSAM02
**
** NOTE: THE OUTPUT FROM THIS EXAMPLE IS BASED ON USING A NON SMS
** MANAGED NON INDEXED VOLUME FOR ALLOCATING THE TEST
** DATASETS (CVAFDD DD).
** IF A SMS MANAGED NON INDEXED VOLUME IS USED THE POSITION
** OF THE VVDS DATASET WILL BE THE SECOND ENTRY IN THE LIST.
**
** DASD VOLUMES USED IN THIS EXAMPLE:
** - 1 3390-3 WHERE THE OUTDD DATASET IS DEFINED
** - 1 3390-3 WHERE THE TEST DATASETS DETAILED ABOVE ARE DEFINED
** THIS VOLUME INITIALIZED USING: VTOC(3326,0,195) NOINDEX
**
**
** OUTPUT IN OUTDD DATASET SHOULD BE THE FOLLOWING:
**
**
** SEQXMP2 START OF OUTPUT MESSAGES
**
**
** DSN: CVAFSEQ1.SEQ01       CCHHR: 0CFE000003
** DSN: CVAFSEQ1.SEQ02       CCHHR: 0CFE000004

**
SEQXMP2 - LOGIC NOTES

This module will perform the following:

Initialization
- Initialize starting CCHHR value to 0 (GT ZERO used in CVAFSEQ)
- Obtain the necessary information from the DASD volume
- Open an output file
- Write necessary messages to the output file

Mainline
- Do while more datasets on volume to process
  - Load 5 entry table with DSCB address
  - Init buffer list hdr to read DSCBS and starting CCHHR
  - Init buffer list entry with DSCB address and length
  - Issue CVAFSEQ macro to read 5 entries
  - Load CCHHR returned from CVAFSEQ into table
  - Process table entries and produce output: DSN/CCHHR list

Finalization
- Write necessary messages to the output file
- Close the output file
- Exit

SEQXMP2 - JOB INFORMATION

Normal end of job:
- RC=00 and OUTDD output as detailed above

Abnormal end of job:
- ABEND 100 - Error opening VTOC on the DASD volume that is associated with the CVAFDD DD statement
- ABEND 101 - Error opening the OUTDD dataset
- ABEND 102 - Error closing the OUTDD dataset

CVAFTST Macro Overview and Specification

The CVAFTST macro determines whether the system supports an indexed VTOC, and, if it does, whether the VTOC on the unit whose UCB is supplied is indexed or nonindexed.

When you issue CVAFTST, register 13 must contain the address of a standard 18 word save area.

You will get a return code of 12 if CVAFTST cannot determine whether an indexed or nonindexed VTOC is on the unit's volume. You should not receive a return code of 12 from CVAFTST if you have opened a data set (including the VTOC) on the volume.

You need no authorization to issue the CVAFTST macro.

See "CVAFDSM Macro Overview and Specification" on page 92 for an example of using the CVAFTST macro with the CVAFDSM macro.

The format of the CVAFTST macro is:
UCB: Specify the VTOC to Be Tested

`UCB=(reg)`

Supplies the address of the UCB for the volume whose VTOC is to be tested. The UCB address can be for a captured UCB, or for an actual UCB above or below the 16 MB line. If your program is in 31-bit mode, this address must be in 31-bit address; the high order byte is part of the address.

**Recommendation:** Code the address of the UCB parameter as register (2-12). Coding an RX-type address gives unpredictable results.

The CVAFTST macro accepts the address of a UCB or UCB copy. Unauthorized programs can get a copy of the UCB by using the UCBSCAN macro and specifying the COPY, UCBAREA, CMXTAREA, and DCEAREA keywords. The UCB copy and common extension copy must be below the 16 MB line and on a word boundary. Data accessed with DCEAREA can be above the 16 MB line. Refer to [z/OS HCD Planning](#) for details.

**Return Codes from CVAFTST**

On return from CVAF, register 15 contains one of the following return codes:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>The system does not support an indexed VTOC. The volume should be considered to have a nonindexed VTOC. The UCB was not inspected to determine its validity or status.</td>
</tr>
<tr>
<td>4 (X'04')</td>
<td>The system supports an indexed VTOC, but the volume has a nonindexed VTOC.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>The system supports an indexed VTOC and the volume has an indexed VTOC.</td>
</tr>
<tr>
<td>12 (X'0C')</td>
<td>The system supports an indexed VTOC, but the volume is not mounted or the VIB is not initialized for it; thus, the status (indexed or nonindexed) of the VTOC cannot be determined.</td>
</tr>
<tr>
<td>16 (X'10')</td>
<td>The system supports an indexed VTOC, but the unit is not a DASD or has a VIO UCB, or the UCB address is not valid. The address of a UCB copy is not valid without a CMXTAREA and a DCEAREA.</td>
</tr>
</tbody>
</table>

**VTOC Index Error Message and Associated Codes**

**Error Message**

When CVAF finds an error in a VTOC index, it issues the following message:

```
IEC606I VTOC INDEX DISABLED ON dev,volser,code,[rba,[secno,offset]]
```

In addition, CVAF puts a return code in the CVSTAT field of the CVPL.

**Explanation:** The Common VTOC Access Facility (CVAF) detected a VTOC index error on the device `dev` with volume serial number `volser`. A number that represents the kind of VTOC index error is provided in the `code` field. The RBA of the VIR in the VTOC index that contains the structure error indicated by `code` is provided in the `rba` field. If the VIR is a VIER, the section number in the VIER containing the
VTOC index entry is supplied in the `secno` field, and the offset into the section of that VTOC index entry is supplied in the `offset` field.

**System Action:** The VTOC index is disabled. The VTOC will be converted to nonindexed format when DADSM next allocates space on the volume. A system dump is written to the SYS1.DUMP data set, and an entry is made in the SYS1.LOGREC data set. The message IEC604I (which indicates that the VTOC convert routines have been used) will be issued later.

**Programmer Response:** Examine the system dump and a print of the VTOC index, and use the information in message IEC606I to determine the cause of the VTOC index structure error.

**Routing and Descriptor Codes:** The routing codes are 4 (direct access pool) and 10 (system/error maintenance), and the descriptor code is 4 (system status).

**Codes Put in the CVSTAT Field**

If you are diagnosing an error and require a description of the CVSTAT field codes, see [z/OS DFSMSdfp Diagnosis](#).

### VTOC Error Responses

The following actions are taken if an error occurs in the VTOC:

- If an index structure error is detected and if the address space is enqueued on the VTOC, then DADSM or CVAF disables the VTOC index. The indexed VTOC bit is zeroed in the format-4 DSCB, a software error record is written to SYS1.LOGREC, and a system dump is taken at the next call to DADSM create or extend. The VTOC is converted to a nonindexed format at the next DADSM create or extend call.

- If a program check, machine check, or other error occurs while using a VTOC access macro, a SYS1.LOGREC record is written, and a system dump is taken.

- An error code is put in the CVSTAT field of the CVPL. The values and explanations of these error codes are listed in [VTOC Index Error Message and Associated Codes](#) on page 138.

### Recovering from System or User Errors

Because an unauthorized user cannot modify a VTOC, neither the VTOC nor the VTOC index need be recovered from an error caused by an unauthorized user.

A system error can affect a VTOC and VTOC index by interrupting DADSM while it is updating, leaving the VTOC or the VTOC index (or both) in a partially-updated state. Both the VTOC and the VTOC index allow DADSM to recover from such an interruption.

For a nonindexed VTOC (or a VTOC with an index that has been disabled), a subsequent call to DADSM create or extend, causes VTOC convert routines to reestablish the free space DSCB chain.

For an indexed VTOC, a subsequent call to any DADSM function causes the recovery of the previous interrupt (either by backing out or completing the interrupted function).
CVAF Macros

GTF Trace

A trace function exists to trace all CVAF calls for VTOC index output I/O, all VTOC output I/O, and all VTOC index and space map modifications. For information on this function, see z/OS DFSMSdfp Diagnosis.

VTOC and VTOC Index Listings

You can obtain dump, formatted, or abridged listings of the VTOC and the VTOC index by using the LISTVTOC command of the IEHLIST utility program. The DFSMSdss print command also provides VTOC and index listing options. The ISMF data set application displays information about the data sets represented in a VTOC.
Chapter 2. Managing the Volume Table of Contents

Creating the VTOC and VTOC Index

To prepare a volume for activity by initializing it, use the Device Support Facilities (ICKDSF) utility to build the VTOC. You can create a VTOC index when initializing a volume by using the ICKDSF INIT command and specifying the INDEX keyword.

To convert a non-indexed VTOC to an indexed VTOC, use the BUILDIX command with the IXVTOC keyword. The reverse operation can be performed by using the BUILDIX command and specifying the OSVTOC keyword.

To refresh a volume VTOC and INDEX in its current format, use the ICKDSF command REFORMAT with the RVTOC keyword. To optionally extend the VTOC and INDEX, use the ICKDSF command REFORMAT with the EXTVTOC and EXTINDEX keywords.

Protecting the VTOC and VTOC Index

Use the following methods in order to protect the VTOC and VTOC index:

RACF®

You can protect the VTOC and VTOC index using the Resource Access Control Facility (RACF), a component of the Security Server for z/OS, by defining the volume serial entity under the RACF DASDVOL class. For you to modify a protected VTOC and VTOC index, programs must be authorized at the following levels:

• UPDATE level to open for output processing a VTOC or any data set with a name beginning with SYS1.VTOCIX.
• ALTER level to allocate, rename, or scratch any data set with a name beginning with SYS1.VTOCIX or to rename a data set to a name beginning with SYS1.VTOCIX.

Neither the VTOC nor the VTOC index is protected from being opened for input processing by the DASDVOL/volume serial entity. Neither the VTOC nor the VTOC index can be protected through the RACF DATASET class. For additional information on using RACF, see z/OS Security Server RACF Security Administrator’s Guide, SA22-7683.

APF

The authorized program facility (APF) must authorize a program in order for you to:

• Open a VTOC for output processing
• Open for output processing, allocate, rename, or scratch any data set whose name begins with SYS1.VTOCIX
• Rename a data set to a name that begins with SYS1.VTOCIX.
Managing the VTOC

For additional information on using APF, see z/OS MVS Programming: Authorized Assembler Services Guide.
Managing the VTOC

Password Protection

The VTOC index data set can be password protected. Protection is the same as for a password-protected data set. Password checking is bypassed if the volume containing the VTOC index is protected by RACF with the DASDVOL class. For additional information, see Chapter 6, “Using Password Protected Data Sets,” on page 233.

Copying/Restoring/Initializing the VTOC

The following topics discuss VTOC considerations when updating volumes:

- “Volumes Containing a Nonindexed VTOC”
- “Volumes Containing an Indexed VTOC”

Volumes Containing a Nonindexed VTOC

When updating volumes containing a non-indexed VTOC keep the following considerations in mind:

1. **Restoring a Volume from a Dump Tape:** There are no operational requirements if you change the volume serial number or do a partial restore that does not modify the VTOC. If you do a restore and change the VTOC size without changing the volume serial number, you must vary the volume offline after it is restored. Do not try to restore on a volume with an indexed VTOC.
2. **Copying a Volume:** There are no operational requirements if you change the volume serial number or do not modify the VTOC of the receiving volume. If you do a copy and change the VTOC size without changing the volume serial number, you must vary the volume offline after it is copied. Do not attempt to copy from a volume with an indexed VTOC.
3. **Shared DASD Considerations:** In shared DASD environments, if the VTOC index is relocated or the volume is changed from indexed VTOC to OS VTOC or from OS VTOC to indexed VTOC, you might consider varying the device offline to the sharing system or systems before beginning the operation.

Volumes Containing an Indexed VTOC

Use Device Support Facilities (ICKDSF) to convert a VTOC to a non-indexed format to update the volume. If you do not, keep the following considerations in mind:

1. **Initializing a Volume:** If you do not change the volume serial number, you must vary the volume offline before starting the job.
2. **Restoring a Volume from a Dump Tape:** There are no operational requirements if you change the volume serial number or do a partial restore that does not modify the VTOC or VTOC index. If you do a restore, and modify the VTOC or VTOC index without changing the volume serial number, you must vary the volume offline after it is restored.
3. **Copying a Volume:** There are no operational requirements if you change the volume serial number of the receiving volume or do a partial dump without modifying the VTOC or VTOC index. If you modify the VTOC or VTOC index without changing the volume serial number, you must vary the receiving volume offline after it is copied.

Deleting a Data Set from the VTOC

You can use the SCRATCH and CAMLST macro to delete a non-VSAM data set or a temporary VSAM data set. SCRATCH processing makes the space occupied by the data set available for reallocation. This process does not automatically erase data from the disk. See “Erasing Sensitive Data” on page 144 for further information.
Managing the VTOC

Specifying the Volumes Affected

When deleting a data set, build a volume list in virtual storage. The volume list consists of an entry for each volume on which the data set resides. If you are deleting an SMS-managed data set, specify at least one SMS-managed volume in the list. The first two bytes of the list indicate the number of entries in the list. Each 12-byte entry consists of a 4-byte device code (the UCBTYP field from the volume’s UCB), a 6-byte volume serial number, and 2 bytes of scratch status information consisting of a secondary status code and a status code, both of which must be initialized to zero.

Volumes are processed according to their order in the volume list. If a volume is not mounted, a message is issued to the operator requesting that the volume be mounted. This only occurs when you indicate the direct access device on which unmounted volumes are to be mounted by loading register 0 with the address of the UCB of the device. (The device must be allocated to your job.) If you do not load register 0 with a UCB address, its contents must be zero, and at least one of the volumes in the volume list must be mounted before the SCRATCH macro instruction is issued. Use the address of a UCB, not a UCB copy, in register 0 with this macro. 31-bit programs must pass a clean UCB addr on RENAME, when applicable.

If the requested volume cannot be mounted, the operator replies by indicating that the request cannot be fulfilled. A status code is then set in the last byte of the volume list entry (the second byte of the scratch status code) for the unavailable volume, and the next volume in the volume list is processed.

Erasing Sensitive Data

You should erase data sets that contain sensitive data by overwriting them with zeros before their space is made available. This can either be done before issuing the SCRATCH macro, or be requested in scratch processing by performing one of the following:

- Providing an associated RACF profile ERASE attribute
- Activating bit 21 (‘X’00 00 04 00’) of the SCRATCH parameter list. See Table 22 on page 147

Authorized callers of SCRATCH can prevent erasure of the data by setting bit 22 to 1, which overrides the RACF profile ERASE attribute.

System-Managed-Storage Considerations

SMS screens all data set SCRATCH requests. If the volumes in your volume list are SMS managed, SMS does a catalog LOCATE to determine the actual volume serial numbers, and deletes the data set from all volumes on which it resides. SMS coordinates the required changes to the VTOC, the VTOC index, and the catalog.

If DADSM encounters a processing error when SMS is active and all the volumes in your list are SMS managed, SMS determines the volume on which the failure occurred. The first entry in your list will be overlaid with the entry for the volume on which the request failed.

You might find that a volume indicated as being in error was not specified in the volume list your program provided. This occurs if the volumes in your list are different from the volumes in the data set’s catalog entry.
Managing the VTOC

If SMS is not active, you cannot delete SMS-managed data sets.

You can delete SMS-managed VSAM data sets using the access method services DELETE command. See z/OS DFSMS Access Method Services for Catalogs for further information.

General Considerations and Restrictions

A data set cannot be deleted if the expiration date in the format-1 DSCB has not passed unless you override the expiration date. You can request SCRATCH to ignore the expiration date by specifying the OVRD option in the CAMLST macro instruction. SCRATCH processing supports three never-scratch dates. To prevent a data set from being scratched, specify one of the following expiration dates:

- 1999.365
- 1999.366
- 1999.999

To delete a virtual input/output (VIO) data set, the data set must be allocated for use by your job step.

You cannot use the SCRATCH macro with either a SYSIN or SYSOUT data set or an z/OS UNIX file. You will receive unpredictable results if you use SCRATCH for z/OS UNIX files.

If you attempt to delete a password-protected data set that is not also RACF protected, the operating system issues message IEC301A to the operator at the console, or the terminal operator of a TSO console, to enter the password. The data set will be scratched if the password supplied is associated with a WRITE protection mode indicator. The protection mode indicator is described in Chapter 6, "Using Password Protected Data Sets," on page 233.

If a data set is RACF-defined (indicated in its format-1 DSCB or described by a RACF profile) or the volume upon which it resides is RACF-defined, you can scratch the data set only if you have ALTER access authority to either the data set/volume serial in the DATASET class or to the volume serial in the DASDVOL class.

Requirement: For an SMS-managed non-VSAM data set, you need RACF authority to the data set or to the catalog to delete it.

For a non-VSAM data set that is not SMS-managed, DADSM invokes RACF to verify authorization. If you have ALTER access authority to the data set/volume serial in the DATASET class, DADSM deletes the data set from the volume. If you have ALTER authority to the data set/volume serial in the DATASET class, or UPDATE access authority to the catalog/volume serial in the DATASET class, you can delete the catalog entry.

Use the STOW macro to delete or rename a member of a PDS or PDSE. STOW is described in z/OS DFSMS Macro Instructions for Data Sets and z/OS DFSMS Using Data Sets. You can also use the ICHPROGM utility to delete a member (see z/OS DFSMSdfp Utilities).
SCRATCH and CAMLST Macro Specification

The format of the SCRATCH and CAMLST macros is:

```
       label
       SCRATCH-listname_addrx

       listname-CAMLST-SCRATCH-,dsname_relexp-,vol_list_relexp

       ,,OVRD
```

`listname_addrx`  Points to the parameter list (labeled listname) set up by the CAMLST macro instruction.

`SCRATCH`  Code this operand as shown.

`dsname_relexp`  Specifies the virtual storage location of a fully-qualified data set name. The area that contains the name must be 44 bytes long.

`vol_list_relexp`  Specifies the virtual storage location of an area that contains a volume list. The area must begin on a halfword boundary.

`OVRD`  When coded as shown, specifies that the expiration date in the DSCB should be ignored.

Example

In the following example, data set A.B.C is deleted from two volumes. The expiration date in the identifier (format-1) DSCB is ignored.

```plaintext
    SR 0,0 SHOW NO UCB IS SUPPLIED
    SCRATCH DELABC DELETE DATA SET A.B.C
      FROM TWO VOLUMES,
      * IGNORING EXPIRATION
      * DATE IN THE DSCB

    DELABC CAMLST SCRATCH,DSABC,,VOLIST,,OVRD
    DSABC DC CL44'A.B.C' DATA SET NAME
    VOLIST DC H'2' NUMBER OF VOLUMES
    DC X'3030200E' 3380 DISK DEVICE CODE
    DC CL6'000017' VOLUME SERIAL NO.
    DC H'0' SCRATCH STATUS CODE
    DC X'3030200E' 3380 DISK DEVICE CODE
    DC CL6'000018' VOLUME SERIAL NO.
    DC H'0' SCRATCH STATUS CODE
```

Recommendation: Check the return codes and SCRATCH status codes.

The SCRATCH macro instruction points to the CAMLST macro instruction. The SCRATCH operand specifies that a data set be deleted. DSABC specifies the virtual storage location of a 44-byte area containing the fully-qualified name of the
Managing the VTOC

data set to be deleted. VOLIST specifies the virtual storage location of the volume list you have built. OVRD specifies that the expiration date in the DSCB of the data set to be deleted should be ignored.

**SCRATCH Parameter List**

The CAMLST macro generates the SCRATCH parameter list, but your code can set several options that CAMLST does not support. See Table 22.

*Table 22. SCRATCH Parameter List*

</table>
Managing the VTOC

Return Codes from SCRATCH

Control returns to the instruction following the instructions generated by the SCRATCH macro. Register 15 contains the SCRATCH return code as shown in Table 23.

SCRATCH returns 4 bytes of diagnostic information in register 0. If an error occurs, DADSM issues message IEC614I, consisting of failure-related information including the return code and the 4 bytes of diagnostic information. See z/OS DFSMSdfp Diagnosis for a description of this information.

The last two bytes of a volume list entry contain the secondary status code and the scratch status code. The secondary status codes are shown in Table 25 on page 149 and the scratch status codes are shown in Table 24 on page 149. To determine if the data set has been deleted from each volume, check the scratch status code. (Even if the scratch status code is zero, the secondary status code might be nonzero for the first entry in the volume list.)

Table 23 describes the conditions indicated by the SCRATCH return code.

Table 23. SCRATCH Return Codes

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000 (X'00')</td>
<td>If the 4 bytes of diagnostic information returned in register 0 are all zeros, the data set was successfully deleted. If they are nonzero, use the SCRATCH diagnostic information tables in z/OS DFSMSdfp Diagnosis to determine the failure-related conditions.</td>
</tr>
<tr>
<td>004 (X'04')</td>
<td>No volume containing any part of the data set was mounted. The data set might be a VIO data set that was not allocated to your jobstep.</td>
</tr>
<tr>
<td>008 (X'08')</td>
<td>An unusual condition was encountered on one or more volumes.</td>
</tr>
<tr>
<td>012 (X'0C')</td>
<td>One of the following conditions occurred:</td>
</tr>
<tr>
<td></td>
<td>• The SCRATCH parameter list is not valid.</td>
</tr>
<tr>
<td></td>
<td>• The volume list is not valid.</td>
</tr>
<tr>
<td></td>
<td>• At entry to SCRATCH, register 0 was not zero and did not point to a valid UCB. The address must be that of a UCB, not a UCB copy.</td>
</tr>
<tr>
<td></td>
<td>The SCRATCH status code will not have been set.</td>
</tr>
</tbody>
</table>
Status Codes from SCRATCH

After the SCRATCH macro instruction is executed (for SCRATCH return codes 0, 4, and 8 only), the last byte of each 12-byte entry in the volume list indicates one of the following conditions:

Table 24. SCRATCH Status Codes

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>The data set has been deleted from this volume.</td>
</tr>
<tr>
<td>1 (X'01')</td>
<td>The VTOC of this volume does not contain the format-1 or format-8 DSCB to be deleted.</td>
</tr>
</tbody>
</table>
| 2 (X'02')  | One of the following conditions occurred:  
- The data set could not be scratched because the correct password was not specified in the two attempts allowed.  
- The user tried to scratch a VSAM data space or an integrated catalog facility VSAM data set.  
- The user tried to scratch the VTOC index data set.  
- An SMS-validation failure occurred.  
- The verify of the last referenced date failed. |
| 3 (X'03')  | The data set was not deleted because either the OVRD option was not specified or the retention cycle had not expired. |
| 4 (X'04')  | One of the following conditions occurred:  
- An invalid format-1 or format-8 DSCB was encountered when processing this volume.  
- An unexpected CVAF error return code was encountered.  
- An installation exit rejected the request.  
- An I/O error occurred while the DASD tracks occupied by the data set were being erased. Either the ERASE option was specified in the scratch parameter list or the ERASE attribute was specified for an RACF-defined data set. |
| 5 (X'05')  | It could not be verified that this volume was mounted, nor was there a unit available for mounting the volume. |
| 6 (X'06')  | The operator was unable to mount this volume. |
| 7 (X'07')  | The data set was not deleted because it was open. |
| 8 (X'08')  | The format-1 or format-8 DSCB indicates the data set is defined to RACF, but either you are not authorized to the data set or volume, or the data set is a VSAM data space. |

After the SCRATCH macro instruction is executed, the next to last byte of the first entry in the volume list indicates one of the following conditions:

Table 25. Secondary Status Codes

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>No secondary status for this volume.</td>
</tr>
<tr>
<td>128 (X'80')</td>
<td>The data set was RACF protected and the calling program was authorized by the RACF DATASET class to scratch the data set. This means that at least one volume entry was protected.</td>
</tr>
</tbody>
</table>

Renaming a Data Set in the VTOC

You can use the RENAME and CAMLST macro to rename a non-VSAM data set. Rename processing causes the data set name in all format-1 or format-8 DSCBs to be replaced with the new name you supply. The new data set name must conform to standard data set naming conventions.
Specifying the Volumes Affected

When renaming a data set, build a volume list in virtual storage. The volume list consists of an entry for each volume on which the data set resides. If you are renaming an SMS-managed data set, specify at least one SMS-managed volume in the list. The first two bytes of the list indicate the number of entries in the list. Each 12-byte entry consists of a 4-byte device code (the UCBTYP field from the volume's UCB), a 6-byte volume serial number, and a 2-byte rename status code that should be initialized to zero.

Volumes are processed according to their order in the volume list. If a volume is not mounted, a message is issued to the operator requesting that the volume be mounted. This only occurs when you indicate the direct access device on which unmounted volumes are to be mounted by loading register 0 with the address of the UCB of the device. (The device must be allocated to your job.) If you do not load register 0 with a UCB address, its contents must be zero, and at least one of the volumes in the volume list must be mounted before the RENAME macro instruction is issued. Use the address of a UCB, not a UCB copy, in register 0 with this macro. 31-bit programs must pass a clean UCB addr on RENAME, when applicable.

If the requested volume cannot be mounted, the operator replies by indicating that the request cannot be fulfilled. A status code is then set in the last byte of the volume list entry (the second byte of the rename status code) for the unavailable volume, and the next volume indicated in the volume list is processed.

System-Managed-Storage Considerations

SMS screens all data set RENAME requests. If the volumes specified in your volume list are SMS managed, SMS does a catalog LOCATE to determine the actual volume serial numbers, and coordinates the required changes to the VTOC, the VTOC index, and the catalog.

If DADSM encounters a processing error while SMS is active and all the volumes in your list are SMS managed, SMS determines the volume on which the failure occurred. The first entry in your list will be overlaid with the entry for the volume on which the request failed.

You might find that a volume indicated as being in error was not specified in the volume list your program provided. This occurs if the volumes in your list are different from the volumes in the data set's catalog entry.

If SMS is not active, you cannot rename SMS-managed data sets.

General Considerations and Restrictions

Multivolume Considerations
To rename a data set that is stored on more than one volume, all volumes must be mounted.

Unrenamable Data Sets and UNIX Files
You cannot use the RENAME macro with either a SYSIN or SYSOUT data set or UNIX file (such as an z/OS UNIX file). You will receive unpredictable results if you use RENAME for UNIX files.

You cannot rename VIO data sets.
Data Set Security
You can rename a RACF-defined data set only if you have ALTER access authority
to the data set in the DATASET class.

If you attempt to rename a password-protected data set, the operating system
issues message IEC301A asking the operator or TSO operator to verify the
password. The data set will be renamed if the password supplied is associated with
a WRITE protection mode indicator. The protection mode indicator is described in
Chapter 6, “Using Password Protected Data Sets,” on page 233.

Renaming a Data Set That Might be in Use
You can rename a data set that is allocated to the current address space but it
cannot be open.

In general, you cannot rename a data set whose name is the same as any data set
that is allocated to another address space in the same system or in the scope of
the SYSDSN enqueue. The system bypasses this restriction if all of the following
are true:

• Your program sets on a certain bit in the CAMLST macro expansion. You can
code this instruction: OI listname+2,X'10'.

• You have at least read authority to the RACF facility class named
STGADMIN.DPDSRN.olddsname, where olddsname is up to 23 characters of the
existing data set name. You can use a generic class name such as
STGADMIN.DPDSRN.SYS2.*. IBM recommends that no one have authority to
STGADMIN.DPDSRN.* because it is too broad.

• The data set is not SMS-managed.

Alternatively, you can use the data set rename option of PDF. If you attempt to
rename a non-SMS-managed, non-VSAM data set, the data set name is in use and
you have the appropriate RACF facility class authority, then PDF asks whether you
wish to proceed because you know that the data set is not actually open. Let the
rename proceed only if you know the data set being renamed is not open on any
system.

Attention: This option should be used with extreme caution. Very few people
should have RACF authority to STGADMIN.DPDSRN.olddsname. Do not use this
option unless you know the data set is not open on any system. After the data set
is renamed, someone could delete it in a different address space. If someone has it
open by the old name, new data sets will appear at those places on the disk. This
would be a security violation that the system does not detect.

The data set rename function writes a type 18 SMF record to provide information to
storage administrators, system programmers, and auditors. The record contains an
indicator of whether it was successful due to the use of this duplicate name override
function. If you request the option in the CAMLST macro expansion but the data set
name is not in use, then the SMF indicator will not be on.
RENAME and CAMLST Macro Specification

The format of the RENAME and CAMLST macros is:

```
RENAME listname_addrx
```

```
listname—CAMLST—RENAME—,dsname_relexp,—,new name_relexp—,vol list_relexp
```

- **listname_addrx**
  Points to the parameter list (labeled listname) set up by the CAMLST macro instruction.

- **RENAME**
  Code this operand as shown.

- **dsname_relexp**
  Specifies the virtual storage location of a fully-qualified data set name to be replaced. The area containing the name must be 44 bytes long.

- **new name_relexp**
  Specifies the virtual storage location of a fully-qualified data set name that is to be used as the new name. The area containing the name must be 44 bytes long.

- **vol list_relexp**
  Specifies the virtual storage location of an area that contains a volume list. The area must begin on a halfword boundary.

Example

In the following example, data set A.B.C is renamed D.E.F. The data set resides on two volumes.

```
SR 0,0 SET REG 0 TO ZERO
RENAME DSABC CHANGE DATA SET NAME A.B.C TO D.E.F
DSABC CAMLST RENAME,OLDNAME,NEWNAME,VOLIST
OLDNAME DC CL44'A.B.C' OLD DATA SET NAME
NEWNAME DC CL44'D.E.F' NEW DATA SET NAME
VOLIST DC H'2' TWO VOLUMES
  DC X'3030200E' 3380 DISK DEVICE CODE
  DC CL6'000017' VOLUME SERIAL NO.
  DC H'0' RENAME STATUS CODE
  DC X'3030200E' 3380 DISK DEVICE CODE
  DC CL6'000018' VOLUME SERIAL NO.
  DC H'0' RENAME STATUS CODE
```

**Recommendation:** Check the return codes and RENAME status codes.
Managing the VTOC

The RENAME macro instruction points to the CAMLST macro instruction. The RENAME operand specifies that a data set be renamed. OLDNAME specifies the virtual storage location of a 44-byte area where you have placed the fully-qualified name of the data set to be renamed. NEWNAME specifies the virtual storage location of a 44-byte area where you have placed the new name of the data set. VOLIST specifies the virtual storage location of the volume list you have built.

**RENAME Parameter List**

The CAMLST macro generates the RENAME parameter list but your code can set several options that CAMLST does not support. See Table 26.

<table>
<thead>
<tr>
<th>Offset</th>

</tbody>
</table>

**Return Codes from RENAME**

Control returns to the instruction following the instructions generated by the RENAME macro. Register 15 contains the DADSM return code as shown in Table 27 on page 154.

DADSM RENAME returns 4 bytes of diagnostic information in register 0. If an error occurs, DADSM issues message IEC614I, consisting of failure-related information including the return code and the 4 bytes of diagnostic information. See Z/OS DFSMSdfp Diagnosis for a description of this information.

Each volume's volume list entry contains the rename status code as shown in Table 28 on page 154. To determine whether the data set has been successfully renamed on each volume, check the rename status code, contained in the last byte of each entry in the volume list.

Table 27 on page 154 describes the conditions indicated by the DADSM return code.
### Table 27. DADSM RENAME Return Codes

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000 (X'00')</td>
<td>If the 4 bytes of diagnostic information returned in register 0 are all zeros, the data set has been successfully renamed. If they are nonzero, use the DADSM RENAME diagnostic information tables in z/OS DFSMSdfp Diagnosis to determine the failure-related conditions.</td>
</tr>
<tr>
<td>004 (X'04')</td>
<td>No volume containing any part of the data set was mounted. The data set can be a VIO data set but cannot be renamed.</td>
</tr>
<tr>
<td>008 (X'08')</td>
<td>An unusual condition was encountered on one or more volumes. The diagnostic information is in register 0. Use the DADSM RENAME diagnostic information tables in z/OS DFSMSdfp Diagnosis to determine the failure-related conditions.</td>
</tr>
</tbody>
</table>
| 012 (X'0C') | One of the following conditions occurred:  
- The DADSM RENAME parameter list is not valid.  
- The volume list is not valid.  
- At entry to RENAME, register 0 was not zero and did not point to a valid UCB. The address must be that of a UCB, not a UCB copy. The RENAME status code will not have been set. |

### Status Codes from RENAME

After the RENAME macro instruction is executed (for RENAME return codes 0, 4, and 8 only), the last byte of each 12-byte entry in the volume list indicates one of the following conditions described in Table 28.

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>The format-1 DSCB for the data set has been renamed in the VTOC on this volume.</td>
</tr>
<tr>
<td>1 (X'01')</td>
<td>The VTOC of this volume does not contain the format-1 or format-8 DSCB of the data set to be renamed.</td>
</tr>
</tbody>
</table>
| 2 (X'02') | One of the following conditions occurred:  
- The data set could not be renamed because the data set was password protected and the password was not supplied in the two attempts allowed.  
- An attempt was made to rename a VSAM data space or an integrated catalog facility VSAM data set.  
- An attempt was made to rename a VTOC index data set.  
- An SMS-validation failure occurred. |
| 3 (X'03') | A format-1 or format-8 DSCB containing the new data set name already exists in the VTOC of this volume, or an attempt was made to rename a data set to a name starting with SYS1.VTOCIX. |
| 4 (X'04') | One of the following conditions occurred:  
- A permanent I/O error occurred while trying to rename the data set on this volume.  
- An invalid format-1 or format-8 DSCB was encountered while processing this volume.  
- No space is available in the index VIER for the new name, and no additional VIERs are available. |
| 5 (X'05') | It could not be verified that this volume was mounted nor was a unit available for mounting the volume. |
### Table 28. RENAME Status Codes (continued)

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>6 (X'06')</td>
<td>The operator was unable to mount this volume.</td>
</tr>
<tr>
<td>7 (X'07')</td>
<td>The data set was not renamed, because it was currently open for processing.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>The data set is defined to RACF, but either you are not authorized to the data set or the data set is defined to RACF on multiple volumes.</td>
</tr>
</tbody>
</table>
Managing the VTOC
Chapter 3. Using Catalog Management Macros

This information covers catalog management macro instructions for compatibility purposes only. Catalog management macro instructions can be used to perform the following functions:

- Retrieve information from an integrated catalog facility catalog.
- Catalog, uncatalog, or re-catalog in an integrated catalog facility catalog the following types of data sets:
  - DASD data sets that are not VSAM or SMS-managed
  - Tape data sets.

Application Program Considerations

A catalog management request can be satisfied in an integrated catalog facility catalog. Consider the following restrictions and limitations in relation to your application programs:

- A catalog management request is expressed in a parameter list pointed to by register 1. Generate the parameter list with a CAMLST macro. The CAMLST and its associated fields must not be located in read-only storage.
- Register 15 contains the return code. These return codes are explained in the sections below.

Catalog Search Order

Catalogs are searched for entries using the following methods:

1. If a catalog is specified in a macro, only that catalog is searched.
2. If the entry is identified with a qualified entry name and its first qualifier is the same as the name or alias of a user catalog, the user catalog is searched. When the entry is found, no other catalog is searched.
3. The master catalog is searched.

See [z/OS DFSMS Access Method Services for Catalogs](#) for more detailed information.
Retrieving Information from a Catalog

To read an entry from a catalog, use the LOCATE and CAMLST macro instructions. You can specify the entry to be read into your output area using the following information:

- The fully- or partially-qualified name of a data set
- The relative block address of the block containing the entry.

If you specify a fully-qualified data set name, a list of volumes on which the data set resides is read into your output area. This volume list always begins with a 2-byte entry indicating the number of volumes in the list.

Restriction: When CAMLST is used to locate a data set that is over 20 volumes in length, only information from the first 20 volumes is returned. If you need to retrieve data from more than 20 volumes, use IGGCSI (Catalog Search Interface). See (link to pertinent section in Man Cat).

For the Catalog interface, a fully-qualified name is one which represents a single data set. A partially-qualified name is one which may contain multiple qualifiers, but does not specify a full data set name.

For example, if LEVEL1.LEVEL2.LEVEL3.LEVEL4 is a data set, then LEVEL1.LEVEL2.LEVEL3.LEVEL4 is a fully-qualified name. The following data set would be considered partially-qualified names:

- LEVEL1.LEVEL2.LEVEL3
- LEVEL1.LEVEL2
- LEVEL1

Restriction: For the catalog interface, you cannot specify an asterisk (*) or an ampersand (&) to specify a partially-qualified data set name.

See [z/OS DFSMSdfp Diagnosis](link) for descriptions of the contents of the volume control block and the other catalog data areas.

See “[Return Codes from LOCATE” on page 163](link) for a description of the LOCATE return codes.

Retrieving Information by Data Set Name (LOCATE and CAMLST NAME)

Specifying a data set name returns a volume list in your output area. A volume list consists of an entry for each volume on which part of the data set resides. For each volume, the list contains the volume serial number, device type, and file sequence number. Volumes are divided by whether they fall within the minimum unit count, or outside of it. Volumes within and without are in descending binary order by device type, except for reusable KSDS. For a reusable KSDS, the volume serial numbers are returned in the order: first index, first data, remaining index, remaining data.

A volume list begins with a 2-byte field containing the number of volumes in the list. The count field is followed by a variable number of 12-byte entries. Each 12-byte entry consists of a 4-byte device code, a 6-byte volume serial number, and a 2-byte volume sequence number. As many as 20 of these 12-byte entries can be built in your output area. LOCATE can return bytes 252 - 254 of your area containing the relative track address of the DSCB on the first or only volume for that data set.
Otherwise, these bytes are zero. Bytes 242 to 251 are reserved, byte 255 contains zeros, and bytes 256 to 264 are also reserved and not intended as a programming interface.

A CAMLST LOCATE on a VSAM cluster returns the volumes for all components. The format of this volume list is as described previously. The output is translated into the format described in the preceding two paragraphs before returning to the caller. The original VSAM or integrated catalog facility return code is saved in register 0.

The macro format for the LOCATE and CAMLST NAME is:

```
LOCATE listname_addrx
```

```
CAMLST NAME dsname_relexp area_relexp
```

*listname_addrx*  
Points to the parameter list (labeled listname) set up by the CAMLST macro instruction.

*NAME*  
To retrieve information from a catalog by name, code this operand as shown.

*dsname_relexp*  
Specifies the virtual storage location of a fully-qualified data set name. The area that contains the name must be 44 bytes long. The name can be defined by a C-type define constant (DC) instruction.
CATALOG Macros

area_relexp  Specifies the virtual storage location of your 265-byte output area, that you must define. The output area must begin on a doubleword boundary.

Example
In the following example, the catalog entry containing a list of the volumes on which data set A.B resides, is read into virtual storage.

```
LOCATE  INDAB
*     READ CATALOG ENTRY FOR DATA SET A.B
*     INTO VIRTUAL STORAGE AREA NAMED LOCAREA.
*     LOCAREA MAY ALSO CONTAIN A 3-BYTE TTR OR A 6-BYTE SERIAL NUMBER
```

The LOCATE macro instruction points to the CAMLST macro instruction. NAME, the first operand of CAMLST, specifies that the system is to search for a catalog entry using the name of a data set. AB, the second operand, specifies the virtual storage location of the fully-qualified data set name LOCAREA, the fourth operand, specifies a 265-byte area you have reserved in virtual storage.

After these macro instructions execute, the 265-byte area contains a volume list or a volume control block for the data set A.B. If the entry has been located and read successfully, register 15 contains zeros. Otherwise, register 15 contains a return code (see "Return Codes from LOCATE" on page 163).

Retrieving Information by Generation Data Set Name (LOCATE and CAMLST NAME)

Specify the name of a generation data set using the fully-qualified generation index name and the relative generation number of the data set. The value of a relative generation number reflects the position of a data set in a generation data group. The following values can be used to identify a data set in a generation data group:

- Zero—specifies the latest data set (highest generation number) cataloged in a generation data group.
- Negative number—specifies a data set cataloged before the latest data set.
- Positive number—specifies a data set not yet cataloged in the generation data group.

**Rule:** If DISP (disposition) is DELETE to make room for other data sets and no generation data group exists, the job will complete indicating a deleted generation name (G0000V00). If a generation data group exists but is not in the range specified for deletion, the step will fail.

Using zero or a negative number as the relative generation number places a volume list (or a volume control block) in your output area and replaces the relative generation number with the absolute generation name.

Using a positive number as the relative generation number creates an absolute generation name and replaces the relative generation number. Because there are no entries in the catalog, zeros are read into the first 256 bytes of your output area.
The format for the LOCATE and CAMLST NAME macros is:

```
(lbl) LOCATE list_addrx

listname CAMLST NAME dsname_relexp area_relexp
```

- `list_addrx` Points to the parameter list (labeled listname) set up by the CAMLST macro instruction.
- `NAME` To read a block from the catalog by generation data set name, code this operand as shown.
- `dsname_relexp` Specifies the virtual storage location of the name of the generation index and the relative generation number. The area that contains these must be 44 bytes long.
- `area_relexp` Specifies the virtual storage location of your 265-byte output area, which you must define. The output area must begin on a doubleword boundary. The output area will contain a volume list that is built from the catalog. If the data set resides on one volume, bytes 252 - 254 can contain the relative track address of the DSCB. This address is relative to the beginning of the volume.

**Example**
In the following example, the list of volumes containing generation data set A.PAY(-3) is read into virtual storage.

```
LOCATE INDGX  READ CATALOG ENTRY
* FOR DATA SET A.PAY(-3)
* INTO YOUR STORAGE
* AREA NAMED LOCAREA
```

Check Return Codes

```
INDX   CAMLST   NAME,APAY,,LOCAREA
APAY    DC    CL44'A.PAY(-3)'
LOCAREA  DS   0D
        DS   265C
```

The LOCATE macro instruction points to the CAMLST macro instruction. NAME, the first operand of CAMLST, initiates a search for a catalog entry using the name of a data set. APAY, the second operand, specifies the virtual storage location of the name of the generation index and the relative generation number of a data set in the generation data group. LOCAREA, the fourth operand, specifies a 265-byte area you have reserved to receive the catalog information.

After executing this macro instruction, the system replaces the relative generation number that you specified with the data set's absolute generation name. Control is returned to your program at the next executable instruction following the LOCATE macro instruction. If the entry has been located and read successfully, register 15 contains zeros. Otherwise, register 15 contains a return code (see Return Codes...
CATALOG Macros

From LOCATE on page 163. See "Retrieving Information by Data Set Name (LOCATE and CAMLST NAME)" on page 158 for a description of the contents of the output area.

Retrieving Information by Alias (LOCATE and CAMLST NAME)

For each of the preceding functions, you can specify an alias as the name of a data set. Functions proceed as previously described with one exception: the true name replaces the specified alias name.

The format for the LOCATE and CAMLST NAME macros is:

```
LOCATE—list_addrx

NAME

dsnname_relexp

area_relexp
```

list_addrx Points to the parameter list (labeled listname) set up by the CAMLST macro instruction.

NAME To retrieve information from a catalog, code this operand as shown.

dsnname_relexp Specifies the virtual storage location of a fully-qualified data set name, the first or only name of which is the alias. The area containing the name must be 44 bytes long. The name can be defined by a C-type DC instruction.

area_relexp Specifies the virtual storage location of your 265-byte output area, that you must define. The output area must begin on a doubleword boundary. The first 256 bytes of the output area will contain a volume list that is read from a catalog. If the data set resides on one volume, bytes 252 - 254 can contain the relative track address of the DSCB. This address is relative to the beginning of the volume.

Example

In the following example, the catalog entry containing a list of the volumes on which data set A.B.C resides is read into virtual storage (data set A.B.C, however, is addressed by an alias name, X.B.C).

```
LOCATE INDAB READ CATALOG ENTRY
* FOR DATA SET X.B.C
* INTO VIRTUAL STORAGE
* AREA NAMED LOCAREA.
```

Check Return Codes

```
INDAB CAMLST NAME,ABC,,LOCAREA
ABC DC CL44'X.B.C'
LOCAREA DS 0D
DS 265C
```

The LOCATE macro instruction points to the CAMLST macro instruction. NAME, the first operand of CAMLST, initiates a search of the catalog for an entry using the
name of a data set. ABC, the second operand, specifies the virtual storage location of the fully-qualified name of a data set (in this case, data set A.B.C is addressed by its alias X.B.C). LOCAREA, the fourth operand, specifies a 265-byte area you have reserved in virtual storage.

See "Return Codes from LOCATE" for a description of the LOCATE return codes.

Reading a Block by Relative Block Address (LOCATE and CAMLST BLOCK)

This format is no longer supported and will result in an error.

Return Codes from LOCATE

Control is returned to your program at the next executable instruction following the LOCATE macro instruction. Register 15 contains one of the following return codes. If register 15 is non-zero, then register 0 contains an ICF catalog return code, described under message IDC3009I in z/OS MVS System Messages, Vol 6 (GOS-IEA).

Table 29. LOCATE Return Codes

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>Operation successful.</td>
</tr>
<tr>
<td>4 (X'04')</td>
<td>Either the required catalog does not exist or it cannot be opened.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>The user is not authorized to perform this operation. Register 0 contains hexadecimal 38.</td>
</tr>
<tr>
<td>12 (X'C')</td>
<td>An invalid low-level GDG name was found.</td>
</tr>
<tr>
<td>16 (X'10')</td>
<td>A data set exists at other than the lowest index level specified. Register 0 contains the number of the index level where the data set was encountered.</td>
</tr>

<td>38 (X'26')</td>
<td>DFSMSshima LOCATE preprocessor has experienced an error.</td>
</tr>
</tbody>
</table>

Note: See z/OS MVS System Messages, Vol 7 (IEE-IEE) and z/OS MVS System Messages, Vol 8 (IEG-IGD) message IDC3009I, for documentation of integrated catalog facility catalog and VSAM catalog return codes.

Using Non-VSAM Data Set Catalog Entries

You can catalog, uncatalog, and recatalog non-VSAM data sets using the CATALOG and CAMLST macro instructions. CATALOG macro instructions are used to point to CAMLST macro instructions and to specify cataloging options.

For a description of the search algorithms used for cataloging, uncataloging, and recataloging non-VSAM data sets, see the DEFINE and the DELETE commands in z/OS DFSMS Access Method Services for Catalogs.

Cataloging a Non-VSAM Data Set (CATALOG and CAMLST CAT)

The format of the CATALOG and CAMLST macros is:
**CATALOG Macros**

**list_addrx**  
Points to the parameter list (labeled listname) set up by the CAMLST macro instruction.

**CAT or CATBX**  
Code this operand as shown. Either CAT or CATBX can be coded.

**name_relexp**  
Specifies the virtual storage location of the fully-qualified name of a data set. The name cannot exceed 44 characters. If the name is less than 44 characters, it must be followed by at least one blank. In a DFSMShsm environment, if the data set name is less than 44 characters, it must be padded with blanks until the 44-character length is reached.

**vol_list_relexp**  
Specifies the virtual storage location of an area that contains a volume list. The list must begin on a halfword boundary and consist of an entry for each volume on which the data set is stored. The first two bytes of the list indicate the number of entries in the volume list; the number cannot be zero. Each 12-byte volume list entry consists of a 4-byte device code, a 6-byte volume serial number, and a 2-byte data set sequence number. The sequence number is always zero for direct access volumes.

**DSCBTTR=dscb_ttr_relexp**  
Specifies the virtual storage location of the 3-byte relative track address (TTR) of the data set control block (DSCB). This DSCB is on the first or only volume of the data set. The address is relative to the beginning of the volume.

**Programming Considerations for Multiple-Step Jobs**

When executing multiple-step jobs, it is preferable to catalog or uncatalog data sets using JCL, instead of using IDCAMS, IEHPROGM, or a user program. Because step allocation and unallocation monitors data sets during job execution and is unaware of functions performed by user programs, conflicting functions can be performed or GDG orientation can be lost.

Unallocation can recatalog existing cataloged data sets at job termination. This action occurs when the data set is opened during the job and the DSCB TTR could not be found in the catalog entry. If you are using the CAMLST macro to uncatalog and then catalog data sets with new volume information, be sure to include the DSCB TTR.
Example
In the following example, the non-VSAM data set named A.B.C is cataloged. The data set is stored on two volumes.

```
CATALOG ADDABC CATALOG DATA SET A.B.C.
```

Check Return Codes

<table>
<thead>
<tr>
<th>ADDABC</th>
<th>CAMLST</th>
<th>CAT,DSNAME,,VOLUMES</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSNAME</td>
<td>DC</td>
<td>CL6'A.B.C' ONE BLANK FOR DELIMITER</td>
</tr>
<tr>
<td>VOLUMES</td>
<td>DC</td>
<td>H'2' DATA SET ON TWO VOLUMES</td>
</tr>
<tr>
<td>DC</td>
<td>X'3010200E' 3380 DISK DEVICE CODE</td>
<td></td>
</tr>
<tr>
<td>DC</td>
<td>CL6'000014' VOLUME SERIAL NUMBER</td>
<td></td>
</tr>
<tr>
<td>DC</td>
<td>H'0' DATA SET SEQUENCE NUMBER</td>
<td></td>
</tr>
<tr>
<td>DC</td>
<td>X'3010200E' 3380 DISK DEVICE CODE</td>
<td></td>
</tr>
<tr>
<td>DC</td>
<td>CL6'0000015' VOLUME SERIAL NUMBER</td>
<td></td>
</tr>
<tr>
<td>DC</td>
<td>H'0' SEQUENCE NUMBER</td>
<td></td>
</tr>
</tbody>
</table>

The CATALOG macro instruction points to the CAMLST macro instruction. CAT, the first operand of CAMLST, specifies that a data set is to be cataloged. DSNAME, the second operand, specifies the virtual storage location of the data set name A.B.C. VOLUMES, the fourth operand, specifies the virtual storage location of the volume list.

Control is returned to your program at the instruction following the CATALOG macro instruction. Register 15 contains one of the return codes described under "Return Codes from CATALOG" on page 168.

Uncataloging a Non-VSAM Data Set (CATALOG and CAMLST UNCAT)
Use this macro to remove a data set reference and unneeded indexes.

The format of the CATALOG and CAMLST macros is:

```
list_addrx
CAMLST

listname,CAMLST
UNCAT or UCATDX

name_relexp
```

<table>
<thead>
<tr>
<th>list_addrx</th>
<th>Points to the parameter list (labeled listname) set up by the CAMLST macro instruction.</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNCAT or UCATDX</td>
<td>Code this operand as shown. Either UNCAT or UCATDX can be coded but, in either case, unneeded indexes, with the exception of the highest-level index, are removed along with the data set reference.</td>
</tr>
<tr>
<td>name_relexp</td>
<td>Specifies the virtual storage location of the fully-qualified name of a data set or index level. The name cannot exceed 44 characters. If the name is less than 44 characters, it must be followed by at least</td>
</tr>
</tbody>
</table>
one blank. In a DFSMShsm environment, if the data set name is less than 44 characters, it must be padded with blanks until the 44-character length is reached.

Example
In the following example, the catalog entry for data set A.B.C is removed from a catalog.

```
CATALOG REMOVE REMOVE REFERENCES TO DATA SET A.B.C FROM CATALOG
```

Check Return Codes

```
REMO
CAMLST    UNCAT,DSNAME
DSNAME   DC   CL6'A.B.C' ONE BLANK FOR DELIMITER
```

The CATALOG macro instruction points to the CAMLST macro instruction. UNCAT, the first operand of CAMLST, specifies that references to a data set are to be removed from the catalog. DSNAME, the second operand, specifies the virtual storage location of the fully-qualified name of the data set whose references are to be removed.

Control is returned to your program at the instruction following the CATALOG macro instruction. Register 15 contains one of the return codes described under "Return Codes from CATALOG" on page 168.

Restriction: The CAMLST UNCAT or UCATDX function is not supported for system-managed data sets. These are ignored. The function is not performed and the return code is 0.

Recataloging a Non-VSAM Data Set (CATALOG and CAMLST RECAT)

You can recatalog a non-VSAM data set using the CATALOG and CAMLST macro instructions. Recataloging is usually necessary if a data set is extended to a new volume.

Build a complete volume list in virtual storage consisting of an entry for each volume on which the data set resides. The first 2 bytes of the list indicate the number of entries in the list; the number must not be zero. Each 12-byte volume pointer consists of a 4-byte device code, a 6-byte volume serial number, and a 2-byte data set sequence number. The sequence number is always zero for direct access volumes.

The format of the CATALOG and CAMLST macros is:

```
label -- CATALOG list_addr
```
list_addrx  Points to the parameter list (labeled listname) set up by the CAMLIST macro instruction.

RECAT    Code this operand as shown.

name_relexp Specifies the virtual storage location of the fully-qualified name of a data set. The name cannot exceed 44 characters. If the name is less then 44 characters, it must be followed by at least one blank. In a DFSMShsm environment, if the data set name is less than 44 characters, it must be padded with blanks until the 44-character length is reached. A C-type DC instruction can define the name.

vol_list_relexp Specifies the virtual storage location of an area that contains a volume list. The area must begin on a halfword boundary.

DSCBTTR=dscb_ttr_relexp Specifies the virtual storage location of the 3-byte relative track address (TTR) of the identifier DSCB. This DSCB is on the first or only volume of the data set. The address is relative to the beginning of the volume.

Example
In the following example, the two-volume data set named A.B.C is recataloged to add a third volume. An entry is added to the volume list, that previously contained only two entries.

`CATALOG RECATLG
* A.B.C ADDING A NEW
* VOLUME`

Check Return Codes

<table>
<thead>
<tr>
<th>RECATLG</th>
<th>CAMLIST</th>
<th>RECAT,DSNAME,,VOLUMES</th>
</tr>
</thead>

<td>X'3010200E' 3380 DISK DEVICE CODE</td>
</tr>
<tr>
<td></td>
<td>DC</td>
<td>CL6'000016' VOLUME SERIAL NUMBER</td>
</tr>
<tr>
<td></td>
<td>DC</td>
<td>H'0' SEQUENCE NUMBER</td>
</tr>
</tbody>
</table>

The CATALOG macro instruction points to the CAMLIST macro instruction. RECAT, the first operand of CAMLIST, specifies that a data set is to be recataloged. DSNAMES, the second operand, specifies the virtual storage location of the fully-qualified name of the data set to be recataloged. VOLUMES, the fourth operand, specifies the virtual storage location of the volume list you have built.
Control is returned to your program at the instruction following the CATALOG macro instruction. If the data set has been successfully recataloged, register 15 contains zeros. Otherwise, register 15 contains one of the return codes described under "Return Codes from CATALOG."

Return Codes from CATALOG

Control is returned at the instruction following the CATALOG macro instruction. Register 15 might contain one of the following return codes. Register 15 contains one of the following return codes. If register 15 is non-zero, then register 0 contains an ICF catalog return code, described under message IDC3009I in z/OS MVS System Messages, Vol 6 (GOS-IEA).

Chapter 4. Executing Your Own Channel Programs

This information describes the execute-channel-program (EXCP) and execute-channel-program-virtual-real (EXCPVR) macro instructions and is provided for compatibility with other IBM operating systems. References to EXCP apply equally to EXCPVR unless otherwise stated. See “Executing Fixed Channel Programs in Real Storage (EXCPVR)” on page 184 for EXCPVR and EXCP differences. IBM recommends using an access method such as VSAM in place of EXCP.

The EXCP macro instruction allows you to control the data organization based on device characteristics. The exceptions to this capability are partitioned data sets extended (PDSEs), extended format data sets, spooled and dummy data sets, TSO terminals, and z/OS UNIX files and file systems. They are not supported for user-written applications using EXCP. This information covers EXCP macro instruction application and function and includes descriptions of specific control blocks and macro instructions. Factors that affect the operation of EXCP, such as device variations and program modification, are also discussed.

Before reading this information, you should be familiar with the operational characteristics of the I/O devices required by your channel programs. Operational characteristics are described in IBM publications for each I/O device. You also need to understand the information in the following publications:

- HLASM Programmer's Guide and Assembler H V2 Programming Guide contain the information necessary to code programs in the assembler language.
- z/Architecture Principles of Operation, SA22-7832, describes channel command words (CCWs) and channel programs.
- z/OS DFSMS Using Data Sets contains the standard procedures for I/O processing under the operating system.
- z/OS DFSMS Macro Instructions for Data Sets describes the system macro instructions that can be used in programs coded in the assembler language.

EXCP is primarily for I/O programming situations that cannot be dealt with using standard access methods. When writing your own access method, include EXCP for I/O operations. You must also use EXCP for processing nonstandard magnetic tape labels, including reading and writing labels and positioning volumes.

To issue EXCP, provide a channel program (a list of channel command words) and control blocks in your program area. The I/O process then schedules I/O requests for the specified device, executes commands, handles interruptions, directs error recovery procedures, and posts the results of I/O requests.

Using EXCP

This information explains the procedures required when issuing the EXCP macro instruction. To issue the EXCP macro instruction directly, perform the following tasks:

1. Construct and open a data control block (DCB) with the DCB and OPEN macro instructions. See “Data Control Block (DCB) Fields” on page 185.
2. Create a channel program containing channel commands for I/O operations on the appropriate device.
3. Construct an input/output block (IOB) containing information about the channel program. See “Input/Output Block Fields” on page 198.
4. Construct an event control block (ECB) to be posted with a completion code when the channel program terminates. See "Event Control Block Fields" on page 206.

5. Issue an EXCP macro instruction to pass the address of the IOB to the routines that initiate and supervise I/O operations.

The I/O process generally handles scheduling the channel program and posting the completion codes.

After issuing EXCP, issue a WAIT or EVENTS macro instruction specifying the address of the ECB, to determine whether the channel program has terminated. If volume switching is necessary (because of unit exception or end of DASD extent), issue an EOV macro instruction. When data set processing has been completed, issue a CLOSE macro instruction to restore the DCB.

Programming interfaces for EXCP are compatible between MVS/370 and MVS/ESA™ or z/OS, except for supporting virtual and central storage addresses above 16 MB. EXCP is available to programs executing in either 24-bit or 31-bit addressing mode. The following restrictions apply:

- EXCP supports only a 24-bit virtual storage interface, except for format-1 CCWs, IDAWs, UCBs, a DCBE, and an XTIOT entry. In addition, all areas related to I/O operations (for example, channel command words, IOBs, DEBs, appendages, and so forth), must remain 24-bit virtual addressable. EXCP (channel command word translator) allows 24-bit virtual I/O buffers to be fixed above 16 MB real. When a channel command word (CCW) references a central storage address above 16 MB, the CCW translator builds one or more indirect addressing words (IDAWs) for that CCW. All virtual addresses, except those in IDAWs or format 1 CCWs, must be below 16 MB. For V=R users, CCWs and IDAWs must be below 16 MB real.
- All user-specified appendage routines are given control in 24-bit addressing mode and must return in the same mode.

### IDAW Requirements

A virtual channel program provided by the EXCP caller can have one or more CCWs with the IDA flag set and the address portion of these CCWs pointing to a single 31-bit or 64-bit IDAW. This EXCP function is referred to as virtual IDAWs. The 31-bit IDAW can contain a valid virtual address up to the maximum 31-bit address. Virtual IDAWs are supported on all virtual CCWs except:

- Transfer in channel (TIC) commands
- Read, read backward, and sense commands, with the skip flag set.
- All non-data-transfer type commands: for example, recalibrate, rewind, forward space, fold, block data check, no operation, control commands

The storage pointed to by a virtual IDAW can be backed by central storage above or below 2 GB. Either type of virtual IDAW can point to storage that is backed above 2 GB.

**Note:** 64-bit IDAWs are supported only in z/Architecture mode and only for direct access storage devices (DASD) and on all IBM-supplied cartridge tape devices. You should examine bit UCBEIDAW in the UCB to determine whether 64-bit IDAWs are supported by the device. As of z/OS 1.6, the system always runs in z/Architecture mode.
The same addressing restrictions apply to EXCPVR inputs except that 31-bit or 64-bit real data areas can be specified by the user-created CCWs through the use of IDAWs. All format 0 CCWs and IDAWs must be below 16 MB real. Format 1 CCWs must be below 2 GB real.

EXCP Requirements

This information describes the channel program that is needed to issue EXCP and the control blocks to be constructed directly or by using macro instructions.

All areas related to the EXCP/EXCPVR I/O operation (for example, CCWs, IDAWs, IOBs, DEBs, DCBs, appendages, and so forth) must remain 24-bit addressable. If the device supports it, however, the EXCP processor allows 24-bit, 31-bit and 64-bit virtual I/O buffers to be fixed above 2 GB real.

For more page-fixing information for EXCPVR, see “Page Fix and EXCPVR Start I/O Appendage” on page 212.

Channel Program

The channel program you supply is composed of CCWs on doubleword boundaries. Each channel command word specifies a command to be executed and, for data transfer commands, the source or destination area. CCW operation codes are described in the IBM publications for each I/O device.

You can specify both data chaining and command chaining by setting applicable chaining bits in the channel command word and indicating the type of chaining in the IOB. If an I/O error occurs while your channel program executes, the corresponding chaining bits in the IOB need to be set. Otherwise, error recovery could be impossible. The integrity of your data could be compromised. (See “Input/Output Block Fields” on page 198 for additional information.) If you specify both data and command chaining in the same channel command word, data chaining takes precedence.

EXCP does not support channel programs that modify themselves, regardless of the method of modification, except as noted in “Virtual and Central Storage Addresses” on page 173. The intended modification in virtual storage has no effect on the running real-channel program (see “Modifying a Channel Program during Execution” on page 173).

Control Blocks Used with EXCP

Using EXCP requires familiarity with the function and structure of the IOB, ECB, DCB, DEB, and optionally IDAW, IOBE, DCBE,UCB and IEBD, DCB, IOB, IOBE, IEDB, and ECB fields are illustrated in “Control Block Fields” on page 185. The DEB fields used for EXCP and EXCPVR are illustrated in “Control Blocks” on page 433 (all the DEB fields are illustrated in “z/OS DFSMSdfp Diagnosis”). The handling of IDAWs is described in “SIO Appendage” on page 213.

All EXCP control blocks that you provide must be located in storage that your program’s protection key allows the program to modify. Descriptions of these control blocks follow.

Input/Output Block

The IOB is used for communication between the problem program and the system. It provides the addresses of other control blocks, and maintains information about the channel program, such as the type of chaining and the progress of I/O
operations. You must define the IOB and specify its address as the only parameter of the EXCP or EXCPVR macro instruction. See "Input/Output Block Fields" on page 198.

Event Control Block
The ECB provides you with a completion code that describes whether the channel program was completed with or without error. A WAIT or EVENTS macro instruction, which can be used to synchronize I/O operations with the problem program, must identify the ECB. You must define the ECB and specify its address in the IOB. See "Event Control Block Fields" on page 206.

Data Control Block
The DCB provides the system with information about the characteristics and processing requirements of a data set to be read or written by the channel program. A DCB must be generated by a DCB macro instruction that includes parameters for EXCP. If you are not using appendages, a short DCB is constructed. Such a DCB does not support reduced error recovery. You specify the address of the DCB in the IOB.

Data Control Block Extension
The DCBE provides further processing options. The DCBE options currently supported by EXCP are the following:
- BLKSIZE
- BLOCKTOKENSIZE
- CAPACITYMODE
- EADSCB
- EODAD
- LOC
- SYNC
See "Data Control Block Extension" on page 196.

Data Extent Block
The DEB contains one or more extent entries for the associated data set and other control information. An extent defines all or part of the physical boundaries on an I/O device occupied by, or reserved for, a particular data set. Each extent entry contains the address of a unit control block (UCB) that provides information about the type and location of an I/O device. More than one extent entry can contain the same UCB address. For all I/O devices supported by the operating system, the DEB is produced during execution of the OPEN macro instruction for the DCB. The system places the address of the DEB into the DCB. See "Data Extent Block Fields" on page 208.

Input/Output Block Common Extension
The IOBE can control the level of ERP processing and provides the anchor to the IEDB. The IOBE is an extension to the IOB and, like the IOB, provides for communication between the user of EXCP and the system. This control block is optional. See "Input/Output Block Common Extension Fields" on page 203.

Input/Output Error Data Block
The system uses the IEDB to provide extended error information. This control block is optional. See "Input/Output Error Data Block Fields" on page 205.
Executing the Channel Program

This information explains how the system uses your channel program and control blocks after you issue EXCP.

Initiating the Channel Program

Issuing EXCP requests execution of the channel program specified in the IOB. The I/O process validates the request by checking fields of the control blocks associated with this request. If the I/O process detects invalid information in a control block, it initiates abnormal termination procedures. The EXCP processor gets the address of the:

- DCB from the IOB
- DEB from the DCB
- UCB from the DEB.

If you have provided a start I/O (SIO) appendage, the EXCP processor passes control to it. The return address from the SIO appendage determines whether the EXCP processor executes or skips the I/O operation. For a description of the SIO appendage and its linkage to the EXCP processor, see “Start-I/O Appendage” on page 211.

Virtual and Central Storage Addresses

The channel program you construct contains virtual addresses.

Unless your program is running with APF-authorization with ADDRSPC=REAL (V=R) on the JCL EXEC statement, the EXCP processor performs the following tasks:

- Copies your virtual channel program and translates the copy into one that uses only central storage addresses
- Fixes in real storage the pages used as I/O areas for the data transfer operations specified in your channel program.

The EXCP processor builds the translated (real) channel program in a portion of real storage.

User-constructed channel programs for I/O operations of an APF-authorized program in a V=R address space are not translated. Because the address space is V=R, any CCWs created by the user have correct real data addresses. (Translation would only re-create the user's channel program, so the CCWs are used directly.)

If an active channel program is modified by data read in or by processor instructions in a V=R address space, it takes effect in an APF-authorized address space, but not in a V=V address space.

Modifying a Channel Program during Execution

Except for APF-authorized programs in a V=R address space, the system builds a translated copy of your channel program in real storage. Channel program changes made by your page-fix or start-I/O appendage will affect the real channel program. Later changes to your copy of your channel program with processor instructions or with data read in by an I/O operation will not affect the real, translated channel program. Thus, in a V=V address space any attempt to modify an active channel program affects only the virtual image of the channel program, not the real channel program being executed by the channel subsystem.
If you wish your changed channel program to be executed, your program can issue another EXCP macro or your channel-end appendage can return at offset 8.

**DASD Channel Program Prefix Commands**

For direct access devices, specify the seek address in the IOB. For a CKD device, the system constructs a CCW chain. The CCW chain issues the seek and the set file mask specified in the DEB, and passes control to the real version of your channel program. You cannot issue the initial seek or set the file mask CCWs. For an ECKD device, the system constructs a define extent or prefix command instead of the seek and set file mask command. The system uses the contents of DEBXDEF, as described in “Control Blocks” on page 433, when building the define extent or prefix command. You can issue a define extent command at the beginning of the channel program. The system copies the data area and replaces the beginning and ending extent addresses and the file mask byte. Your program can issue the DEVTYPE macro to learn whether the device supports ECKD. Use the minimum type of call or the INFOLIST type with INFO=DASD.

For both CKD and ECKD, the file mask is set to prohibit seek-cylinder CCWs, or, if space is not allocated in full cylinders, seek-head commands. If the data set is open for INPUT, write CCWs are also prohibited. For an ECKD device, your channel program can contain locate-record CCWs.

The DEVTYPE macro with the INFO=DASD parameter will also tell your program whether the device supports the locate record extended command and it has controller cache. See “DEVTYPE—Info Form” on page 258.

**DASD Rotational Positioning Sensing**

Your channel program can be more efficient for device and channel usage if it supplies sector numbers. Your program can read sector numbers with the read sector command or calculate them with the sector conversion routine. That routine is described in “Obtaining the Sector Number of a Block on an RPS Device” on page 222.

**Command Retry Considerations**

Command retry is a function of many IBM 3990 storage controllers. When the channel subsystem receives a retry request, it repeats the execution of the CCW, without requiring any additional input/output interrupts. For example, a storage control might initiate a retry procedure to recover from a transient error.

A command retry during the execution of a channel program can cause the following conditions to be detected by the initiating program:

- **Modifying CCWs:** For an APF-authorized program running in a V=R address space, a CCW used in a channel program must not be modified before the CCW operation has been successfully completed. Without the command retry function, a command is fetched only once from storage by a channel. This allowed a program to determine through condition codes or program controlled interruptions (PCI) that a CCW had been fetched and accepted by the channel. The CCW could be modified before execution. With the command retry function, this procedure cannot be repeated because the channel fetches the CCW from storage again on a command retry sequence. In the case of data chaining, the channel retries commands starting with the first CCW in the data chain.
• Program Controlled Interrupts (PCI): A CCW containing a PCI flag can cause multiple program-controlled interrupts. This will happen if the PCI-flagged CCW was retried during a command retry procedure and a PCI could be generated each time the CCW is executed.

• Residual Count: If a channel program is prematurely terminated during the retry of a command, the residual count in the channel status word (CSW) will not necessarily indicate how much storage was used. For example, if the storage control detects a wrong-length record error condition, an erroneous residual count is stored in the CSW until the command retry is successful. When the retry is successful, the residual in the CSW reflects the correct length of the data transfer.

• Command Address: When data chaining with command retry, the CSW might not indicate how many CCWs have been executed at the time of a PCI. For example:

<table>
<thead>
<tr>
<th>CCW#</th>
<th>Channel Program</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Read, data chain</td>
</tr>
<tr>
<td>2</td>
<td>Read, data chain</td>
</tr>
<tr>
<td>3</td>
<td>Read, data chain, PCI</td>
</tr>
<tr>
<td>4</td>
<td>Read, command chain</td>
</tr>
</tbody>
</table>

- Testing Buffer Contents on Data Read: Any program that tests a buffer to determine when a CCW has been executed and continues to execute based on this data can get incorrect results if an error is detected and the CCW is retried.

Magnetic Tape Considerations

For a magnetic tape device, the system constructs a CCW chain to set the mode specified in the DEB and pass control to the real version of your channel program. (You cannot set the mode yourself.) For cartridge tape devices, the mode byte also prohibits supervisor channel command words such as the mode set command. If your program opens a tape for input or read backwards and you do not have RACF authority to write on the volume, the system normally prevents writes. With a reel tape the system does this by requiring the operator to remove the write ring. With a cartridge tape, the system does this using the Mode Set command. See z/OS DFSMS Using Magnetic Tapes for more information on tape handling.

Lost Data Condition on IBM 3800

With the IBM 3800 Printing Subsystem, a cancel key or a system-restart-required paper jam causes both a lost data indicator to be set in DCBIFLGS and a lost page count and channel page identifier to be stored in the UCB extension. Reset the lost data indicator bit (DCBIFLDT) and the first two bits in the DCBIFLGS field to zero before reissuing requests to the printer. For additional information see IBM 3800 Printing Subsystem Programmer's Guide and IBM 3800 Printing Subsystem Models 3 and 8 Programmer's Guide.

Completing Execution

The system considers the channel program completed when it receives a channel-end condition in the subchannel status word (SCSW). Unless a channel-end (CHE) or abnormal-end (ABE) appendage directs otherwise, a
completion code is placed in the ECB, IOB, and IEDB. The completion code refers to errors associated with channel end. If device and channel end occur simultaneously, errors associated with device end (that is, unit exception or unit check) are also accounted for.

If device end follows channel end and an error is associated with device end, the completion code in the ECB will not indicate the error. However, the status of the unit and channel is saved by the system for the device. The next I/O request directed to the I/O device from any address space is marked as intercepted. The error is assumed to be permanent, and the completion code in the ECB for the intercepted request indicates interception. The DCBIFLGS field of the DCB will also indicate a permanent error. Note that, if a write-tape-mark or erase-long-gap CCW is the last or only CCW in your channel program, the I/O process does not attempt recovery procedures for device end errors. In these circumstances, command chaining a NOP CCW to your write-tape-mark or erase-long-gap CCW ensures initiation of device-end error recovery procedures.

To be prepared for device-end errors, you should be familiar with device characteristics that can cause such errors. After one of your channel programs has terminated, do not release buffer space until determining that your next request for the device has not been intercepted. You can reissue an intercepted request.

**Interruption Handling and Error Recovery Procedures**

An I/O interruption allows the processor to respond to signals from an I/O device that indicate either termination of a phase of I/O operations or external action on the device. A complete explanation of I/O interruptions is contained in the publication *z/Architecture Principles of Operation*. For descriptions of interruption by specific devices, see the IBM publications for each device.

If error conditions are associated with an interruption, the system schedules the appropriate device-dependent error routine. The operating system might then start another request that is not related to the channel program in error. If the error recovery procedures (ERPs) fail to correct the error, the system places an error code in the ECB, IOB, and IEDB.

A channel program might depend upon the successful completion of a previous channel program (as when one channel program retrieves data to be used in building another). The previous channel program is called a related request and must be identified to the system. For a description of this procedure, see [IOBFLAGS in “Input/Output Block Fields” on page 198](#) and “Purging and Restoring I/O Requests” on page 293.

If a permanent error occurs in the channel program of a related request, the system removes the request queue elements for all dependent channel programs and returns them to the caller without executing the request. For all requests dependent on the channel program in error, the system places completion codes in the ECBs. The system also places ones in the first two bit positions of the DCBIFLGS field of the DCB. Any requests for a DCB with error flags are posted complete without execution. To reissue requests that depend on the channel program in error, reset the first two bits of the DCBIFLGS field of the DCB to zero. Then reissue EXCP for each desired channel program.

**Reexecuting Channel Programs by Error Recovery Procedures:** Under some circumstances the ERP might reexecute a channel program from the beginning. You will want to build channel programs that the ERP can restart after any CCW has failed.
If a CCW modifies a data area used by an earlier CCW, the channel program might not reexecute properly.

The following are some situations where a channel program might not give correct results when reexecuted by an APF-authorized program in a V=R address space (see "Modifying a Channel Program during Execution" on page 173):

- The channel program modifies itself.
- The application program or the PCI appendage modifies the channel program or a data area before receiving notification that the channel program has completed.
- Generally you can attempt to add CCWs to the end of the channel program.

**Example:** The following is an example of a DASD channel program that will not always execute correctly. Using this channel program is inadvisable.

```
CCW X'47',LRArea,X'60',X'LRArea Locate Record
CCW X'86',Data,X'60',X'LData Read Data
CCW X'92',Search,X'60',X'LSearch Read Count
CCW X'22',Sector,X'20',1 Read Sector for this count
LRArea DC 0XL16 Area for Locate Record command
DC X'06010002' Operation, auxiliary, block count (2)
Seek DC X'xxxxxxxx' BBCCHH for seek
Search DC X'xxxxxxxxx' Search argument
Sector DC X'FF0000' Sector and transfer length factor
Data DC ----
```

The application program would have to store appropriate values at labels "Seek" and "Search" before issuing EXCP. (It will execute more efficiently if an appropriate value is stored at "Sector" also.)

If all or part of the third CCW executes (Read Count), then reexecution of the channel program by the ERP will give different results.

This programming example demonstrates the use of mixed case letters that IBM High Level Assembler handles.

**Requesting Extended Error Information:** You can request that EXCP and EXCPVR processing return extended error information. This extended error information consists of sense information and a completion code, which you can use to help more accurately diagnose I/O errors later encountered. Extended error information is available for all devices.

To request extended error information, you must perform the following steps:

- Follow the EXCP/EXCPVR initialization procedures described in "Input/Output Block Fields" on page 198, including building and initializing the DCB, IOB and ECB.
- Define an input/output block common extension (IOBE) and an input/output error data block (IEDB) using the IOSDIIOBE and IOSDIEDB mapping macros, respectively. Each must be defined on word boundaries. You must supply both an IOBE and an IEDB to receive extended error information. Initialize the fields as described in "Input/Output Block Common Extension Fields" on page 203 and "Input/Output Error Data Block Fields" on page 205.
- Set register 0 to the address of the IOBE.
- Set register 1 to the address of the IOB.
- Set flag IOBCEF on in the IOB to indicate that the IOB extension is present.
• Issue the EXCP or EXCPVR macro (see "Using Executable Macro Instructions with EXCP" on page 180 and "Executing Fixed Channel Programs in Real Storage (EXCPVR)" on page 184 respectively).
The IEDB contains the following status information:

- The completion code from I/O processing that gives the status. The completion codes and their meanings are shown in Figure 18 on page 207.
- The sense information, set only after a unit check. Once set, the sense information remains until overlaid by the next unit check. Since the system never clears this area, you might want to clear it before issuing EXCP. See the appropriate device publication for an explanation of the sense information.

**Requesting Different Levels of ERP Processing:** You can request the system to limit error recovery procedure (ERP) processing to selected functions, typically when EXCP or EXCPVR processing has encountered an I/O error. The processing selections available depend upon the device type.

For all devices, except magnetic tape subsystems that use cartridges, the following processing levels are available:

- **No ERP processing.** ERP processing does not attempt error recovery or issue messages. However, ERP processing can perform recovery for non-error unit checks for logging, forced logging mode and buffered log overflow. To request no ERP processing, set at least one of the DCBIFIOE bits on in the DCBIFLGS field in the DCB.
- **Full ERP processing.** ERP processing performs such functions as logging the errors, logging data collected by a control unit for a device, retrying errors, issuing error messages and processing requests from the device. You do not have to request full ERP processing; it is the system default.

For magnetic tape subsystems that use cartridges, such as the 3490 or 3590-1, the following processing levels are available:

- **Basic ERP processing.** ERP processing logs the errors, logs data collected by a control unit for a device and processes requests from a device. In this case, the system does not issue messages or retry errors. To request basic ERP processing, set one of the DCBIFIOE bits on in the DCBIFLGS field in the DCB.
- **Intermediate ERP processing.** ERP processing performs the functions provided by basic processing and also issues any permanent error messages. To request intermediate ERP processing, define an IOBE and set IOBEPMSG on in IOBEERPM. In addition, set at least one of the DCBIFIOE bits on in the DCBIFLGS field in the DCB.
- **Full ERP processing.** ERP processing performs such functions as logging the errors, logging data collected by a control unit for a device, retrying errors, issuing error messages and processing requests from the device. You do not have to request full ERP processing; it is the system default. Bits in DCBIFIOE must be 0. The DCB macro assembles them as zeros.

**VIO considerations:** When you issue EXCP or EXCPVR against a VIO data set, the system simulates all the common channel commands. When working with VIO data sets, if you supply an IEDB the system verifies its validity, but will not set any fields in it in the current level of the operating system.

**Invalid ending status:** If the ending status of a channel program is a channel error, then the ending address for the channel program is unpredictable. Normally
the ending address is stored in IOBCMD31 or the first three bytes of IOBCSW. A channel error is indicated when the subchannel status indicates program check, protection check, channel data check, channel control check, interface control check, or chaining check.

Using Executable Macro Instructions with EXCP

When using the EXCP macro instruction, also use OPEN, CLOSE, and, in some cases, the EOV macro instruction. The parameters of the EOV and EXCP macro instructions are described here. The parameters and different forms of the OPEN (without TYPE=J) and CLOSE macro instructions are described in [Z/OS DFSMS Macro Instructions for Data Sets]. The OPEN macro with the TYPE=J parameter is described in this publication. See “Executing Fixed Channel Programs in Real Storage (EXCPVR)” on page 184 for a description of the EXCPVR macro.

Allocating the Data Set or Device

You allocate the data set or device by using step allocation (see [Z/OS MVS JCL Reference, SA22-7597]) or by using dynamic allocation (see [Z/OS MVS Programming: Authorized Assembler Services Guide, SA22-7608] or [Z/OS TSO/E Command Reference, SA22-7782]).

With dynamic allocation, you can use the XTIOT option, which is bit S99TIOEX. It causes creation of an XTIOT entry instead of an entry in the TIOT. The XTIOT resides above the 16 MB line. This option requires your program to be APF authorized, in supervisor state, or in a system key (0 – 7).

With dynamic allocation, you can use the NOCAPTURE option, which is bit S99ACUCB. If the actual UCB address is above the 16 MB line and you do not code LOC=ANY option on the DCBE macro, then, OPEN and EOV will capture it and EOV and CLOSE will uncapture it. (Capturing means to create a 24-bit address for a UCB that has an actual address above the 16 MB line. This NOCAPTURE option also causes creation of an XTIOT instead of a TIOT entry, but it does not require your program to have authorization). If you code the LOC=ANY option on the DCBE, then OPEN will not capture the UCB and its address will be in a four-byte field in the DEB.

With dynamic allocation, you can use the S99DSABA bit, which allows the DSAB control block to reside above the 16 MB line. If you turn S99DSABA on, then you must also turn on S99TIOEX and your program must be authorized. BSAM, BPAM, and QSAM also support S99DSABA.

To learn whether the allocation has any of these three options, you can issue the DEVTYPE macro with the INFO=AMCAP option. On a system before z/OS Release 11, bits S99DSABA and S99TIOEX will be off. These options should only be used when NON_VSAM_XTIOT=YES is in use. This is DFAXTBAM.

Initializing Data Control Blocks

The OPEN macro instruction initializes one or more DCBs so that their associated data sets can be processed. Issue OPEN for all DCBs used by your channel programs. (A dummy data set cannot be opened for EXCP.) Some of the procedures performed by OPEN are:

• Checking data set access authorization
• Constructing the data extent block (DEB)
• Completing the fields in the DCB and DCBE
• Verifying or creating standard labels
• Positioning tape
• Loading your appendage routines.
• Capturing the UCB if the DCBE option "LOC" was set or defaulted to "BELOW", that is LOC=BELOW or not coded, or the "NON_VSAM_XTIOT" option of the DEVSUPxx member of PARMLIB was set or defaulted to "NO", that is NON_VSAM_XTIOT=NO or not coded. In other words, OPEN does not capture the UCB if LOC and NON_VSAM_XTIOT were specified as follows: LOC=ANY and NON_VSAM_XTIOT=YES.

The parameters and different forms of the OPEN macro instruction are described in z/OS DFSMS Macro Instructions for Data Sets and "OPEN - Initialize Data Control Block for Processing the JFCB" on page 291.

Direct Data Set Considerations
To process a multivolume direct data set (BDAM) with EXCP, use the open routines to build a data extent block for each volume and to issue mount messages for them. This can be done by reading in the JFCB with a RDJFCB macro instruction and opening each volume of the data set with a separate DCB. See "Using BSAM or EXCP for Random I/O to a Multivolume Data Set" on page 281 for an example of how to code a routine to do this, and "Reading and Modifying a Job File Control Block (RDJFCB Macro)" on page 273 for further uses of the RDJFCB macro.

VSAM Data Set Considerations
With a DCB used to open a component of a VSAM data set you can perform the following tasks:
• Verify that an application has master password or RACF alter authority for the data set.
• Read from or write to a data set to repair data set or catalog damage if normal VSAM processing cannot. Because of the potential for damaging a valid data set or catalog, exercise extreme caution when writing an application using this interface.

You can specify a DCB when opening a component (data or index) of a VSAM data set if the following conditions are met:
• The application has master password or RACF alter authority for the data set.
• The component must not reside on multiple volumes.
• The component must not be a member of a concatenation.
• The DCB must specify the EXCP access method.
• The data set disposition must be either (OLD,KEEP,KEEP) or (SHR,KEEP,KEEP).
• The DCB must specify either the INPUT or UPDAT option.
• Your program must be either APF authorized or in supervisor state.

When opening a VSAM component on a volume that supports extended attribute DSCBs, the specified DCB must point to a DCBE with the EADSCB=OK keyword. When EADSCB=OK is specified, your program must support extended attribute DSCBs. These are format-8 and format-9 DSCBs, where the extent descriptors may contain 28-bit cylinder numbers.

Executing a Channel Program
The EXCP macro instruction initiates channel program I/O operations. Whenever you want to execute one of your channel programs, issue EXCP.
The format of the EXCP macro is:

```
EXCP label iob_addr
```

*iob_addr*—RX-type address, (2-12), or (1)

The address of the input/output block of the channel program to be executed.

If your program is also supplying an IOBE, then set register 0 as described in "Requesting Extended Error Information" on page 177.

**End of Volume**

The EOV macro instruction identifies end-of-volume and end-of-data-set conditions.

For an end-of-volume condition, EOV causes switching volumes and verifying or creating standard labels. For an end-of-data-set condition (except when another data set is concatenated), EOV causes your end-of-data set routine to be entered. Before processing trailer labels on a tape input data set, decrement the DCBBLKCT field. Your program issues EOV for any of the following reasons:

- Switching magnetic tape or direct access volumes is necessary
- Performing a secondary allocation on the same or another volume for a direct access data set opened for output
- Switching to the next concatenated data set is necessary.

For magnetic tape, issue EOV when either a tapemark is read or a write command received a unit exception condition. You can also issue EOV to go to the next volume or data set even though neither a tapemark was read nor end-of-tape reached. Bit settings in the 1-byte DCBOFLGS field of the DCB determine the action taken when EOV is executed. Before issuing EOV for magnetic tape or DASD make sure that appropriate bits are set in DCBOFLGS. Bit positions 2, 3, 6, and 7 of DCBOFLGS are used only by the system; you are concerned with bit positions 0, 1, 4, and 5. The use of these DCBOFLGS bit positions is as follows:

<table>
<thead>
<tr>
<th>Table 31. DCBOFLGS Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Position</strong></td>
</tr>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
</tbody>
</table>

If bits 0 and 5 of DCBOFLGS are both off when EOV is executed, EOV spaces the tape past a tapemark, and standard labels, if present, are verified on both the old and new volumes. The direction of spacing depends on bit 1. If bit 1 is off, the tape is spaced forward; if bit 1 is on, the tape is backspaced.

For tape, if bit 0 is on, but bit 5 is off, EOV writes a tapemark at the current position, which is assumed to be following the last data record of the data set on
the current volume. EOV also writes labels if it is a labeled tape. See [z/OS DFSMS Using Magnetic Tapes](https://www.ibm.com) for information on label processing. For DASD, if bit 0 is on, EOV attempts to write a file mark. See the DCBFDAD description in on page 193 for more information. Labels, if specified, are created on the old and the new volume.

When you issue EOV, the system might rebuild the DEB at another location. After each EOV, obtain the rebuilt DEB address from the DCB. If the data set was allocated with the nocapture option of dynamic allocation, then EOV might have uncaptured the UCB for the previous volume. If so, that UCB might become invalid. Note that the 24-bit address of the new UCB might be the same as the previous UCB.

After issuing EOV for sequentially organized output data sets on direct access volumes, you can determine whether additional space was obtained on the same or a different volume. Do this by examining the DEB and the UCB. If the volume serial number in the UCB has not changed, additional space was obtained on the same volume. Otherwise, space was obtained on a different volume.

The format of the EOV macro is:

```
dcb_addr—RX-type address, (2-12), or (1)
label
EOV—db_c_addr
,MODE= 24,31
```

* `dcb_addr`—RX-type address, (2-12), or (1)
  The address of the DCB that is opened for the data set. If this parameter is specified as (1), register 1 must contain this address.

* `MODE=24` or `31`
  Indicates how the registers are set. With either value, your program can be in 24-bit or 31-bit mode. The modes are:

  24 If you do not specify the MODE operand, this mode is assumed. The expansion of the EOV macro stores the DCB address into register 1. The high-order byte of register 1 is ignored during EOV processing. The DCB must be below 16MB, but the calling program can be above the line.

  31 The EOV macro expansion code puts the DCB address into register 15 and sets register 1 to zeros. The DCB address must be below 16 MB, because providing a DCB above 16 MB causes an ABEND50D. The high-order byte of the address specified in the EOV macro must be zero.

To determine how the system disposes of a tape volume when an EOV macro is issued, see the description of the DISP parameter of the OPEN macro in [z/OS DFSMS Macro Instructions for Data Sets](https://www.ibm.com).

**Restoring Data Control Blocks**

The CLOSE macro instruction restores one or more DCBs so that processing of their associated data sets can be terminated. Issue CLOSE for all DCBs that were used by your channel programs. Some of the procedures performed when CLOSE is executed are:

- Releasing data extent block
- Removing information transferred to DCB fields when OPEN was executed
• Verifying or creating standard labels
• Volume disposition
• Releasing programmer-written appendage routines
• Uncapture UCB if the actual UCB is above the line and the allocation was done
  with the nocapture option

When CLOSE is issued for a data set on magnetic tape volume, labels are
processed according to bit settings in the DCBOFLGS field of the DCB. Before
issuing CLOSE for magnetic tape, set the appropriate bits in DCBOFLGS. The
significant DCBOFLGS bit positions are listed in the EOV macro instruction
description.

When CLOSE is issued for a data set open for output on a direct access device,
the system will try to write a file mark if fields are as described in
“Device-Dependent Parameters” on page 191.

The parameters and different forms of the CLOSE macro instruction are described
in z/OS DFSMS Macro Instructions for Data Sets.

## Executing Fixed Channel Programs in Real Storage (EXCPVR)

The EXCPVR macro instruction provides you with the same functions as the EXCP
macro instruction (that is, a device-dependent means of performing input/output
operations). In addition, it allows your program to improve the efficiency of the I/O
operations in a paging environment by translating its own virtual channel programs
to real channel programs. In order to issue EXCPVR, your program must be
executing in protection key zero to seven, executing in supervisor state, or be APF
authorized.

You can specify 31-bit real data areas by creating CCWs that point to IDAWs or by
using format 1 CCWs and setting bit IOBEFMT1. That bit is described in
“Input/Output Block Common Extension Fields” on page 203.

The program issuing the EXCPVR must remain in authorized state until completion
of the channel programs. A description of how to authorize a program is in z/OS
MVS Programming: Authorized Assembler Services Guide.

The format of the EXCPVR macro is:

```
  EXCPVR:iob_addr
```

*iob_addr*—RX-type address, (2-12), or (1)
  the address of the input/output block of the channel program to be executed.

If your program is also supplying an IOBE, then set register 0 as described in
“Requesting Extended Error Information” on page 177.

To use EXCPVR, follow the procedures needed to execute an EXCP request and
also follow the procedures listed below. In a V=R address space, steps 1 and 2 are
not necessary.
1. Code PGFX=YES in the DCB associated with the EXCPVR requests and provide a page-fix (PGFX) appendage by specifying SIOA=symbol in the DCB. In a V=R address space, this step is not necessary.

2. Fix the data area containing your channel program, the data areas referred to by your channel program, the PCI appendage (if your program can generate program-controlled interrupts), and any area referred to by the PCI appendage including the DEB, IOB, etc. To fix these areas, build a list in your PGFX appendage containing the addresses of these virtual areas. Any area that you know already is in fixed storage for the duration of the I/O can be omitted from the page fix list.

The following two items must be done in your start I/O (SIO) appendage. The SIO appendage is described in "Start-I/O Appendage" on page 211.

3. Determine whether the data areas in virtual storage specified in the address fields of your CCWs cross page boundaries. If they do, build an indirect data address list (IDAL) and put the address of the IDAL in the affected CCW and turn on the IDA bit in the CCW. Refer to z/Architecture Principles of Operation for more information.

4. Translate the addresses in your CCWs from virtual to central storage addresses.

All other areas related to the EXCP/EXCPVR I/O operation (that is, CCWs, IDAWs, IOBs, DEBs, DCBs, appendages, and so forth) must remain 24-bit addressable. The system allows both 24-bit and 31-bit virtual I/O buffers to be fixed above 16MB real.

---

**Control Block Fields**

Control block field information covered here includes fields of the DCB, DCBE, input/output block, IOBE, IEDB, event control block, and data extent block.

To use the DCBD macro to map the DCB, see "DSORG Parameter of the DCBD Macro" on page 195.

**Data Control Block (DCB) Fields**

The EXCP form of the DCB macro instruction produces a DCB that can be used with the EXCP macro instruction. Code a DCB macro instruction for each data set to be processed by your channel programs. (Notation conventions and format illustrations of the DCB macro instruction are given in z/OS DFSMS Macros and Instructions for Data Sets.) DCB parameters that apply to EXCP depend on the following elements of the DCB that are generated:

- **Foundation block:** This portion is required and is always 12 bytes in length. If the DCBMACRF field indicates that a DCB portion before this is missing or short, the system ignores values in those fields.
- **EXCP interface:** This portion is optional. If you specify any parameter in this category, 20 bytes are generated.
- **Foundation block extension and common interface:** This portion is optional and is always 20 bytes in length. If this portion is generated, the device-dependent portion is also generated.
- **Device dependent:** This portion is optional and is generated only if the foundation block extension and common interface portion is generated. Its size ranges from 4 to 20 bytes, depending on specifications in the DEVD parameter. If you do not specify the DEVD parameter and the foundation extension and common interface portions are generated, 20 bytes for this portion are also generated.
Some of the procedures performed by the system when the DCB is opened and closed (such as writing file marks for output data sets on direct access volumes) require information from optional DCB fields. Make sure that the DCB is large enough to provide information for the procedures you want the system to handle.

Figure 9 on page 187 shows the relative position of each portion of an opened DCB. The fields, corresponding to the DCB macro instruction parameters, are also identified, except for DDNAME. (DDNAME is not included in a DCB that has been opened.) The fields in parentheses represent system information that is not associated with parameters of the DCB macro instruction.

Sources of information for DCB fields other than the DCB macro instruction are data definition (DD) statements or dynamic allocation parameters, data set labels, and DCB modification routines. You can use any of these sources to specify DCB parameters. However, if a particular portion of the DCB is not generated by the DCB macro instruction, the system will not accept information intended for that portion from any alternative source.

You can provide symbolic names for the fields in one or more EXCP DCBs by coding a DCBD macro to generate a dummy control section (DSECT). For further information, see "DSORG Parameter of the DCBD Macro" on page 195.

The EXCP DCB does not have a field to contain the current or maximum block size but the DCBE does have such a field.
The device-dependent portion of the data control block varies in length and format according to specifications in the DSORG and DEVD parameters. Illustrations of this portion for each device type are included in the description of the DEVD parameter.

</tr>
</tbody>
</table>

**DCBTLIOT:** If the data set allocation was dynamic and had the XTIOT (S99TIOEX) or nocapture (S99ACUCB) option, then this field contains zeroes. You can use DEBXTNP, DEBXDSAB and DSABTIOT to get the TIOT entry address. If the allocation was not dynamic or did not have the XTIOT or nocapture option, this field is unsigned (16-bit) offset in the TIOT to the entry.

Foundation Block Parameters

**DDNAME**=*symbol*

The name of the data definition (DD) statement that describes the data set to be processed. This parameter is required and must be supplied before your program issues the OPEN macro.

**MACRF=E**

The EXCP macro instruction is to be used in processing the data set. This operand must be coded and must be supplied before your program issues the OPEN macro.

**REPOS=Y or N**

Magnetic tape volumes: This parameter indicates to the system whether the user is keeping an accurate block count. (Maintain the block count in the DCBBLKCT field.) The system ignores this parameter when the program is executing and the device is not magnetic tape.

The EOV and CLOSE functions can record the block count in the IBM standard or ISO/ANSI standard trailer labels.

On input, the EOV and CLOSE functions can compare the DCB block count with the block count in the standard trailer labels to detect missing or duplicate blocks. This is supported on reel and cartridge tapes.

On input or output, the EOV and CLOSE functions can compare the DCB block count with the block count calculated from tape cartridge subsystems to detect missing or duplicate blocks. The system does this for any label type and for unlabeled tapes. Refer to z/OS DFSMS Using Magnetic Tapes.

For open magnetic tape devices with reels (not cartridges), coding REPOS=Y allows the dynamic device reconfiguration (DDR)
function to move the volume to another tape drive if the drive has a failure. With a cartridge, restart can do this without your program maintaining block count.

For open magnetic tape devices with reels (not cartridges), restart requires the block count in order to restore the tape to its position at the time of the checkpoint. With a cartridge, restart can do this without requiring that you maintain a block count.

The system performs the following tasks:
- Y-The count is accurate.
- N-The block count is inaccurate.

If the operand is omitted, N is assumed.

**EXCP Interface Parameters**

If you do not code any of the parameters described here, the DCB macro does not create this portion of the block and OPEN will ignore any value that your program sets. You can code values to affect the macro expansion and change any of these fields before the end of the DCB OPEN exit routine. For more information on EXCP appendages, see "Making Appendages Available to the System" on page 210.

- **EOEA=symbol** Last two characters of an EOE appendage name that you have entered into SYS1.LPALIB or SYS1.SVCLIB.
- **PCIA=symbol** Last two characters of a PCI appendage name that you have entered into SYS1.LPALIB or SYS1.SVCLIB.
- **SIOA=symbol** Last two characters of a SIO appendage name that you have entered into SYS1.LPALIB or SYS1.SVCLIB.
- **PGFIX=YES** The SIO appendage includes a page-fix entry point. Refer to "Executing Fixed Channel Programs in Real Storage (EXCPVR)" on page 184 and "Page Fix and EXCPVR Start I/O Appendage" on page 212.
- **CENDA=symbol** Last two characters of a CHE appendage name that you have entered into SYS1.LPALIB or SYS1.SVCLIB.
- **XENDA=symbol** Last two characters of an ABE appendage name that you have entered into SYS1.LPALIB or SYS1.SVCLIB.
- **OPTCD=Z** Indicates that, for devices that have a magnetic tape reel (input only), a reduced error recovery procedure (4 reads only) will occur when a data check is encountered. Only specify this operand when the tape is known to contain errors and the application does not require that all records be processed. Its proper use would include error frequency analysis in the SYNAD routine. Specification of this parameter will also cause generation of a foundation block extension. This parameter does not apply to magnetic tape subsystems that use cartridges. Your program can change this parameter value at any time.
- **IMSK=value** Specification indicates that the system will not use the system’s error routines.

**Foundation Block Extension and Common Interface Parameters**

**EXLST=address**

The address of an exit list that you have written for exception conditions. The format and purpose of the exit list are provided in *Z/OS DFSMS Using Data Sets*. 

Chapter 4. Executing Your Own Channel Programs 189
EODAD=address
The address of your end-of-data-set routine for input data sets. If this routine is not available when it is required, the task is abnormally terminated.

It is required when you issue an EOV macro for the last volume containing data and bit 0 of DCBOFLGS indicates that the last operation was a read. (See "End of Volume" on page 182 for more information concerning EOV.) An exception to this is when another data set is concatenated after the current data set.

The EODAD address used here is a 24-bit address in the DCB. If you use the DCB extension (DCBE), its 31-bit EODAD address is used.

DSORG=PS or PO or DA or IS
The data set organization (one of the following codes). Each code indicates that the format of the device-dependent portion of the DCB is to be similar to that generated for a particular access method:

<table>
<thead>
<tr>
<th>Code</th>
<th>DCB Format:</th>
</tr>
</thead>
<tbody>
<tr>
<td>PS</td>
<td>QSAM or BSAM</td>
</tr>
<tr>
<td>PO</td>
<td>BPAM</td>
</tr>
<tr>
<td>DA</td>
<td>BDAM</td>
</tr>
<tr>
<td>IS</td>
<td>QISAM or BISAM</td>
</tr>
</tbody>
</table>

When writing in a partitioned or sequential DASD data set, you can cause EOV or CLOSE to write a file mark. Refer to "Device-Dependent Parameters" on page 191 for further information.

Do not issue the STOW macro against an EXCP DCB; it can corrupt the directory contents.

IOBAD=address
The address of an input/output block. You can use this field for any purpose.

RECFM=code
The record format of the data set. (Record format codes are given in z/OS DFSMS Macro Instructions for Data Sets) When writing a data set to be read later, RECFM, LRECL, and BLKSIZE should be specified to identify the data set attributes. LRECL and BLKSIZE can only be specified in a DD statement, in an SVC 99 call, or in the JFCB, because these fields do not exist in a DCB used by EXCP.

IBM recommends that when you are creating a data set you issue a RDJFCB macro and set JFCLRECL and JFCBLKSIZE before issuing OPEN TYPE=J. This will allow LRECL and BLKSIZE to be in the data set label.

The RECFM parameter is not used by the EXCP routines. It provides information stored for subsequent use by access methods that read or update the data set.

The following parameters are optional. The system does not manage the buffers described.
BFALN=F or D  The word boundary alignment of each buffer, either word or doubleword.

BUFL=length  The length in bytes of each buffer; the maximum length is 32760.

BUFCB=address  The address of a buffer pool control block, that is, the 8-byte field preceding the buffers in a buffer pool. If the low order bit is on, the address is invalid and if you issue the FREEPOOL macro, it has no effect. The FREEPOOL macro sets the low order bit on. The DCB macro sets the low order bit on if the common interface portion is valid.

BUFNO=number  The number of buffers assigned to the associated data set; the maximum number is 255. For an EXCP DCB, OPEN ignores this parameter and the BFALN, BUFL, and BUFCB parameters. They have an effect only if your program uses those fields or if your program issues a GETPOOL or GETBUF macro.

Buffer number and block size affect the data transfer rate and the operating system overhead per block. Using more buffers reduces (per block transferred) the system overhead and the time needed for the DASD to select a cylinder and rotate to the requested record (device latency time). If you allocate more buffers than your program can process effectively, the virtual pages containing those buffers might be paged out, adding to the system overhead for the job. A large number of buffers also causes a large amount of real storage to be allocated to the job while the data is being transferred.

A job in a low-performance group can get swapped out more frequently than a higher-priority job. The number of buffers allocated for the job effect the number of pages that have to be swapped out.

Programs that access data sets with small block size (for example, 80) can easily make effective use of 30 buffers, which fit in, at most, two 4096-byte pages. The use of 30 buffers in this case is more efficient than 5, resulting in only 1 channel program rather than 6 channel programs to transfer 30 blocks.

Using data sets with large blocking factors such as half-track blocking on a 3380 or 3390 can be effective if only three or four buffers are specified, rather than five or more. The slightly lower DASD performance and small increase in system instruction costs should be more than offset by a reduction in paging or swapping in a constrained environment.

The DCB OPEN installation exit can use installation criteria for a default buffer number for EXCP DCBs (for a description of the OPEN installation exit, see z/OS DFSMS Using Data Sets). Your program can use the BUFNO value that the OPEN installation exit might set.

Device-Dependent Parameters

DCBE=  the DCBE= parameter is a device independent parameter but is included here because if DCBE= is specified the entire device-dependent section of the DCB is generated. DCBE= is specified when the DCB extension (DCBE) is required. The first word of the DCB (at offset +0) points to the DCBE when 2 bits at offset 32 (X'20') are on as follows:
Table 32. DCB bits to signify presence of DCBE

<table>
<thead>
<tr>
<th>Name</th>
<th>Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCBH1</td>
<td>X'80'</td>
</tr>
<tr>
<td>DCBH0</td>
<td>X'04'</td>
</tr>
</tbody>
</table>

Coding DCBE= in the DCB macro sets these 2 bits on. For further DCBE information see "Data Control Block Extension" on page 196. See z/OS DFSMS Macro Instructions for Data Sets for more information on the DCBE= parameter of the DCB macro.

**DEVD=**

The device in which the data set might reside. The codes are listed in order of descending space requirements for the DCB:

Table 33. DCB DEVD options

<table>
<thead>
<tr>
<th>Code</th>
<th>Device</th>
</tr>
</thead>
<tbody>
<tr>
<td>DA</td>
<td>Direct access</td>
</tr>
<tr>
<td>TA</td>
<td>Magnetic tape</td>
</tr>
<tr>
<td>PR</td>
<td>Printer</td>
</tr>
<tr>
<td>PC</td>
<td>Card punch</td>
</tr>
<tr>
<td>RD</td>
<td>Card reader</td>
</tr>
</tbody>
</table>

If you do not want to select a specific device until job setup time, specify the device type requiring the largest area; that is, DEVD=DA.

The following diagrams illustrate the device-dependent portion of the DCB for each combination of device type specified in the DEVD parameter and data set organization specified in the DSORG parameter. Fields that correspond to device-dependent parameters in addition to DEVD are indicated by the parameter name.

When processing concatenated data sets, the system changes the value in DCBDEVT as appropriate as it reaches each new data set. These values are described in z/OS DFSMS Macro Instructions for Data Sets.

![Diagram of DCB DEVD options](image)

Figure 10. Device-dependent portion of the DCB with DEVD=DA and DSORG=PS (or DSORG=PO)

The fields in parentheses represent information not associated with parameters of the DCB macro instruction. EOV sets all of these fields. OPEN sets DCBDVTBA.
and DCBDEV, but not DCBFDAD. Your program can modify DCBFDAD,
DCBKEYLE, or DCBTRBAL as described in the text.

When writing on DASD, maintain certain fields of the device-dependent portion of
the DCB, the system uses the information in the following instances:

- To write a file mark for output data sets
- When releasing unused space at the end of the allocated area
  You can request partial space release using the management class, RLSE on the
  DD SPACE parameter, TSO/E ALLOCATE command RELEASE parameter or
  PARTREL macro.
- When adding to the data set with DISP=MOD or the EXTEND or OUTINX
  options of OPEN
- When DFSMSdss copies the data set.

Maintain the following fields of the device dependent portion of the DCB when
writing on DASD:

- The track balance (DCBTRBAL) field that contains a 2-byte unsigned binary
  number that indicates the remaining number of bytes on the current track. It is
  recommended that your program not directly calculate this number but use the
  TRKCALC macro (see “Performing Track Calculations (TRKCALC macro)” on
  page 297). Both the calculation values and the algorithm differ among device
  types.
- The full disk address (DCBFDAD) field that indicates the location of the current
  record. The address is in the form MBBCCHHR. For the actual form of
  MBBCCHR, see Table 38 on page 219.

If space is available for output data sets, the system uses the contents of the full
disk address (DCBFDAD) field, plus one, to write a file mark when the DCB is
closed or EOV is issued. If the track balance field (DCBTRBAL) is less than 8, the
file mark is written on the next sequential track.

Note that the track containing your last data block, as identified by DCBFDAD,
might not be the best place for a file mark. Consider the following:

- If the file mark is near the end of the track and a future user extends the data set
  using DISP=MOD on the DD statement or using the OPEN EXTEND or OUTINX
  option, then the first new block might be on the next track. This leaves a file
  mark inside the data.
- For compatibility with BSAM and QSAM when you are writing fixed-standard
  records, you should cause the file mark to be written wherever the next block
  would have been written, as if all blocks were full size. The file mark should not
  be “squeezed” on to the current track.

If the system is to write a file mark, you must maintain the contents of these two
fields and set bit 0 of DCBOFLGS. For further information on DCBOFLGS, see
“End of Volume” on page 182. Use the OPEN macro instruction to initialize
DCBDVTBA and DCBDEV. You can use DCBDVTBA or DCBDVTBL with the
DEVTAB parameter of the TRKCALC macro (see “Performing Track Calculations
(TRKCALC macro)” on page 297 for the TRKCALC description).
The system uses the contents of the block count (DCBBLKCT) field to write the block count in trailer labels when the DCB is closed or when the EOV macro instruction is issued. For tape cartridges, the system also compares this count with a count calculated from hardware information. OPEN and EOV set this DCB field to zero except when reading standard labeled tape backward. In that case OPEN or EOV set DCBBLKCT to the block count in the trailer label.

The I/O process increments this field by the contents of the IOBINCAM field of the IOB upon completion of each I/O request.

When using EXCP to process a tape reel data set open at a checkpoint, it is necessary to maintain the correct count; otherwise, the data set could be incorrectly positioned when restart occurs. If you code REPOS=Y, you must maintain the count for repositioning during dynamic device reconfiguration. Do not modify the DCB.

The following DCB operands pertain to specific devices and can be specified only when the DEVD parameter is specified.

**KEYLEN=length**

For direct access devices, the length in bytes of the key of a physical record, with a maximum value of 255. When a block is read or written, the number of bytes transmitted is the key length.
plus the record length. This parameter does not directly affect EXCP processing, but is stored in the data set label.

\[\text{DEN=\text{value}}\] For magnetic tape, the tape recording density in bits per inch is shown in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Density</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>800 (NRZI)</td>
</tr>
<tr>
<td>3</td>
<td>1600 (PE)</td>
</tr>
<tr>
<td>4</td>
<td>6250 (GCR)</td>
</tr>
</tbody>
</table>

NRZI—Non return-to-zero change to ones recording PE—phase encoded recording GCR—group coded recording

If this parameter is omitted, the highest density available on the device is assumed. Refer to [z/OS DFSMS Macro Instructions for Data Sets](z/OS DFSMS Macro Instructions for Data Sets) for further information on DEN.

\[\text{TRTCH=\text{value}}\] For magnetic tape subsystems with Improved Data Recording Capability, the tape recording techniques consist of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Tape recording technique</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMP</td>
<td>Record data in compacted format.</td>
</tr>
<tr>
<td>NOCOMP</td>
<td>Record data in standard uncompacted format.</td>
</tr>
</tbody>
</table>

For 7-track magnetic tape, the tape recording technique:

<table>
<thead>
<tr>
<th>Value</th>
<th>Tape recording technique</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>Data conversion feature is available.</td>
</tr>
<tr>
<td>E</td>
<td>Even parity is used. (If omitted, odd parity is assumed.)</td>
</tr>
<tr>
<td>T</td>
<td>BCDIC to EBCDIC translation is required.</td>
</tr>
</tbody>
</table>

\[\text{MODE=\text{value}}\] For a card reader or punch, the mode of operation. Either C (column binary mode) or E (EBCDIC code) can be specified. This field and parameter do not directly affect EXCP processing but your program can use the field. This is useful to allow you to specify the value on the DD statement.

\[\text{STACK=\text{value}}\] For a card punch or card reader, the stacker bin to receive cards, either 1 or 2. This field and parameter do not directly affect EXCP processing but your program can use the field. This is useful to allow you to specify the value on the DD statement.

\[\text{PRTSP=\text{value}}\] For a printer, the line spacing is 0 — 3. This field and parameter do not directly affect EXCP processing but your program can use the field. This is useful to allow you to specify the value on the DD statement.

**DSORG Parameter of the DCBD Macro**

In addition to the operands described in [z/OS DFSMS Macro Instructions for Data Sets](z/OS DFSMS Macro Instructions for Data Sets) for the DSORG parameter of the DCBD macro, you can specify the following operand:

\[\text{DSORG=X}A\text{ or }\text{XE}\]

Specify the section of the DCB to be mapped.

\[\text{XA}\]

Specifies a DCB with the foundation block and EXCP interface.
XE Specifies a DCB with the common interface, foundation block extension, and foundation block.

Code DSORG=(XA,XE) to map all four sections of the DCB.

**Data Control Block Extension**

The data control block extension (DCBE) provides further processing options. EXCP supports these options:

- The **BLKSIZE** parameter when you issue the OPEN and EOV macros.
- The **BLOCKTOKENSIZE** parameter to signify that your program is able to handle a DASD data set that has the large format attribute. The data set is not necessarily large. If you code BLOCKTOKENSIZE=LARGE, then it means that your program can handle a data set that exceeds 65535 tracks or might grow above that size. Look for these differences:
  - If the data set is a large format data set, then in the DSCB the DS1LARGE bit is on and the two bytes in DS1LSTAR that contain a relative track number are logically extended with the DS1TTTHI byte. See the format 1 DSCB description in Chapter 1, "Using the Volume Table of Contents," on page 1.
  - The two bytes in each DEBNMTRK field are logically extended by the DEBNMTRKHI byte. See "Control Blocks" on page 433.
  - If your program calls either of the track conversion routines that CVTPRLTV or CVTPCNVT point to, then your program should use the +12 entry points instead of the +0 entry points.

If you do not code BLOCKTOKENSIZE=LARGE on the DCBE macro, then:

- If the OPEN macro option is not INPUT and the data set is large format, then OPEN will issue a 213-14 ABEND.
- If the OPEN macro option is INPUT and the data set has more than 65535 tracks on the volume, then OPEN will issue a 213-16 ABEND.

- The **CAPACITYMODE** parameter to write more data on an IBM 3590 Magnetic Tape Subsystem that emulates an IBM 3490 when you issue the OPEN macro.
- The **EADSCB=OK** parameter to specify that your application program support one of the following, as appropriate:
  - VTOC data sets that describes a volume that supports extended attribute DSCBs. An extended address volume may have these DSCBs allocated to it. The VTOC may contain format-8 and format-9 DSCBs. If you do not code this option, the OPEN function will issue ABEND 113-48 and message IEC142I. Code this option when your application program supports format-8 and format-9 DSCBs.
  - An extended address volume may have these DSCBs allocated to it. The DSCBs that describe this data set may contain format-8 and format-9 DSCBs. Track addresses in DSCBs pointed to by a format-8 DSCB may contain cylinders addresses above 65,520. If you do not code this option, the OPEN function will issue ABEND 113-44 and message IEC142I. Code this option when your application program supports MACRF=E (EXCP) and the data set has format 8 and 9 DSCBs.

- The **EODAD** parameter when you issue an EOV macro.
- The **LOC** parameter when you issue an OPEN macro. To successfully open a data set that has been allocated with the XTIOT, UCB NOCAPTURE, and/or DSAB above the line dynamic allocation options, it is required to specify the DCBE option "LOC" equal to "ANY" and the "NON_VSAM_XTIOT" option of the DEVSUPxx member of PARMLIB equal to "YES" (LOC=ANY and NON_VSAM_XTIOT=YES).
Note: The LOC=ANY option is represented by the DCELOCANY bit in the DCBE. The NON_VSAM_XTIOT option of the DEVSUPxx member of PARMLIB is represented by DFAXTBAM bit in the DFA as mapped by IHADFA.

- The SYNC parameter to control buffered tape marks on an IBM 3590 when you issue the OPEN, EOV, or CLOSE macros.

Note that the DCBE can be above the 16 MB line even though your user program is running in 24-bit mode. See [z/OS DFSMS Macro Instructions for Data Sets](#) for more information concerning the DCBE.

**Set and Retrieve Data Set Block Size**

The DCBE has a field to contain the current or maximum block size for the data set.

In order to use this field, your program must code a value for the BLKSIZE keyword on the DCBE macro or turn on the DCBEULBI bit. The keyword value can be numeric or a non-relocatable symbolic expression. The value can be 0.

If you code a zero value or turn on DCBEULBI, then OPEN stores into DCEBLKSI the block size value from the data set label if opening for input or output with DISP=MOD, which can be disk or tape. If your program issues the OPEN macro with the OUTPUT or OUTIN option, then OPEN tries to calculate an optimal value for BLKSIZE as it does for BSAM and QSAM. The system-determined block size function is described in [z/OS DFSMS Using Data Sets](#). The basic principle is that your program supplies the LRECL value and RECFM value (not U) and OPEN calculates an optimal BLKSIZE value for the device and stores it into DCEBLKSI.

**Attention:** OPEN might calculate a BLKSIZE value in the DCBE that exceeds the maximum that is supported by the regular access methods or other programs that read your program's data sets. For example, on magnetic tape the value probably will exceed 32760. If this is a problem, you can do the following:

Supply a DCB OPEN exit routine as described in [z/OS DFSMS Using Data Sets](#). If your exit routine finds that the DCEBLKSI field is still 0, it means that the data set label and the DD statement do not have a value for BLKSIZE. If your program is opening for output, it can leave the DCBE alone and let OPEN calculate an optimal BLKSIZE value or it can calculate one. This is your program's last chance to set it before the system stores the BLKSIZE value in various system control blocks and the data set label. Your DCB OPEN exit routine can issue the DEVTYPE macro with the INFO=AMCAP parameter to learn the optimal and maximum BLKSIZE values for the device. If it is too large, your program can calculate a smaller valid value. Store a value into DCEBLKSI before OPEN can set it. The INFO=AMCAP parameter of DEVTYPE is described on "DEVTYPE—Info Form" on page 258.

Why should your program do this?

- To decrease your program's dependence on the device type
- The system stores this value in the data set label for use by z/OS and on other systems
- The system stores this value in various SMF records to improve monitoring of system resources
- DFSMSrmm™ retains this information for its tape reports.
Unlike the regular access methods, EXCP processing does not do complete checking of the BLKSIZE value in an EXCP DCBE.

**Input/Output Block Fields**

The input/output block (IOB) is not automatically constructed by a macro instruction; it must be defined as a series of constants and be on a word boundary. For unit-record and tape devices, the IOB is 32 bytes long. For direct access, teleprocessing, and graphic devices, 8 additional bytes must be provided. You can use the system mapping macro IEZIOB, which expands into a DSECT, to help in constructing an IOB. IEZIOB fields that are not described here are not part of the programming interface.

In [Figure 15 on page 199](#) the shaded areas indicate fields in which you must specify information. The other fields are used by the system and must be defined as all zeros. You cannot place information into these fields, but you can examine them.

You do not have to set the following IOB fields to any particular value before issuing EXCP because the system itself sets them:

- IOBSENS0
- IOBSENS1
- IOBECBCC
- IOBCSW
- IOBSIOCC
Set bit positions 0, 1, 6, and 7. One-bits in positions 0 and 1 (IOBDATCH and IOBCMDCH) indicate data chaining and command chaining, respectively. (If you specify both data chaining and command chaining, the system does not use error recovery routines except for the direct access and tape devices.) If an I/O error occurs while your channel program executes, a failure to set the chaining bits in the IOB that correspond to those in the CCW might make successful error recovery impossible. The integrity of your data could be compromised.

A one-bit in position 6 (IOBUNREL) indicates that the channel program is not a related request; that is, the channel program is not related to any other channel program. See bits 2 and 3 of IOBFLAG2 below.
If you intend to issue an EXCP or XDAP macro with a BSAM, QSAM, or BPAM DCB, you should turn on bit 7 (IOBSPSVC) to prevent access-method appendages from processing the I/O request.

**IOBFLAG2 (1 byte)**

If you set bit 6 in the IOBFLAG1 field to zero, bits 2 and 3 (IOBRRT3 and IOBRRT2) in this field must then be set to one of the following:

- 00, if any channel program or appendage associated with a related request might modify this IOB or channel program.
- 01, if the conditions requiring a 00 setting do not apply, but the CHE or ABE appendage might retry this channel program if it completes normally or with the unit-exception or wrong-length-record bits on in the CSW.
- 10 in all other cases.

The combinations of bits 2 and 3 represent related requests, known as type 1 (00), type 2 (01), and type 3 (10). The type you use determines how much the EXCP processor can overlap the processing of related requests. Type 3 allows the greatest overlap, normally making it possible to quickly reuse a device after a channel-end interruption. (Related requests that were executed on a pre-MVS system are executed as type-1 requests if not modified.)

**IOBSNS0 and IOBSNS1 (2 bytes)**

are set by the EXCP processor when a unit check occurs. These are the first two sense bytes. Occasionally, the system is unable to obtain any sense bytes because of unit checks when sense commands are issued. In this case, the system simulates sense bytes by moving X'10FE' to IOBSNS0 and IOBSNS1.

The first six of these 16 bits have these device-independent meanings:

- 1... ..... Command reject
- .1... ..... Intervention required
- ...1. ..... Bus out check
- ....1... Equipment check
- .....1... Data check
- ..... .1.. Overrun

The last ten of these 16 bits have device-dependent meanings. See appropriate hardware documentation.

If you wish to retrieve more than two sense bytes, supply an IOBE and IEDB as described in "Interruption Handling and Error Recovery Procedures" on page 176.

**IOBECBCC (1 byte)**

The first byte of the completion code for the channel program. The system places this code in the high-order byte of the event control block when the channel program is posted complete. The completion codes and their meanings are listed under "Event Control Block Fields" on page 206.

**IOBECBPT (3 bytes)**

The address of the 4-byte event control block (ECB) you have provided.
IOBFLAG3 (1 byte)
Used by the system. If the channel program is format 1 CCWs, then at IOBFLAG3 are these fields: IOBCMD31 is four bytes and contains the virtual address pointing after the last-executed CCW of the channel program. IOBCSW8 is eight bytes and contains an emulated CSW like IOBCSW.

IOBCSW (7 bytes)
The low-order 7 bytes of the simulated channel status word that are placed into this field each time a channel-end or PCI interruption occurs. The first three bytes are the virtual address pointing after the last-executed CCW in your channel program. The next two bytes are status bytes. The last two bytes is the residual count, which is the number of bytes not transferred in the last CCW.

Note: The virtual address pointing after the last-executed CCW of the channel program in IOBCMD31 or IOBCSW may be zero for either of the following reasons:
- the system determined that the address was invalid
- the last-executed CCW was a CCW that was added by the system.

If the address pointing after the last-executed CCW is zero or the second status byte shows any of the following errors, then the address contents are invalid: program check, protection check, channel-data check, channel-control check, interface-control check or chaining check. These six status bits are X'3F'. This byte is named IOBCSTAT. If your appendage determines that the ERP has not yet run, then do not modify IOBSTRTB and do let the ERP try to recover. If the ERP has completed and one or more of these six bits is on or the address is zero, then the status of the channel program is not known.

IOBSIOCC (1 byte)
If the channel program is format 0 CCWs, then in bits 2 and 3, the start subchannel (SSCH) condition code for the instruction the system issues to start the channel program. If the channel program is format 1 CCWs, then at IOBSIOCC is the field IOBSTART, which contains the four byte starting address of the channel program to be executed. (The IOBE field IOBESIOC is used instead of IOBSIOCC.)

IOBSTRTB (3 bytes)
If the channel program is format 0 CCWs, the three byte starting address of the channel program to be executed.

IOBFLAG4 (1 byte)
Set bit 3 (IOBCEF) to indicate whether you are supplying an IOB common extension (IOBE). If this bit is 1, then register 0 contains the IOBE address when you issue EXCP. Refer to "Requesting Extended Error Information" on page 177 and "Requesting Different Levels of ERP Processing" on page 179.

IOBDCBPT (3 bytes)
The address of the DCB of the data set to be read or written by the channel program.

Reserved (1 byte)
Used by the system.
IOBRESTR+1 (3 bytes)
If a related channel program is permanently in error, this field is used to chain together IOBs that represent dependent channel programs. To learn more about the conditions under which the chain is built, see "Purging and Restoring I/O Requests" on page 293.

IOBINCAM (2 bytes)
For magnetic tape, the amount by which the system increments the block count (DCBBLKCT) field in the device-dependent portion of the DCB. You can alter these bytes at any time. For forward operations, these bytes should contain a binary positive integer (usually +1); for backward operations, they should contain a binary negative integer. When these bytes are not used, all zeros must be specified. See Figure 12 on page 194.

IOBERRCX (2 bytes)
Used by the system.

IOBSEEK (first byte, M)
For direct access devices, the extent entry in the data extent block that is associated with the channel program (0 indicates the first entry; 1 indicates the second, and so forth). For teleprocessing and graphic devices, it contains the UCB index.

IOBSEEK (last 7 bytes, BBCCHHR)
For direct access devices, the seek address for your channel program.
Input/Output Block Common Extension Fields

You can construct an IOB common extension (IOBE) block to receive extended error information or to control the level of error recovery procedure (ERP) processing. To provide an IOBE, set IOBCEF in IOBFLAG4 on and set the IOBE address in register 0 when you issue EXCP or EXCPVR. (The IOBE is mapped by IOSDIOBE macro).

Set reserved bytes to X'00'. The IOBE can reside above or below 16MB virtual. See Figure 16 for a diagram of this control block.

Table 34. IOBE Structure Mapping.

#### Input/Output Error Data Block Fields

The system uses the IEDB to provide extended error information. You provide an IEDB by setting its address in an IOBE. Set reserved fields to X’00’. The system moves the sense bytes to IEDBSNS. If fewer than 32 sense bytes are available, there might be residual data. The IEDB must reside below 16MB virtual. Refer to “Requesting Extended Error Information” on page 177 for more information on using the IEDB. See Figure 17 on page 206 for a diagram of this control block.

The system never clears this field.</td>
</tr>
</tbody>
</table>

Event Control Block Fields

Define an event control block (ECB) as a 4-byte area on a word boundary. When the channel program has been completed, the system places a completion code containing status information into the ECB (Figure 18 on page 207). Before examining this information, test for the setting of the complete bit. If the complete bit
is not on, and your problem program cannot perform other useful operations, issue a WAIT or EVENTS macro instruction that specifies the ECB. Do not construct a program loop to test for the complete bit.

You do not have to set any particular values in the ECB before issuing EXCP or EXCPVR because the system clears it.

![WAIT bit=0 COMPLETE bit=1 Remainder of completion code](image)

Figure 18. Event Control Block after Posting of Completion Code

**Wait bit**
One in this position indicates that the WAIT or EVENTS macro instruction has been issued, but the channel program has not been completed.

**Complete bit**
A one in this position indicates that the channel program has been completed. If it has not been completed, a zero bit is in this position.

**Completion code**
This code, which includes the wait and complete bits, might be one of the following 4-byte hexadecimal expressions. If an appendage posts the ECB, it might use other 4-byte codes in which the first two bits are 01. Refer to "Start-I/O Appendage" on page 211 and "Channel-End Appendage" on page 218.

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>Permanent I/O error</td>
</tr>
<tr>
<td>42</td>
<td>Extent error (DASD only). Either IOBSEEK lies outside the extents described by the DEB or the channel program attempted execution outside the current extent.</td>
</tr>
<tr>
<td>44</td>
<td>An error occurred after the previous I/O request to the device was posted complete. The appendages and (if allowed to execute) the ERP have determined that this is a permanent error. The I/O request is terminated with the permanent error. The CSW contents and sense data in the IOB do not apply to the attempted operation. They apply to the previous operation attempted for any data set on the device. You can reissue the EXCP macro instruction to restart the channel program.</td>
</tr>
<tr>
<td>45</td>
<td>A program check or machine check occurred in IOS while processing the I/O request.</td>
</tr>
<tr>

<td>The channel program was purged.</td>
</tr>
<tr>
<td>4B</td>
<td>An error occurred during tape repositioning that was requested by the tape ERP.</td>
</tr>
<tr>
<td>4F</td>
<td>Error recovery routines were entered following a direct access error but are unable to read the home address or record 0.</td>
</tr>
</tbody>
</table>
51  Simulated error status. The appendages and, if allowed to execute, the ERP have determined that this is a permanent error. The I/O request is terminated with the permanent error. This code indicates that the device is in a permanent error state, boxed, or not connected. The code can indicate also that a missing interrupt was detected and that the I/O operation was terminated as a result of recovery operations by the missing interrupt handler.

74  Simulated error status. This code is set as a result of attempting to start an I/O operation to a device that is in a permanent error state, boxed, or not connected. This code is also set if a missing interrupt was detected and the I/O operation was terminated as a result of recovery operations by the missing interrupt handler. The system has set this code temporarily in IOBECBCC and IEDB to invoke the ERP, if allowed to execute, and the appendages to determine if the error is permanent or correctable. If the error is determined to be permanent the system will change the value to 51. The system does not set the 74 code in the ECB.

7F  Normal I/O completion, but does not appear in the ECB.

Data Extent Block Fields

The data extent block is constructed by the system when an OPEN macro instruction is issued for the DCB. You cannot modify the fields of the DEB, but you can examine them. The DEB is mapped by the IEZDEB macro. The DEB fields used for EXCP and EXCPVR are illustrated in Control Blocks on page 433 (all the DEB fields are illustrated in z/OS DFSMSdfp Diagnosis).

EXCP and EXCPVR Appendages

An appendage is a routine that provides additional control over I/O operations. Using appendages, you can examine the status of I/O operations and determine the actions to be taken for various conditions. An appendage can receive control as shown in Table 36.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Appendages get control in supervisor state, receiving the pointers from the EXCP processor described in the following table. The appendages receive control in 24-bit addressing mode and must return in the same mode.
Register | Content
--- | ---
1 | Points to the request queue element.
2 | Points to the input/output block.
3 | Points to the data extent block.
4 | Points to the data control block.
6 | Points to the seek address (MBBCCHHR) if control is given to an end-of-extent appendage.

The track address of the block reference (CCHH) may contain 28-bit cylinder numbers for devices with more than 65,520 cylinders. Showing nibbles it is in the form of CCCCcccH, where ccc represent bits 0-11 of the 28-bit cylinder number and CCCC represents bits 12-27 the 28-bit cylinder number. Use the TRKADDR macro to manipulate 16-bit and 28-bit cylinder numbers correctly.

7 | Points to the unit control block (UCB) and always contains a clean 31-bit UCB address. If the DEB flag “DEB31UCB” is off, then the UCB address is captured below the 16 MB line. Whereas if DEB31UCB is on, then the address might point above the 16 MB line even though the appendages always are entered in 24-bit mode. The UCB address is captured by OPEN or EOV until EOV or CLOSE uncaptures it if the DCBE option “LOC” was not set or defaulted to “BELOW”, that is LOC=BELOW or not coded, or the "NON_VSAM_XTIOT" option of the DEVSUPxx member of PARMLIB was set or defaulted to "NO", that is NON_VSAM_XTIOT=NO or not coded. In other words, OPEN does not capture the UCB if LOC and NON_VSAM_XTIOT were specified as follows: LOC=ANY and NON_VSAM_XTIOT=YES.

13 | Points to a 16-word area you can use to save input registers or data.

14 | Points to the location in the system where control is to be returned following execution of an appendage. When returning control to the system, you can use displacements from the return address in register 14. Allowable displacements are summarized and described later for each appendage in [Table 37 on page 210](#).

15 | Points to the entry point of the appendage. When the PGFX appendage is entered, points to the SIO entry point.

The processing done by appendages is subject to the following requirements and restrictions:

- Register 9, if used, must be set to binary zeros before control is returned to the system. All other registers, except those indicated in the descriptions of the appendage, must be saved and restored if you use them. [Table 37 on page 210](#) summarizes register conventions.
- No SVC instructions or instructions that change the status of the system (for example, WTO, LPSW, or similar privileged instructions) can be issued.
- Loops testing for the completion of I/O operations cannot be used.

The information here describes appendage types, with explanations of when they are created, how they return control to the system, and which registers they can...
use without saving and restoring their contents. If you do not supply a particular appendage, or supply no appendage, the system acts as though that appendage had returned at offset 0 from register 14.

</tbody>
</table>

Note: The register conventions for passing parameters from appendages to the system are described in the individual appendage descriptions.

Making Appendages Available to the System

Prior to execution, appendages must be members of either the SYS1.LPALIB or SYS1.SVCLIB data set. To put appendages into SYS1.LPALIB or SYS1.SVCLIB, link-edit them into these data sets after the system has been built. Each appendage must have an 8-character member name, the first six characters being IGG019 and the last two being anything in the range from WA to Z9. If your program runs in a V=R address space and uses a PCI appendage, the appendage and any routine that the PCI appendage refers to must be placed in either SYS1.SVCLIB or the fixed link pack area (LPA). For information on providing a list of programs to be fixed in storage, see \textit{z/OS MVS Initialization and Tuning Guide}.

The Authorized Appendage List (IEAAPP00)

If an unauthorized program opens a DCB to be used with an EXCP macro instruction, the names of any appendages associated with the DCB must be listed in the IEAAPP00 member of SYS1.PARMLIB. (An unauthorized program is one that runs in a protection key greater than 7 and has not been marked as authorized by the Authorized Program Facility.) Once you have added your appendages to SYS1.LPALIB or SYS1.SVCLIB after the system was built, you can add IEAAPP00 to SYS1.PARMLIB and put the names of the appendages in it in one job step with the IEBUPDTE utility or with another program that updates partitioned data sets.

The following example shows JCL statements and IEBUPDTE input that add IEAAPP00 to SYS1.PARMLIB and put the names of one EOE appendage, two SIO appendages, two CHE appendages, and one ABE appendage in IEAAPP00:

```
// JOB...
// EXEC PGM=IEBUPDTE,PARM='NEW'
//SYSSPRINT DD SYSOUT=A
//SYSSUT2 DD DSN=SYS1.PARMLIB,DISP=SHR
//SYSSIN DD *
./ ADD NAME=IEAAPP00
```
EOEAPP WA,
SIOAPP X1,X2,
CHEAPP Z3,Z4,
ABEAPP Z2,
./ ENDUP
/*

Note the following about the IEBUPDTE input:

- The type of appendage is identified by six characters that begin in column 1. EOEAPP identifies an EOE appendage, SIOAPP an SIO appendage, CHEAPP a CHE appendage, and ABEAPP an ABE appendage. (The PCI appendage identifier, PCIAPP, is not shown, because the example does not add a PCI appendage name to IEAAPP00.)
- Only the last two characters in an appendage's name are specified, beginning in column 8.
- Each statement that identifies one or more appendage names ends in a comma, except the last statement.

You can also use IEBUPDTE to add appendage names later or to delete appendage names. The following example shows JCL statements and IEBUPDTE input that adds the names of a PCI and an ABE appendage to the IEAAPP00 appendage list created in the preceding example, and deletes the name of an SIO appendage from that list:

```
// JOB . . .
// EXEC PGM=IEBUPDTE,PARM='NEW'
//SYSPRINT DD SYSOUT=A
//SYSUT2 DD DSN=SYS1.PARMLIB,DISP=SHR
//SYSIN DD *
./ ADD NAME=IEAPP00 PCIAPP Y1,
EOEAPP WA,
SIOAPP X1,
CHEAPP Z3,Z4,
ABEAPP Z2,Z4
./ ENDUP
/*
```

Note the following about the IEBUPDTE input:

- The command to IEBUPDTE is ADD but a replace occurs because PARM='NEW' is specified.
- All the appendage names that are to remain in IEAAPP00 are repeated.
- IGG019Z4 is both a CHE and an ABE appendage.

**Start-I/O Appendage**

Unless an ERP is in control, the system passes control to the SIO appendage just before the system translates and starts your channel program. It is called even if the channel program is not later translated. Your SIO appendages can build the channel program. The system does not test IOBSTART until after the SIO appendage returns.

Optional return vectors give the I/O requester the following choices:

- Reg. 14 + 0 — Normal return. Normal channel program translation and initiation of I/O.
- Reg. 14 + 4 — Skip the I/O operation. The channel program is not initiated. The channel program is not posted complete. You can post the channel program complete by using the POST macro. For more information on the POST macro,
The POST macro to posts the channel program as complete when the following actions occur:
- The necessary registers are saved.
- The completion code is set in register 10. These are the four bytes of an ECB.
- From the IOB, the ECB address is set in register 11.
- The POST macro is issued, POST (11),(10),LINKAGE=BRANCH
- On return, the necessary registers are reestablished.

Page Fix and EXCPVR Start I/O Appendage
This appendage is a combination of two independent appendages. The complete appendage is a reenterable subroutine with two entry points, one for the SIO appendage and one for the PGFX appendage.

The SIO entry point is located at offset +0 in the SIO subroutine; from this entry point you might have an instruction to branch to any other location in the appendage. The entry point of the PGFX appendage is at offset +4 in the SIO subroutine. The address of offset +0, the SIO appendage entry address, is set in register 15 as the entry point of the PGFX appendage, allowing you to use the same entry linkage code for both entry points.

PGFX Appendage
This appendage creates a list of the addresses of lists the areas that must be fixed to prevent paging exceptions during the execution of the current input/output (I/O) request. While this appendage can be entered more than once for one I/O request, each time it is entered it must create the same list of areas to be fixed. The appendage can use the 16-word save area pointed to by register 13. Registers 10, 11, and 13 can be used as work registers.

Each page-fix entry placed in the list by the appendage must have the following doubleword format:

<table>
<thead>
<tr>
<th>30</th>
<th>31</th>
<th>32</th>
<th>33</th>
<th>63</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>

On return from the PGFX appendage to the system (via the return address provided in register 14), register 10 must point to the first page-fix entry and register 11 must contain the number of page-fix entries in the work area. The system then fixes the pages corresponding to the areas listed by the PGFX appendage. The pages remain fixed until the associated I/O request terminates.

If either the channel end appendage or the abnormal end appendage returns via the return address in register 14 plus 8, the PGFX appendage is not normally reentered. Instead, the SIO appendage is entered, and the page-fix list built by the PGFX appendage is still active. When a PURGE macro has been issued (for instance, when a storage swap has occurred), the PGFX appendage is entered after either the channel end appendage or the abnormal end appendage returns via
the return address in register 14 plus 8. When I/O is restored, the PGFX appendage is entered. The page-fix list must be in page-fixed storage.

**SIO Appendage**

If you are using EXCPVR to execute a channel program, translate the virtual addresses in the operands of your channel program to central storage addresses. This should be done in the SIO appendage. If indirect data addressing is required, use the SIO appendage to build the indirect data address lists (IDALs) and turn on the IDA indicators in the associated CCWs.

EXCPVR may be used for VIO data sets with the following considerations for the SIO appendage:

- The use of IDAWs and an IDAL is not required.
- Addresses in the CSWs, IDAWs, or an IDAL must be virtual. They must not be converted to central storage addresses.

The UCBVRDEB bit in the UCBJBNR byte can be checked to determine if the data set is being processed with VIO.

**Translating Virtual Addresses and Building the IDAL:** Convert the virtual addresses in the channel program to central storage addresses. Also check the areas whose addresses appear in your CCWs to determine whether the data areas cross certain boundaries. Bit IOBEEIDA, described in Figure 16 on page 203 specifies whether you are using four-byte (31 bit) or eight-byte (64 bit) IDAWs. With four-byte IDAWs, consider 2 KB boundaries. With eight-byte IDAWs, consider 4 KB boundaries. If data areas do cross boundaries, provide an additional IDAW in the IDAL for each crossed boundary. The channel subsystem uses the IDAL to identify the address where it will continue reading or writing when a boundary is crossed during a read or write operation. The IDAL must contain central storage addresses when it is processed by the channel subsystem.

Before you convert the virtual addresses in the channel program to real addresses, you must first page fix the data areas in central storage. After the data areas have been page fixed, you can use the LRA instruction to convert the virtual addresses in the channel program to central storage addresses provided that the central storage addresses are below 2 GB. The LRA instruction returns a 31-bit central storage address regardless of whether you are in 24-bit or 31-bit addressing mode, but fails in those addressing modes if the central storage address is above 2 GB. If the central storage address is above 2 GB, you must either use the LRAG or STRAG instruction to convert the virtual address to a real address or use the LRA instruction (after first switching to 64-bit addressing mode). If all of the central storage addresses associated with the data buffers are below 2 GB, then you can use 2KB (31-bit) IDAWs to address the data. Otherwise, you must use 4KB (64-bit) IDAWs to address the data. For the most efficient use of system resources, code LOC=(ANY,64) or LOC=(BELOW,64) when you obtain storage with the GETMAIN or STORAGE macro. See z/OS MVS Programming: Assembler Services Reference ABE-HSP and “IDAW Requirements” on page 170.

**Notes:**

1. 64-bit IDAWs are supported only in z/Architecture mode and only for direct access storage devices (DASD) and on all IBM-supplied cartridge tape devices. You should examine bit UCBIEIDAW in the UCB to determine whether 64-bit IDAWs are supported by the device.
2. If your program switches to 64-bit addressing mode, you must ensure that you save and restore the high 32 bits of any register that you modify. If you fail to do this, unpredictable consequences can occur for other 64-bit programs in your address space.

Note:

The following illustration shows the relationship between the CCW and the IDAWs.

Format 0 CCW

<table>
<thead>
<tr>
<th>Command Code</th>
<th>Address of the IDAL</th>
<th>X4</th>
<th></th>
<th>Byte Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>7 8</td>
<td>31 32</td>
<td>39 40</td>
<td>47 48</td>
</tr>
</tbody>
</table>

IDAL

- 0: First indirect data address word
- 4: Second indirect data address word
- 8: Subsequent indirect data address word

Format 1 CCW

<table>
<thead>
<tr>
<th>Command Code</th>
<th>X4</th>
<th>Byte Count</th>
<th>Address of the IDAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>7 8 15 16</td>
<td>31 32</td>
<td>63</td>
</tr>
</tbody>
</table>

IDAL

- 0: First indirect data address word
- 4: Second indirect data address word
- 8: Subsequent indirect data address word

Note the following information about IDAL:

- If IOBEEIDA is not 1, then after the first entry, put one entry in the IDAL for each 2 KB page boundary that your data area crosses. If IOBEEIDA is 1 (to signify four-byte IDAWs), put one entry in the IDAL for each 4 KB page boundary that your data area crosses.
- If the format 0 CCW has an IDAL address rather than a data address, bit 37 must be set on to signal this to the channel. The equivalent format 1 CCW bit is bit 13.
- The maximum number of entries that are needed in the IDAL is determined from the count in the CCW as follows:
  
  Number of IDAL entries=((CCW byte-count – 1)/P) + 1. Substitute 2048 for P in this formula with 4-byte IDAWs. Substitute 4096 for P with eight-byte IDAWs. (Round up to the next highest integer if the remainder is not zero.)

The number of 4-byte IDAL entries that are required depends on the number of 2 KB boundaries that are crossed by the data. For example, if your data is 800 bytes long and does not cross a 2 KB boundary, no IDAL entries are required. If your data...
crosses a 4 KB boundary, then two IDAL entries are required. If your data is 5000 KB long, at least two IDAL entries are required. If your data crosses two 4 KB boundaries, four IDAL entries are required.

The first indirect address is the central storage address of the first byte of the data area. The second and subsequent indirect addresses are the central storage addresses of the second and subsequent 2 KB or 4 KB boundaries of the data area. For example, if the data area central storage address is X'707FF' and the byte count is X'1802', the 4-byte IDAL would contain the following central storage addresses (assuming the central storage addresses are contiguous):

707FF
70800
71000

If the data area central storage address is X'707FF' and the byte count is X'800', the IDAL would contain the following addresses:

707FF
70800

Program-Controlled Interruption Appendage

This appendage is entered if the channel finds one or more program-controlled-interruption (PCI) bits on in a channel program. It can be entered as many times as the channel finds PCI bits on, or more often. Before the appendage is entered, the contents of the subchannel status word are placed in the channel status word field of the input/output block.

A PCI appendage is reentered if an ERP is retrying a channel program in which a PCI bit is on. The IOB error flag is set when the ERP is in control (IOBFLAG1 = X'20'). (For special PCI conditions encountered with command retry, see "Command Retry Considerations" on page 174.)

To post the channel program from a PCI appendage after an EXCP (not EXCPVR), if the step is running ADDRSPC=VIRT (V=V), or an authorized program is running V=R, the procedure described for the SIO appendage is used.

If the step is running ADDRSPC=REAL (V=R) and an authorized program issued the EXCP request or if an EXCPVR request was issued, the PCI appendage uses central storage addresses. Use the following procedure to post the channel program from the PCI appendage. For more information on the POST macro, see z/OS MVS Programming: Authorized Assembler Services Reference LLA-SDU.

The POST macro is coded as follows:

```
POST ecbaddr,compcode,ASCB=addr,ERRET=addr,ECBKEY=key,
    LINKAGE=BRANCH,MEMREL=NO
```

The ERRET routine address must point to a BR 14 instruction. This instruction must be in storage addressable from any address space (for example, CVTBRET) and addressable by 24 bits.

**Note:** Using this keyword, only registers 9 and 14 are restored when returning from the POST macro.

The following procedure posts the channel program from the PCI appendage.
1. Save necessary registers as registers 9 and 14 are only restored on the return from the POST macro.
2. Set the ECB key in register 0.
3. Set the 4-byte completion code in register 10.
4. Set the ECB address in register 11.
5. Set the error routine address in register 12, by setting it to address of CVTBRET and turn on the high-order bit (X'80') of the high-order byte.
6. Set the ASCB address in register 13. If you do not have the ASCB address, you can use the following procedure to obtain the ASCB address:
   a. Issue the EPAR instruction to obtain the ASID. For information on the EPAR instruction, see z/Architecture Principles of Operation.
   b. Issue the LOCASCB macro to obtain the ASCB address. The LOCASCB macro is documented in z/OS MVS Programming: Authorized Assembler Services Reference LLA-SDU.
7. Issue the POST macro,
   POST (11),(10),ASCB=(13),ERRET=(12),ECBKEY=(0),LINKAGE=BRANCH
8. On return, reestablish necessary registers.

To return control to the system for normal operation, use the return address in register 14.

**End-of-Extent Appendage**

If an end-of-cylinder or file-protect condition occurs, the system updates the seek address to the next higher cylinder or track address and retries the request. If the new seek address is within the data set's extent, the request is executed; if the new seek address is not within the data set's extent, the EOE appendage is entered. To try the request in the next extent, move the new seek address to the location pointed to by register 6.

If a file protect is caused by a full seek (command code=07) embedded within a channel program, the request is flagged as a permanent error, and the ABE appendage is entered.

The end-of-extent (EOE) appendage is entered when the seek address specified in the input/output block is outside the allocated extent limits indicated in the data extent block.

The simplest way to compare two track or block addresses to see their relative positions on the volume is to use the CLC instruction; however that technique works only if both addresses (CCHH or CCHHR) contain cylinder numbers of less than 65536. To handle any addresses that are more or less than cylinder 65536, use the TRKADDR macro with the COMPARE option. See “Compare two track addresses (TRKADDR COMPARE)” on page 307.

Using the return address in register 14 to return control to the system, causes the ABE appendage to be entered. An end-of-extent error code (X'42') is placed in the ECB code field of the input/output block for subsequent posting in the ECB.

You can use the following optional return addresses:

- Contents of register 14 plus 4: The channel program is posted complete with X'42'. The ABE appendage is not reentered for this request.
- Contents of register 14 plus 8: The request is tried again.
Registers 10 through 13 in an EOE appendage can be used without saving and restoring their contents.

**Abnormal-End Appendage**

To determine the method the system uses to handle an abnormal condition use the abnormal-end (ABE) appendage. The following information explains how to use the ABE appendage.

This appendage can be entered on abnormal conditions, such as unit exception, wrong-length indication, out-of-extent error, intercept condition (that is, device end error), unit check, program check, protection check, channel data check, channel control check, interface control check, and chaining check. It can also be entered when an EXCP is issued for a DCB that has already been purged under the following conditions:

- If IOBECBCC is set to X'41', this appendage was entered because of a unit exception or wrong-length record indication or both. The system previously called the channel-end appendage, if present. For further information on these conditions, see "Channel-End Appendage" on page 218.

- If the IOBECBCC is set to X'42', this appendage was entered because of an out-of-extent error. The system previously called the end-of-extent appendage, if present.

- If this appendage is entered with IOBECBCC set to X'4B', the tape error recovery procedure (ERP) either encountered an unexpected load point, or found zeros in the command address field of the CSW.

- If the IOBECBCC is set to X'7E', the appendage was first entered because of an intercept condition. If it is then determined that the error condition is permanent, the appendage will be reentered with the IOBECBCC set to X'44'. The intercept condition signals that an error was detected at device end after channel end on the previous request.

- If the IOBECBCC was set to X'48', the appendage was entered because of an EXCP being issued to an already purged DCB. This applies only to related requests.

- If the appendage is entered with IOBECBCC set to X'7F', it might be because of a unit check, program check, protection check, channel data check, channel control check, interface control check, or chaining check. If the IOBECBCC is X'7F', it is the first detection of an error in the associated channel program. If the IOBIOERR flag (bit 5 of the IOBFLAG1) is on, the IOBECBCC field will contain X'41', X'42', X'48', X'4B', or X'4F', indicating a permanent I/O error.

To determine if an error is permanent, check the IOBECBCC field of the IOB. To determine the type of error, check the channel status word field and the sense information in the IOB. However, when the IOBECBCC is X'42', X'48', or X'4F', these fields are not applicable. For X'44', the CSW is applicable, but the sense is valid only if the unit check bit is set.

By using the return address in register 14 to return control to the system, the channel program is posted complete, and its request element is made available. You can use the following optional return addresses:

- Contents of register 14 plus 4: The channel program is not posted complete, but its request element is made available. You can post the channel program by using the calling sequence described under the SIO appendage.

- Contents of register 14 plus 8: The channel program is not posted complete, and its request element is placed back on the request queue to be retried. Reinitialize
the IOBFLAG1, IOBFLAG2, and IOBFLAG3 fields of the input/output block and
set the IOBERRCT field to zero. As an added precaution, clear the IOBSENS0,
IOBSENS1, and IOBCSW fields.

- Contents of register 14 plus 12: The channel program is not posted complete,
and its request element is not made available. (Use this return only if the
appendage has passed the request queue element to the exit effector for use in
scheduling an asynchronous routine.)

Registers 10 through 13 in an ABE appendage can be used without saving and
restoring their contents.

Channel-End Appendage

This appendage is entered when a channel end (CHE), unit exception (UE) with or
without channel end or when channel end with wrong-length record (WLR) occurs
without any other abnormal-end conditions.

By using the return address in register 14 to return control to the EXCP processor,
the channel program is posted complete, and its request element is made available.
In the case of unit exception or wrong-length record, the ERP is performed before
the channel program is posted complete, and the IOBIOERR flag (X'04') in
IOBFLAG1 is set on. The CSW status can be obtained from the IOBCSW field.

If the appendage takes care of the wrong-length record or unit exception or both, it
can turn off the IOBIOERR (X'04') flag in IOBFLAG1 and return normally. The event
will then be posted complete (completion code X'7F' under normal conditions, taken
from the high-order byte of the IOBECBCC field). If the appendage returns normally
without resetting the IOBIOERR flag to zero, the request will be routed to the
associated device ERP. If the ERP could not correct the error, the ABE appendage
will be entered with the completion code in IOBECBCC set to X'41'. (See Step 1 of
"Abnormal-End Appendage" on page 217.)

You can use the following optional return addresses:

- Contents of register 14 plus 4: The channel program is not posted complete, but
its request element is made available. You can post the channel program by
using the calling sequence described under the SIO appendage. This is
especially useful to post an ECB other than the ECB in the input/output block.

- Contents of register 14 plus 8: The channel program is not posted complete, and
its request element is placed back on the request queue so that a channel
program at the same or different address can be executed. For correct execution
of the channel program, reinitialize the IOBFLAG1, IOBFLAG2, and IOBFLAG3
fields of the input/output block and set the error counts field to zero. As an added
precaution, clear the IOBSENS0, IOBSENS1, and IOBCSW fields. You can
change IOBSTART before returning. If the device is DASD, you can change the
IOBSEEK field but the first byte must refer to an extent with the same UCB
address. The system will call appendages as for a new EXCP or EXCPVR.

- Contents of register 14 plus 12: The channel program is not posted complete,
and its request element is not made available. (Use this return only if the
appendage has passed the request queue element to the exit effector for use in
scheduling an asynchronous routine. For information on asynchronous exit
routines, see "z/OS MVS Programming: Authorized Assembler Services Guide".)

Registers 10 through 13 in a CHE appendage can be used without saving and
restoring their contents.
Converting a Relative Track Address to an Actual Track Address

Convert a relative track address to the actual address by using a resident system conversion routine that can be called in 24 or 31 bit mode.

The conversion routine has two entry points. One, at the address in the CVTPCNVT field of the communication vector table (CVT), is intended for data sets with up to 65535 tracks. The other, at offset +12 from the address in CVTPCNVT, is intended for any data set. Call the conversion routine with one of the following instructions:

- BALR 14,15 Call +0 entry point for track conversion
- BASR 14,15 Call +0 entry point for track conversion
- BAL 14,12(,15) Call +12 entry point for track conversion
- BAS 14,12(,15) Call +12 entry point for track conversion

IBM does not provide a macro for this conversion routine's invocations.

The address of the CVT is in storage location 16 (field FLCCVT of the PSA data area, mapped by macro IHAPSA).

The conversion routine does all its work in general registers. Load registers 0, 1, 2, 14, and 15 with input to the routine. Register usage is as follows:

| Table 38. Registers and Their Use for Converting Relative to Actual |
|-----------------------|-----------------------|
| Register | Use |
| 0 | Must be loaded with a 4-byte value of the relative track number.  
  If entered at CVTPCNVT+0, this value must be in the form TTRn, where:  
  TT: The track number relative to the beginning of the data set  
  R: The block identification on that track  
  n: If the DEB is for a partitioned concatenation, (the DSORG field in the DCB indicates PO), then supply the concatenation number for the data set. A value of 0 indicates the first data set, 1 indicates the second data set and so forth. If your partitioned concatenation includes PDSEs or z/OS UNIX directories, each of them is represented by a dummy extent in the DEB. EXCP and EXCPVR are not valid for those extents. If the data set is not concatenated or the concatenation is not partitioned, set to 0.  
  If entered at CVTPCNVT+12, this value must be in the form TTTR, where:  
  TTT: The track number relative to the beginning of the data set  
  R: The block identification on that track  
  This entry point is intended for any type of data set. |
| 1 | Must be loaded with the address of the data extent block (DEB) of the data set. Each DEB resides below 16 MB. When you call the +0 entry point, the called routine clears the high order byte of this register. When you call the +12 entry point, this byte must contain X’00’. Note that if the DEB31UCB bit is zero, the UCB address field is three bytes in DEBUCBA. If the DEB31UCB bit is one, the UCB address field is four bytes in DEBUCBAD. |
Table 38. Registers and Their Use for Converting Relative to Actual (continued)

<td>8 (X'08')</td>
<td>Internal access method control blocks are invalid. Call IBM service if the control blocks should be valid.</td>
</tr>
<tr>
<td>12(X'0C')</td>
<td>Internal access method control blocks are invalid. Call IBM service if the control blocks should be valid.</td>
</tr>
<tr>
<td>16 (X'10')</td>
<td>Passed concatenation number is too big for the data set.</td>
</tr>
<tr>
<td>20 (X'14')</td>
<td>The combination of the DEBNMTRK and DEBNMTRKHI fields in the last extent shows that the input track number points into this extent, but the calculated CCHH does not lie within this extent.</td>
</tr>
</tbody>
</table>
Converting an Actual Track Address to a Relative Track Address

Convert an actual track address to a relative track address by using a resident system conversion routine that can be called in 24 or 31 bit mode.

The conversion routine has two entry points. One, at the address in the CVTPRLTV field of the communication vector table (CVT), is intended for data sets with up to 65535 tracks. The other, at offset +12 from the address in CVTPRLTV, is intended for any data set. Call the conversion routine with one of the following instructions:

- BALR 14,15 Call +0 entry point for track conversion
- BASR 14,15 Call +0 entry point for track conversion
- BAL 14,12(,15) Call +12 entry point for track conversion
- BAS 14,12(,15) Call +12 entry point for track conversion

IBM does not provide a macro for this conversion routine's invocations.

The conversion routine will return either TTR0 (if entered at CVTPRLTV+0) or TTTR (if entered at CVTPRLTV+12), where TTR0 and TTTR are as described in Table 38 on page 219.

The address of the CVT is in storage location 16 (field FLCCVT of the PSA data area, mapped by macro IHAPSA).

The conversion routine does all its work in general registers. Load registers 1, 2, 14, and 15 with input to the routine. Register usage is as follows:

**Table 40. Registers and Their Use for Converting Actual to Relative**

<table>
<thead>
<tr>
<th>Register</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Loaded with the resulting TTR0 or TTTR to be passed back to the caller. These two formats are as described for register 0 in Table 38 on page 219.</td>
</tr>
<tr>
<td>1</td>
<td>Must be loaded with the address of the data extent block of the data set. Each DEB resides below 16 MB. When you call the +0 entry point, the called routine clears the high order byte of this register. When you call the +12 entry point, this byte must contain X'00'.</td>
</tr>
<tr>
<td>2</td>
<td>Must be loaded with the address of an 8-byte area containing the actual address to be converted to a TTR0 or TTTR. The actual address is of the form MBBCCHHR.</td>
</tr>
<tr>
<td>3–8</td>
<td>Not used by the conversion routine.</td>
</tr>
<tr>
<td>9–13</td>
<td>Used by the conversion routine and not restored.</td>
</tr>
<tr>
<td>14</td>
<td>Must be loaded with the address to which control is to be returned after execution of the conversion routine.</td>
</tr>
<tr>
<td>15</td>
<td>Used by the conversion routine as a base register and must be loaded with the content of field CVTPRLTV of the CVT.</td>
</tr>
</tbody>
</table>

**Return Codes from the Conversion Routine**

When control is returned to your program, register 15 contains one of the following return codes:

**Table 41. Actual to Relative Conversion Routine Return Codes**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>Successful conversion.</td>
</tr>
</tbody>
</table>
### Table 41. Actual to Relative Conversion Routine Return Codes (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 (X'04')</td>
<td>CCHH is outside of extent M. Returned relative track number is invalid. If you called the +12 entry point, then it has set the output R byte to X'FE'.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>Internal access method control blocks are invalid. Call IBM service if the control blocks should be valid.</td>
</tr>
<tr>
<td>12(X'0C')</td>
<td>Internal access method control blocks are invalid. Call IBM service if the control blocks should be valid.</td>
</tr>
<tr>
<td>16 (X'10')</td>
<td>Passed extent number M is too big for the data set. If you called the +12 entry point, then it has set the output R byte to X'FE'.</td>
</tr>
<tr>
<td>20 (X'14')</td>
<td>The calculated relative track number is too large to be returned. If you called the +0 entry, then the track number exceeds X'FFFF', so the routine returned X'FFFFFE00'. If you called the +12 entry point, then the track number exceeds X'FFFFFFE', so the routine returned X'FFFFFFFE'. The likely causes of this are that the DEB is not valid or (for entry +0) the data set is a large format data set, but the track location is more than X'FFFF' tracks into the data set.</td>
</tr>
</tbody>
</table>

**Note:** For return codes 4, 16 and 20 with the +12 entry point, this routine returns a different value for the R byte (X'FE') than was passed to it.

### Using the IECTRKAD callable service or the TRKADDR macro

The IECTRKAD callable service or the TRKADDR macro can be used to perform the following operations on both 16-bit and 28-bit cylinder addresses:

- Calculate the relative track number on the volume
- Compare two track addresses
- Extract the 28-bit cylinder number
- Extract the 4-bit track number
- Increment the track address by one track and increments the cylinder number if necessary.
- Normalize cylinder number to permit comparing one cchh against another
- Convert a relative track number to a 28-bit cylinder address
- Set the cylinder number in a 28-bit track address
- Convert a normalized track address into an absolute 28-bit track address.

See "Call for converting and comparing 28-bit cylinder addresses (IECTRKAD)" on page 349 and "Perform calculations and conversions with 28-bit cylinder addresses (TRKADDR macro)" on page 306 for more information.

### Obtaining the Sector Number of a Block on an RPS Device

For programs that can be used with both RPS and non-RPS devices, test the UCBRPS bit (bit 3 at offset 17 of the UCB) to determine whether the device has rotational position sensing. If the UCBRPS bit is off, do not issue a channel program with a set sector command to the device. The address of the sector conversion routine's entry point is in the CVT0SCR1 field of the CVT.

Your program can call the conversion routine by issuing a BASR 14,15 or BAS 14,16(15) instruction. If you are passing the track balance to the routine, invoke the routine using a BAS 14,8(15) or BAS 14,20(15). If you are computing the sector value on modulo devices with variable length records, pass the track balance to the sector convert routine.
The sector convert routine can be called in 24-bit or 31-bit mode at any of its entry points. When calling in 24-bit mode all addresses must point below the 16MB line.

**Notes:**

1. The sector convert routine does not support PDSEs or extended format data sets. Using the sector convert routine against a PDSE or extended format data set returns results that are inconsistent with the physical record format.
2. The sector convert routine does not support data sets that are not DASD or do not have a UCB. Examples include tape, dummy data sets (DD DUMMY), spooled data sets (*, DATA or SYSOUT), TSO terminals and z/OS UNIX files such as zFS and HFS files. You will receive unpredictable results if you use the conversion routine with a data set or file that is not on DASD or does not have a UCB.

For RPS devices, the conversion routine does all its work in general registers. Load registers 0, 2, 14, and 15 with input to the routine. Register usage is as follows:

*Table 42. Registers and Their Use for A Sector Convert Routine*

<table>
<thead>
<tr>
<th>Register</th>
<th>Use</th>
</tr>
</thead>
</table>
| 0        | For fixed, standard blocks or fixed, unblocked records not in a partitioned data set: Register 0 must contain a 4-byte value in the form `XXKR`, where:  
  - XX A 2-byte field containing the physical block size  
  - K  A 1-byte field containing the key length  
  - R  A 1-byte field containing the number of the record for which a sector value is desired.  
  
  To indicate fixed-length records, turn off (set to 0) the high-order bit of register 0.  
  
  Passing the track balance: Register 0 must contain a 4-byte value of the track balance of the record preceding the required record.  
  
  For all other cases: Register 0 must contain a 4-byte value in the form `BBIR`, where:  
  - BB The total number of key and data bytes on the track up to, but not including, the target record  
  - I A 1-byte key indicator (1 for keyed records, 0 for records without keys)  
  - R A 1-byte field containing the number of the record for which a sector value is desired. To indicate variable-length records, turn on (set to 1) the high-order bit of register 0. |
| 1        | Not used by the sector-convert routine. |
| 2        | When called at offset 0 or 8, must contain a 4-byte field where:  
  - The first byte is the UCB device type code for the device (obtainable from UCB+19)  
  - The remaining 3 bytes are the address of a 1-byte area that is to receive the sector value.  
  
  If called at offset 16 or 20, must contain the address of a 1-byte area that is to receive the sector value. |
<p>| 3-8      | Not used. |
| 9-10     | Used by the convert routine and not saved or restored. |</p>

Chapter 5. Using XDAP to Read and Write to Direct Access Devices

The execute direct access program (XDAP) is a macro instruction used to read, verify, or update a block on a direct access volume. This information covers the XDAP macro instruction, including information for compatibility with other IBM operating systems, what the XDAP macro does, and how to use it. It also discusses the macro instructions used with XDAP and the control blocks that are generated. However, IBM suggests using an access method such as VSAM in place of XDAP.

Because most of the specifications for XDAP are similar to those for the execute channel program (EXCP) macro instruction, you should be familiar with the information in "IDAW Requirements" on page 170 of this publication. You should also be familiar with the information in Z/OS DFSMS Using Data Sets that provides how-to information for using the access method routines of the system control program.

If you are not using the standard IBM data access methods, by issuing XDAP you can generate the control information and channel program necessary for reading or updating the records of a data set. **Restriction:** XDAP does not support partitioned data set extended (PDSEs), extended-format data sets, UNIX files, UNIX system services data sets, or SYSIN and SYSOUT data sets.

While XDAP cannot be used to add blocks to a data set, it can be used to change the keys of existing blocks. Any block configuration and any data set organization can be read or updated.

XDAP requires less storage than do the standard access methods. However, XDAP does not provide many of the control program services that are included in the access methods. For example, when XDAP is issued, the system does not block or unblock records and does not verify block length.

All virtual addresses that you use with XDAP except the OPEN and CLOSE parameter lists, DCBE, and IOBE must be 24-bit.

**Using XDAP**

To issue XDAP, provide the actual track address of the track containing the block to be processed. Also provide either the block identification or the key of the block, and specify which you should use to locate the block. If a block is located by identification, both the key and data portions of the block can be read or updated. If a block is located by key, only the data portion can be processed.

For additional control over I/O operations, you can write appendages that must be entered into the LPA library. Descriptions of these routines and their coding specifications are included under "IDAW Requirements" on page 170.

When using the XDAP macro instruction, code a DCB macro instruction in your program to generate a data control block (DCB) for the data set to be read or updated. Also code an OPEN macro instruction that initializes the data control block and produces a data extent block (DEB). The OPEN macro instruction must be executed before any XDAP macro instructions are executed.
Using XDAP

When the XDAP macro instruction is assembled, a control block and the following executable code are generated. This control block can be logically divided into three sections:

- An event control block (ECB) that is supplied with a completion code each time the direct access channel program is terminated.
- An input/output block (IOB) that contains information about the direct access channel program.
- A direct access channel program consisting of three or four channel command words (CCWs). The type of channel program generated depends on the parameters of the XDAP macro instruction. When executed, it locates a block by either its actual address or its key and reads, updates, or verifies the block.

When the channel program has terminated, a completion code is placed into the event control block. After issuing XDAP and the direct access program has terminated, regain control by using a WAIT macro instruction to specify the address of the event control block. If volume switching is necessary, issue an EOV macro instruction. Once processing of the data set is completed, issue a CLOSE macro instruction to restore the data control block.

The parameters of the XDAP macro instruction are described in "Executing Direct Access Programs" on page 227.

Macro Instructions Used with XDAP

When using the XDAP macro instruction, you must also code DCB, OPEN, CLOSE and, in some cases, the EOV macro instructions. Special requirements or options for the other required macro instructions are explained in the following:

- "Defining a Data Control Block (DCB)"
- "Initializing a Data Control Block (OPEN)"
- "End of Volume (EOV)" on page 227
- "Restoring a Data Control Block (CLOSE)" on page 227

Defining a Data Control Block (DCB)

Issue a DCB macro instruction for each data set to be read, updated, or verified by the direct access channel program. To learn which macro instruction parameters to code, see "Data Control Block (DCB) Fields" on page 185.

Initializing a Data Control Block (OPEN)

The OPEN macro instruction initializes one or more data control blocks so that their associated data sets can be processed. Issue OPEN for all data control blocks used by the direct access program. Some of the procedures performed when OPEN is executed include the following actions:

- Constructing a data extent block
- Transferring information from DD statements and data set labels to the DCB
- Verifying or creating standard labels
- Loading programmer-written appendage routines.

The two parameters of the OPEN macro instruction are the address or addresses of the data control blocks to be initialized and the method of I/O processing of the data set. The processing method can be specified as INPUT, OUTPUT, UPDAT, or EXTEND; however, if nothing is specified, INPUT is assumed. The parameters and different forms of the OPEN macro instruction are described in "z/OS DFSMS Macro Instructions for Data Sets."
End of Volume (EOV)

The EOV macro instruction identifies end-of-volume (EOV) and end-of-data-set conditions. For an end-of-volume condition, EOV causes switching of volumes and verification or creation of standard labels. For an end-of-data-set condition (except when another data set is concatenated), EOV causes your end-of-data-set routine to be entered. When using XDAP, issue EOV if switching of direct access volumes is necessary or if secondary allocation is to be performed for a direct access data set opened for output. For details about the parameters of the EOV macro instruction, see "End of Volume" on page 182.

Note: Should EOV call DADSM EXTEND to extend on the same volume or a new volume (which implies DASD output), EXTEND will issue an enqueue on SYSVTOC. If the EOV request is issued for a data set on a volume where the application already holds the SYSVTOC enqueue, this will cause abnormal termination. For this case, a circumvention would be to allocate the output data set large enough to not require a secondary extent or request the output data set be on a volume that is different than the one for which it holds the SYSVTOC enqueue.

Restoring a Data Control Block (CLOSE)

The CLOSE macro instruction restores one or more data control blocks so that processing of their associated data sets can be terminated. Issue CLOSE for all data sets used by the direct access channel program. When CLOSE is executed, some of the following procedures are performed:

- Releasing the data extent block
- Removing information that was transferred to data-control block fields when OPEN was executed
- Verifying or creating standard labels
- Releasing programmer-written appendage routines.

The CLOSE macro instruction must identify the address of at least one data control block to be restored, and can specify other parameters. The parameters and different forms of the CLOSE macro instruction are described in \textit{z/OS DFSMS Macro Instructions for Data Sets}.

Executing Direct Access Programs

The XDAP macro instruction produces the XDAP control block (that is, the ECB, IOB, and channel program) and executes the direct access channel program.

The format of the XDAP macro instruction is:

```
XDAP(ecb_symbol,,type,,dcb_addr,,area_addr)
```

```text
(label

(length_value

(key_addr,keylength_value)

(blkref_addr

(sector_addr

(MF=E
```

Chapter 5. Using XDAP to Read and Write to Direct Access Devices 227
Using XDAP

`ecb_symbol`—symbol or (2-12)
The symbolic name to be assigned to the XDAP event control block.
Registers can be used only with MF=E.

`type`—`RI` or `RK` or `WI` or `WK` or `VI` or `VK`
The type of I/O operation intended for the data set and the method by which blocks of the data set are to be located. One of the combinations shown must be coded in this field. The codes and their meanings are:
Using XDAP

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read a block.</td>
</tr>
<tr>
<td>W</td>
<td>Update a block.</td>
</tr>
<tr>
<td>V</td>
<td>Verify that the device is able to read the contents of a block, but do not transfer data.</td>
</tr>
<tr>
<td>I</td>
<td>Locate a block by identification. (The key portion, if present, and the data portion of the block are read, updated, or verified.)</td>
</tr>
<tr>
<td>K</td>
<td>Locate a block by key. (Only the data portion of the block is read, updated, or verified.) If you code this value, code the <code>key_addr,keylength_value</code> operands.</td>
</tr>
</tbody>
</table>

`dcb_addr`—A-type address or (2-12)

The address of the data control block for the data set.

`area_addr`—A-type address or (2-12)

The address of an input or output area for a block of the data set.

`length_value`—absexp or (2-12)

The number of bytes to be transferred to or from the input or output area. If blocks are to be located by identification and the data set contains keys, the value must include the length of the key. The maximum number of bytes transferred is 32 767.

`key_addr`—RX-type address or (2-12)

When blocks are to be located by key, the address of a virtual storage field that contains the key of the block to be read, updated, or verified.

`keylength_value`—absexp or (2-12)

When blocks are to be located by key, the length of the key. The maximum length is 255 bytes.

`blkref_addr`—RX-type address or (2-12)

The address of a field in virtual storage that contains the actual track address of the track containing the block to be located. The actual address of a block is in the form MBBCHHR, where:

- **M**: Indicates which extent entry in the data extent block is associated with the direct access program
- **BB**: Must be zero
- **CC**: The cylinder address
- **HH**: The actual track address
- **R**: The block identification. R is not used if blocks are to be located by key.

The track address of the block reference (CCHH) may contain 28-bit cylinder numbers for devices with more than 65,520 cylinders. Showing nibbles it is in the form of CCCCcccH, where ccc represent bits 0-11 of the 28-bit cylinder number and CCCC represents bits 12-27 the 28-bit cylinder number. Use the TRKADDR macro to manipulate 16-bit and 28-bit cylinder numbers correctly.

(For more detailed information, see "Converting a Relative Track Address to an Actual Track Address" on page 219.)

`sector_addr`—RX-type address or (2-12)

The address of a 1-byte field containing a sector value. The `sector_addr` parameter is used for rotational position sensing (RPS) devices. The parameter is optional, but its use will improve channel performance. When the parameter is coded, a set-sector CCW (using the sector value indicated by the data address field) precedes the search-ID-equal command in the...
Using XDAP

channel program. The sector_addr parameter is ignored if the type parameter is coded as RK, WK, or VK. If a sector address is specified in the execute form of the macro, then a sector address, not necessarily the same, must be specified in the list form. The sector address in the executable form will be used.

Exception: No validity check is made on either the address or the sector value when the XDAP macro is issued. However, a unit check/command reject interruption will occur during channel-program execution if the sector value is not valid for the device or if the sector_addr operand is used when accessing a device without RPS.

MF=E You can use the L-form of the XDAP macro instruction for a macro expansion consisting of a parameter list, or the E-form for a macro expansion consisting of executable instructions.

MF=E The first operand (ecb_symbol) is required and can be coded as a symbol or supplied in registers 2 through 12. The type, dcb_addr, area_addr, and length_value operands can be supplied in either the L- or E-form. The blkref_addr operand can be supplied in the E-form or moved into the IOBSEEK field of the IOB by your program. The sector_addr is optional; it can be coded either in both the L- and E-form or in neither.

MF=L The first two operands (ecb_symbol and type) are required and must be coded as symbols. If you choose to code length_value or keylength_value, they must be absolute expressions. Other operands, if coded, must be A-type addresses. (blkref_addr is ignored if coded.)

The XDAP macro builds a channel program containing A-type addresses. These addresses refer to storage within the L-form of the macro. If you copy the L-form of the macro to a work area so that the program can be reentrant, the E-form of the XDAP macro does not update the A-type addresses. This results in an invalid channel program.

The dcb_addr, area_addr, blkref_addr, and sector_value operands can be coded as RX-type addresses or supplied in registers 2 through 12. The length_value and keylength_value operands can be specified as absolute expressions or decimal integers or supplied in registers 2 through 12.

Control Blocks Used with XDAP

The control blocks generated during execution of the XDAP macro instruction consist of the following:

Input/Output Block

The input/output block is 40 bytes in length and immediately follows the event control block. "Control Block Fields" on page 185 contains a diagram of the IOB Figure 15 on page 199. You might want to examine the IOBSSENS0, IOBSSENS1, and IOBCSW fields if the ECB is posted with X'41'.

Event Control Block

Refer to "Event Control Block Fields" on page 206 for information on event control block fields.
Direct Access Channel Program

The direct access channel program is 24 bytes in length (except when set sector is used for RPS devices) and immediately follows the input/output block. Depending on the type of I/O operation that is specified in the XDAP macro instruction, one of four channel programs can be generated. The three channel command words for each of the four possible channel programs are shown in Table 43.

### Table 43. Channel Program Command Words Used by XDAP

<table>
<thead>
<tr>
<th>Type of I/O Operation</th>

<td>Transfer in Channel</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>Write Data</td>
</tr>
</tbody>
</table>

**Note:** For verifying operations, the third CCW is flagged to suppress the transfer of information to virtual storage.

When a sector address is specified with an RI, VI, or WI operation, the channel program is 32 bytes in length. Each of the channel programs in Table 43 would be preceded by a set sector command.

RPS Device Sector Numbers

To obtain the performance improvement given by rotational position sensing, specify the `sector_addr` parameter in the XDAP macro. For programs that can be used with both RPS and non-RPS devices, test the UCBRPS bit to determine whether the device has rotational position sensing. If the UCBRPS bit is off, do not issue a channel program with a set sector command to the device.

The `sector_addr` parameter on the XDAP macro specifies the address of a 1-byte field in virtual storage. Store the sector number of the block to be located in this field. You can obtain the sector number of the block by using a resident system conversion routine. See "Obtaining the Sector Number of a Block on an RPS Device" on page 222.
Chapter 6. Using Password Protected Data Sets

This information covers password protection for data sets. The use of password protection is not recommended, but is provided for compatibility with other IBM operating systems. You should use RACF protection (using SAF) instead.

The password protection described does not apply to data sets and catalogs managed by the Storage Management Subsystem (SMS) or to VSAM data sets. SMS ignores passwords. In addition, the PROTECT macro and SVC does not support a volume on a unit defined as dynamic.

If a SAF (system authorization facility)-compliant security product is active and provides protection for the data set, then the system bypasses password protection for that data set. Additionally, the system always bypasses password protection for VSAM and for SMS-managed data sets. The system provides SMS-managed data set and catalog protection through the SAF interface. For more SAF information, see "System Authorization Facility" in z/OS MVS Programming: Assembler Services Guide and z/OS MVS Programming: Assembler Services Reference ABE-HSP.

For information about VSAM data set protection, see z/OS DFSMS Using Data Sets and z/OS DFSMS Access Method Services for Catalogs.

The following are some reasons to use SAF instead of password protection:

- If you give a password to someone, you have no control over to whom they choose to give it.
- Data sets tend to have various passwords, making you write them down. This is less secure than if you can memorize one SAF password.
- Batch job access or interactive non-TSO access requires that a system operator supply a password. Your communication to the operator is likely to be insecure. That operator might not be present when your job runs. The operator might have to give each data set's password to other operators.
- The program is halted while each password is supplied. This is contrary to the increased automation of modern systems.
- There is no way to know who has used a particular password.
- It is human nature not to change passwords, especially if there are many. As time passes, there is a greater danger of them being exposed.
- If more than a small number of data sets have passwords, then the time for the system to find the PASSWORD data set entry increases greatly. With RACF, the increase is much less. With a RACF generic profile there is no increase in search time when a new data set uses the same profile.
- With DASD shared between systems, the password definitions on each system are independent. They can get out of synchronization.
- The PASSWORD data set entry contains the data set name but not the volume serial number. If you create a data set before defining a password, you could find that someone has already defined a password for that data set name. Your data set will require the existing password just to scratch or rename it.
- Password protection is not supported on system-managed volumes or on dynamic devices.

To use the data set protection feature of the operating system, create and maintain a PASSWORD data set consisting of records that associate the names of the...
Password Protection

protected data sets with the passwords assigned to each data set. The ways to maintain the PASSWORD data set consist of:

- Writing your own routines
- Using the PROTECT macro instruction
- Using the utility control statements of the IEHPROGM utility program
- If you have TSO, using the TSO PROTECT command.

This information discusses only the first two methods. The last two methods are discussed in the publications shown in the following list.

Before using this information, you should be familiar with the contents of the following publications:

- z/OS DFSMS Using Data Sets describes the data set protection feature.
- The following publications describe the operator messages and replies associated with the data set protection feature:
  - z/OS MVS System Messages, Vol 1 (ABA-AOM)
  - z/OS MVS System Messages, Vol 2 (ARC-ASA)
  - z/OS MVS System Messages, Vol 3 (ASB-BPX)
  - z/OS MVS System Messages, Vol 4 (CBD-DMO)
  - z/OS MVS System Messages, Vol 5 (EDG-GFS)
  - z/OS MVS System Messages, Vol 6 (GOS-IEA)
  - z/OS MVS System Messages, Vol 7 (IEB-IEE)
  - z/OS MVS System Messages, Vol 8 (IEF-IGD)
  - z/OS MVS System Messages, Vol 9 (IGF-IWM)
  - z/OS MVS System Messages, Vol 10 (IXC-IZP)
- z/OS MVS JCL Reference describes the data definition (DD) statement parameter used to indicate that a data set is to be password protected. It is a subparameter of the LABEL parameter.
- z/OS DFSMSdfp Utilities describes how to maintain the PASSWORD data set using the utility control statements of the IEHPROGM utility program.
- z/OS TSO/E Command Reference describes how to use the TSO PROTECT command.

Providing Data Set Security

In addition to the usual label protection that prevents the opening of a data set without the correct data set name, the operating system provides data set security options that prevent unauthorized access to confidential data. Password protection prevents access to data sets until a correct password is entered by the system operator, or, for TSO, by a remote terminal operator.

The following types of access are allowed to password-protected data sets:

- PWREAD/PWRITE—A password is required for read or write access.
- PWREAD/NOWRITE—A password is required for read access. Writing is not allowed.
- NOPWREAD/PWRITE—Reading is allowed without a password. A password is required to write.

To prepare for use of the data set protection feature, place a sequential data set named PASSWORD on the system residence volume. This data set must contain at least one record for each data set placed under protection. Each record consists of
Password Protection

a data set name, a password for that data set, a counter field, a protection-mode indicator, and a field for recording any information you wish to log. On the system residence volume, these records are formatted as a key area (data set name and password) and a data area (counter field, protection-mode indicator, and logging field). The data set is searched on the key area.

- The area allocated to the data set should not have been previously used for a PASSWORD data set, as this might cause unpredictable results when adding records to the data set.
- If the system residence volume does not contain a PASSWORD data set, the system allows no access to password protected data sets. Do not rely on this for protection because anyone who creates a data set named PASSWORD on the system residence volume can define a password for any data set.
- Data sets on magnetic tape are protected only when standard labels are used.

You can write routines to create and maintain the PASSWORD data set. For information on using the PROTECT macro instruction to maintain the PASSWORD data set, see "Maintaining the PASSWORD Data Set Using PROTECT" on page 238. Using the IEHPROGM utility program to maintain the PASSWORD data set is described in z/OS DFSMSdfp Utilities. These routines can be placed in your own library or in the system's library (SYS1.LINKLIB). You can use a data management access method to read from and write to the PASSWORD data set.

Password-protected data sets can only be accessed by programs supplying the correct password. Upon receiving a request to open a protected data set, the operating system checks whether the data set has already been opened for this job step and if the access mode is compatible with the previously used protection mode. If neither condition is satisfied, a message requesting the password is sent to the operator console. If the program attempting to open the data is running under TSO in the foreground, the message is sent to the TSO terminal operator.

PASSWORD Data Set Characteristics

The PASSWORD data set and your operating system must reside on the same volume. That volume is the IPL volume. It is called the system residence volume. The space allocated to the PASSWORD data set must be contiguous. The amount of space allocated depends on the number of data sets you want to protect. Each entry in the PASSWORD data set requires 132 bytes of space. The organization of the PASSWORD data set is physical-sequential; the record format is unblocked, fixed-length records (RECFM=F). Each record that forms the data area is 80 bytes long (LRECL=80,BLKSIZE=80) and is preceded by a 52-byte key (KEYLEN=52). The key area contains the fully-qualified data set name (up to 44 bytes long) and a password, one to eight alphanumeric characters in length, left justified with blanks added to fill the areas.

Restriction: The PASSWORD data set cannot be large format or extended format.

Attention: Data sets on magnetic tape complying with the specifications of the International Organization for Standardization (ISO) 1001-1979 or the American National Standards Institute (ANSI) X3.27-1978 do not include generation and version numbers as part of generation data set names. If included in the PASSWORD data set, generation and version numbers for these data sets are ignored.

You should protect the PASSWORD data set by creating a password record for it when your program initially builds the data set or you should use RACF to control access. Thereafter, the PASSWORD data set cannot be opened (except by the
Password Protection

operating system routines that scan the data set) without entering the password. If a problem occurs on a password-protected system data set, maintenance personnel require the password to access the data set and resolve the problem.

Creating Protected Data Sets

The data definition (DD) statement parameter LABEL= can be used to indicate that a data set is to be password protected. For data sets on DASD, an alternative method for a previously allocated data set is to use the PROTECT macro instruction, the IEHPROGM utility, or the TSO PROTECT command. You can create a data set and set the protection indicator in its label without entering a password record for it in the PASSWORD data set. In this case the system allows no access to the data set.

Operating procedures at your installation must ensure that password records for all data sets currently password-protected are entered in the PASSWORD data set. For installations where independent computing systems share common DASD resources, PASSWORD data sets on all systems must contain the appropriate password records for any protected data set on shared DASD.

Under certain circumstances, the order in which data sets are allocated and deallocated from multiple systems on shared DASD could result in loss of protection or corruption of data. For example, if a set is allocated and opened by a user on system A and then scratched by a different user on system B, the first user has a window to the unallocated (free) area. If any data set, protected or unprotected, is allocated in that space by a user on either system while the window is open, the new data set has no protection from the user with the window. The most common solution to this problem is to use GRS (see z/OS MVS Planning: Global Resource Serialization).

While the allocation disposition is still NEW, a password-protected data set can be used without supplying a password. Once the data set is deallocated, a subsequent attempt to open it results in termination of the program unless the password record is available and the correct password is supplied. If the protection mode is NOPWREAD and the request is to open the data set for input or read backward, no password is required.

Tape Volumes Containing Multiple Password-protected Data Sets

To password protect a data set on a tape volume containing other data sets, password protect all the data sets on the volume. (Standard labels—SL, SUL, AL, or AUL—are required. For definitions of these label types and the protection-mode indicators that can be used, see z/OS DFSMS Using Magnetic Tapes.)

If you issue an OPEN macro instruction to create a data set following an existing password-protected data set, the password of the existing data set will be verified during open processing for the new data set. The password supplied must be associated with a PWRITE protection-mode indicator.

Protection Feature Operating Characteristics

The topics that follow discuss the protection feature operating characteristics:

- “Terminating the Protection Feature Process” on page 237
- “Password Protection When Switching Volumes” on page 237
- “Password Protection When Concatenating Data Sets” on page 237
- “Maintaining the Counter for Password Protection” on page 237
Terminating the Protection Feature Process
Processing is terminated if:
• The operator cannot supply the correct password for the protected data set within two attempts.
• A password record does not exist in the PASSWORD data set for the protected data set being opened.
• The protection-mode indicator in the password record and the method of I/O processing specified in the open routine do not agree; for example, OUTPUT specified against a read-only protection-mode indicator.
• There is a mismatch in data set names for a data set involved in a volume switching operation. This is discussed in the next paragraph.

Password Protection When Switching Volumes
Password protection is retained when volumes of a multivolume data set are switched. If the following conditions are met, the system accepts a newly-mounted tape volume to be used for input or a newly-mounted direct access volume:
• The data set names are the same in the password record for the data set and the job file control block (JFCB). (This ensures that the problem program has not changed the data set name in the JFCB since the data set was opened.)
• The protection-mode indicator in the password record is compatible with the processing mode, and a valid password has been supplied.

The system accepts a newly-mounted tape volume for output under any of the following conditions:
• The security indicator in the HDR1 label indicates password protection; the data set name in the password record is the same as the data set name in the JFCB; and the protection-mode indicator is compatible with the processing mode. (If the data set name in the JFCB has been changed, a new password is requested from the operator.)
• The security indicator in the HDR1 label does not indicate password protection. (A new label is written with the security indicator indicating password protection.)
• Only a volume label exists. (An HDR1 label is written with the security indicator indicating password protection.)

Password Protection When Concatenating Data Sets
A password is requested for every protected data set that is involved in a concatenation of data sets.

Password Protection SCRATCH and RENAME Functions
To delete or rename a protected data set, the job step making the request must be able to supply the password. The system checks to see if the job step is currently authorized to write to the data set. If the job step is not, a password must be provided that is associated with a WRITE protection-mode indicator.

Maintaining the Counter for Password Protection
The operating system increments the counter in the password record on each usage, but no overflow indication will be given (overflow after 65535 openings). Provide a counter maintenance routine to check and, if necessary, reset this counter.
Password Protection

Maintaining the PASSWORD Data Set Using PROTECT

To use the PROTECT macro instruction, your PASSWORD data set must be on the system residence volume. The PROTECT macro can be used to:

- Add an entry to the PASSWORD data set
- Replace an entry in the PASSWORD data set
- Delete an entry from the PASSWORD data set
- Obtain a list of information about an entry in the PASSWORD data set; this list contains the security counter, access type, and the 77 bytes of security information in the data area of the entry.

The PROTECT macro also updates the DSCB of a protected direct access data set to reflect its protection status; this feature eliminates the need for job control language when you protect a data set.

PROTECT does not support data sets on dynamic devices.

Record Format

When using the PROTECT macro, the PASSWORD data set must contain at least one record for each protected data set. The password (the last eight bytes of the key area), that you assign when you protect the data set for the first time, is called the control password.

You can create as many secondary records for the same protected data set as needed. Passwords assigned to these additional records are called secondary passwords. This feature allows several users to access the same protected data set while you control the way it is used. For example, one user could be given read/write authorization while another user is assigned a password that allows only read access.

Protection-Mode Indicator

You can set the protection-mode indicator (third data byte) in the password record to one of the following values:

- X'00' to indicate that the password is a secondary password and the protected data set is to be read only (PWREAD).
- X'80' to indicate that the password is the control password and the protected data set is to be read only (PWREAD).
- X'01' to indicate that the password is a secondary password and the protected data set is to be read and written (PWREAD/PWWRITE).
- X'81' to indicate that the password is the control password and the protected data set is to be read and written (PWREAD/PWWRITE).

The checking sequence for the protection status of a data set produces the following defaults:

<table>
<thead>
<tr>
<th>If control password is:</th>
<th>Secondary password must be:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. PWREAD/PWRITE or PWREAD/NOWRITE</td>
<td>PWREAD/PWRITE or PWREAD/NOWRITE</td>
</tr>
<tr>
<td>2. NOPWREAD/PWRITE</td>
<td>NOPWREAD/PWRITE</td>
</tr>
</tbody>
</table>
Password Protection

If the control password is set to either of the settings in item 1 and you try to set the secondary password to NOPWREAD/PWRITE, the secondary password reverts to PWREAD/PWRITE.

If the control password is changed from either of the settings in item 1 to the setting in item 2, the secondary password is reset to NOPWREAD/PWRITE.

If the control password is changed from the setting in item 2 to a setting in item 1, the secondary password is set to PWREAD/PWRITE.

Because the DSCB of the protected data set is updated only when the control password is changed, protection attributes for secondary passwords might conflict with the protection attributes of the control password.

PROTECT Macro Specification

The format of the PROTECT macro is:

```
label
        PROTECT—parameter_list_address
```

*parameter list address*—A-type address, (2-12), or (1)

Indicates the location of the parameter list. The parameter list must be created before the PROTECT macro is issued. The address of the parameter list can be passed in register 1, in any of registers 2 through 12, or as an A-type address. The first byte of the parameter list must be used to identify the function (add, replace, delete, or list). See Figure 19 on page 240 through Figure 22 on page 244 for the parameter lists and codes used to identify the functions.

*Requirement:* The parameter lists and the areas addressed by the list must reside below 16 MB virtual. PROTECT will fail the request if the actual UCB of the system residence volume is above 16 MB or if PROTECT tries to update the data set's DSCB and one of its UCBs is above the 16 MB line.
Password Protection

PROTECT Macro Parameter Lists

ADD Function:

Figure 19. Parameter List for ADD Function

0 X'01'   Entry code indicating ADD function.
4 Data set name length.
5 Data set name pointer.
13 Control password pointer.
   The control password is assigned when the data set is placed under protection for the first time. The pointer can be 3 bytes of binary zeros if the new password is the control password.
16 Number of volumes.
   If the data set is not cataloged, to have it flagged as protected, specify the number of volumes in this field. A zero requests that the catalog information be used.
17 Volume list pointer.
   If the data set is not cataloged, to have it flagged as protected, provide the address of a list of volume serial numbers in this field. Zeros request that the catalog information be used.
20 Protection code.
   A 1-byte number indicating the type of protection: X'00' indicates default protection (for the ADD function; the default protection is the type of protection specified in the control password record of the data set); X'01' indicates that the data set is to be read and written; X'02' indicates that the data set is read only; and X'03' indicates that the data set can be read without a password, but a password is needed for write access. The PROTECT macro uses the protection code value, specified in the parameter list, to set the protection-mode indicator in the password record.
21 New password pointer.
   If the data set is being placed under protection for the first time, the new password becomes the control password. If you are adding a secondary entry, the new password is different from the control
password.
Password Protection

24 String length.
The length of the character string (maximum 77 bytes) to be placed in the optional information field of the password record. If you do not want to add information, set this field to zero.

25 String pointer.
The address of the character string placed in the optional information field. If you do not want to add information, set this field to zero.

REPLACE Function:

0 X'02'. Entry code indicating REPLACE function.

4 Data set name length.

5 Data set name pointer.

9 Pointer to current password.
The address of the password that is going to be replaced.

13 Control password pointer.
The address of the password assigned to the data set when it was first placed under protection. The pointer can be set to 3 bytes of binary zeros if the current password is the control password.

16 Number of volumes.
If the data set is not cataloged, to have it flagged as protected, specify the number of volumes in this field. A zero requests that the catalog information be used.

17 Volume list pointer.
If the data set is not cataloged, to have it flagged as protected, provide the address of a list of volume serial numbers in this field. If this field is zero, the catalog information is used.

20 Protection code.
A 1-byte number indicating the type of protection: X'00' indicates default protection (for the REPLACE function the default is the type of protection specified in the control password record of the data set); X'01' indicates that the data set is to be read and written; X'02'
Password Protection

indicates that the data set is to be read only; and X'03' indicates that the data set can be read without a password, but a password is needed for write access.

21 New password pointer.
The address of the password to be used to replace the current password.

24 String length.
The length of the character string (maximum 77 bytes) to be placed in the optional information field of the password record. If you do not want to add information, set this field to zero.

25 String pointer.
The address of the character string to be placed in the optional information field. If you do not want to add information, set this field to zero.

DELETE Function:

Figure 21. Parameter List for DELETE Function

0 X'03'. Entry code indicating DELETE function.
4 Data set name length.
5 Data set name pointer.
9 Current password pointer.
The address of the password to be deleted. You can delete either a control or secondary entry.
13 Control password pointer.
The address of the password assigned to the data set when it was placed under protection for the first time. The pointer can be 2 bytes of binary zeros if the current password is also the control password.
16 Number of volumes.
If the data set is not cataloged, to have it flagged as protected, specify the number of volumes in this field. A zero requests that the catalog information be used.
17 Volume list pointer.
If the data set is not cataloged, to have it flagged as protected, provide the address of a list of volume serial numbers in this field. Zeros request that the catalog information will be used.
Password Protection

**LIST Function:**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 X'04'</td>
<td>Entry code indicating LIST function.</td>
</tr>
<tr>
<td>1 80-byte buffer pointer</td>
<td>The address of a buffer to receive the information returned to your program by the macro instruction.</td>
</tr>
<tr>
<td>4 Data set name length</td>
<td></td>
</tr>
<tr>
<td>5 Data set name pointer</td>
<td></td>
</tr>
<tr>
<td>9 Current password pointer</td>
<td>The address of the password of the record to be listed.</td>
</tr>
</tbody>
</table>

**Return Codes from the PROTECT Macro**

When the PROTECT macro finishes processing, register 15 contains one of the following return codes:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>Updating of the PASSWORD data set completed successfully.</td>
</tr>
<tr>
<td>4 (X'04')</td>
<td>The password of the data set name was already in the PASSWORD data set.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>The password of the data set name was not in the PASSWORD data set.</td>
</tr>
<tr>
<td>12 (X'0C')</td>
<td>A control password is required or the one supplied is incorrect.</td>
</tr>
<tr>
<td>16 (X'10')</td>
<td>The supplied parameter list was incomplete or incorrect.</td>
</tr>
<tr>
<td>20 (X'14')</td>
<td>There was an I/O error in the PASSWORD data set or the system residence volume (which contains the PASSWORD data set), has an actual UCB that resides above the 16 MB line.</td>
</tr>
<tr>
<td>24 (X'18')</td>
<td>The PASSWORD data set was full.</td>
</tr>
<tr>
<td>28 (X'1C')</td>
<td>The validity check of the buffer address failed.</td>
</tr>
<tr>
<td>32 (X'20')</td>
<td>The LOCATE macro failed. LOCATE’s return code is in register 1, and the number of indexes searched is in register 0.</td>
</tr>
<tr>
<td>36 (X'24')</td>
<td>The OBTAIN macro for the user data set failed. OBTAIN’s return code is in register 1. The user data set resides on a volume that has an actual UCB that resides above the 16 MB line. Register 1 contains a 4, which simulates an OBTAIN return code.</td>
</tr>
<tr>
<td>40 (X'28')</td>
<td>The DSCB could not be updated.</td>
</tr>
<tr>
<td>44 (X'2C')</td>
<td>The PASSWORD data set does not exist.</td>
</tr>
<tr>
<td>48 (X'30')</td>
<td>Tape data set cannot be protected.</td>
</tr>
<tr>
<td>52 (X'32')</td>
<td>Data set in use.</td>
</tr>
<tr>
<td>56 (X'38')</td>
<td>The data set uses the virtual storage access method (VSAM).</td>
</tr>
</tbody>
</table>
### Table 44. PROTECT Return Codes (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>60 (X'3C')</td>
<td>The data set is cataloged as being on more than 20 volumes. The DSCBs on the first 20 volumes have been updated. PROTECT does not support updating the rest.</td>
</tr>
</tbody>
</table>

**Notes:**
1. A message is written to the console indicating that the PASSWORD data set is full.
2. The PASSWORD data set has been updated, but the DSCB has not been flagged to indicate the protected status of the data set.
Password Protection
Chapter 7. Using System Macro Instructions

This information covers system macro instructions. The macros are grouped functionally where appropriate and perform the stated functions.

- Ensure data security (DEBCHK macro)
- Obtain device characteristics from control blocks and system tables (DEVTYPE macro)
- Modify the JFCB (RDJFCB and OPEN TYPE=J macros)
- Manipulate I/O activity queues (PURGE and RESTORE macros)
- Perform track capacity calculations (TRKCALC macro).
- Perform calculations and conversions with 28-bit cylinder addresses (TRKADDR macro).

Some functions of these macros tend to depend on the internal logic of the system.

Before reading this information, you should be familiar with the publications *High Level Assembler/MVS & VM & VSE Language Reference*. They contain the information necessary to code programs in the assembler language.

Ensuring Data Security by Validating the Data Extent Block (DEBCHK macro)

Protecting one user's data from inadvertent or malicious access by an unauthorized user depends on protection of the data extent block (DEB). The DEB is a critical control block because it contains information about the device a data set is mounted on, and describes the location of data sets on direct access device storage volumes.

To ensure that only a valid system-provided DEB (normally built by open) is passed to data management functions, the DEBCHK verify function is used. OPEN places the address of DEBs it creates to a DEB table, which is used by the verify function. If you code a routine that builds a DEB, add the address of the DEB you built to the DEB table. If you code a routine that depends on the validity of a DEB that is passed to your routine, verify that the DEB passed to your routine has a valid entry in the DEB table and points to your DCB or access method control block (ACB). Use the TYPE=ADD and the TYPE=VERIFY operands of the macro, respectively.

To prevent an asynchronous routine from changing or deleting, or assigning a new DEB to a DCB, hold the local lock. In this case, use the branch entry to the DEBCHK verify routine and use the DEB address returned in register 1, not the DEB address in the DCB. The DCB will remain valid as long as your program holds the local lock or prevents untrustworthy programs from running.

Your program must be executing in 24-bit or 31-bit addressing mode when you call the DEBCHK macro.

The DEBCHK macro instruction provides the following four functions:

- Adds the address of a DEB to the DEB table. If the TYPE=ADD function is interrupted before the DEB is successfully added to the DEB table, a subsequent TYPE=VERIFY will fail.
System Macros

- Verifies that the DEB table associated with a specific job step contains the address of a valid DEB and that the DEB points to the DCB (or ACB). A problem program can use this function to verify that a DEB is valid.

- Deletes the address of a DEB from the DEB table. Any program that deletes a user DEB must, before it deletes the DEB, issue a DEBCHK macro with a TYPE=DELETE operand to delete the address of the DEB from the DEB table. If the DEB validity-checking routine encounters an error while deleting the address from the DEB table, the job step is abnormally terminated.

- Deletes the address of a DEB from the DEB table in the same way as the preceding function, except that, instead of terminating the job step, this function merely returns an error code in register 15. This function is provided to prevent recurring abnormal termination.

The DEB fields used for EXCP and EXCPVR are illustrated in "Control Blocks" on page 433 (all the DEB fields are illustrated in z/OS DFSMSdfp Diagnosis).

DEBCHK Macro Specification

The format of the DEBCHK macro is:

```
/cbaddr/DEBCHK TYPE=VERIFY,ADD,DELETE,PURGE AM=amtype (amaddr) ((amreg))
```

The macro format is:

- `cbaddr` Control block address.
  - for `BRANCH=NO`
    - RX-type address, (2-12), or (1)
  - `MF=L`

A control block address passed to the DEBCHK routine. This operand is ignored if MF=L is coded. For verify, add, and delete requests, `cbaddr` is the address of a DCB or ACB that points to the DEB whose address is either verified to be in the DEB table, added to the DEB table, or deleted from the DEB table. For the purge function, `cbaddr` is the address of the DEB whose pointer is to be purged from the table: No reference is made to the DCB or ACB.

**Recommendation:** A spooled DCB’s DEB does not point back to the DCB, but to the spooled ACB; in this case, the DEBCHK should be issued against the ACB.

- for `BRANCH=YES`
  - The A-type address of a 4-byte field, or a register (3-9) or (12), that points to the DCB or ACB containing the DEB to be verified.
TYPE=VERIFY or ADD or DELETE or PURGE
Indicates the function to be performed. If MF=L is coded, TYPE is ignored. The functions are:

VERIFY This function is assumed if the TYPE operand is not coded. The control program checks the DEB table to determine whether the DEB pointer is in the table at the location indicated by the DEBTBLOF field of the DEB. The DEB is also checked to verify that DEBDCBD points to the DCB (or ACB) passed to DEBCHK. The DEBAMTYP field in the DEB is compared to the AM operand value, if given. The two must be equal. TYPE=VERIFY can be issued in either supervisor or problem state.

ADD The DEB and the DCB (or ACB) must point to each other before the DEB address can be added to the DEB table. Before the DEB pointer can be added to the table, the DEB itself must be queued on the current TCB DEB chain (the TCBDEB field contains the address of the first DEB in the chain). DEBCHK adds the DEB address to the DEB table at some offset into the table. DEBCHK places a value in the DEBTBLOF field of the DEB and inserts the access method type into the DEBAMTYP field of the DEB. DEBCHK places a zero in the DEBAMTYP field if the AM operand is not coded. TYPE=ADD can be issued only in supervisor state.

DELETE The DEB and the DCB (or ACB) must point to each other before the DEB address can be deleted from the DEB table. TYPE=DELETE can be issued only in supervisor state.

PURGE DEBCHK removes the DEB pointer from the DEB table without checking the DCB (or ACB). TYPE=PURGE can be issued only in supervisor state.

AM Specifies an access method value. Each value corresponds to a particular access method type (note that BPAM and SAM have the same values):

<table>
<thead>
<tr>
<th>Value</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>(X'00')</td>
<td>NONE</td>
</tr>
<tr>
<td>(X'01')</td>
<td>VSAM</td>
</tr>
<tr>
<td>(X'02')</td>
<td>EXCP</td>
</tr>
<tr>
<td>(X'04')</td>
<td>Not supported</td>
</tr>
<tr>
<td>(X'08')</td>
<td>GAM</td>
</tr>
<tr>
<td>(X'10')</td>
<td>TAM</td>
</tr>
<tr>
<td>(X'20')</td>
<td>BPAM</td>
</tr>
<tr>
<td>(X'20')</td>
<td>SAM</td>
</tr>
<tr>
<td>(X'40')</td>
<td>BDAM</td>
</tr>
<tr>
<td>(X'81')</td>
<td>SUBSYS</td>
</tr>
<tr>
<td>(X'84')</td>
<td>Not supported</td>
</tr>
</tbody>
</table>

The operand can be coded in one of the following three ways, only the first of which is valid for the list form (MF=L) of the instruction.
**System Macros**

*amtype*  
Refers to the access method: BDAM, SAM, BPAM, TAM (which refers to BTAM only), GAM, EXCP, or VSAM. **SUBSYS** identifies a subsystem of the operating system, such as a job entry subsystem. **NONE** indicates that no access method or subsystem is specified.

*(amaddr)*  
The RS-type address of the access method value. This format cannot be coded when **MF=L** is used.

*(amreg)*  
One of the general registers 1 through 14 that contains the access method value in its low-order byte (bit positions 24 through 31). The high-order bytes are not inspected. This form cannot be used when **MF=L** is coded.

The use of *amaddr* and *amreg* should be restricted to those cases where the access method value has been generated previously by the **MF=L** form of DEBCHK. If **MF=L** is not coded, the significance of the AM operand depends upon the TYPE.

If TYPE is **ADD** and AM is specified, the access method value is inserted in the DEBAMTYP field of the DEB, and all subsequent DEBCHK macros referring to this DEB must either specify the same AM or omit the operand. When the AM operand is omitted for TYPE=**ADD**, a null value (0) is placed in the DEB and all subsequent DEBCHK macros must omit the AM operand.

If AM is specified when the TYPE is **PURGE**, **DELETE**, or **VERIFY**, the access method value is compared to the value in the DEBAMTYP field of the DEB. If AM is omitted, no comparison is made.

**BRANCH=NO** or **YES**  
Specifies whether you want to use the branch entry to the DEBCHK verify routines.

**NO**  
**SAVREG**  
**TCBADDR**  
**KEYADDR**  
**KEYREG**  
Specifies branch entry is not to be used. The program ignores operands SAVREG, TCBADDR, KEYADDR, and KEYREG. Your program must be running in TCB mode.

**YES**  
Specifies the branch entry is to be used. **TYPE=VERIFY** must be implicitly or explicitly specified. The operands TCBADDR and KEYADDR/KEYREG are required. AM and MF are ignored. Notes for **BRANCH=YES**:

- Your program can run in TCB or SRB mode.
- Registers 1, 2, 10, 11, 14, and 15 must not be used for SAVREG=.
- Registers 1, 2, 10, 11, 14, 15, and the register specified for SAVREG= must not be used for cbaddr, TCBADDR=, or KEYADDR=KEYREG=.
- The contents of registers 10, 11, and 14 are unpredictable on completion. Also, if you do not specify SAVREG=, the contents of register 2 are unpredictable.
System Macros

- At completion, register 1 contains the address of the DEB, and register 15 contains either 0, 4, or 16 (see Return Codes from DEBCHECK for codes and their meanings).
- Can be specified when operating in 24-bit or 31-bit addressing mode.

TCBADDR=address—RX-type address, (3-9), or (12)

Specifies the word or register containing the address of the TCB to be used by the DEBCHECK verify routine. Use this operand only with BRANCH=YES.

KEYADDR=address—RX-type address

Specifies the location, or a register that points to the location, of a byte containing the key to be used when accessing the DCB (or ACB). The protection key is in bits 0 to 3. Use this operand only with BRANCH=YES.

KEYREG=reg

Specifies the register containing the key value in bit positions 24-27 to be used when accessing the DCB (or ACB). Use this operand only with BRANCH=YES.

SAVREG=reg

Specifies the register in which register 2 is to be saved. Use this operand only with BRANCH=YES.

MF=L

Indicates the list form of the DEBCHECK macro instruction. When MF=L is coded, a parameter list is built, consisting of the access method value that corresponds to the AM keyword. This value can be referred to by name in another DEBCHECK macro by coding AM=(amaddr), or it can be inserted into the low-order byte of a register before issuing another DEBCHECK macro by coding AM=((amreg)).

Return Codes from DEBCHECK

Register 15 contains one of the following codes:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>The requested function completed successfully and register 1 contains the address of the DEB.</td>
</tr>
<tr>
<td>4 (X'04')</td>
<td>Either (a) the DEB table associated with the job step does not exist; or (b) the DEB field that is an index into the DEB table contains an invalid value; or (c) the control block address is not the same as the content of the DEB table entry.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>An invalid TYPE was specified. (The DEBCHECK routine was entered by a branch, not by the macro.)</td>
</tr>
<tr>
<td>12 (X'0C')</td>
<td>Your program was not authorized and TYPE was not VERIFY.</td>
</tr>
<tr>
<td>16 (X'10')</td>
<td>DEBDCBADD did not contain the address of the DCB (or ACB) that was passed to the DEBCHECK routine.</td>
</tr>
<tr>
<td>20 (X'14')</td>
<td>The AM value does not equal the value in the DEBAMTYP field.</td>
</tr>
<tr>
<td>24 (X'18')</td>
<td>The DEB is not on the DEB chain and TYPE=ADD was specified.</td>
</tr>
<tr>
<td>28 (X'1C')</td>
<td>TYPE=ADD was specified for a DEB that was already entered in the DEB table.</td>
</tr>
<tr>
<td>32 (X'20')</td>
<td>The DEB table exceeded the maximum size and TYPE=ADD.</td>
</tr>
</tbody>
</table>
Obtaining I/O Device Characteristics (DEVTYPE macro)

Use the DEVTYPE macro instruction to request information relating to the characteristics of an I/O device and to cause this information to be placed into a specified area. (The results of a DEVTYPE macro instruction executed before a checkpoint is taken should not be considered valid after a checkpoint/restart occurs.) The IHADVA macro maps the data returned by the DEVTYPE macro - see “IHADVA Mapping macro” on page 270.

The topics that follow discuss the DEVTYPE macro, device characteristics, and the output for specific devices.

Your program can issue the DEVTYPE macro while executing in 24- or 31-bit mode. If your program is executing in 31-bit mode, the parameter list, information list, and the UCB address list can reside above the 16 MB line.

Table 51 on page 266 shows the output for each device type that results from issuing the DEVTYPE macro without the INFOLIST parameter.

For all currently supported devices, DEVTYPE does not return enough information to perform space calculations. TRKCALC should be used to perform space calculations. For information on using the TRKCALC macro, see “Performing Track Calculations (TRKCALC macro)” on page 297.

DEVTYPE Macro Specification

There are four forms of DEVTYPE macro invocation covered here. They are the standard form, execute form, list form, and INFO form.

Restrictions:

- If you do not code the BELOW or ANY value for the UCBLIST parameter, then you can assemble and run DEVTYPE as described in this document on any release of DFSMS.
- If you code the BELOW or ANY value for the UCBLIST parameter, then the program cannot be assembled on MVS/DFP Version 3 but the system will ignore the BELOW or ANY value if you assemble it on DFSMS.
- If you code the INFOLIST or INFO parameter, then the macro cannot be assembled or run on MVS/DFP Version 3.
- If you omit INFOLIST, INFO, BELOW and ANY and the PLISTVER parameter, then you can assemble the program on DFSMS but it will not run on MVS/DFP Version 3. If you code PLISTVER=0, then you can assemble the program on DFSMS but not on MVS/DFP and you can run the program on either level of the system. During assembly your program can choose which parameters to code by using the technique described in “Determining DFARELS During Assembler Macro Phase” on page 312.

There are two types of call to the standard form of the DEVTYPE macro.

- The minimum type call refers to the DD statement for the device. It has no list or execute forms.
- The UCBLIST/INFOLIST type call requires you to specify either the UCBLIST or INFOLIST parameter or both.
System Macros

The format of the different types of call to the standard form of DEVTYPE macro follow. The parameter descriptions follow the formats.

**Minimum Type Call**
The minimum type of call refers to the DD statement for the device. For this type call, as the parameters are passed in general registers no list or execute form exists. It returns the device information to the area you specify.

The format of the minimum type call of the DEVTYPE macro is:

```
label DEVTYPE ddloc,area_addr,DEVTAB,RPS
```

**UCBLIST or INFOLIST Type of Call**
The UCBLIST or INFOLIST type call requires you to specify either the UCBLIST or INFOLIST parameter or both.

The format of the UCBLIST or INFOLIST type call is:

```
label DEVTYPE ddloc,UCBLIST=(ucbl_addr,ucbl_num),ANY
```

```
label DEVTYPE ddloc,(area_addr,area_size),INFOLIST=codel_addr,MAX
```

**ddloc**—A-type address or (1-12)
The name of an 8-byte field that contains the symbolic name of the DD statement to which the device is assigned. The name must be left justified in the 8-byte field, and must be followed by blanks if the name is fewer than eight characters. Each DEVTYPE macro executable invocation must have either ddloc to identify an allocated data set or UCBLIST= to identify one or more devices.

You can specify ddloc as (1) only if you omit all keywords.

**area_addr**—Rx-type address or (0, 2-12)

The name of an area into which the device information is to be placed. If your program does not specify the UCBLIST or INFOLIST function, the area is two, five, or six words long, depending on whether you specify the DEVTAB and RPS operands. If your program specifies the UCBLIST parameter without INFOLIST the area must be 6 words long for each UCB. The area must be on a word boundary.

If your program specifies the INFOLIST parameter, then the length of the area depends on what you coded for INFO on the referenced...
DEVTYPE macro. The INFO description states how many bytes are returned for each value you specify in the INFO list. To calculate the area size needed, multiply the sum of those values by *ucbl_num* in UCBLIST. If you omit UCBLIST (and specify *ddloc*), do not multiply.

Note that if you specify UCBLIST (and not *ddloc*) then *(area_addr,area_size)* must still be the second positional parameter. If you code *(area_addr,area_size)* before all the keywords, then code it after one comma. If you code *(area_addr,area_size)* after a keyword, then code *(area_addr,area_size)* after two commas.

area_size=absolute expression or (2-12)
The size (in bytes) of the area into which the device information is to be placed. See Table 45

<table>
<thead>
<tr>
<th>Table 45. Minimum size of area</th>
</tr>
</thead>
<tbody>
<tr>
<td>ddloc specified</td>
</tr>
<tr>
<td>----------------</td>
</tr>
<tr>
<td>Yes</td>
</tr>
<tr>
<td>Yes</td>
</tr>
<tr>
<td>No</td>
</tr>
<tr>
<td>No</td>
</tr>
</tbody>
</table>

**DEVTAB[,RPS]**
DEVTAB is only meaningful for direct access devices. If DEVTAB is specified, the following number of words of information is placed in your area:
- For direct access devices: 5 words
- For non-direct access devices: 2 words.

If you do not specify DEVTAB, INFOLIST, or UCBLIST, one word of information is placed in your area if the reference is to a graphics or teleprocessing device; for any other type of device, two words of information are placed in your area.

**RPS**
If RPS is specified, DEVTAB must also be specified. The RPS parameter causes one additional word of rotational position sensing information to be included with the DEVTAB information.

**UCBLIST=(ucbl_addr,ucbl_num [,BELOW or ANY])**
UCBLIST provides a list service in which the caller passes a list of 4-byte UCB addresses and specifies the number of UCB address
System Macros

entries that are in the list. You must specify the UCBLIST parameter or ddloc. The BELOW or ANY are optional keywords that indicate whether the address passed by the UCB parameter contains a 3-byte or 4-byte UCB address. This keyword only applies to callers running in AMODE 31. If the caller is running in AMODE 24, the keyword ANY is ignored and the high-order byte is treated as ‘X'00’.

If you do not specify INFOLIST, then the information returned is always returned in 6-word entries (one entry per UCB address) regardless of the device type. The words that would contain information not applicable to the device for that entry are not altered.

The DEVTYPE macro will accept a captured UCB or an actual UCB address above or below the 16 MB line, via the UCBLIST = parameter. It will also accept 24- or 31-bit addresses of UCB copies. The UCB copy must be on a word boundary, but can be above or below the 16 MB line. Unauthorized programs can get a copy of the UCB by using the UCBSHelper macro and specifying the COPY and UCBAREA keywords. Refer to z/OS HCD Planning for details.

ucbl_addr—A-type address or (2-12)
Name of an area containing a list of 4-byte UCB addresses.

ucbl_num—absolute expression or (2-12)
Number of 4-byte UCB address entries in the list.

BELOW The UCB parameter contains addresses of UCBs that reside in storage below 16 MB, or a captured UCB. This is the default. If BELOW is specified, the high-order byte of the UCB address is treated as ‘X'00’.

ANY The UCB parameter contains a 4-byte UCB address. If ANY is specified when invoking in 31-bit mode, DEVTYPE treats each word in the UCB address list as a 31-bit address.

INFOLIST=codel_addr
The name of an area that specifies the types of information DEVTYPE is to return. Coding INFOLIST=0 has the same effect as omitting it. If you specify INFOLIST, then you must also specify ddloc or UCBLIST and you must specify (area_addr,area_size). The format of the returned words is described under DEVTYPE, DASD, and SUFFIX (see page 260).

codel_addr—A-type address or (2-12)
Specifies an area which contains an instance of the DEVTYPE macro where you coded only the INFO keyword.

PLISTVER=0 or 1 or MAX
Specifies the version of the parameter list for the macro to generate.

0 The program cannot be assembled on a level of the system earlier than DFSMS/MVS Release 3, which was released in 1996. It can run on any system level that supports the coded parameters. You cannot code this with the INFOLIST or INFO parameter. The parameter list will be 20 bytes long.

1 The program can be assembled and run only on
DFSMS/MVS Release 3 or later. The parameter list will not be acceptable for systems prior to DFSMS/MVS. This specification generates a 24-byte parameter list.

**MAX**

In the current release, this has the same effect as coding 1.

In a future release, this value might allow a parameter list that is incompatible with an earlier release. This is the default and generates a 24-byte parameter list.

**DEVTYPE—Execute Form**

The execute form of the DEVTYPE macro is:

```
DEVTYPE 
[label] 
.ddloc 
 UCBLIST=(ucbl_addr,ucbl_num,BELOW) 
 ,ANY 
 , area_addrx,area_size 
 , INFOLIST=codel_addrx 
 ,PLISTVER=MAX 
 ,MF=(E,name) 
```

**ddloc**—RX-type address or (1-12)

Has the same meaning as the standard form of the macro (see also the UCBLIST parameter below for execute form requirements of the ddloc parameter).

**area_addrx**—RX-type address or (2-12)

Has the same meaning as the standard form of the macro. This parameter must be coded on the list and/or the execute form.

This must be coded on the execute form.

**area_size**—RX-type address or (2-12)

This form has the same meaning as the standard form of the macro. This parameter must be coded on the list and/or on the execute form.

This must be coded on the execute form.

**UCBLIST**=(ucbl_addr,ucbl_num,BELOW or ANY)

This format has the same meaning as the standard form of the macro. You must specify either the UCBLIST or the ddloc parameter on either the execute or list form. You can code them on both forms. Either parameter on the execute form overrides the same parameter on the list form.

**ucbl_addrx**—RX-type address or (2-12)

This format has the same meaning as the standard form of the macro.

**ucbl_num**—absolute expression or (2-12)

This format has the same meaning as the standard form of the macro except that in the execute form, the maximum value of an absolute expression is 4095. You can supply a larger value in a register.
System Macros

**BELOW**  This format has the same meaning as the standard form of the macro. If you write two or three values for UCBLIST on the execute form, it replaces and overrides all three values in the list form. If you omit UCBLIST on the execute form, DEVTYPE will use the values in the list form. This is the default.

**ANY**   This format has the same meaning as the standard form of the macro. If you write two or three values for UCBLIST on the execute form, it replaces and overrides all three values in the list form. If you omit UCBLIST on the execute form, DEVTYPE will use the values in the list form.

**INFOLIST=codel_addrx**  This format has the same meaning as the standard form of the macro. You can code INFOLIST=0 to remove a previous INFOLIST value that is in the list form.

  codel_addrx—RX-type address or (2-12)
  This format has the same meaning as the standard form of the macro.

**PLISTVER=0 or 1 or MAX**  This format has the same meaning as on the standard form of the macro. If you code a non-default value for PLISTVER on the list form, then code the same value on the execute form.

**MF=(E,name)**  Specifies the execute form of DEVTYPE. The execute form of the DEVTYPE macro is valid only with the UCBLIST or INFOLIST function.

  E  Specifies the execute form of the macro. Use the execute form to modify a parameter list and call the DEVTYPE function.

  name—RX-type address or (1-12)
  Label of the parameter list constructed by the corresponding MF=L form.

**DEVTYPE—List Form**  The list form of the DEVTYPE macro follows:

```
label DEVTYPE addloc UCBLIST=YES
    (ucbl_addr,ucbl_num)
    ,BELLOW
    ANY
    (area_addr,area_size)
    ,INFOLIST=codel_addr
    ,PLISTVER=MAX
    ,MF=L
```

*label*  Label of the parameter list to be used. When you specify *label* with MF=L, *label* must be the same as *name* on MF=(E,*name*).
System Macros

\textit{ddloc}—A-type address
This format has the same meaning as the standard form of the macro.

\textbf{UCBLIST=YES or (ucbl\_addr,ucbl\_num,BELOW or ANY)}
This format has the same meaning as the standard form of the macro. This is the default.

\textbf{YES}
DEVTYPE allows UCBLIST=YES as a place holder when \textbf{MF=L} is coded. It has no effect on the macro expansion.

\textbf{ucbl\_addr}—A-type address
This format has the same meaning as the standard form of the macro.

\textbf{ucbl\_num}—absolute expression.
This format has the same meaning as the standard form of the macro.

\textbf{BELOW}
This format has the same meaning as the standard form of the macro. This is the default.

\textbf{ANY}
This format has the same meaning as the standard form of the macro.

Coding UCBLIST=YES has no effect on the macro expansion. Do not code UCBLIST=YES with a DD name parameter on the same macro.

\textbf{area\_addr}—A-type address
This format has the same meaning as the standard form of the macro. This parameter must be coded on the list and/or the execute form.

\textbf{area\_size}—absolute expression
This format has the same meaning as the standard form of the macro. This parameter must be coded on the list and/or the execute form.

\textbf{INFOLIST=codel\_addr}
This format has the same meaning as the standard form of the macro.

\textbf{codel\_addr}—A-type address or (2-12)
This format has the same meaning as the standard form of the macro.

\textbf{PLISTVER=0 or 1 or MAX}
This format has the same meaning as on the standard form of the macro. If you code a non-default value for PLISTVER on the list form, then code the same value on the execute form.

\textbf{MF=L}
Specifies the list form of DEVTYPE. The list form of the DEVTYPE macro is valid only with the UCBLIST or INFOLIST function. By specifying MF=L you construct a parameter list, and you can subsequently supply the values by specifying the execute form of the macro.

\textbf{DEVTYPE—Info Form}
The INFO form of the DEVTYPE macro is used to generate a code list for the INFOLIST parameter. The INFO form is not executable. It has no list or execute form.
form. When you specify the INFOLIST parameter of DEVTYPE, it refers to an expansion of DEVTYPE with only the INFO parameter.

The INFO form of the DEVTYPE macro is:

![Diagram of the INFO form of the DEVTYPE macro]

INFO=(AMCAP or DEVTYPE or DASD or SUFFIX)

Specifies the types of information that you wish to retrieve. Specify any combination of the indicated values in any order. You can specify the same value more than once in the list. The parentheses around the INFO value can be omitted if there is only one value.

Specifying the INFO keyword causes the macro expansion to be a list, and it will not be executable. If you specify the INFO keyword, then omit the MF keyword or specify MF=L. Note that the E-form does not provide for updating any of these values. This means that you can specify INFOLIST to refer to a DEVTYPE expansion that is assembled in a reentrant CSECT.

DEVTYPE will return information in the area that you supply in the area_addrx parameter. Each type of information that you request is of a fixed length, as stated below. At execution time, the DEVTYPE macro will check whether the area is long enough. The information will be returned in the order in which you specify the values with the INFO= keyword. If the requested information has no meaning for the device or data set, then DEVTYPE clears the appropriate storage. This means that each piece of information will be returned at a predictable offset in your area.

IBM can add support to DEVTYPE for new INFO= codes in a future level of the system. DEVTYPE in the current level is expected to tolerate object code assembled on such a future level. DEVTYPE in the current level is expected to return the appropriate number of bytes. They should be binary zeroes or partial information padded on the right with binary zeroes. In either case DEVTYPE will also set a return code=0 with a reason code=4 to indicate this condition. If the information returned by the future code cannot validly be zero, then you can test for zeroes to determine which field or fields are not supported. You can also test the DFA to determine the level of the system.

DEVTYPE is not designed to support downward compatibility of source code; that is, you will not be able to assemble source code containing future INFO values on the current level.
System Macros

AMCAP

Returns 32 bytes for the access method capacity as follows:

Table 46. INFO=AMCAP 32-byte return data

<table>
<thead>
<tr>
<th>Offset</th>
<th>Bytes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0(0)</td>
<td>1</td>
<td>Flags.</td>
</tr>
<tr>
<td>0(0)</td>
<td>1... 7</td>
<td>BSAM, QSAM, and (if DASD) BPAM support the large block interface and the block size limit is in the next doubleword.</td>
</tr>
<tr>
<td>1(1)</td>
<td>7</td>
<td>Reserved, currently set to zeros.</td>
</tr>
<tr>
<td>8(8)</td>
<td>8</td>
<td>Maximum block size supported. If you specify a DD name to DEVTYPE for a data set concatenation, this value is the largest for any of the DDs. This value might exceed 32760 for a magnetic tape or dummy data set and therefore require EXCP or the access method large block interface. On output, OPEN does not allow a block size that exceeds this value except with EXCP. On certain cartridge tape drives, exceeding this limit can cause bypassing of hardware buffering. In the future, IBM might support values that exceed 32760 for other device types.</td>
</tr>
<tr>
<td>16(10)</td>
<td>8</td>
<td>Recommended maximum block size. This is less than or equal to the maximum block size supported. Above this length the device might be less efficient or less reliable. If you specify a DD name to DEVTYPE for a data set concatenation, this value is the largest for any of the DDs (refer to Table 47). Consult hardware documentation for further information.</td>
</tr>
<tr>
<td>24(18)</td>
<td>8</td>
<td>Maximum unspanned logical record length supported by BSAM, QSAM, or BPAM. Various types of data sets on the device might have various maximum record lengths. Therefore, if UCBLIST was coded on DEVTYPE and not a DD name, this value is the smallest for the possible data set types for BSAM, QSAM, and BPAM.</td>
</tr>

DEVTYPE

Returns a copy of the four-byte UCBTYP field of the UCB. See the description of word 0 in "Device Characteristics Information" on page 262.

DASD

Returns 16 bytes as follows:

Bytes 0-3

Number of cylinders on the device, excluding alternates. For a VIO data set, this number is the number of simulated cylinders needed to contain the data set.

Bytes 4-7

Number of tracks per cylinder.

Bytes 8-9

Flags (two bytes)
ECKD supported. This means that the following commands are supported:

- Define Extent (X'63') at the beginning of the channel program, except with VIO.
- Locate Record (X'47')
- Read Multiple Count, Key and Data (X'5E')
- Write Count, Key and Data Next Track (X'9D')

For VIO data sets, this bit is on because these commands are always supported. For a non-VIO DASD, this bit also means that the device supports the Define Extent command, but EXCP allows it only at the beginning of your channel program. See "DASD Channel Program Prefix Commands" on page 174.

Locate Record Extended CCW is supported. For VIO data sets, this bit is on because those commands are always supported.

Controller cache supported.

Flag DVAIXVLD. Flags DVACYLMG (byte 8 bit 4) and DVAEADSCB (byte 8 bit 5), along with field DVAVIRSZ (bytes 14-15) valid and possibly zero.

Flag DVACYLMG. Cylinder-managed space exists on this volume and begins at DVALCYL (bytes 10-11) in multicylinder units of DVAMCU (byte 9). DVAEADSCB (byte 8 bit 5) is also set with this flag on. Valid when DVAIXVLD (byte 8 bit 3) is set.

Flag DVAEADSCB. Extended attribute DSCBs, Format 8 and 9 DSCBs, are allowed on this volume. Valid when DVAIXVLD (byte 8 bit 3) is set.

Flag DVASSDEV. The device is solid state.

Flag DVACRYPT. Data encrypted device.

Byte 9

Field DVAMCU. Minimum allocation size in cylinders for cylinder-managed space. Each extent in this space must be a multiple of this value. Also referred to as the multicylinder unit (MCU). This is the smallest unit of disk space in cylinders that can be allocated in cylinder managed space. Valid when DVACYLMG (byte 8 bit 4) is set. This field is zero on releases before z/OS 1.10 or if the status is not yet known. In these two cases DVAIXVLD (byte 8 bit 3) is not set.

Bytes 10-11

Field DVALCYL. First cylinder address divided by 4095 where space is managed in multicylinder units. Valid when DVACYLMG (byte 8 bit 4) is set. When valid and zero the volume has no cylinder-managed space. This field is zero on releases before z/OS 1.10 or if the status is not yet known. In these two cases DVAIXVLD (byte 8 bit 3) is not set.
System Macros

**Byte 12**
Track set size. Zero if device does not support read-any or write-any. See 3990 Reference for more information.

**Bytes 13**
Reserved. DEVTYPE currently returns zeroes but could return something different in a future release.

**Bytes 14-15**
Block size of the index data set. Valid when byte 8 bit 3 is on. When valid and zero the volume has no working VTOC index. This field is zero on releases before z/OS 1.10 or if the status is not yet known. In these cases byte 8 bit 3 is not set.

**SUFFIX**
Returns in two bytes the length of the suffix that the system adds to each block in an extended format data set that can be stored on the device. Use this information for space calculations such as with the TRKCALC macro and for determining optimal block size. For device types that support extended format data sets, DEVTYPE returns 32. A non-zero value does not mean that the data set actually is extended format or that the device supports extended format data sets. Not all storage controllers can support extended format data sets. In a future release this value might change.

### Device Characteristics Information

The following information is placed into your area as a result of issuing a DEVTYPE macro if you do not code the INFOLIST parameter.

**Word 0:** Describes the device as defined in the UCBTYP field of the UCB. The IHADVA macro maps these four bytes this way:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Length</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>DVAOPTS</td>
<td>Model and option bits that depend on the device</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>DVACLASS</td>
<td>Device class. Exactly one bit is on except that X'41' means a channel-to-channel adapter. X'80'=magnetic tape, X'40'=unit record, X'20'=DASD, X'10'=display and X'08'=character reader. A value of X'01' indicates a simulated device that does not have a UCB. These meanings are described in Table 49.</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>DVAUNIT</td>
<td>Device type. Depends on the device class.</td>
</tr>
</tbody>
</table>

### Simulated Device Characteristics:

Any reference to one of the following types in Table 49 causes the information shown to be placed in word 0 and word 1 of the output area.

<table>
<thead>
<tr>
<th>Data Set Type</th>
<th>Word 0 in Hexadecimal</th>
<th>Word 1 in Hexadecimal</th>
</tr>
</thead>
<tbody>
<tr>
<td>DUMMY application process queue</td>
<td>0000 0000</td>
<td>0000 0000</td>
</tr>
<tr>
<td>TSO terminal</td>
<td>0000 0101</td>
<td>0000 7FF8</td>
</tr>
<tr>
<td>SYSIN, SYSOUT, or subsystem (SUBSYS=)</td>
<td>0000 0102</td>
<td>0000 7FF8</td>
</tr>
<tr>
<td>UNIX system services (possibly HFS) file</td>
<td>0000 0103</td>
<td>0000 7FF8</td>
</tr>
</tbody>
</table>
System Macros

The system also uses a copy of the UCBTYP word in these places:

- In catalog entries for DASD and tape data sets. Some of the model and option bits are zero. See output of the IDCAMS LISTCAT command.
- As the device code returned by the LOCATE macro in the volume list. See "Retrieving Information from a Catalog" on page 158. Some of the model and option bits are zero.
- Input to the SCRATCH macro. See "Deleting a Data Set from the VTOC" on page 143 and "SCRATCH and CAMLST Macro Specification" on page 146.
- Input to the RENAME macro. See "Renaming a Data Set in the VTOC" on page 149 and "RENAME and CAMLST Macro Specification" on page 152.

Word 1

Maximum block size without using the large block interface of the access method. The maximum value is 32760 bytes. For direct access devices, this value is the smaller of either the maximum size of a nonkeyed block or the maximum block size allowed by the operating system; for magnetic tape devices, this value is the maximum block size allowed by the access methods. For these and other device types, see Table 50 on page 265.

If your program specifies either DEVTAB or UCBLIST without INFOLIST, the next three words contain the following information about direct access devices:

Word 2

Bytes 0-1 The number of physical cylinders on the device, including alternates. Treat this as an unassigned 16-bit number.

**Recommendation:** Before you use bytes 0 and 1, read the description of word 4, byte 1, bit 0. For a VIO data set, that bit is zero, and the number of cylinders is as many as are needed to contain the simulated data set. This can differ from the number for the real device being simulated.

Bytes 2-3 The number of tracks per cylinder.

Word 3

Bytes 0-1 Maximum track length. Note that this value is not equal to the value in word 1 (maximum block size).

Byte 2 Block overhead, keyed block—the number of bytes required for gaps and check bits for each keyed block other than the last block on a track.

**Recommendation:** Before using bytes 2 and 3, read the description of word 4.

Byte 3 Block overhead—the number of bytes required for gaps and check bits for a keyed block that is the last block on a track.

Bytes 2-3 Block overhead—the number of bytes required for gaps and check bits for any keyed block on a track including the last block. Use of this form is indicated by a 1 in bit 4, byte 1 of word 4.
System Macros

Basic overhead—the number of bytes required for the count field. Use of this form is indicated by a 1 in bit 3, byte 1 of word 4.

Word 4

Byte 0

Block overhead, block without key—the number of bytes to be subtracted from word 3, bytes 2 or 3 or bytes 2 and 3, if a block is not keyed.

If bit 3, byte 1 of word 4 is 1, this byte contains the modulo factor for a modulo device.

Byte 1

Bit 0

If on, the number of cylinders, as indicated in word 2, bytes 0 and 1 is not valid. If the number of cylinders on the volume exceeds 65520, then this bit is on. To retrieve the number of cylinders for any DASD, you can use the INFO=DASD operand of the DEVTYPE macro.

Bit 1

If on, ECKD supported. This means that the following commands are supported:

- Define Extent (X'63') at the beginning of the channel program, except with VIO.
- Locate Record (X'47')
- Read Multiple Count, Key and Data (X'5E')
- Write Count, Key and Data Next Track (X'9D')

For VIO data sets, this bit is on because these commands are always supported. For a non-VIO DASD, this bit also means that the device supports the Define Extent command, but EXCP allows it only at the beginning of your channel program. See “DASD Channel Program Prefix Commands” on page 174.

Bits 2-3

If both on, indicates the drive is attached to a cache storage control.

Bit 3

If on, indicates a modulo device (such as 3380, 3390).

Bit 4

If on, bytes 2 and 3 of word 3 contain a halfword giving the block overhead for any block on a track, including the last block.

Bit 5

If on, the device supports paging CCWs.

Bit 6

If on, the device has no alternate cylinders.

Bit 7

If on, a tolerance factor must be applied to all blocks except the last block on the track.

Bytes 2-3

Tolerance factor—this factor is used to calculate the effective length of a block. The calculation should be performed in the following order:
System Macros

Step 1  Add the block's key length to the block's data length.

Step 2  Test bit 7 of byte 1 of word 4. If bit 7 is 0, perform step 3. If bit 7 is 1, multiply the sum computed in step 1 by the tolerance factor. Shift the result of the multiplication 9 bits to the right.

Step 3  Add the appropriate block overhead to the value obtained above.

If bit 3, byte 1 of word 4 is 1, bytes 2 and 3 contain the overhead for the data or key field.

If your program specifies DEVTAB and RPS, or specifies UCBLIST without INFOLIST, the next word contains the following information:

Word 5

| Bytes 0-1 | R0 overhead for sector calculations |
| Byte 2   | Number of sectors for each track    |
| Byte 3   | Number of data sectors for each track |

Table 50 and Table 51 on page 266 show the output for each device type that results from issuing the DEVTYPE macro.

If your program specifies UCBLIST and not INFOLIST, the output consists of one 6-word entry for every UCB address contained in the UCB list.

</tbody>
</table>

Note:
1. Although certain models can have a larger line size, the minimum line size is assumed.
2. The IBM 4248 Printer returns 132 characters even if the 168 Print Position Feature is installed on the device.
3. The IBM 3800 Printing Subsystem can print 136 characters per line at 10-pitch, 163 characters per line at 12-pitch, and 204 characters per line at 15-pitch. The machine default is 136 characters per line at 10-pitch.
4. The 3424 Magnetic Tape Unit is available only in Brazil, S.A.

**Recommendation:** For all currently supported devices, DEVTYPE does not return enough information to perform space calculations. Use the TRKCALC macro and the sector conversion routine to perform space calculations. For information on using the TRKCALC macro, see “Performing Track Calculations (TRKCALC macro)” on page 297. For information on the sector conversion routine, see “Obtaining the Sector Number of a Block on an RPS Device” on page 222.

**DEVTYPE—Return Codes and Reason Codes**

Control is returned to your program at the next executable instruction following the DEVTYPE macro instruction. Register 15 contains a return code from the DEVTYPE macro, and register 0 contains the reason code. Registers 2 to 14 contents are unchanged. Register 1 contents are unpredictable. The return codes and their meanings are as follows:
Return Code | Meaning
---|---
0 (X'00') | Information has been successfully stored in your work area.

Reason Code | Meaning
---|---
0 (X'00') | All the information is available.
4 (X'04') | DEVTYPE did not recognize one or more INFO parameter codes. DEVTYPE cleared the appropriate amount of the return area and processed the rest of the INFO codes.

4 (X'04') | Invocation error.

Reason Code | Meaning
---|---
4 (X'04') | DD name not defined.
8 (X'08') | Parameter list not valid. The error might be version code, length, zero field, or return area is not large enough. DEVTYPE does not do a complete UCB check in the current release. The UCB address might not be valid because the correct value was not coded for the third value of the UCBLIST parameter.

8 (X'08') | Unsupported device class.

Reason Code | Meaning
---|---
12 (X'0C') | DEVTYPE does not support the device class. It must be DASD, tape, subsystem (including spooled), unit record, TSO terminal, dummy, communications, graphics or channel-to-channel adapter. If UCBLIST was coded, then DEVTYPE has ignored the rest of the list.

---

**DEVTYPE—Example 1—Referring to a DD Statement**

```assembly
DEVTYPE MYDD,DEVINFO,DEVTAB

MYDD DC CL8'DATATAB'
DEVINFO DC 5F'0'
```

Example 1 of DEVTYPE returns 20 bytes of device information if DATATAB is a DASD data set or 8 bytes otherwise.

**DEVTYPE—Example 2—Includes Building a Parameter List**

```assembly
MVC DTLIST,KDTLIST BUILD PARAMETER LIST IN DYNAMIC STORAGE
*************************************************************************
* RETRIEVE FOUR BYTE UCBTYP FOR SYSUT1 DEVICE
*************************************************************************
DEVTYPE MF=(E,DTLIST),(,(AREA,L'AREA)

*************************************************************************
* RETRIEVE 20 BYTES (DASD INFO AND UCBTYP) FOR THE UNIT DESCRIBED BY THE
* UCB THAT UCBAD POINTS TO. THE AREA ADDRESS AND LENGTH ARE STILL
```
System Macros

Example 2 of DEVTYPE builds a parameter list in dynamically-acquired storage so the program can be reentrant. It then supplies additional parameters in the first execute form and overrides some of them in the second execute form. In effect, the first specification of DEVTYPE is:

```
DEVTYPE FIRSTDD,(AREA,L'AREA),INFOLIST=ILIST1
```

ILIST1 describes four bytes to be returned. They are at the beginning of a 20-byte area - DEVTYPE clears the extra 16 bytes. The list form at KDTLIST specifies parameters that will not be overridden by the first execute form. The execute form specifies parameters that are determined during execution. In effect, the second specification of DEVTYPE is:

```
DEVTYPE ,(AREA,L'AREA),INFOLIST=ILIST2,UCBLIST=(UCBAD,1)
```

The INFOLIST describes 20 bytes to be returned.

The first execute form illustrates an unusual technique of coding a keyword parameter (MF) before two positional parameters. The first positional value is null, and the second position is (AREA,L'AREA). This generally is not a good technique because it is confusing. It is used here only to show the flexibility that Assembler H and High Level Assembler allow.

For another example of DEVTYPE, see Figure 29 on page 313

**DEVTYPE—Example 3—Building a Parameter List and Using IHADVA**

This example is the same as the previous one, but it uses the IHADVA macro to map the DEVTYPE output and several unusual techniques to demonstration the possibilities.

```
MVC DTLIST,KDTLIST Build parameter list in dynamic storage
```

```
* Retrieve four-byte UCBTYP for SYSUT1 device in 20-byte area.
```

```
*******************************************************************************

```

```
NUMCYL DS F NUMBER OF CYLINDERS ON VOLUME
```

```
TRKCYL DS F NUMBER OF TRACKS PER CYLINDER
```

```
DS CL8 MISCELLANEOUS
```

```
TYP2 DS CL4 UCBTYP FROM UCB POINTED TO
```

```
* FROM UCBAD
```

```
Example 2 of DEVTYPE builds a parameter list in dynamically-acquired storage so the program can be reentrant. It then supplies additional parameters in the first execute form and overrides some of them in the second execute form. In effect, the first specification of DEVTYPE is:

```
DEVTYPE FIRSTDD,(AREA,L'AREA),INFOLIST=ILIST1
```

ILIST1 describes four bytes to be returned. They are at the beginning of a 20-byte area - DEVTYPE clears the extra 16 bytes. The list form at KDTLIST specifies parameters that will not be overridden by the first execute form. The execute form specifies parameters that are determined during execution. In effect, the second specification of DEVTYPE is:

```
DEVTYPE ,(AREA,L'AREA),INFOLIST=ILIST2,UCBLIST=(UCBAD,1)
```

The INFOLIST describes 20 bytes to be returned.

The first execute form illustrates an unusual technique of coding a keyword parameter (MF) before two positional parameters. The first positional value is null, and the second position is (AREA,L'AREA). This generally is not a good technique because it is confusing. It is used here only to show the flexibility that Assembler H and High Level Assembler allow.

For another example of DEVTYPE, see Figure 29 on page 313
Example 3 of DEVTYPE builds a parameter list in dynamically-acquired storage so
the program can be reentrant. It then supplies additional parameters in the first
execute form and overrides some of them in the second execute form. In effect, the
first specification of DEVTYPE is:

```
DEVTYPE FIRSTDD,(DVAIDASD,L'DVAIDASD+LenDEVTYPE),INFOLIST=ILIST1
```

ILIST1 describes four bytes to be returned at the beginning of a 20-byte area. The
length attribute of the INFO=DAF area is L'DVAIDASD, which is 16. The constant
LenDEVTYPE is the length of the INFO=DEVTYPE area, which is four bytes.
DEVTYPE clears the extra 16 bytes. The list form at KDTLIST specifies parameters
that will not be overridden by the first execute form. The execute form specifies
parameters that are determined during execution.

The DTUsing USING DVAUCBTY,DVAIDASD line is a labeled dependent USING
statement. It applies the 4-byte DVAUCBTY DSECT on top of the storage at
DVAIDASD. One purpose of the symbol DTUsing could be to allow a later DROP
statement to end the addressability but that is not the purpose of the label here.
The purpose here is to avoid an assembler warning message ASMA303W. Multiple
address resolutions may result from this USING and the USING on statement
number nn*. It would be on the second labeled USING if it did not have the same
label.

In effect, the second specification of DEVTYPE is:

```
DEVTYPE ,(L'DVAIDASD+LenDEVTYPE),INFOLIST=ILIST2,UCBLIST=(UCBAD,1)
```

The INFOLIST describes 20 bytes to be returned. The second USING with the label
DTUsing defines addressability to the last four of the 20 bytes. The first 16 bytes
have no USING because they are a part of the DYNAMIC DSECT and already
have addressability that is not shown. This technique of using one DSECT (defined
by IHADVA DSECT=YES,INFO=DEVTYPE) apply to two places in different areas of
the program is allowed by named USINGs without loading another base register.

The IHADVA DSECT=NO,INFO=DAF line defines 16 bytes of variables that DEVTYPE
sets. The first symbol is DVAIDASD and its length attribute is 16.
System Macros

The DS CL(LenDEVTYPE) line defines variables that are described by the DSECT
generated by the IHADVA DSECT=YES,INFO=DEVTYPE line.

IHADVA Mapping macro

The IHADVA macro supports two parameters:

DSECT={YES|NO}

If you code DSECT=YES, you get a single area with a DSECT. This is the
default. Its name depends on whether you code INFO= and what you code for
it. The DSECT name depends on the first value that you code for INFO=.

The following applies if you code DSECT=NO:

- If you omit INFO= or you code INFO=None, then the area begins with the
  symbol DVAAREA and it is not a DSECT.
- If you code any combination of INFO values other than NONE, then
  DVAAREA is not defined and there is no DSECT.

INFO={NONE|DEVTYPE|DASD|SUFFIX|AMCAP}

If you omit the INFO keyword, then the mapping is for all of the following at the
same origin:

- the minimum type of call
- UCBLIST= without INFO=
- INFO=DASD
- INFO=DEVTYPE
- INFO=SUFFIX
- INFO=AMCAP

INFO=None.

This generates the mapping for the minimum type of call or when you code
UCBLIST= without INFO=. You cannot code NONE in combination with any
other value.

INFO=DASD

Generate the mapping for the area returned by coding INFO=DASD. The
DSECT name or first symbol is DVAIDASD.

INFO=DEVTYPE

Generate the mapping for the area returned by coding INFO=DEVTYPE.
The DSECT name or first symbol is DVAUCBTY.

INFO=SUFFIX

Generate the mapping for the area returned by coding INFO=SUFFIX. The
DSECT name or first symbol is DVASUFFIX.

INFO=AMCAP

Generate the mapping for the area returned by coding INFO=AMCAP. The
DSECT name or first symbol is DVAAMCAP.

Reading and Modifying a Job File Control Block (RDJFCB Macro)

To accomplish the functions that are performed as a result of an OPEN macro instruction, the open routine requires access to information that you have supplied in a data definition (DD) statement. This information is stored by the system in a job file control block (JFCB). Some information is placed into the JFCB when the data set is allocated, while other information is placed there only when the data set is opened. Which fields are updated and when they are updated will vary depending upon factors such as what is specified in the JCL DD statement, what the application does, whether the data set is SMS managed or not, and so on. Fields that have not been updated yet will contain binary zeroes.

In certain applications, you might find it necessary to modify the contents of a JFCB (previously specified in the allocation parameters) before issuing an OPEN macro instruction against a data set. For example, suppose that you are adding records to the end of a sequential data set. You might want to add a secondary allocation quantity to allow the existing data set to be extended when the space currently allocated is exhausted. To assist you, the system provides the RDJFCB macro instruction. This macro instruction causes a JFCB to be moved to an area specified in an exit list. Use of the RDJFCB macro instruction with an exit list is shown under "Example" on page 277. When you subsequently issue the OPEN macro instruction, you can specify the TYPE=J operand to open the data set using the JFCB in the area you specified.

You can use RDJFCB and a DCB to learn the data set name, AMP parameters and volume serials of a VSAM data set. You can use any valid combination of MACRF and DSORG in the DCB. The simplest would be DSORG=PS,MACRF=R. You cannot use the JFCB with OPEN TYPE=J to open a VSAM data set.
If you specify the XTIOT, UCB NOCAPTURE or DSAB-above-the-line options of dynamic allocation, then the system creates an XTIOT. With these options, if the access method is not EXCP and the data set is not VSAM, then RDJFCB requires that you code the LOC=ANY option on the DCBE macro, and the NON_VSAM_XTIOT=YES option in the DEVSUPxx member of SYS1.PARMLIB is in effect.

The RDJFCB macro also allows you to retrieve allocation information for the data sets in a concatenation. You can either select data sets or, by default, retrieve the information for all data sets in the concatenation.

You can retrieve the following items:
- All JFCBs
- All volume serial numbers
- Block size limit
- The path name (PATH=) associated with any DD. In these cases the data set name in the JFCB is a dummy value.

“Type 07 JFCB Exit List Entry” on page 279 describes how you can use RDJFCB to retrieve this information.

Tip: If you set the bit JFCNWRIT in the JFCBTSDM field to 1 before you issue the OPEN macro instruction, the JFCB is not written back at the conclusion of open processing. OPEN TYPE=J normally moves your program's modified copy of the JFCB, to replace the system copy. To ensure that this move is done, your program must set bit zero of the JFCBMASK+4 field to 1. IBM recommends not setting on JFCNWRIT. If the user JFCB (which the system used to open the data set) is not written back, errors can occur during termination processing for EOV, CLOSE, or the job/step because OPEN might have updated information in the user JFCB which will not be reflected in the system copy of the JFCB. For example, when a nonspecific tape data set is opened, OPEN will update the user supplied JFCB with the volume serial number of the tape selected. However, the system copy of the JFCB will not reflect this volume serial number. This could cause errors during termination processing for EOV, CLOSE, or the job/step (for example, the data set might not be cataloged even though the job requested it).

Your program can also use the SWAREQ macro to access JFCBs and JFCBXs. It requires your program to access the DSAB or DSABs and the TIOT or XTIOTs. You can use the GETDSAB macro for this and you will need several mapping macros. SWAREQ and GETDSAB are documented in z/OS MVS Programming: Authorized Assembler Services Guide. The RDJFCB macro is designed to be simpler to use and does not require examining system control blocks.

Some of the modifications that can be made to the JFCB include:
- Moving the creation and expiration date fields of the DSCB into the JFCB
- Modifying the number-of-volumes field in the JFCB

The number-of-volumes field can be modified only to be a value not greater than the total number of volume serial numbers available in the JFCB and any JFCBXs (extensions). The JFCB can have five volume serial numbers. Each JFCBX can have 15 volume serial numbers. Whether or not a JFCBX is required and how many JFCBXs are required is determined during data set allocation. A JFCBX cannot be dynamically created after allocation. Therefore, the maximum value of the number-of-volumes field is based on the JFCB and how many
System Macros

JFCBXS exist. Setting the number-of-volumes field to a value greater than that maximum will not cause a JFCBX to be dynamically created.

- Moving the DCB fields from the DSCB into the JFCB
- Adding volume serial numbers to the JFCB (see "RDJFCB Security" on page 279)
  Volume serial numbers in excess of five are written to the JFCBX (extension). The JFCBX cannot be modified by user programs.
- Modifying the sequence number field of the volume in the JFCB. For DISP=NEW the modified volume sequence will be honored during OPEN TYPE=J only for tape and only when the file sequence number in the JFCB is also modified.
- Modifying the sequence number field of the data set in the JFCB. This specifies the file for a subsequent OPEN TYPE=J to process. You can use this technique to write many data sets on a tape volume or set of volumes. Use RDJFCB and increase the sequence number of the data set by 1 before each OPEN TYPE=J. If the device supports buffered tape marks, you can obtain significantly better performance by requesting the SYNC=None option on the DCBE macro. It allows the device to enter "streaming mode" and to write tape marks much faster. A side effect is that any I/O error can be reflected at an unpredictable time. This can result in an ABEND in OPEN or CLOSE for a user data block. It also means that if a device malfunction occurs, it might result in the loss of more than one data set that the application had closed previously. To position rapidly to a tape data set other than the next data set, you can use the technique described in "High-Speed Cartridge Tape Positioning" on page 290.
- Changing the data set name field or member field in the JFCB. See "RDJFCB Security" on page 279 and "RDJFCB Use by Authorized Programs" on page 280. You can open a VTOC by reading the JFCB, changing the data set name to 44 bytes of X'04' and then issuing the OPEN macro with TYPE=J. Use BSAM or EXCP. If you use BSAM, also code RECFM=F, KEYLEN=44 and BLKSIZE=96 on the DCB macro. For an extended address volume the DCB macro must point to a DCBE where the EADSCB=OK keyword is specified. You'll find examples of opening an EXCP DCB for a VTOC in "Example of Using the CVAFFILT Macro" on page 105 and "Example of using the CVAFSEQ macro to process a volume in physical sequential order" on page 127.
- Setting bit JFCQDSP in field JFCBFLG3 to invoke the tape volume DEQ at demount facility (see "DEQ at Demount Facility for Tape Volumes" on page 280)
- Modifying the JFCBIDO field in the JFCB to cause high-speed positioning to a specific data block on a tape volume on a device that supports cartridge tapes (see "High-Speed Cartridge Tape Positioning" on page 290)
- Setting bit JFCNDSCB to prevent OPEN from merging fields from the data set label to the JFCB. This means that you must supply the information from other sources, such as the JFCB or the DCB. A data set label is a DSCB or standard tape label. This bit does not control all fields. For example it does not control the creation and expiration dates. Note that if you set this bit on, it can cause incorrect positioning in the data set after an automatic step restart when using DISP=MOD or the OPEN macro with the EXTEND option. Setting this bit on can interfere with the system correcting JFCBDSCB (TTR of DSCB on first volume). Setting this bit on is not a good programming practice because it depends on internal system logic.
- Setting bit JFCNDCB to prevent OPEN from merging fields from the DCB to the JFCB. This interferes with correct information being set in the data set label and it interferes with OPEN doing certain checks. Setting this bit on is not a good programming practice because it depends on internal system logic.
System Macros

The secondary allocation quantity will be moved from the DSCB into the JFCB unless prevented by the setting of JFCNWRIT or JFCNDSCB.

**RDJFCB Macro Specification**

The RDJFCB macro instruction moves a job file control block (JFCB) into an area of your choice as identified by the EXLST parameter of the DCB macro for each data control block specified.

The format of the RDJFCB macro is:

```
label
    RDJFCB (dcb_addr), (dcb_addr), option1, (option1), (option2), (, option2)
```

- **option1:**
  - INPUT
  - EXTEND
  - OUTPUT
  - INOUT
  - OUTIN
  - OUTINX
  - RDBACK
  - UPDAT

- **option2:**
  - DISP
  - LEAVE
  - REREAD
  - Rewind

**Tip:** If you wish to have multiple DCBs with or without options, code each DCB (and options) as shown in the diagram and precede each additional DCB with a comma. Examples of the standard form of the RDJFCB macro are:

```
RDJFCB (DCB1)
RDJFCB (DCB1,INPUT)
RDJFCB (DCB1,(INPUT))
RDJFCB (DCB1,(INPUT,REREAD))
RDJFCB (DCB1,DCB2)
RDJFCB (DCB1,DCB2,(INPUT,REREAD),DCB3,INPUT)
```

*Figure 23. Examples of Standard Form of the RDJFCB macro*

`dcb_address`, or `(options)`

(Same as the `dcb_address`, `option1`, and `option2` operands of the
System Macros

OPEN macro instruction, as shown in z/OS DFSMS Macro Instructions for Data Sets, except for the MODE operand, which is not valid with the RDJFCB macro.

The option operands do not affect RDJFCB processing. You can, however, specify them in the list form of the RDJFCB macro instruction and refer to the generated parameter list with the execute form of the macro.

- You can also use the MF parameter on an RDJFCB macro. Its syntax, use, and effect are the same as is documented for the OPEN macro in z/OS DFSMS Macro Instructions for Data Sets. In addition, you can code an execute-form RDJFCB macro that refers to a list-form OPEN macro that does not have MODE=31.

- The RDJFCB parameter list, the DCB, and the JFCB area specified in the exit list as well as the exit list itself must reside below 16 MB, although the calling program can be above 16M.

Example
In Figure 24 on page 278, the macro instruction at EX1 creates a parameter list for two data control blocks: INVEN and MASTER. In creating the list, both data control blocks are assumed to be opened for input; option2 for both blocks is assumed to be DISP. The macro instruction at EX2 moves the system-created JFCBs for INVEN and MASTER into the area you specified, thus making the JFCBs available to your problem program for modification. The macro instruction at EX3 modifies the parameter list entry for the data control block named INVEN and indicates, through the TYPE=J operand, that the problem program is supplying the JFCBs for system use.
Multiple data control block addresses and associated options can be specified in the RDJFCB macro instruction. This facility makes it possible to read several job file control blocks in parallel.

An exit list address must be provided in each DCB specified by an RDJFCB macro instruction. Each exit list must contain an active entry of either or both types supported by RDJFCB.

RDJFCB processes the first of each of the two types of its entries in the exit list. For example, in a three-entry list containing types 07, 07 and 13, RDJFCB will process the first and third entries and ignore the second entry. An ignored entry has no effect on the RDJFCB return code.

Each of the entries is briefly explained in the following text. A full discussion of the exit list and its use is contained in "z/OS DFSMS Using Data Sets".

After RDJFCB is performed, register 15 contains one of the following codes:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>RDJFCB function completed successfully.</td>
</tr>
</tbody>
</table>
Table 52. Return Codes from the RDJFCB Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 (X'04')</td>
<td>One or more DCBs encountered one of the following conditions and were skipped. DCBs that were not skipped were processed successfully.</td>
</tr>
<tr>
<td></td>
<td>• The DCB was being processed by Open/Close/EOV or a similar function.</td>
</tr>
<tr>
<td></td>
<td>• No data set with the DDNAME that is in the DCB is allocated.</td>
</tr>
<tr>
<td></td>
<td>• The DCB is not open and its DDNAME is blank.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>One or more DCBs had an ARL that could not be processed. Each ARL contains a reason code describing its status.</td>
</tr>
<tr>
<td></td>
<td>One or more DCBs might have encountered a condition described under return code 4. This type of ARL does not contain a reason code.</td>
</tr>
</tbody>
</table>

**Type 07 JFCB Exit List Entry**

The type 07 JFCB exit list entry allows you to perform a variety of tasks, as described in the following text.

The format of the type 07 JFCB exit list entry is:

<table>
<thead>
<tr>
<th>Hexadecimal Code (High-Order Byte)</th>
<th>Contents of Exit List Entry (Three Low-Order Bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>07</td>
<td>Address of a 176-byte area required if the RDJFCB or OPEN (TYPE=J) macro instruction is used.</td>
</tr>
</tbody>
</table>

The virtual storage area into which the JFCB is read must be:

• Located within the user's region
• On a word boundary
• At least 176 bytes long.

**Requirement:** Users running in 31-bit addressing mode must ensure that this area is located below 16 MB virtual. Each exit list entry must be 4 bytes long. The system recognizes only the first occurrence of an exit list entry code. Indicate the end of the exit list by setting the high-order bit in the entry code byte to 1.

The DCB can be either open or closed when this macro instruction is executed. If accessing concatenated sequential data sets and the DCB is open, the RDJFCB routine reads the JFCB for the current data set. In all other cases, the RDJFCB routine reads the JFCB for the first or only data set.

If the RDJFCB routine fails while processing a DCB associated with your RDJFCB request, or you do not provide a virtual storage address in the three low-order bytes of the exit list entry, your task is abnormally terminated. None of the options available through the DCB ABEND exit, as described in z/OS DFSMS Using Data Sets, are available when a RDJFCB macro instruction is issued.

**RDJFCB Security:** OPEN TYPE=J compares the volume serial numbers specified in the user-supplied JFCB with the volume serial numbers in the system's copy of the JFCB. Each different volume serial number will be enqueued exclusively. The
volumes stay enqueued until the job step terminates, because the CLOSE routines will not dequeue the volumes. If the job step already has the volume open, OPEN TYPE=J continues. If the volume is enqueued by another job step, an ABEND 413 occurs with a return code of X'04'.

Some JFCB modifications can compromise the security of existing password-protected or RACF-protected data sets. The following modifications are specifically not allowed, unless the program making the modifications is authorized (an authorized program is one that is either in supervisor state, executing in one of the system protection keys (keys 0 through 7), or authorized under the authorized program facility) or can supply the password:

- Changing the disposition of a password-protected data set from OLD or MOD to NEW.
- Changing the data set name or one or more of the volume serial numbers when the disposition is NEW.
- Changing the label processing specifications to bypass label processing.

Changing the data set name in the JFCB has no effect on the name of the data set. You are just referring to a different data set. If the DISP setting is NEW, it does not cause the changed data set name to be created. If OPEN allocates the changed data set name, it is as if the DD had DISP=OLD. To create a data set on DASD, your program should call dynamic allocation by issuing SVC 99 (Requesting dynamic allocation functions) in [Z/OS MVS Programming: Authorized Assembler Services Guide]. Alternately your program might be able to use the REALLOC macro, but note that it requires authorization and carries restrictions. See "Creating (Allocating) a DASD Data Set Using REALLOC" on page 47.

RDJFCB Use by Authorized Programs: Except when opening a VTOC, if you change the data set name in the JFCB and your job step is APF-authorized, you should do a system enqueue on the major name of "SYSDSN" for the substituted data set name. Issuing an ENQ macro for a major name of SYSDSN requires authorization.

If your program changes the data set name or the volume serial number and is not authorized, OPEN TYPE=J calls dynamic allocation for the new name. CLOSE will automatically unallocate the data set.

To use the correct interface with other system functions (for example, partial release), the ENQ macro should include the TCB of the initiator and the length of the data set name (with no trailing blanks). When you complete processing of the data set, you should use the DEQ macro to release the resources. If your program is not authorized and issues an OPEN TYPE=J macro, and the substituted data set name is already enqueued by another job step, an ABEND 913 occurs with a return code of X'1C'.

To open a VTOC data set to change its contents (that is, open it for OUTPUT, OUTIN, INOUT, UPDAT, OUTINX, or EXTEND), your program must be authorized under the Authorized Program Facility (APF). APF provides security and integrity for your data sets and programs. Details on how to authorize your program are provided in [Z/OS MVS Programming: Assembler Services Guide], [Z/OS MVS Programming: Authorized Assembler Services Guide], and [Z/OS MVS Programming: Assembler Services Reference ABE-HSF].

You cannot extend a VTOC by this means.
Restriction: Do not change the data set name to NULLFILE (signifying a dummy data set). Changing the name to NULLFILE can prevent the device allocated for the data set specified on the DD statement from being deallocated at job/step termination.

Using BSAM or EXCP for Random I/O to a Multivolume Data Set: If you open a BDAM DCB for a multivolume data set, OPEN links your program to all volumes simultaneously so that your program can ignore volume boundaries and treat all volumes of the data set as one entity. If you open a BSAM or EXCP DCB for a multivolume data set, OPEN gives your program access to only one volume at a time. This is true for both disk and tape. To switch to another volume, your program issues a CHECK or FEOV macro for BSAM or EOV macro for EXCP. To return to a previous volume, you must close and reopen the data set, which would be slow.

Your program can use RDJFCB and OPEN TYPE=J with one DCB per volume to process all the volumes in parallel. Your program must keep track of which DCB is for each volume. Your program uses the RDJFCB macro to read in the JFCB, and uses OPEN with TYPE=J to open each volume of the data set. The coding example in Figure 25 on page 282 illustrates the procedure with EXCP DCBs.

This technique does not work for a JFCB disposition of NEW because OPEN TYPE=J honors modifications to the JFCB volume sequence number JFCBVLSQ only for tape and only if the JFCB file sequence is also modified.

This technique does not work with a striped data set because OPEN always opens all volumes of a striped data set in parallel as for BDAM.

If you are using BSAM to read non-striped volumes in parallel, you should avoid using the CHECK macro because it can automatically move to the next volume when you reach the end of the current volume. Use WAIT or EVENTS instead of CHECK. Refer to z/OS DFSMS Using Data Sets and z/OS DFSMS Macro Instructions for Data Sets for information about WAIT or EVENTS. If you optimize I/O with the MULTACC parameter of the DCBE macro, you also must issue TRUNC macros.

With tape, you cannot open more than one DCB per allocated drive. You can calculate the number of allocated drives from the TIOT entry length or by issuing the IEFDSRV macro. IEFDSRV returns the number of devices in DVAR_NUM_DVENT. Refer to z/OS MVS Programming: Assembler Services Reference IAR-XCT.

If your program does any of the following it will damage the data set:

- If you use BSAM and the OPEN option is not UPDAT and you issue WRITE macros, you might cause the data set to be extended to new tracks or to the next volume. In the latter case you have two DCBs open to one volume and they can interfere with each other.
- If you use BSAM and the OPEN option is not UPDAT and the last operation before CLOSE is WRITE (and CHECK, WAIT or EVENTS), then CLOSE marks that volume as being the last volume of the data set. The result might be every volume marked as being the last one. This is true also if you use EXCP and CLOSE finds that bit 0 of DCBOFLGS is on. For EXCP, see Table 31 on page 182 and “Device-Dependent Parameters” on page 191. If a program later tries to read the volumes of the data set sequentially, such as a program backing it up, that program will not read past the end of this volume. In addition, a later program trying to add records to the end of a volume by opening with the
EXTEND or OUTINX option or with the OUTPUT or OUTIN option with
DISP=MOD, can add them to the wrong volume.

If the data set is newly allocated on DASD, space has been allocated only on the
first volume unless you used the guaranteed space option of SMS. For both DASD
and tape, if the data set has not yet been written on the volume, the OPEN fails.

<table>
<thead>
<tr>
<th>Hexadecimal Code (High-Order Byte)</th>
<th>Contents of Exit List Entry (Three Low-Order Bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>Address of an allocation retrieval list.</td>
</tr>
</tbody>
</table>
Using RDJFCB to Retrieve Allocation Information: RDJFCB uses DCB exit list entry type 13 to retrieve allocation information (JFCBs and volume serial numbers) for data sets that might be concatenated. The exit list entry code is X'13', and is defined as “retrieve allocation information.” The second through fourth bytes of this entry must point to an allocation retrieval list (ARL), as described in Table 53. If you issue RDJFCB, this DCB exit list entry retrieves all JFCBs for the specified concatenated data sets, and lists of all volume serial numbers for these data sets. The block size, as specified on the DD statement of each data set, is put into the extended information segment following the volume serial numbers. If this block size field is 0, the block size of the data set is in the JFCB. You can either select JFCBs in the concatenation or, by default, retrieve all of them. RDJFCB uses the parameter list to receive and return information about the request. See Figure 26 on page 287 for an example of usage.

OPEN TYPE=J does not recognize this exit list entry.

You can use the IHAARL macro (shown here) to generate and map the ARL. Your program might issue a GETMAIN or STORAGE macro for the ARL, or, if you specify DSECT=NO, the ARL is generated within your program’s storage. The ARL must be below 16 MB. The allocation retrieval area (ARA), acquired by RDJFCB through a GETMAIN macro, can be above or below 16 MB.

The format of the IHAARL macro is:

```
IHAARL(label, DSECT=NO, PREFIX=prefix, DESCR=YES)
```

DSECT=YES or NO

Specifies whether the symbol at the beginning of the generated area appears on a DSECT instruction or a DC instruction. For DSECT=NO, the symbol appears on a DC instruction. The default is DSECT=YES.

PREFIX=prefix

Allows you to invoke the macro more than once per assembly. Specifies a character string with which all generated symbols are to be prefixed. Do not specify delimiters, such as quotation marks. If you omit this operand or specify a null value, the prefix defaults to the characters ARL.

DESCR=YES or NO

Specifies whether the macro expansion includes the macro description (prolog). The default is DESCR=NO.

Table 53 and Table 54 on page 284 describe the formats of the allocation retrieval list and allocation retrieval area, respectively.

</tbody>
</table>

When you have finished using information from the retrieval areas, you should issue FREEMAIN or STORAGE macro to free any areas that were acquired through
System Macros

GETMAIN (including the ARA, acquired by RDJFCB). When coding the FREEMAIN or STORAGE macro, specify the length, subpool, and address values from the ARLRLEN, ARLPOOL, and ARLAREA fields, respectively. The DSECT name is ARAXINFO.

Code the FREEMAIN macro as shown:

FREEMAIN RU,LV=length,SP=subpool,A=address

If RDJFCB successfully fills in the ARL field, register 15 is set to zero. Otherwise see Table 52 on page 278.

Example: In Figure 26 on page 287, the macro instruction at ALLOCINF creates a parameter list for one DCB (INDCB), assumed to be open for input. The JFCBs and volume serial numbers are retrieved for all data sets allocated to DDNAME SYSLIB.

Figure 26. Sample Code Retrieving Allocation Information (Part 1 of 2)
DEQ at Demount Facility for Tape Volumes

This facility is intended to be used by long-running programs that create an indefinitely long tape data set (such as a log tape). Use of this facility by such a program permits the processed volumes to be allocated to another job for processing (such as data reduction). This processing is otherwise prohibited unless the indefinitely long data set is closed and dynamically deallocated.

You can invoke this facility only through the RDJFCB/OPEN TYPE=J interface by setting bit JFCDQDSP (bit 0) in field JFCBFLG3 at offset 163 (X'43') to 1. The volume serial of the tape is dequeued when the volume is demounted by OPEN or EOV with message IEC502E when all the following conditions are present:

- The tape volume is verified (where a tape is considered verified after file protect, label type, and density conflicts have been resolved) for use by OPEN or EOV (see page 288 for more information concerning verified).
- JFCDQDSP is set to 1.
- The program is APF authorized (protect key and supervisor/problem state are not relevant).
- The tape volume is to be immediately processed for output. That is, either OPEN verifies the volume and the OPEN option is OUTPUT, OUTIN, or OUTINX; or

---

Figure 26. Sample Code Retrieving Allocation Information (Part 2 of 2)
EOV verifies the volume and the DCB is opened for OUTPUT, OUTIN, INOUT, or EXTEND, and the last operation against the data set was an output operation (DCBOFLWR is set to 1).

For EOV to find JFCDQDSP set to 1, the program must not inhibit the rewrite of the JFCB by setting bit 4 of JFCBTSMD to 1.

The tape volume is considered verified after file protect, label type, and density conflicts have been resolved. The volume is dequeued when demounted after this verification, even if further into OPEN or EOV processing the volume is rejected because of expiration date, security protection, checkpoint data set protection, or an I/O error.

When the volume serial is dequeued, the volume becomes available for allocation to another job. However, because the volume DEQ is performed without deallocating the volume, care must be exercised both by the authorized program and the installation to prevent misuse of the DEQ at demount facility. A discussion of such misuse follows:

- The authorized program must not close and reopen the data set using the tape volume DEQ at demount facility, if it does, one of the following can occur:
  - The dequeued volume can be mounted and in use by another job. When the volume is requested for mounting, for the authorized program, the operator is unable to satisfy the mount. Therefore, the operator must either cancel the requesting job, cancel the job using the volume, wait for the requesting job to time out, or wait for the job using the volume to terminate.
  - The dequeued volume can be allocated to another job, but not yet in use. The operator mounts the volume to satisfy the mount request of the authorized job. When the volume is requested for mounting by the other job, the operator is unable to satisfy the mount request, and is faced with the same choices as in the previous item.
  - The dequeued volume can not yet be allocated to another job and the volume is mounted to satisfy the mount request of the authorized job. Another job can allocate the volume and, when the volume is requested for mounting, the situation is the same as in the previous item.

It is the responsibility of the installation that permits a program to run with APF authorization to ensure that it does not close and reopen a data set using the DEQ at demount facility.

- Care should be exercised when an authorized program uses the DEQ at demount facility (data set 1), but processes another tape data set (data set 2). Assume the same volume serial numbers have been coded in the DD statements for data set 1 and data set 2. As the volumes of data set 1 are demounted, they are dequeued even though those volumes still might be requested for data set 2. All the problems explained in the preceding list can occur as data set 2 and another job contend for a dequeued volume.

This problem should not occur, given the intended use of the DEQ at demount facility; that is, a long-running application creating an indefinitely long tape data set. This type of application is not normally invoked through batch execution with user-written DD statements.

- After a volume has been demounted and dequeued because of the DEQ at demount facility, the volume is not automatically rejected by the control program when mounted in response to a specific or nonspecific mount request. Without the use of the facility, the control program can recognize (by the ENQ) that the volume is in use, and reject the volume. Therefore, operations procedures, in effect to prevent incorrect volumes from being mounted, should be reviewed in
the light of reduced control program protection from such errors when the DEQ at demount facility is used. Specifically, if a volume is remounted for an authorized program and the volume had been used previously by that authorized program, duplicate volume serial numbers will exist in the JFCB, and the control program will be unable to release the volume during EOV processing.

- Checkpoint/restart considerations are discussed in [z/OS DFSMShsm](https://www.ibm.com). Checkpoint/Restart.

### High-Speed Cartridge Tape Positioning

High-speed positioning for cartridge tape is available when opening a tape data set on an IBM standard-labeled tape for either EXTEND (OUTINX, EXTEND, or DISP=MOD). High-speed positioning is also available when opening to the beginning of such a data set. To invoke high-speed positioning, your program must modify certain fields in the JFCB and use OPEN TYPE=J to open the data set. When you write or read on an IBM 3590 Model A60 at the right hardware level it is not important to use the procedure described here. The magnetic tape subsystem gives these performance benefits automatically. This procedure will not degrade performance.

**Tip:** On an IBM 3480, IBM 3490, or older models of IBM 3590, this technique offers significantly better performance than the technique for setting the data set sequence number. In addition, systems with DFSMSrmm use this faster technique automatically for all cartridge tapes. For the IBM 3590 Model A60, both techniques give high performance.

Use the following procedure to modify the JFCB:

1. Issue the RDJFCB macro to have the system move the JFCB into your work area.
2. Set the JFCPOSID flag in the JFCBFLG3 flag byte to indicate that you are providing a block ID for a high-speed search.
3. Move the block ID into the JFCRBIDO field of the JFCB. If you are opening to the beginning of a data set, use the block ID of the first header label record of that data set. If you are opening to the end of a data set (for example, to extend it), use the block ID of the tape mark immediately following the last block of user data in that data set.
4. Issue the OPEN TYPE=J macro to have the system use your modified JFCB.

After the tape is positioned, OPEN processes the trailer labels for the data set being extended.

If you set the JFCPOSID flag off, OPEN positions the volume normally, as though the high-speed positioning feature were not active.

If you set the JFCPOSID flag on, but do not provide a block ID in the JFCRBIDO field, OPEN positions the volume normally and does one of the following:

- If you are opening to the beginning of a data set, OPEN inserts the block ID of the first header label record of that data set into the JFCRBIDO field.
- If you are opening to the end of the data set, OPEN inserts the block ID of the tape mark immediately following the last block of user data for that data set into the JFCRBIDO field.

OPEN does not update your copy of the JFCB. To retrieve the new value in the system's copy of the JFCB, issue RDJFCB after OPEN.
If the JFCPOSID flag is on during CLOSE processing, (because you set it on before OPEN), CLOSE inserts the block ID for the first header label record of the next data set (which might not exist) into the JFCRBIDC field. Therefore, if you unallocate the cartridge tape device and want to use the current block ID for subsequent processing, save the block ID before you close the data set.

OPEN resets the JFCPOSID flag if any one of the following conditions exists:

• Your program issues an OPEN which is not TYPE=J
• The requested tape volume is not an IBM standard-labeled volume
• The requested unit is not a buffered tape device.

Exceptions:

1. If you specify dynamic deallocation (with SVC99, FREE=CLOSE on the DD statement, or the FREE option on the CLOSE macro), the block ID for the next data set will not be available to your program.

2. When using high-speed positioning, specify the data set sequence number normally, either explicitly by LABEL=(seqno,SL) on the DD statement, or by default.

After the system routines have used the JFCRBIDO field for high-speed positioning, they clear JFCRBIDO in the system's copy of the JFCB to prevent misinterpretation during a subsequent OPEN.

**OPEN - Initialize Data Control Block for Processing the JFCB**

The OPEN macro instruction initializes one or more data control blocks (DCBs) so that their associated data sets can be processed.

A full explanation of the operands of the OPEN macro instruction is contained in the publication [*z/OS DFSMS Macro Instructions for Data Sets*]. The TYPE=J option, because it is used in conjunction with modifying a JFCB, should be used only by the system programmer or under the system programmer’s supervision.

The format of the OPEN TYPE=J macro is:
**System Macros**

```
OPEN (dcb_addr), TYPE=J
```

**option1:**

- `INPUT`
- `EXTEND`
- `OUTPUT`
- `INOUT`
- `OUTIN`
- `OUTINX`
- `RDBACK`
- `UPDAT`

**option2:**

- `DISP`
- `LEAVE`
- `REREAD`
- `REWIND`

**Tip:** If you wish to have multiple DCBs with or without options, code each DCB (and options) as shown in the diagram and precede each additional DCB with a comma.

---

```
OPEN (DCB1), TYPE=J
OPEN (DCB1, INPUT), TYPE=J
OPEN (DCB1, (INPUT)), TYPE=J
OPEN (DCB1, (INPUT, REREAD)), TYPE=J
OPEN (DCB1, DCB2), TYPE=J
OPEN (DCB1, DCB2, (INPUT, REREAD), DCB3, INPUT), TYPE=J
```

**Figure 27. Examples of Standard Form of the OPEN TYPE=J Macro**

**TYPE=J**

Specifies that, for each DCB referred to, you have supplied a job file control block (JFCB) to be used during initialization. A JFCB is an internal representation of information in a DD statement.

During initialization of a data control block, its associated JFCB can be modified with information from the DCB or an existing data set label or with system control information.

When the TYPE=J operand is specified, also supply a DD statement. However, the amount of information that is given in the DD statement is at your discretion, because you can modify many fields of the system-created JFCB. If you specify DUMMY on your DD statement, the open routine ignores the JFCB DSNAME and opens the data set as dummy. (See Figure 24 on page 278 for an example of coding that modifies a
The DD statement must specify at least the device allocation (see z/OS MVS JCL User's Guide for methods of preventing share status) and a ddname corresponding to the associated DCB DCBDDNAM field.

The MODE operand is not shown here because it is not allowed with the TYPE=J operand of the OPEN macro instruction.

Since OPEN with TYPE=J does not accept a JFCBX from the caller, you cannot change volume serials after the first five volumes.

OPEN TYPE=J will not change the volume attributes (PRIVATE, PUBLIC, or STORAGE) which are assigned to the volume during allocation. For example, if a volume status of PRIVATE is needed but allocation is going to assign a status of PUBLIC, then VOL=PRIVATE should be specified on the DD statement.

---

**Purging and Restoring I/O Requests**

The system's purge routines perform either a halt or a quiesce operation. In a halt operation, the purge routines stop the processing of specified I/O requests initiated with an EXCP or EXCPVR macro instruction. In a quiesce operation, the purge routines includes the following procedures:

- Allow the completion of I/O requests (initiated with an EXCP or EXCPVR macro instruction) that were passed to the system for execution and are executing
- Stop the processing of requests that have not yet been initiated or passed to the system, but save the IOBs of the requests so they can be reprocessed (restored) later.

The system's restore routines make it possible to reprocess I/O requests that are quiesced.

**Restriction:** Purge and restore processing performed for I/O requests that are not initiated by an EXCP or EXCPVR macro is not covered here. User applications that use the PURGE and RESTORE macros with the sequential access method (SAM) against partitioned data sets (PDSs) (for example, to synchronize the I/O) cannot do so against PDSEs, sequential extended format data sets, or z/OS UNIX files, because SAM does not use EXCP or EXCPVR to access these types of data.

To pass control to the purge and restore routines, build a parameter list and place its address in register 1, then issue the macro instruction.

24-bit or 31-bit addressing mode can be used for the PURGE or RESTORE macro (and the parameter list).

**PURGE Macro Specification**

The PURGE macro is used to halt or finish I/O requests.

Refer to "General-Use Mapping Macros" in z/OS MVS Programming: Authorized Assembler Services Reference ALE-DYN for information about using the 31-bit interface provided by the PURGE function.

The format of the PURGE macro is:
The format and contents of the parameter list are as follows:

<table>
<thead>
<tr>
<th>Byte</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A byte that specifies the actions of the purge routines. The bit settings and their meanings are:</td>
</tr>
<tr>
<td></td>
<td>1... .... Purge I/O requests to a single data set. The setting of this bit only takes effect if bit 2 of byte 12 is 0 and bit 6 of byte 0 is 0.</td>
</tr>
<tr>
<td></td>
<td>0... .... Either purge I/O requests associated with a TCB or address space, or purge I/O requests to more than one data set. If bit 2 of byte 12 is 1, then the request is to purge I/O associated with an address space. If bit 2 of byte 12 is 0 and bit 6 of byte 0 is 1, then the request is to purge I/O associated with a TCB. If bit 2 of byte 12 is 0 and bit 6 of byte 0 is 0, then the request is to purge I/O to more than one data set.</td>
</tr>
<tr>
<td></td>
<td>.1.. .... Post ECBs associated with purged I/O requests.</td>
</tr>
<tr>
<td></td>
<td>..1. .... Halt I/O-request processing. (Quiesce I/O-request processing, if 0.)</td>
</tr>
<tr>
<td></td>
<td>...1 .... Purge related requests. (Only valid if a data-set purge is requested.)</td>
</tr>
<tr>
<td></td>
<td>.... 0... Reserved—must be zero.</td>
</tr>
<tr>
<td></td>
<td>.... .1.. Do not purge the TCB request-block chain of asynchronously scheduled processing.</td>
</tr>
<tr>
<td></td>
<td>.... ..1. Purge I/O requests associated with a TCB. The setting of this bit will only take affect if bit 2 of byte 12 is 0.</td>
</tr>
<tr>
<td></td>
<td>.... ...1 This is a 16-byte parameter list. Additional purge options are specified in bytes 12 to 15. (If this bit is off, the list is 12 bytes long, and the purge routines do not put a return code in byte 4 of this list or in register 15.)</td>
</tr>
<tr>
<td>1,2,3</td>
<td>The address of a DEB when purging I/O requests to a single data set. The address of the first DEB in a chain of DEBs when purging I/O requests to more than one data set. (The next-to-the-last word of each DEB must point to the next DEB in the chain; the second word of the last DEB must contain zeros.)</td>
</tr>
<tr>
<td>4</td>
<td>A byte of zeros. (If bit 7 of byte 0 is on, the purge routines will put a code in byte: X'7F' when the purge operation is successful; X'40' when it is not successful. If bit 7 of byte 0 is off, then X'7F' appears in this byte.)</td>
</tr>
</tbody>
</table>
If you turned on bit 6 of byte 0, the address of the TCB associated with the I/O requests you want purged. Will be zeros if the TCB is the one you are running under.

Value of X'00' or X'02' means that EXCP is the owner.

The address of a word in storage or the address of the DEBUSPRG field (that is X'11' bytes more than the DEB address in this parameter list). At the address you specify, the purge routines store a pointer to the purged I/O restore list, that in turn contains a pointer to the first IOB in the chain of IOBs. The location of the pointer and format of the chain are shown in Figure 28 on page 296.

Note: This field is only relevant for quiesce options.

A byte that allows you to specify additional purge options. The bit settings and their meanings are:

Note: The following applies only if bit 7 of byte 0 is set to 1.

...1 .... Purge I/O requests associated with an address space. (Your program must be in supervisor state.) The setting of this bit will take affect regardless of the setting of bit 6 of byte 0 and bit 0 of byte 0.

...1 .... If this is a data-set purge, check the validity of all the DEBs associated with the purge operation. Validate this parameter list, whatever the type of purge operation, by ensuring that there are no inconsistencies in the selection of purge options. (If your program is in problem state, these actions are taken regardless of the bit setting.)

.... 1... Ensure that I/O requests will be reprocessed (restored) under their original TCB. (If zero, and bit 7 of byte 0 is on, the I/O requests are reprocessed under the TCB of the program making the restore request.)

.... .0. Must be zero.

A byte of zeros.

If bit 2 of byte 12 is on, the 2-byte ID of the address space associated with the I/O requests you want purged.

Control is returned to your program at the instruction following the PURGE macro instruction.

**Return Codes from PURGE**

If the purge operation was successful, register 15 contains zeros. Otherwise, register 15 contains one of the following return codes:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 (X'04')</td>
<td>Your request to purge I/O requests associated with a given TCB was not honored because that TCB did not point to the job step TCB, while the requester is in problem state.</td>
</tr>
</tbody>
</table>
### System Macros

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 (X'08')</td>
<td>Either you requested an address-space purge operation, but were not in supervisor state, or you requested a data set purge operation, but failed to supply a DEB address in bytes 1, 2, and 3 of the purge parameter list.</td>
</tr>
<tr>
<td>20 (X'14')</td>
<td>Another purge request has preempted your request. You might want to reissue your purge request in a time-controlled loop.</td>
</tr>
</tbody>
</table>

**Exception:** If you set bit 7 in byte 0 of the parameter list to zero, register 15 will contain zeros, regardless of the outcome of the purge operation.

### Modifying the IOB Chain

This procedure is not recommended. However, to change the order in which purged I/O requests are restored or prevent a purged request from being restored, you can change the sequence of IOBs in the IOB chain or remove an IOB from the chain. The address of the IOB chain can be obtained from the purge I/O restore list (see Figure 28). (The address of the purge I/O restore list is shown at bytes 9 through 11 of the purge parameter list.) Note that some IOBs could be in a different protection key.

**Figure 28. The IOB Chain**

**RESTORE Macro Specification**

The RESTORE macro is used to reprocess I/O requests.
The format of the RESTORE macro is:

```
/SM590000/SM590000
RESTORE
restore_address
/SM590000/SM630000
```

`restore_address`—RX-type address, (2-12) or (1)
Address that you specified at byte 9 of the purge parameter list. See 295 for information about byte 9.

Performing Track Calculations (TRKCALC macro)

The TRKCALC macro performs DASD track capacity calculations. This macro is intended for EXCP applications and other advanced applications. You can use TRKCALC to determine:

- The number of equal-length records that can be written on a track
- The total track capacity
- Whether a record can be written in the space remaining on a track and return the new track balance
- What the track balance would be if the last record were removed from a track
- The length of the longest possible record that can be written to a track.

The TRKCALC routine issues no SVC instructions or I/O. TRKCALC can be called in an SRB routine or in TCB mode. It can be called in 24-bit or 31-bit addressing mode and in supervisor or problem state.

TRKCALC works equally well for any track. It does not use the address of the track.

Using TRKCALC

This information provides an overview of how to use TRKCALC to accomplish various tasks. See “TRKCALC Macro Specification” on page 298 for details on how to code the TRKCALC parameters and on how output is returned.

Determining the number of equal-length records that can be written on a track

To determine the number of equal-length records that can be written on a track, code TRKCALC with FUNCTN=TRKCAP. You must specify the number of existing records on the track and the key and data length of the new records (using either the R, K, and DD keywords or the R, K, and DD bytes in the RKDD parameter).

If you wish to regard the track as being empty, specify an R value of 1. Otherwise, specify an R value that is one greater than the number of existing records on the track.

If the length of any existing record differs from the length of the new records (as specified in the DD value), then code the BALANCE parameter. Otherwise, omit the BALANCE parameter.

Determining the total track capacity

To determine the total track capacity, code

```
FUNCTN=TRKBAL, REMOVE=YES
```
and either R=1 or the R byte in RKDD set to 1.

**Note:** This value is useful only as input for the BALANCE parameter on later calls to TRKCALC to represent an empty track. You cannot write a record of this size.

**Determine whether a record can be written in the space remaining on a track and return the new track balance**

To determine whether a record can be written in the space remaining on the track and return the new track balance, code

```
FUNCTN=TRKBAL, REMOVE=NO
```

and the BALANCE parameter. You can supply this new track balance with the BALANCE parameter on a later call to TRKCALC.

**Determine the track balance if the last record were removed from a track**

To determine what the track balance would be if the last record were removed from the track, code `FUNCTN=TRKBAL` and `REMOVE=YES`. Use the R, K and DD parameters or the RKDD parameter to identify the record to be removed. It must be the last record on the track.

**Determine the length of the longest possible record that can be written on a track**

To determine the length of the longest possible record that can be written on a track, code `FUNCTN=TRKBAL`, `REMOVE=NO`, `MAXSIZE=YES`. You must specify the number of existing records on the track (using either the R keyword or the RKDD parameter) and a data length of `X'FFFF'` (using either the DD keyword or the RKDD parameter). The DD value of `X'FFFF'` is greater than is supported on any disk. Expect a return code 8, which means that the record does not fit and TRKCALC returned the size of the largest possible record.

If you wish to regard the track as being empty, specify an R value of 1.

If the track is not empty, specify an R value that is one greater than the number of existing records on the track and code the BALANCE parameter. In this case, TRKCALC will give return code 8 and the length of the longest possible record that will fit on the rest of the track.

**Note:** The value returned might be larger than what is supported by any access method other than EXCP.

**Restrictions**

Non-EXCP user applications cannot expect consistent information from TRKCALC for PDSEs, because of the unique structure and format of PDSEs. However, processing will complete without error indications.

TRKCALC does not support z/OS UNIX files. You will receive unpredictable results if you use TRKCALC for z/OS UNIX files.

**TRKCALC Macro Specification**

The standard, list, execute, and DSECT forms of the macro are described. Examples of the TRKCALC macro follow the macro descriptions.
System Macros

TRKCALC—Standard Form

The format of the TRKCALC macro is:

```
listname TRKCALC

TRKCALC
  FUNCTN=TRKBAL
  DEVTAB=addr
  UCB=addr
  TYPE=addr
  ,BALANCE=addr
  ,LOC=ANY
  ,REMOVE=NO
  ,MAXSIZE=YES
  ,RKDD=addr
  ,R=addr
  ,K=addr
  ,DD=addr
  ,REGSAVE=YES
  ,MF=I
```

**FUNCTN=TRKBAL or TRKCAP**

Specifies the function to be performed. Specify one of the three keywords, DEVTAB, UCB, or TYPE, to provide the information source for the macro.

**TRKBAL**

If REMOVE=NO is specified, TRKBAL calculates whether an additional record fits on the track and what the new track balance would be if the record were added. If REMOVE=YES is specified, TRKBAL calculates what the track balance would be if a record were removed from the track. The record to be added or removed from the track is defined by the RKDD parameter, or by the R, K, and DD parameters.

If R is equal to 1 (or the R value in the RKDD parameter is 1) and REMOVE=NO is specified, TRKCALC will treat record 1 as if it were being added to an empty track; if R is equal to 1 and REMOVE=YES is specified, TRKCALC will treat record 1 as if it were being deleted from the track, leaving an empty track.

If R is not equal to 1, the specified record is added to or removed from the track. If the input track balance is not supplied through the BALANCE parameter, it is assumed that the track contains equal-sized records as specified in the RKDD parameter (or in the R, K, and DD parameters).

When REMOVE=NO is specified, one of the following occurs:

- If the record fits on the track, register 0 contains the new track balance.
- If the record does not fit on the track and MAXSIZE=NO is specified, a record does not fit return code is placed in register 15.
If the record does not fit and MAXSIZE=YES is specified, one of the following happens:

- The data length of the largest record that fits in the remaining space is returned in register 0.
- A code is returned that indicates no record fits in the remaining space.

When REMOVE=YES is specified, one of the following occurs:

- If R is equal to 1, register 0 contains the track capacity.
- If R is not equal to 1, registers 0 contains the input track balance (supplied through the BALANCE parameter) incremented by the track balance used by the input record. If the input balance is not supplied, register 0 contains the track capacity left after R–1 records are written on the track.

**TRKCAP**

Calculates, and returns in register 0, the number of fixed-length records that can be written on a whole track (R is equal to 1) or on a partially-filled track (R is not equal to 1). The records are defined by the K and DD values of the RKDD parameter, or by the K and DD parameters.

Depending on the value for R, one of the following occurs:

- If R is equal to 1, TRKCALC ignores the BALANCE parameter and makes the calculation as if the track were empty.
- If R is not equal to 1 and the BALANCE parameter is omitted, the calculation is made for a track that already contains R–1 records of the length defined by the K and DD values.
- If R is not equal to 1 and the BALANCE parameter is supplied, the calculation is made for a track whose remaining track balance is the value of the BALANCE parameter.

**DEVTAB=** addr—RX-type address, (2-12), (0), (14)

addr specifies a word that contains the address of the device characteristics table entry (DCTE). If you specify a register, it contains the actual address of the DCTE. The address of the DCTE can be found in the word beginning at the DCBDVTBL field of an opened DCB.

**UCB=** addr—RX-type address, (2-12), (0), (14)

addr specifies the address of a word that contains the address of the UCB. If you specify a register, it contains the actual address of the UCB.

The TRKCALC macro accepts the address of a UCB or UCB copy. Unauthorized programs can get a copy of the UCB by using the UCBSCAN macro and specifying the COPY and UCBAREA keywords. See z/OS HCD Planning for more information.

**TYPE=** addr—RX-type address, (2-12), (0), (14)

You can specify the address of the UCB device type (UCBTBYT4), or you can specify the 1-byte UCB device type in the low-order byte of a register.
System Macros

LOC=BEL O W or ANY
Optional parameter indicating whether the value passed by the UCB parameter is a 4-byte or a 3-byte address. This parameter only applies to callers running in AMODE 31. If the caller is running in AMODE 24, this parameter is ignored and the high-order byte is treated as X'00'.

BELOW The UCB parameter contains a UCB address for a UCB which resides in storage below 16 megabytes, or a captured UCB. This is the default.
If LOC=BEL OW is specified, the high-order byte of the UCB address will be treated as X'00'.

ANY The address passed in the UCB parameter contains a 3-byte or 4-byte UCB address.
If LOC=ANY is specified when invoking in 31-bit mode, TRKCALC will treat the UCB address as a 31-bit address.

BALANCE=addr—RX-type address, (2-12), (0), (14)
You can specify either the address of a halfword containing the current track balance, or you can specify the balance in the low-order two bytes of a register. The value supplied could be the value returned when you last issued TRKCALC. If R is equal to 1, the balance is reset to track capacity by TRKCALC, and your supplied value is ignored. This is an input value and is not modified by the TRKCALC macro. The resulting track balance is returned in register 0 and in the TRKCALC parameter list field STAR BAL. The value you supply for this parameter must be a valid value for the device type in use.

REMOVE=YES or NO
Indicates if a record is to be deleted from the track.
YES Specifies that the record identified by the record number (specified in the R keyword) is being deleted from the track. The track balance is incremented instead of decremented.
YES is valid only on a FUNCTN=TRKBAL call.
NO Specifies that a record is not to be deleted from the track. NO is the default.

MAXSIZE=YES or NO
YES If the specified record does not fit, the largest length of a record with the specified key length that fits is returned (register 0).
YES is valid only on a FUNCTN=TRKBAL call.
NO Maximum size is not returned. NO is the default.

RKDD=addr—RX-type address, (2-12), (0), (14)
addr specifies a word containing a record number (1 byte), key length (1 byte), and data length (2 bytes) (bytes 0, 1, and 2 and 3, respectively) or a register containing the record number, key length, and data length. R, K, and DD can be specified by this keyword, or you can use the following three keywords instead.

R=addr—RX-type address, (2-12), (0), (14), or n
You can specify either the address of the record number, or you
can specify the record number using the low-order byte of a register or immediate data (n). Specify a decimal digit for n (immediate data).

\[ K = \text{addr} \text{— RX-type address, (2-12), (0), (14), or n} \]

You can specify either the address of a field containing the hexadecimal value of the record's key length, or you can specify the record's key length using the low-order byte of a register or immediate data (n). Specify a decimal digit for n (immediate data).

\[ DD = \text{addr} \text{— RX-type address, (2-12), (0), (14), or n} \]

You can specify either the address of a field containing the hexadecimal value of the record's data length, or you can specify the record's data length using the low-order two bytes of a register or immediate data (n). Specify a decimal digit for n (immediate data).

\[ \text{REGSAVE=} \text{YES or NO} \]

Specifies whether registers are to be saved.

- **YES**: Specifies registers 1 through 14 are saved and restored in the caller-provided save area (pointed to by register 13) across the TRKCALC call. Otherwise, registers 1, 9, 10, 11, and 14 are modified. Registers 0 and 15 are always modified by a TRKCALC call.
- **NO**: Specifies registers are not saved across a TRKCALC call. NO is the default.

\[ \text{MF=} \text{I} \]

 Specifies storage definition for the TRKCALC parameter list and parameter list initialization, using the given keywords, then calling the TRKCALC function. MF=I is the default.

**TRKCALC—Execute Form**

A remote parameter list is referred to and can be modified by the execute form of the TRKCALC macro. The TRKCALC routine is called. The function of the operands is the same as for the standard form.

The format of the execute form of the TRKCALC macro is:
The TRKCALC macro accepts the address of a UCB or UCB copy. Unauthorized programs can get a copy of the UCB by using the UCBSCAN macro and specifying the COPY and UCBAREA keywords. See z/OS HCD Planning for more information.

**FUNCTN=TRKBAL or TRKCAP**

Is coded as shown in the standard form. If this keyword is omitted, any specification of REMOVE, MAXSIZE, LAST, and the RX form of BALANCE is ignored. In addition, DEVTAB is assumed if UCB is coded and a failure occurs, or if TYPE is specified. When you use FUNCTN, one of the keywords (DEVTAB, UCB, or TYPE) must be specified to provide an information source.

**DEVTAB=addr or =*-RX-type address, (2-12), (8), (14)**

Is coded as shown in the standard form except for the * subparameter. Specify an * when you have inserted the address of the device characteristics table entry (DCTE) in the parameter list.

**UCB=addr or =*-RX-type address, (2-12), (8), (14)**

Is coded as shown in the standard form except for the * subparameter. Specify an * when you have inserted the address of the UCB in the parameter list.

**TYPE=addr or =*-RX-type address, (2-12), (8), (14)**

Is coded as shown in the standard form except for the * subparameter. Specify an * when you have inserted the address of the UCB type (UCBTYP) in the parameter list.

**LOC=BELOW or ANY**

Is coded as shown in the standard form.

**BALANCE=addr or =*-RX-type address, (2-12), (8), (14)**

Is coded as shown in the standard form except for the * subparameter. Specify an * when you have inserted the balance in the parameter list.

**REMOVE=YES or NO**

Is coded as shown in the standard form.
System Macros

MAXSIZE=YES or NO
Is coded as shown in the standard form.

RKDD=addr—RX-type address, (2-12), (0), (14)
Is coded as shown in the standard form.

R=addr—RX-type address, (2-12), (0), (14) or n
Is coded as shown in the standard form.

K=addr—RX-type address, (2-12), (0), (14), or n
Is coded as shown in the standard form.

DD=addr—RX-type address, (2-12), (0), (14), or n
Is coded as shown in the standard form.

REGSAVE=YES or NO
Is coded as shown in the standard form.

MF=(E, addr)
This operand specifies that the execute form of the TRKCALC macro instruction and an existing data management parameter list are used.

E Coded as shown.

addr—RX-type address, (0), (1), (2-12), or (14)
Specifies the address of the parameter list.

TRKCALC—List Form
The list form of the TRKCALC macro constructs an empty, in-line parameter list. By coding only MF=L, you construct a parameter list, and the actual values can be supplied by the execute form of the TRKCALC macro. Any parameters other than MF=L are ignored.

The format of the list form of the TRKCALC macro is:

```
lbl TRKCALC MF=L
```

TRKCALC—DSECT Only
This call gives a symbolic expansion of the parameter list for the TRKCALC macro. No DSECT statement is generated. If a name is specified on the macro call, it applies, after any necessary boundary alignment, to the beginning of the list. The macro-generated symbols all begin with the characters STAR.

The format of the DSECT form of the TRKCALC macro is:

```
lbl TRKCALC MF=D
```

Input Register Usage for All Forms of MF

<table>
<thead>
<tr>
<th>Register</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 2-12, 14</td>
<td>Available to provide input for keywords.</td>
</tr>
</tbody>
</table>
System Macros

1. Only to provide the address of the parameter list for an MF=E call.

13. Input for keywords if REGSAVE=YES is not specified.

15. Work register to build the TRKCALC parameter list for the MF=E call; it is not available as an input register.

Output from TRKCALC

**FUNCTN=TRKBAL:**

<table>
<thead>
<tr>
<th>Output</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>R15=X'00'</td>
<td>The record fits on the track. Register 0 and STARBAL contain the new track balance.</td>
</tr>
<tr>
<td>R15=X'04'</td>
<td>Record does not fit on the track. If MAXSIZE=YES is specified, a partial record does not fit either. Register 0 and STARBAL are set to zero.</td>
</tr>
<tr>
<td>R15=X'08'</td>
<td>Record does not fit on the track. MAXSIZE=YES is specified, and a partial record does fit. Register 0 and STARBAL are set to the maximum number of data bytes that fit on the remainder of the track with the specified key length. The key length is excluded from the count of maximum data bytes.</td>
</tr>
<tr>
<td>R15=X'0C'</td>
<td>The user supplied a device type, but the device characteristics table indicated that no device of that type was generated on the system. Register 0 is set to zero.</td>
</tr>
</tbody>
</table>

**STARBAL**

This is the track balance field of the TRKCALC parameter list. This field is first set to the track capacity if R is equal to 1, or to the supplied BALANCE value if R is not equal to 1, or to the calculated balance if R is not equal to 1 and BALANCE are omitted. STARBAL is updated to the new track balance if the record fits; otherwise, STARBAL is left with the input track balance value.

**FUNCTN=TRKCAP :**

<table>
<thead>
<tr>
<th>Output</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>R15=X'00'</td>
<td>Register 0 contains the number of records that fit on the track if R is equal to 1, or the number of records that fit on the remainder of the track if R is not equal to 1.</td>
</tr>
<tr>
<td>R15=X'04'</td>
<td>No records of the length specified fit on a full track (R is equal to 1) or a partial track (R is not equal to 1). Register 0 is set to zero.</td>
</tr>
<tr>
<td>R15=X'0C'</td>
<td>The user supplied a device type, but the device characteristics table indicated that no device of that type was generated on the system. Register 0 is set to zero.</td>
</tr>
</tbody>
</table>

**STARBAL**

This is the track balance field of the TRKCALC parameter list. This field is first set to the track capacity if R is equal to 1, or to the supplied BALANCE value if R is not equal to 1, or to the calculated balance if R is not equal to 1 and BALANCE is omitted. STARBAL is updated to the new track balance if the record fits; otherwise, STARBAL is left with the input track balance value.
when the request specified MAXSIZE=NO or was defaulted to MAXSIZE=NO. If the record does not fit on the track with MAXSIZE=YES specified, STARBAL is set to the maximum number of data bytes of a partial record that can fit on the remainder of the track with the specified key length (Register 15 set to 8) or STARBAL is set to zero when a partial record could not fit on the remainder of the track (Register 15 set to 4).

Return Codes from TRKCALC
The TRKCALC macro passes a return code in register 15. The return codes and their meanings are as follows:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>Indicates that register 0 contains the new track balance.</td>
</tr>
<tr>
<td>4 (X'04')</td>
<td>Indicates that the record did not fit (register 0 = 0).</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>Indicates that the record did not fit. (Register 0 contains the maximum data length that does fit.)</td>
</tr>
<tr>
<td>12 (X'0C')</td>
<td>The system could not find an entry in the device characteristics table whose attributes match those of the user-specified device type. Register 0 is set to zero.</td>
</tr>
</tbody>
</table>

TRKCALC Macro Examples
In this example, TRKCALC is coded to determine how many records of a given size with 10-byte keys fit on an IBM 3380 track. After issuing the macro, the number of records is saved in NUMREC:

```assembler
TRKCALC FUNCTN=TRKCAP,TYPE=UTYPE,R=1,K=10,DD=DL, X
   MF=(E,(1))
   .
   ST 0,NUMREC SAVE NUMBER OF RECORDS
   .
DL DC H'xxxx' DATA LENGTH
UTYPE DC X'0E'
NUMREC DS F MAX # OF RECORDS
```

In this example, TRKCALC is coded to determine whether another record can fit on a track of a 3380, given a track balance.

```assembler
TRKCALC FUNCTN=TRKBAL,TYPE=UTYPE,R=REC,K=KL,DD=DD, X
   BALANCE=BAL,MAXSIZE=YES,MF=(E,(1))
   .
UTYPE DC X'0E'
REC DC X'xx'
KL DC X'xx'
DD DC H'xxxx'
BAL DC H'xxxx'
```

Perform calculations and conversions with 28-bit cylinder addresses (TRKADDR macro)

TRKADDR is an assembler macro that performs conversion and compare operations on DASD track addresses in the form CCCCcccH, where CCCC is the 16 low order bits of the cylinder number and ccc is the 12 high order bits of the cylinder number. This is referred to as a 28-bit cylinder address. TRKADDR works
equally well with track addresses that contain a cylinder number less than or
greater than 16 bits. It works with all DASD types that are supported by z/OS. Its
functions include:
• Calculate the relative track number on the volume
• Compare two track addresses
• Extract the 28-bit cylinder number
• Extract the 4-bit track number
• Increment the track address by one track and increments the cylinder number if
  necessary.
• Normalize cylinder number to permit comparing one cchh against another
• Convert a relative track number to a 28-bit cylinder address
• Set the cylinder number in a 28-bit track address
• Convert a normalized track address into an absolute 28-bit track address.

Unless otherwise stated, you can specify any registers from 0 to 15 except that
register 0 cannot be used to address storage. TRKADDR does not use any other
registers, even register 13. You can invoke TRKADDR in 24-bit, 31-bit or 64-bit
mode. If you use the SYSSSTATE macro with AMODE64=YES in an earlier source
code statement, then TRKADDR might generate more efficient code.

Calculate the relative track number on the volume (TRKADDR
ABSTOREL)

The format of the execute form of the TRKADDR ABSTOREL macro is:

```
TRKADDR ABSTOREL label, cchh, (reg), REG=(rega, regb)
```

Converts absolute track address (CCCCcccH) to a relative track number. Calculates
the relative track number on the volume and stores the result in the first register.
The second register is used as a work register.

Parameters

- **cchh**
  Input: Track address in absolute format

- **(reg)**
  This is a register from 1 to 15 containing the address of the cchh.

- **rega**
  Output: Relative track number

- **regb**
  Work register

Compare two track addresses (TRKADDR COMPARE)

The format of the execute form of the TRKADDR COMPARE macro is:
System Macros

Compares two track addresses in storage using the two registers as work registers. Sets condition code as for CLC machine instruction. Normalizes the two input values (CCCCcccH to cccCCCCH) and then compares the two normalized values. The input values are returned unchanged.

Parameters

cchh1 and cchh2
Input: Track addresses in absolute format to be compared. These value are returned unchanged.

(reg1) and (reg2)
This is a register from 1 to 15 containing the address of the cchh.

rega, regb
Work registers

Extract 28-bit cylinder number (TRKADDR EXTRACTCYL)
The format of the execute form of the TRKADDR EXTRACTCYL macro is:

Extracts the 28-bit cylinder number to a register (CCCCcccH to 0cccCCCC). The input field is returned unchanged.

Parameters

cchh
Input: Track address in absolute format

(reg)
This is a register from 1 to 15 containing the address of the cchh.

rega
Output: Cylinder number from the input track address

Extract 4-bit track number (TRKADDR EXTRACTTRK)
The format of the execute form of the TRKADDR EXTRACTTRK macro is:

Extracts the 4-bit track number to a register (CCCCcccH to 0000000H). The input field is returned unchanged.
Parameters

\textit{cchh}

Input: Track address in absolute format

\textit{(reg)}

This is a register from 1 to 15 containing the address of the \textit{cchh}.

\textit{rega}

Output: Track number from the input track address

**Increment track address (TRKADDR NEXTTRACK)**

The format of the execute form of the TRKADDR NEXTTRACK macro is:

\begin{verbatim}
//SM590000/SM590000
TRKADDR NEXTTRACK
label,
(cchh),
(reg),
REG=(rega)
//SM590000/SM630000
\end{verbatim}

Increments the track address by one track and increments the cylinder number if necessary. The modified value is returned in the input \textit{cchh} field. The register is used as a work register.

**Parameters**

\textit{cchh}

Input/Output: Track address in absolute format \(\text{CCCCcccH}\). Upon completion of the operation, this parameter contains the incremented track address in absolute format.

\textit{(reg)}

This is a register from 1 to 15 containing the address of the \textit{cchh}.

\textit{rega}

Work register

**Normalize cylinder number (TRKADDR NORMALIZE)**

The format of the execute form of the TRKADDR NORMALIZE macro is:

\begin{verbatim}
//SM590000/SM590000
TRKADDR NORMALIZE
label,
(cchh),
(reg),
REG=(rega)
//SM590000/SM630000
\end{verbatim}

Reverses the 16-bit and 12-bit portions of the cylinder number and stores the result in the 32-bit register with the H digit so you can use a simple unsigned comparison. The \text{CCCCcccH} becomes \text{cccCCCCH}. Use this when comparing one \textit{cchh} against another. Normalize each and do an unsigned comparison.

**Parameters**

\textit{cchh}

Input: Track address in absolute format.

\textit{(reg)}

This is a register from 1 to 15 containing the address of the \textit{cchh}.
System Macros

`rega`

Output: Normalized track address

**Convert a relative track number to a 28-bit cylinder address (TRKADDR RELTOABS)**

The format of the execute form of the TRKADDR RELTOABS macro is:

```
TRKADDR RELTOABS
label,
cch,
(reg)
```

Converts relative track number to absolute format (CCCCcccH). RELTOABS converts a relative track number to a 28-bit cylinder address form in the passed `cchh` field. The register must be the first in an even/odd pair. The odd register must contain the relative track number on the volume. The macro modifies both registers. In 24-bit and 31-bit addressing modes these are four-byte registers. In 64-bit mode, they are eight-byte registers.

**Parameters**

`cchh`

Output: Converted track address in absolute format.

`(reg)`

This is a register from 1 to 15 containing the address of the `cchh`.

`reg_pair`

Input: The first register of an even/odd pair where the odd register contains the track address to be converted.

**Set cylinder number from register (TRKADDR SETCYL)**

The format of the execute form of the TRKADDR SETCYL macro is:

```
TRKADDR SETCYL
label,
cch,
(reg)
```

Stores the cylinder number from the register to the 28-bits in the `cchh` and sets H to 0 (0cccCCCC to CCCCCccc0). Destroys the register.

**Parameters**

`cchh`

Output: Contains the cylinder number

`(reg)`

This is a register from 1 to 15 containing the address of the `cchh`.

`rega`

Input: Contains the cylinder number to be converted
Convert normalized track address into an absolute 28-bit track address (TRKADDR NORMTOABS)

The format of the execute form of the TRKADDR NORMTOABS macro is:

```
/SM590000/SM590000
TRKADDR NORMTOABS
label, cchh, (reg), REG=(rega, regb)
```

Reverses the 12-bit and 16-bit portions of the cylinder number and stores the result in the 32-bit register with the H digit. The cccCCCCH becomes CCCCcccH. Use this to convert a normalized track address to an absolute 28-bit track address.

**Parameters**

- **cchh**
  - Input: Cylinder address to be converted

- **(reg)**
  - This is a register from 1 to 15 containing the address of the cchh.

- **rega**
  - Output: Contains the converted value

- **regb**
  - Work register

**Determining Level and Name of DFSMS**

You can use the IHADFA mapping macro to determine the level and name of DFSMS. It maps the data facilities area. Use the CVT mapping macro to define symbol CVTDFA, which points to the DFA. The DFARELS field in the DFA is four bytes that designate the product level.

**Determining Version, Release, and Modification Level of DFSMS**

The first byte of DFARELS contains a binary value that indicates the level of DFSMS on which your program is running:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Your program is not executing on DFSMS; it is executing on MVS/XA DFP Version 2 or MVS/DFP Version 3 and the following three bytes also contain zeroes. On those two products you can determine the release level by examining the two-byte field DFAREL. DFAREL is described in the comments in IHADFA.</td>
</tr>
<tr>
<td>1</td>
<td>Your program is running on DFSMS/MVS and the following three bytes designate the version, release and modification level of DFSMS/MVS. A value of 'X'01010200' in DFARELS designates DFSMS/MVS Version 1, Release 2, Modification level 0.</td>
</tr>
<tr>
<td>2</td>
<td>Your program is running on the level of DFSMS that is exclusive to OS/390 or one of the first two releases of z/OS. A value of 'X'02020A00' in DFARELS designates DFSMS for OS/390 Version 2 Release 10, Modification level 0. DFSMS was not modified in the first two releases of z/OS, so these releases also have a value of 'X'02020A00'.</td>
</tr>
</tbody>
</table>
If the value of DFSMS is '03010300' or greater, it means the system is z/OS Version 1 Release 3.0 or later. This means that field DFAELNM points to a structure that contains the name of DFSMS. See DFAELNM in "Data Facilities Area (DFA) Fields" on page 439.

Determining Name of DFSMS

If the value of DFARELS is '03010300' or greater, it means the system is z/OS Version 1 Release 3.0 or later. This means that field DFAELNM points to a structure that contains the name of DFSMS. See DFAELNM in "Data Facilities Area (DFA) Fields" on page 439.

Determining DFARELS During Assembler Macro Phase

Your program can test the DFARELS field during execution as described earlier. This does not allow you to assemble a program that optionally uses a new macro parameter that is available only on a certain level of the system. Your program receives syntax error messages if assembled on an older level of the system.

A solution is to test a macro variable symbol set by the IHADFA macro. The name of the symbol is &IHADFARELS and it is a character type of global variable symbol. Your program's test of its value must follow the IHADFA invocation.

The other system facilities determine whether your program can run on a different release than the one on which it was assembled. For some new functions the older release will ignore the new function. Other new functions will fail on an older release.

The IHADFA macro sets the variable symbol &IHADFARELS to an eight-character value. Each pair of characters in the value represents the decimal value of one byte.
in D Farels. They are not hexadecimal digits because the EBCDIC values of "A" to "F" are not in proper collating sequence with the numeric digits. For example the value for z/OS Version 1 Release 10 is '03011000', '03' represent the name z/OS, '01' represents Version 1, '10' represents release 10, '00' represents modification level 0.

This is an example of a program using &IHADFARELS:

```
xxxx CSECT
  ...
  GBLC &IHADFARELS Set by IHADFA macro to be system level
  IHADFA , Set &IHADFARELS and define DFARELS
xxxx CSECT Reset CSECT
  ...

* Expand one of two macro invocations. Either works on any DFSMS
* release. If in 31-bit mode on 1.3 or later, then ANY means a UCB
* may be above the line. Neither works on DFP Version 3 when assembled
* on DFSMS.
  AIF ('&IHADFARELS' LT '01010300').OLD
  * If executing in 31-bit mode on 1.3 or later, this requires that each
  * UCB address be 31-bit. They may point below the line. On an older
  * level of DFSMS, the ANY has no effect. DFP 3.x will reject it.
  DEVTYPE UCBLIST=(MYLIST,1,ANY),MF=(E,DEVLIST)
  AGO .CONT
  .OLD DEVTYPE UCBLIST=(MYLIST,1),MF=(E,DEVLIST)
  .CONT ANOP

MYLIST DC A(0)
DEVLIST DEVTYPE ,(DEVINFO,24),MF=L
```

Figure 29. Sample &IHADFARELS Program

The IHADFA macro as shipped prior to DFSMS/MVS V1R3 did not set &IHADFARELS. You can use the technique in the example even if IHADFA does not set &IHADFARELS.

This technique of using IHADFA to decide on another macro invocation assumes that IHADFA resides in a complete macro library for the same release as the other macro. It might not work properly with a macro from a different release or product.

Following is an example of determining whether a mapping macro has defined a symbol that is needed during the assembly. During execution, the program tests D Farels to determine how to execute.
GBLC &IHADFARELS Set by IHADFA macro to be system level

Figure 30. Example of Determining Symbol Definition
Chapter 8. Displaying Messages on Cartridge Magnetic Tape Subsystems (MSGDISP macro)

This information covers using the MSGDISP macro to display messages on magnetic tape devices that have displays. With MSGDISP, you can specify the message to be displayed and how to display it (for example, steady or flashing). The standard, executes, and list forms of the macro are described here. The six main parameters of the macro and their functions are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOUNT</td>
<td>Displays an 'M' in position 1 of the display area during a mount request until a volume is loaded and made ready. The 'M' is followed by the volume serial number and label type.</td>
</tr>
<tr>
<td>VERIFY</td>
<td>Shows that a volume has been accepted by displaying its serial number and label type in positions 2 through 8.</td>
</tr>
<tr>
<td>RDY</td>
<td>Displays text in positions 2 through 7 while a data set is open.</td>
</tr>
<tr>
<td>DEMOUNT</td>
<td>Places a volume disposition indicator in position 1 of the display until a volume is demounted.</td>
</tr>
<tr>
<td>RESET</td>
<td>Clears the display area.</td>
</tr>
<tr>
<td>GEN</td>
<td>Provides the full range of display options, including the option to alternate two messages.</td>
</tr>
</tbody>
</table>

All except the RDY parameter require that the caller be in supervisor state, have a storage protect key of 0 through 7, or be authorized by the authorized program facility.

You can issue the MSGDISP macro in 24- or 31-bit addressing mode. When you use 31-bit addressing mode, all addresses must be valid 31-bit addresses.

The MSGDISP macro generates a parameter list as input to the message display service routine. You can code an installation exit routine named IGXMSGEX, which gains control when MSGDISP is processing MOUNT, DEMOUNT, VERIFY, or GEN requests. The exit can change the message text displayed (two 8-byte strings) and 1 bit of the format control byte. See the publication z/OS DFSMS Installation Exits for details.
MSGDISP—Displaying a Mount Message

The format of the MSGDISP macro with the MOUNT parameter is:

```
MSGDISP MOUNT, Label, UCB=(reg), LABEL='S', LABEL='A', LABEL='N', LABEL='X', addr,
MF=L, (E, addr), SER='volser', MEDIATYPE=n, INDEX=NO, TEST=YES, WAIT=NO
```

**MOUNT**
Displays an 'M' in position 1 of the display area during a mount request. The 'M' is followed by a volume serial number and label type. The display flashes on and off until a volume is loaded and ready. If the device is ready at the time a mount request is issued, the 'M' is not displayed.

**UCB=(reg)→(2-12)**
Specifies a register containing the UCB address for the device. Use the address of a UCB, not a UCB copy.

**LABEL='A' or 'N' or 'S' or 'X' or addr**
Displays the label type of the mounted volume in position 8. If you specify an unknown label type other than a blank, a “?” is displayed.

- **'A'**
  Specifies ISO/ANSI (AL) or ISO/ANSI with user labels (AUL). Apostrophes are required.

- **'N'**
  Specifies no labels (NL), LTM (VSE), or bypass label processing (BLP) Apostrophes are required.

- **'S'**
  Specifies IBM Standard (SL) or IBM Standard with user labels (SUL). Apostrophes are required.

- **'X'**
  Specifies nonstandard labels (NSL). Apostrophes are required.

**addr**—RX-type address, A-type address, or (2-12)
Specifies the address of an area containing an “A”, “N”, “S”, or “X”. (See the following explanations of these characters.) For MF=L, you can only specify an A-type address.

**MF=L or (E, addr)**
Specifies either the execute or the list form of MSGDISP. If you do not specify this parameter, the standard form of the macro is used.
Cartridge Messages

L Specifies the list form of MSGDISP. This generates a parameter list that can be used as input to the execute form. The execute form can modify the parameter list.

(E,addr)
Specifies that the execute form of the macro and an existing parameter list are used.

addr—RX-type address, (1), or (2-12)
Specifies the address of the parameter list.

SER='volser' or addr
Specifies the serial number of the volume to be mounted. The serial number is displayed in positions 2 through 7. If you do not specify SER, the system supplies the volume serial number. If the serial number is not available, a scratch volume is used, unless the volume use attribute indicates a default of "PRIVAT".

'volser'
Specifies the volume serial number as a literal. Specify in apostrophes.

addr—RX-type address, A-type address, or (2-12)
Specifies the address of the volume serial number. For MF=L, you can only specify an A-type address.

MEDIATYPE=n
Specifies what media type to mount for SCRTCH or PRIVAT mounts. The MEDIATYPE keyword applies only when volumes are to be mounted on devices that reside in a Manual Tape Library (MTL). If MEDIATYPE is specified for devices outside of a Manual Tape Library, it is ignored. The value n can be specified as a literal, the address of a 1 byte field containing the value, or the name of the addressable field containing the value. Valid values for MEDIATYPE are the numbers 1 through 8.

TEST=NO or YES
Specifies whether the macro expansion is to include code that tests the UCB to determine whether message display is supported. If the result of the test is that the message display is not supported, an SVC is not invoked.

NO Specifies that the macro expansion is not to include code that tests the UCB to determine whether the device supports message display.

YES Specifies testing the UCB by the MSGDISP macro before attempting to invoke the message display service routine.

Requirement: TEST=YES requires you to include the UCB mapping macro (IEFUCBOB) in the source code.

Restriction: There is a restriction when using TEST=YES. Programs running in AMODE 24 and invoking the MSGDISP macro with the TEST=YES parameter cannot pass the actual address of a UCB that resides above the 16 MB line. These programs must pass the captured UCB address or, if an actual address is passed, the UCB must reside below the 16 MB line.
Cartridge Messages

INDEX=NO or YES
Specifies whether the automatic cartridge loader (ACL) should be indexed to satisfy a scratch mount request.

NO Specifies that indexing should not be done regardless of the state of the ACL.

YES Specifies that indexing should be done if:
- The ACL is present and loaded, and
- The request is for SCRTCH or PRIVAT.

WAIT=NO or YES
Specifies when control is returned to you.

NO Specifies that the MSGDISP function is not to wait for completion of I/O initiated on the caller’s behalf. When MSGDISP returns, the I/O request might still be running. I/O return codes are not returned, and I/O errors are recorded in the same manner as any permanent error by the error recovery procedure.

YES Specifies that control is to be returned after I/O is complete.

MSGDISP—Displaying a Verify Message

The format of the MSGDISP macro with the VERIFY parameter is:

```
/SM590000/SM590000
MSGDISP VERIFY
label, UCB=(
reg), LABEL='A'
'S'
'N'
'X'
addr
/SM590000/SM590000
, MF=L (E, addr)
, SER='volser'
addr
/SM590000/SM590000
, TEST=YES
/SM590000/SM630000
, WAIT=NO

VERIFY
Displays the serial number and label type of a volume that has been accepted for processing. The serial number is displayed on the pod in positions 2 through 7, and the 1 character label type in position 8. Position 1 remains blank. The display lasts until the next display request is executed.

UCB=(reg)–(2-12)
Specifies a register containing the UCB address for the device. Use the address of a UCB, not a UCB copy.

LABEL='A' or 'N' or 'S' or 'X' or addr
Specifies label type of the mounted volume in position 8 of the display. If an unknown label type other than a blank is specified, a “?” is displayed.
Cartridge Messages

'A'
   Specifies ISO/ANSI (AL) or ISO/ANSI with user (AUL) labels.
   Apostrophes are required.

'N'
   Specifies no labels (NL), LTM (VSE), or bypass label processing (BLP).
   Apostrophes are required.

'S'
   Specifies IBM Standard (SL) or IBM Standard with user (SUL) labels.
   Apostrophes are required.

'X'
   Specifies nonstandard (NSL) labels. Apostrophes are required.

addr—RX-type address, A-type address, or (2-12)
   Specifies the address of an area containing an “A”, “N”, “S”, or “X” (see
   explanations below for these characters). For MF=L, you can only
   specify an A-type address.

MF=L or (E,addr)
   Specifies either the execute or list form of MSGDISP. If you do not specify
   this parameter, the standard form of the macro is used.

L
   Specifies the list form of MSGDISP. This generates a parameter list that
   can be used as input to the execute form. The execute form can modify
   the parameter list.

(E,addr)
   Specifies that the execute form of the macro and an existing parameter
   list is to be used.

addr—RX-type address, (1), or (2-12)
   Specifies the address of the parameter list.

SER='volser' or addr
   Specifies the serial number of the volume that has been verified. The serial
   number displays in positions 2 through 7. If you do not specify SER, the
   system supplies the volume serial number. If the serial number is not
   available, a scratch volume is used, unless the volume use attribute
   indicates a default of “PRIVAT”.

'volser'
   Specifies the volume serial number as a literal. Express in
   apostrophes.

addr—RX-type address, A-type address, or (2-12)
   Specifies the address of the volume serial number. For
   MF=L, you can only specify an A-type address.

TEST=NO or YES
   Specifies whether the macro expansion is to include code that will test the
   UCB to determine whether message display is supported. If the result of the
   test is that the message display is not supported, an SVC is not invoked.

NO
   Specifies that the macro expansion is not to include code that tests
   the UCB to determine whether the device supports message display.

YES
   Specifies testing the UCB by the MSGDISP macro before
   attempting to invoke the message display service routine.

Requirement: TEST=YES requires you to include the UCB
   mapping macro (IEFUCBOB) in the source code. If
Cartridge Messages

This provision is not followed, a program check in expansion code might result. Programs running in AMODE 24 and invoking the MSGDISP macro with the TEST=YES parameter cannot pass the actual address of a UCB that resides above the 16 MB line. These programs must pass the captured UCB address or, if an actual address is passed, the UCB must reside below the 16 MB line.

**WAIT=NO or YES**

- **WAIT=NO** Specifies when control is to be returned to you and that the MSGDISP function is not to wait for completion of I/O initiated on the caller's behalf. When MSGDISP returns, the I/O request might still be running.
- **NO** Specifies that the MSGDISP function is not to wait for completion of I/O that is initiated on the caller's behalf. When MSGDISP returns, the I/O request might still be running. I/O return codes are not returned, and I/O errors are recorded in the same manner as any permanent error by the error recovery procedure.
- **YES** Specifies that control is to be returned after I/O is complete.

**MSGDISP—Displaying a Ready Message**

The format of the MSGDISP macro with the RDY parameter is:

```
/SM590000/SM590000
MSGDISP RDY
label
,DCB=addr
,MF=(E,addr)
/TXT='msgtxt'
addr

/SM590000
```

- **RDY** Displays the text supplied in the TXT parameter in positions 2 through 7 while the data set is open. The display is steady (not flashing) and is enclosed in parentheses. The display is also written to the tape pool console (routing code 3, descriptor code 7).
- **DCB=addr** Specifies the address of a DCB opened to a data set on the mounted volume. If multiple devices are allocated, the message display is directed to the one containing the volume currently in use.

**Tip:** If multiple devices or multiple volumes are allocated, you can update a message display after an end-of-volume condition by using the EOV user exit specified in a DCB exit list. In the case of a concatenated data set with unlike characteristics, the DCB OPEN exit can also be used to update the display.

- **addr**—RX-type address, A-type address, or (2-12)
  Specifies the address of the opened DCB. For MF=L, you can only specify an A-type address.
**Cartridge Messages**

MF=L or (E, addr)

Specifies either the execute or list form of MSGDISP. If this parameter is not specified, the standard form of the macro is used.

L

Specifies the list form of MSGDISP. This generates a parameter list that can be used as input to the execute form. The execute form can modify the parameter list.

(E, addr)

Specifies that the execute form of the macro and an existing parameter list is to be used.

addr—RX-type address, (1), or (2-12)

Specifies the address of the parameter list.

TXT='msgtxt' or addr

Specifies up to six characters to display in positions 2 through 7 of the display. If you do not specify TXT, blanks are displayed.

'msgtxt'

Specifies the text as a literal. Express in apostrophes.

addr—RX-type address, A-type address, or (2-12)

Specifies the address of an area containing the text to be displayed. For MF=L, you can only specify an A-type address.

---

**MSGDISP—Displaying a Demount Message**

The format of the MSGDISP macro with the DEMOUNT parameter is:

```plaintext
MSGDISP—DEMOUNT—,UCB=(reg)

'MF='L

'(E,addr)

'MLABEL='A'

'MSER='volser_to_mount'

'MEDIATYPE=n

'INDEX=NO

'TEST=YES

'WAIT=NO
```

---

Chapter 8. Displaying Messages on Cartridge Magnetic Tape Subsystems (MSGDISP macro) 321
Cartridge Messages

DEMOUNT
Displays a volume disposition indicator in position 1 until the volume is demounted. Optionally, you can display the serial number of the volume to be demounted at the same time. The display flashes on and off. If a volume is not mounted on the device when the display request is executed, blanks are displayed.

The demount message can be displayed alternately (flashing) with a mount message for the next volume by specifying the MSER parameter.

UCB=(reg)-(2-12)
Specifies a register containing the UCB address for the device. Use the address of a UCB, not a UCB copy.

DISP='D' or 'K' or 'R' or addr
Specifies the character to display in position 1 of the pod, representing the volume disposition.

'D'
Specifies demount a public volume. Apostrophes are required. “D” also displays when you specify an invalid character or when the volume use attribute is unknown (as in an automatic volume recognition (AVR) error when reading a label).

'K'
Specifies keep a private volume and return it to the library. Apostrophes are required.

'R'
Specifies retain a private volume near the device for further use. Apostrophes are required.

addr—RX-type address, A-type address, or (2-12)
Specifies the address of an area containing a “D”, “K”, or “R”. For MF=L, you can only specify an A-type address.

MF=L or (E, addr)
Specifies either the execute or list form of MSGDISP. If you do not specify this parameter, the standard form of the macro is used.

L
Specifies the list form of MSGDISP. This generates a parameter list that can be used as input to the execute form. The execute form can modify the parameter list.

(E, addr)
Specifies that the execute form of the macro and an existing parameter list is to be used.

addr—RX-type address, (1), or (2-12)
Specifies the address of the parameter list.

MLABEL='A' or 'N' or 'S' or 'X' or addr
Displays the label type of the volume to be loaded and made ready following a demount, in position 8. If you specify an unknown label type other than a blank, a “?” is displayed. You can only specify this parameter if you also specify the MSER parameter.

'A'
Specifies ISO/ANSI (AL) or ISO/ANSI with user (AUL) labels. Apostrophes are required.
Cartridge Messages

'N'
Specifies no labels (NL), LTM (leading tape mark, created by VSE), or bypass label processing (BLP). Apostrophes are required.

'S'
Specifies IBM Standard (SL) or IBM Standard with user (SUL) labels. Apostrophes are required.

'X'
Specifies nonstandard (NSL) labels. Apostrophes are required.

addr—RX-type address, A-type address, or (2-12)
Specifies the address of an area containing an "A", "N", "S", or "X" (see the following explanations of these characters). For MF=L, you can only specify an A-type address.

MSER="volser-to-mount" or addr
Displays the mount message for the next volume alternately (flashing) with the demount message. The display continues until you demount the current volume. At that time, the mount message will display (flashing) until you load the volume and make the device ready. If no volume is mounted at the time the demount and mount messages are executed, only the mount message will display (flashing) until the volume is loaded and ready.

'volser-to-mount'
Specifies the volume serial number of the volume to be mounted, as a literal. Apostrophes are required.

addr—RX-type address, A-type address, or (2-12)
Specifies the address of the volume serial number of the volume to be mounted. For MF=L, you can only specify an A-type address.

SER="volser" or addr
Specifies the serial number of the volume to be demounted. The serial number is displayed in positions 2 through 7. If you do not specify SER, the system supplies the volume serial number. If the serial number is not available, a scratch volume is used, unless the volume use attribute indicates a default of "PRIVAT".

'volser'
Specifies the volume serial number as a literal. Specify with apostrophes.

addr—RX-type address, A-type address, or (2-12)
Specifies the address of the volume serial number. This parameter is not valid for the MF=L form. For MF=L, you can only specify an A-type address.

MEDIATYPE=n
Specifies what media type to demount for SCRTCH or PRIVAT demounts. The MEDIATYPE keyword applies only when volumes are to be demounted on devices that reside in a Manual Tape Library (MTL). If MEDIATYPE is specified for devices outside of a Manual Tape Library, it is ignored. The value n can be specified as a literal, the address of a 1 byte field containing the value, or the name of the addressable field containing the value. Valid values for MEDIATYPE are the numbers 1 through 8.

INDEX=NO or YES
Specifies whether the ACL should be indexed to satisfy a scratch mount request.

NO Specifies that indexing should not be done regardless of the state of the ACL.
### Cartridge Messages

**YES** Specifies that indexing should be done if:

- The ACL is present and loaded, and
- The request is for SCRTCH or PRIVAT.

**TEST=NO or YES**

Specifies whether the macro expansion is to include code that tests the UCB to determine whether message display is supported. If the result of the test is that the message display is not supported, an SVC is not invoked.

**NO** Specifies that the macro expansion is not to include code that tests the UCB to determine whether the device supports message display.

**YES** Specifies testing the UCB by the MSGDISP macro before attempting to invoke the message display service routine.

**Requirement:** TEST=YES requires you to include the UCB mapping macro (IEFUCBOB) in the source code. If this provision is not followed, a program check in expansion code might result. Programs running in AMODE 24 and invoking the MSGDISP macro with the TEST=YES parameter cannot pass the actual address of a UCB that resides above the 16 MB line. These programs must pass the captured UCB address or, if an actual address is passed, the UCB must reside below the 16 MB line.

**WAIT=NO or YES**

Specifies when control is to be returned to you.

**NO** Specifies that the MSGDISP function is not to wait for completion of I/O initiated on the caller's behalf. When MSGDISP returns, the I/O request might still be running. I/O return codes are not returned, and I/O errors are recorded in the same manner as any permanent error by the error recovery procedure.

**YES** Specifies that control is to be returned after I/O is complete.

### MSGDISP—Resetting the Message Display

The format of the MSGDISP macro with the RESET parameter is:

```
!SM590000!SM590000
MSGDISP RESET
!SM590000!SM630000
```

`RESET` Clears all existing data on the display. If you specify WAIT=NO and the last service requested was a demount, the display is not cleared.

After being cleared, the display shows the internal status of the device (for example, a message indicating that the device is ready).
Cartridge Messages

**UCB=(reg)-(2-12)**

Specifies a register containing the UCB address for the device. Use the address of a UCB, not a UCB copy.

**UCBL=addr—RX-type address, A-type address, (0), or (2-12)**

Specifies the address of a list containing a maximum of 64 words. Each word in the list contains the address of a UCB representing a device whose display is to be reset. The end of the list is indicated by a ‘1’ in the high-order bit of the last address in the list. If an error is encountered while processing the list, register 1 points to the associated UCB when you regain control.

You cannot specify UCBL with TEST=YES and WAIT=NO.

**MF=L or (E,addr)**

Specifies either the execute or the list form of MSGDISP. If you do not specify this parameter, the standard form of the macro is used.

- **L**
  
  Specifies the list form of MSGDISP. This generates a parameter list that can be used as input to the execute form. The execute form can modify the parameter list.

- **(E,addr)**
  
  Specifies that the execute form of the macro and an existing parameter list is to be used.

**TEST=NO or YES**

Specifies whether the macro expansion is to include code that tests the UCB to determine whether message display is supported. If the result of the test is that the message display is not supported, an SVC is not invoked.

- **NO**
  
  Specifies that the macro expansion is not to include code that tests the UCB to determine whether the device supports message display. NO is the default?

- **YES**
  
  Specifies testing the UCB by the MSGDISP macro before attempting to invoke the message display service routine. You cannot specify TEST=YES if you also specify the UCBL parameter.

**Requirement:** TEST=YES requires you to include the UCB mapping macro (IEFUCBOB) in the source code. If this provision is not followed, a program check in expansion code might result. Programs running in AMODE 24 and invoking the MSGDISP macro with the TEST=YES parameter cannot pass the actual address of a UCB that resides above the 16 MB line. These programs must pass the captured UCB address or, if an actual address is passed, the UCB must reside below the 16 MB line.

**WAIT=NO or YES**

Specifies when control is to be returned to you.

- **NO**
  
  Specifies that the MSGDISP function is not to wait for
Cartridge Messages

completion of I/O initiated on the caller’s behalf. When MSGDISP returns, the I/O request might still be running. I/O return codes are not returned, and I/O errors are recorded in the same manner as any permanent error by the error recovery procedure.

You cannot specify WAIT=NO if you also specify the UCBL parameter.

YES Specifies that control is to be returned after I/O is complete.

Demount messages can be reset only if WAIT=YES is specified.

MSGDISP—Providing the Full Range of Display Options

The format of the MSGDISP macro with the GEN parameter is:

```
/SM590000/SM590000
MSGDISP GEN
label,UCB=(reg)
,FLASH=(BLINK,STEADY,STEADY2,BLINK2,ALT)
,MF=(L,E,addr)
,INDEX=(YES,NO)
,TEST=(YES,NO)
,TXT=(msgtxt,txt2,addr)
,VOL=(STATIC,REMOVE,INSERT,SWAP)
,WAIT=(YES,NO)
```
Cartridge Messages

**GEN**
Specifies the full range of display options.

**UCB= (reg)–(2-12)**
Specifies a register containing the UCB address for the device. Use the address of a UCB, not a UCB copy.

**FLASH=STEADY or STEADY2 or BLINK or BLINK2 or ALT**
Specifies message display mode.

**Hint:** If you specify VOL=SWAP, messages will always be displayed as if you had specified FLASH=ALT.

**STEADY**
Specifies that the primary message (TXT) is to be displayed without flashing.

**STEADY2**
Specifies that the alternate message (TXT2) is to be displayed without flashing.

**BLINK**
Specifies that the primary message (TXT) flash on and off at a rate of approximately two seconds on and one-half second off.

**BLINK2**
Specifies that the alternate message (TXT2) flash on and off at a rate of approximately two seconds on and one-half second off.

**ALT**
Specifies that the primary and alternate messages (TXT and TXT2) flash on and off alternately, at a rate of approximately two seconds on and one-half second off.

**MF=L or (E,addr)**
Specifies either the execute or the list form of MSGDISP. If you do not specify this parameter, the standard form of the macro is used.

**L**
Specifies the list form of MSGDISP. This generates a parameter list that can be used as input to the execute form. The execute form can modify the parameter list.

**(E, addr)**
Specifies that the execute form of the macro and an existing parameter list is to be used.

**addr**
Specifies the address of the parameter list.
Specify either an RX-type address or a register in the range of 2 through 12.

**INDEX=NO or YES**
Specifies whether the ACL should be indexed to satisfy a scratch mount request.

**NO**
Specifies that indexing should not be done regardless of the state of the ACL.

**YES**
Specifies that indexing should be done if:
- The ACL is present and loaded, and
- The request is for SCRTCH or PRIVAT.

**TEST=NO or YES**
Specifies whether to test the UCB to determine if the device is capable of displaying messages.
Cartridge Messages

NO Specifies that the macro expansion is not to include code that tests the UCB to determine whether the device supports message display.

YES Specifies testing the UCB by the MSGDISP macro before attempting to invoke the message display service routine.

Requirement: TEST=YES requires you to include the UCB mapping macro (IEFUCBOB) in the source code. If this provision is not followed, a program check in expansion code might result. Programs running in AMODE 24 and invoking the MSGDISP macro with the TEST=YES parameter cannot pass the actual address of a UCB that resides above the 16 MB line. These programs must pass the captured UCB address or, if an actual address is passed, the UCB must reside below the 16 MB line.

TXT='msgtxt' or addr
Specifies 8 characters to be shown in positions 1 through 8 of the display. If you do not specify TXT, blanks are displayed.

'msgtxt'
Specifies the 8 characters as literals. Apostrophes are required.

addr—RX-type address, A-type address, or (2-12)
Specifies the address of an area containing the 8 characters. For MF=L, you can only specify an A-type address.

TXT2='altmsgtxt' or addr
Specifies 8 alternate characters to display in positions 1 through 8 of the display. If you do not specify TXT2, blanks are displayed.

'altmsgtxt'
Specifies the 8 characters as literals. Apostrophes are required.

addr—RX-type address, A-type address, or (2-12)
Specifies the address of an area containing the 8 characters. For MF=L, you can only specify an A-type address.

VOL=STATIC or REMOVE or INSERT or SWAP
Specifies message display mode, based on volume status.

STATIC Specifies that messages display without regard to volume status until the next message request is executed, or until the next command initiates volume movement.

REMOVE Specifies that messages display until the current volume is demounted. This parameter is ignored if a volume is not mounted when the request is executed.

INSERT Specifies that messages display until a volume is present, the tape is threaded, and the
active/inactive switch is in the active position. This parameter is ignored if a volume is loaded and ready when the request is executed.

**SWAP**

Specifies that messages always display as if FLASH=ALT were specified. The data from TXT and TXT2 displays alternately (flashing) until the current volume has been demounted. Then only TXT2 displays (flashing) until a new volume is loaded and ready. If no volume is mounted when this parameter is specified, only TXT2 data displays (flashing) until a new volume is loaded and ready.

**WAIT=NO or YES**

Specifies when control is to be returned to you.

- **NO**
  
  Specifies that the MSGDISP function is not to wait for completion of I/O initiated on the caller's behalf. When MSGDISP returns, the I/O request might still be running. I/O return codes are not returned, and I/O errors are recorded in the same manner as any permanent error by the error recovery procedure.

- **YES**
  
  Specifies that control is to be returned after I/O is complete. This is the default.

### Return Codes from MSGDISP

When the system returns control to the problem program, the low-order byte of register 15 contains a return code. The low-order byte of register 0 can contain a reason code. These codes are described in the following table:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td></td>
<td>Successful completion.</td>
</tr>
<tr>
<td>4 (X'04')</td>
<td>1 (X'01')</td>
<td>Invalid input parameter.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>2 (X'02')</td>
<td>Invalid DCB or DEBCHK error.</td>
</tr>
<tr>
<td></td>
<td>3 (X'03')</td>
<td>Environmental error.</td>
</tr>
<tr>
<td></td>
<td>4 (X'04')</td>
<td>Authorization (TESTAUTH) violation.</td>
</tr>
<tr>
<td></td>
<td>5 (X'05')</td>
<td>Invalid UCB. Requires the address of a UCB, not a UCB copy.</td>
</tr>
<tr>
<td></td>
<td>6 (X'06')</td>
<td>Invalid request.</td>
</tr>
<tr>
<td></td>
<td>11 (X'0B')</td>
<td>Unsuccessful ESTAE macro call.</td>
</tr>
<tr>
<td></td>
<td>12 (X'0C')</td>
<td>Unsuccessful GETMAIN request.</td>
</tr>
<tr>
<td></td>
<td>12 (X'O0C')</td>
<td>I/O error (The system posted the request for an error).</td>
</tr>
</tbody>
</table>

An I/O error occurs for load display if the drive display has a hardware failure.

If you get return code X'04' or X'0C' on a RESET UCBL operation, when you regain control, register 1 points to the UCB associated with the error.

---

**Chapter 8. Displaying Messages on Cartridge Magnetic Tape Subsystems (MSGDISP macro)**

329
Chapter 9. Using DFSMSdfp Callable Services

This information describes the DFSMSdfp-related callable services. Callable services reside in SYS1.CSSLIB, the callable system service library. They are invoked from a user program by issuing a CALL statement, accompanied by a parameter identifying the desired service and a list of service-specific arguments and storage areas. The intent is that if you link edit any of the routines described here with your program, the routine continues to execute correctly on future levels of the operating system.

The DFSMSdfp callable services provide 15 callable system services. They can be invoked by the high-level languages supported by z/OS Language Environment and by assembler language callers.

**Note:** Nine of these callable services are related to using the character data representation architecture (CDRA) identifiers. They are application program interfaces (APIs) that are needed to consistently and correctly process graphic character data. We have listed them here (see “Character Data Representation Architecture (CDRA) APIs” on page 352), but for detailed information on their use, refer to [Character Data Representation Architecture Reference and Registry](#).

These services enable programs written in assembler language or high-level languages to use:

- **IECTRKAD** to perform conversions and compares of DASD track addresses that contain 16-bit or 28-bit cylinder numbers.
- **IGWARLS** to query the information in the catalog for record-level sharing (RLS), including the values of the LOG, BWO, and LOGSTREAMID parameters, the VSAM QUIESCED indicator, the RLS_RECOVERY_TIMESTAMP fields, and whether the sphere requires forward recovery.
- **IGWABWO** to communicate with DFSMSdfp to retrieve or set various data set–related indicators. Through the use of these indicators, your program can determine if a data set is eligible for backup while it is open for update and, if eligible, what action can or should be taken. See [Table 55 on page 343](#) for an explanation of the indicators.
- **IGWASMS** to return certain data set attributes for SMS managed data sets. These data set attributes are:
  - **SMSDATA**—SMS class names, that is, storage class, management class, and data class.
  - **DSTYPE**—Currently indicates whether the data set is a PDSE-type data set, HFS, or neither.

  **Note:** If IGWASMS is called for a non-SMS managed data set, zeros are returned for the DSTYPE attribute.
- **IGWASYS** to determine the version, release, and modification level of DFSMSdfp on your system, and the status of the SMS subsystem.
- **IGWLSHR** to determine the DFSMSdfp share attributes in use on the current system.

This information describes calling the service from a nonreentrant program written in assembler language. See [z/OS MVS Programming: Assembler Services](#).
Callable Services

Reference ABE-HSP for information on using CALL in a reentrant program. For information on using CALL in programs written in high-level languages, see the applicable language documentation.

Your program can call the DFSMSdfp callable services in either 24- or 31-bit AMODE. The program can be executed in any protection key and in either supervisor or problem state. When you invoke any of the callable services, your program must provide the address of a standard 18 word save area in register 13. The syntax diagrams here show a CALL statement in assembler language. These callable services can be invoked in the following two ways:

- A CALL statement is coded in the invoking application. The callable services IGWASYS, IGWASMS, IGWABWO, IGWLSHR or IGWARLS, among others, are in SYS1.CSSLIB. When link-editing the invoking application, specify SYS1.CSSLIB in the library concatenation.
- The invoking application can issue a LINK or LOAD/CALL to the desired service, IGWASYS, IGWASMS, IGWABWO, IGWLSHR, or IGWARLS. For an example of using a LINK macro, see 337. For an example of using CALL and LOAD/CALL macros, see 335 and 339.

To invoke the callable services write a set of arguments in a specific order on the invocation. The number of arguments associated with each callable service is fixed, and the types of arguments are restricted to 32-bit binary integers (hereafter referred to as integers) and fixed-length EBCDIC character strings. The CALL statement format is described in the following information:

- "Call for DFSMS Level Determination" on page 335
- "Call for Data Set Attribute Retrieval" on page 335
- "Call for Data Set Backup-While-Open Support" on page 337
- "Call for DFSMSdfp Share Attributes" on page 343
- "Call for Record-Level Sharing Query (IGWARLS)" on page 345
- "Call for converting and comparing 28-bit cylinder addresses (IECTRKAD)" on page 349

Call for DFSMS Level Determination

The DFSMS level determination call (IGWASYS) returns the version, release and modification levels of DFSMS. It also returns a code number to represent the name of the product that contains DFSMS. These four numbers represent the environment that DFSMS was designed to run in. That level might be earlier than the release for the rest of the operating system.

An alternative technique to determine the level of the system is described in "Determining Level and Name of DFSMS" on page 311.
Callable Services

Format

The format of the system attribute IGWASYS call statement is:

```
CALL IGWASYS , return_code , reason_code ,
      level_indicator , system_level , system_attr
```

Parameters

**return_code**
Return code from IGWASYS. The return code is also returned in register 15. For an explanation, see "IGWASYS, IGWASMS, IGWABWO, IGWLSHR Return and Reason Codes" on page 344. This is an output argument that must be defined as an integer.

**reason_code**
Reason code from the IGWASYS service. The reason code is also returned in register 0. For an explanation, see "IGWASYS, IGWASMS, IGWABWO, IGWLSHR Return and Reason Codes" on page 344. This is an output argument that must be defined as an integer.

**level_indicator**
The product whose level information is requested. This is an input argument. Define level_indicator as an integer. Code a value of 1 to request the level of MVS/XA DFP Version 2 or MVS/DFP Version 3 or code a 2 to request the level of DFSMS/MVS or later. This value affects what the system returns in system_level, which is described below.

**system_level**
The product level that is installed on the system invoking the service. This is an output argument and is a four-element array of integers. The array elements consist of the following integers:

- Version number
- Release number
- Modification level
- Special indicator

If you pass a value of 1 for level_indicator, DFSMS returns the system_level values as 3, 3, 2 and 1. The first three values reflect the fact that DFSMS contains the functions of MVS/DFP Version 3 Release 3 modification level 2. The system sets the fourth value to 1 to indicate that the system is actually at a level higher than 3.3.2. If your program were executing on MVS/DFP 3.3.2, then these four values would have been returned as 3, 3, 2 and 0.

If you pass a value of 2 for level_indicator, IGWASYS sets the fourth system_level word to a code that represents the product name that IGWASYS is part of. On no level of the system will this word contain a value that is smaller than on a prior release. One of the following values is returned:

1 "DFSMS/MVS". With MVS/ESA SP Version 5, it constituted an
Callable Services

MVS/ESA system. With OS/390 MVS, it was part of OS/390 Version 1 or Version 2. The first three system_level words represent DFSMS/MVS.

2 DFSMS is part of OS/390 and not a separate product. The first three system_level words show OS/390 Version 2, Release 10, Modification Level 0, or later. Those words represent the OS/390 level that DFSMS was designed to support. You will see these values also on z/OS DFSMS Version 1 Release 1 and 2 because DFSMS was not changed from OS/390 2.10.

3 DFSMS is part of z/OS and not a separate product. The first three system-level words show z/OS Version 1, Release 3, Modification Level 0, or later. Those words represent the z/OS level that the DFSMS was designed to support.

>3 DFSMS is part of hypothetical replacement product after all versions and releases of z/OS. The system never returns this value. It represents IBM's intent in case there is such a product. The other words represent the operating system level that the DFSMS was designed to support.

If the next release of the system does not contain a new level of DFSMS, IGWASYS will continue to return the original DFSMS release. This is to help with diagnosis of configuration problems and service.

The intent is that in any future level of the system, your program can determine whether it is running on a particular level or it is running on some later level. If that is what you wish your program to do, then it is suggested that your program test all four words of system level. First test the fourth word to ensure that it has a value of 1 or greater. Then test the other three words to see whether they designate the appropriate version, release and modification level. It is IBM's intent that if one of the values in the first column of the figure below is smaller than was returned for the corresponding value in the prior release, then one of the values in the second column contains a larger value than was returned in the prior release:

<table>
<thead>
<tr>
<th>Third word (modification level)</th>
<th>Fourth, first or second word</th>
</tr>
</thead>
<tbody>
<tr>
<td>Second word (release)</td>
<td>Fourth or first word</td>
</tr>
<tr>
<td>First word (version)</td>
<td>Fourth word</td>
</tr>
</tbody>
</table>

system_attr

System attributes are returned in the system_attr array. This is an output argument. The array elements are defined as follows:

1 Status of the Storage Management Subsystem. A value of 0 indicates inactive; 1 indicates active.

2–4 Reserved elements; 0 is returned.

Define as a four-element array of integers.

Return Codes

See Table 56 on page 344 for the IGWASYS return and reason codes.
Example

The following example shows a system attribute call using a CALL statement.

```
CALL IGWASYS,(RC1,RS1,CODE1,LEVEL,ATTR) Test pre-DFSMS/MVS
LTR R15,R15 Test return code
BNZ BADSYS
CLC LEVEL+,F'2', Test for MVS/XA DFP Version 2
BE OLDSYS
MVC SYSNAME,UNKNOWN Assume name is unknown

```

Figure 31. Example of an IGWASYS Call Statement

Call for Data Set Attribute Retrieval

The data set attribute retrieval call (IGWASMS), returns the names of the data set's related SMS classes and whether it is a PDSE, or an HFS data set, or neither.
Callable Services

Format

The format of the data set attribute IGWASMS call statement is:

```
CALL IGWASMS,label(return_code,reason_code,
prob_det,dsname_length,dsname,sms_data,ds_type)
```

Parameters

`return_code`
Return code from IGWASMS. The return code is also returned in register 15. Return codes are explained in "IGWASYS, IGWASMS, IGWABWO, GWSHR Return and Reason Codes" on page 344. This is an output argument that must be defined as an integer.

`reason_code`
Reason code from IGWASMS. The reason code is also returned in register 0. Reason codes are explained in "IGWASYS, IGWASMS, IGWABWO, GWSHR Return and Reason Codes" on page 344. This is an output argument that must be defined as an integer.

`prob_det`
Problem determination data. See "IGWASYS, IGWASMS, IGWABWO, GWSHR Return and Reason Codes" on page 344 for more information about problem determination data. This is an output argument that must be defined as a two-element array of integers.

`dsname_length`
Length, in bytes, of the data set name provided by the caller in `dsname`. The value can be a number from 1 to 44. This is a required input argument that must be defined as an integer.

`dsname`
Name of the data set on which the IGWASMS service. For VSAM data sets, the cluster name must be specified. This is a required input argument that must be defined as EBCDIC character data of length `dsname_length`.

`sms_data`
The SMS class names associated with the specified data set returned, left-justified with blanks padded on the right. The array elements are returned in the following circumstances:
- Storage class name, or blanks if the data set is not an SMS data set.
- Management class name, or blanks if the data set has no associated management class.
- Data class name, or blanks if the data set has no associated data class.
This is an output argument that must be defined as a three-element array, where each entry is a 30 (byte) character EBCDIC string.

`ds_type`
The type of data set, `dsname`, is returned. A value of 1 indicates the data set is a PDSE-type data set. A value of 2 indicates the data set is an HFS-type data set. An HFS data set defines a file system and is not a file
within the file system. A value of 0 indicates that it is neither. No other values are currently defined. This is an output argument that must be defined as an integer.

Return Codes

See Table 56 on page 344 for the IGWASMS return and reason codes.

Example

The following example shows sample coding for a data set attribute call using a LINK statement.

```
LINK EP=IGWASMS,MF=(E,ASMSLIST)
```

```
RC2 DC F'0'
RS2 DC F'0'
PROB1 DC 2F'0'
DSNLEN1 DC A(L'DSN1) 
DSN1 DC CL12'THIS.DATASET'
SMSDATA DC 3CL30' '
DSTYPE DC F'0'
ASMSLIST DC A(RC2)
   DC A(RS2)
   DC A(PROB1)
   DC A(DSNLEN1)
   DC A(DSN1)
   DC A(SMSDATA)
   DC A(DSTYPE)
```

*Figure 32. Example of an IGWASMS Call LINK Statement*

Call for Data Set Backup-While-Open Support

The data set backup-while-open support call (IGWABWO) communicates with DFSMSdfp to retrieve or set indicators related to taking data set backups while they are open for update.

Format

The format of the IGWABWO callable service is:

```
CALL IGWABWO=label,(return_code,reason_code,)
prob_det,read_write,dsname_length,dsname,select,
bwo_FLAGS,bwo_recov,bwo_resrv)
```

Parameters

*return_code*  Return code from IGWABWO. The return code is also returned in register 15. Return codes are explained in IGWASYS, IGWASMS.
Callable Services

IGWABWO, IGWLISHR Return and Reason Codes” on page 344. This is an output argument that must be defined as an integer.

reason_code  Reason code from IGWABWO. The reason code is also returned in register 0. Reason codes are explained in “IGWASYS, IGWASMS, IGWABWO, IGWLISHR Return and Reason Codes” on page 344. This is an output argument that must be defined as an integer.

prob_det  Problem determination data. See “IGWASYS, IGWASMS, IGWABWO, IGWLISHR Return and Reason Codes” on page 344 for more information about problem determination data. This is an output argument that must be defined as a two-element array of integers.

read_write  Function indicator for this service. A caller-supplied value of 0 indicates that this is a READ-type request for the backup-while-open (BWO) data of the specified data set. A value of 1 indicates a WRITE-type request, that is, an initialization or update of the specified data set’s BWO data with the supplied arguments bwo_flags, bwo_recov, and bwo_resrv. The select argument indicates which arguments are to be processed. This is a required input argument that must be defined as an integer.

dsnname_length  Length, in bytes, of the data set name provided by the caller in dsname. The value can be a number from 1 to 44. This is a required input argument that must be defined as an integer.

dsnname  Name of the data set that the IGWABWO service operates on. Only system-managed VSAM-type data sets are eligible to be backed up while they are open for update. The dsname specified must be the base cluster name of a VSAM data set. This is a required input argument that must be defined as EBCDIC character data of length dsnname_length.

select  Indicates which of the following arguments will be processed. Arguments are specified by selecting the appropriate value. This is a required input argument.

1 to process bwo_flags
2 to process bwo_recov
3 to process bwo_flags and bwo_recov

Regardless of how many arguments are to be processed, all three fields (bwo_flags, bwo_recov, and the reserved bwo_resrv field) must be defined in your program and included in the invocation. Those not selected will receive no value in a READ-type request. The values of those not selected will be ignored in a WRITE-type request.

bwo_flags  This argument is a three-element array, whose elements correspond to the three BWO flags associated with an SMS data set. bwo_flags is an output argument for read_write=0 type requests, and a required input argument for read_write=1 type requests.

1. The first element is associated with flag, BWO1. 1 is on, 0 is off.
2. This element corresponds to flag, BWO2. 1 is on, 0 is off.
3. This element corresponds to flag, BWO3. 1 is on, 0 is off.

Define as a three-element array of integers.

bwo_recov  This argument is an 8-byte storage area containing the recovery
Callable Services

timestamp associated with a data set that is eligible for BWO. 
_bwo_recov_ is an output argument for read_write=0 type requests, 
and a required input argument for read_write=1 type requests. The 
format of the timestamp for CICS VSAM data sets is as follows:

- The first word contains the date in packed decimal format, 
  0CYYDDDF, where:
  
  **0C** is the century - 00 represents 19YY, 01 represents 20YY 
  **YY** is the last two digits of the year 
  **DDD** is the day of the year (Julian date) 
  **F** is the sign (F for positive number)

- The second word contains the time in packed decimal format, 
  HHMMSSSTF, where:
  
  **HH** Hours, based on a 24-hour clock 
  **MM** Minutes 
  **SS** Seconds 
  **T** Tenths of a second 
  **F** is the sign (F for positive number)

_bwo_resrv_ This argument is reserved for future use. While the _bwo_resrv_ 
argument cannot be written or read, it must be defined in your 
program and included in the invocation. Define as EBCDIC 
character data of length 16 bytes.

Return Codes

See [Table 56 on page 344](#) for the IGWABWO return and reason codes.

Example

The following example shows sample coding for WRITE and READ-type 
backup-while-open calls using LOAD and CALL statements.
Using the Backup-While-Open Facility

The following information describes the usage of the backup-while-open (BWO) facility. BWO flags and the BWO recovery field can be retrieved or updated using the IGWABWO service described in "Call for Data Set Backup-While-Open Support" on page 337. The BWO indicators are described in Table 55 on page 343.

For environments that require high-availability, it might not be possible or desirable to stop or quiesce an application to produce consistent backup copies of the application's data sets.

For these environments DFSMSdfp provides support to allow SMS-managed VSAM data sets that are open for output to be backed up. The support is only useful for applications (such as database systems) that can recover a restored database to a point of consistency. This is typically done from a log (forward recovery log) maintained by the application that contains record images of all changed (added, deleted, or updated) records. These images can then be reapplied to a backup copy of the database, logically recreating the status of the database at a particular point in time.
The support provided by BWO might not be necessary for online applications that can quiesce the database data sets to ensure no output or update activity against the data set while the backup is in progress. Quiescing a data set in this context means the data set is closed and unallocated.

The following discussion of the operation of this support uses these terms:

- **Database manager** - the application that controls access to the data sets to be processed. In order for BWO support to be effective, the database manager must have some logging facility to allow point-in-time reconstruction of a database.
- **Backup manager** - the applications or products that perform the backup and restore functions, such as DFSMShsm and DFSMSdss.
- **Recovery manager** - the component that manages the inventory of recovery logs and applies the changes from the appropriate log(s) to the restored data set.

The following paragraphs describe the relationships between the BWO support and a user of BWO. Refer to Table 55 on page 343 for the various states of the BWO flags in the following discussion. The BWO indicators are retained in the catalog. The BWO flag states are set or reset using the DFSMSdfp callable system service IGWABWO.

- At initial allocation (IDCAMS DEFINE, IDCAMS or TSO ALLOCATE, JCL and dynamic allocation), the data set is not enabled for BWO (default, BWO flag state is 000).
- The database manager should check the BWO flags prior to opening the data set to ensure it is not downlevel (BWO flag state is 101 or 001). If the data set is downlevel, the recovery manager must be used to apply log changes to the data set.
- The database manager must set flag BWO1 (BWO flag state 100) on for each data set that is allowed to be backed up while open for output. This authorizes the backup manager to initiate backups without serializing the data set, whether or not it is being accessed by the application.
- The backup manager must retrieve the BWO flags prior to the start of the backup. If BWO1 is on, then a backup can be taken without any serialization; otherwise, normal data set serialization must be performed by the backup manager.

  When the backup completes, the backup manager must retrieve the BWO flags again. If the BWO flag state has changed, then at some point during the backup an action occurred that prevented creation of a valid backup. The backup manager should discard the backup just created.

- When the data set needs to be recovered, it is first restored using the backup manager. Data sets are serialized during restore to prevent applications from accessing them. The backup manager must set the BWO flags at the completion of the restore to indicate whether the restore was done using a backup copy that was created with or without serialization.
  - If the backup was taken without serialization, the BWO flags must be set to 101.
  - If the backup was taken with serialization, the BWO flags must be set to 000.

In either case, the application administrator should decide whether or not to apply recovery logs.

The database manager should not allow access to the data set until the recovery manager has completed processing.

- The recovery manager should change the BWO flags to 001 before opening the data set, apply the logs, and then set the flags to 000 to indicate that the data set is again ready for online activity.
set has been processed and is consistent. The database manager can then reestablish normal access to the data set (thus opening the data set for use).

- For a data set that is enabled for BWO, in certain instances the system prevents starting a backup copy without serialization (for example, during a CI/CA split) by setting the BWO flags to 010. This indicates a backup should not be started without serialization (BWO1 off), and that a backup that is currently in process should be considered invalid. When the condition that prevented the starting of a backup is ended, the system resets the BWO flags to 110. This indicates that a backup can now be started without serialization, and that any backup in progress should be discarded.

- If the database data sets are accessed by batch programs (when the database manager is not accessing the data sets) that do not create forward recovery logs, the database manager should clear the BWO1 flag and set the BWO3 flag at close (that is, OX1). The setting of the BWO2 flag should not be changed. If the backup manager discovers this BWO state at the end of backup without serialization, the backup is not valid and should be discarded. The backup manager can start a backup with serialization if the BWO flag state is 011, but the flags should be reset to 000.

Notes:
1. Since backups can result in heavy I/O activity, you might want to take backups during the time of least activity against the data set to avoid affecting the application response time.
2. The BWO flags are not locked between reading and setting them with IGWABWO. The application is responsible for providing serialization when the settings of the flags are changed.
3. KSDS data sets require special consideration. Inserts and updates can result in control interval (CI) and control area (CA) splits. Backups taken without serialization during CI and CA splits are discarded by the IBM products to prevent missing or duplicate records in the backup copies. The frequency of CI and CA splits depends on the insert activity, the update activity that increases the lengths of records, and the amount of free space in CI and CA. For KSDS data sets that are BWO enabled, run backups during periods of low inserts and updates or ensure adequate free space in control intervals and control areas.
4. Backups without serialization can be taken (on data sets defined with share option 1 or 2) when:
   - The database contains alternate indices in the upgrade set.
   - The database is accessed by pathnames, or with ddname or dsname sharing.
5. Data sets can be opened regardless of the setting of the BWO flags. It is the database manager's responsibility to determine whether the contents of the data set are consistent.
6. The database manager can use the BWO recovery field to store information (such as the log RBA or log timestamp) for the recovery manager to use in locating the appropriate recovery logs.
7. BWO concept only applies to logical data set backup/restore. It does not apply to physical data set backup/restore or full volume dump/restore.

Table 55 on page 343 describes the meaning of each of the BWO (BWO1, BWO2, and BWO3) indicators.
# Callable Services

## Table 55. Backup-While-Open Indicators

<table>
<thead>
<tr>
<th>BWO Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>Data set does not support backup without serialization.</td>
</tr>
<tr>
<td>001</td>
<td>Forward recovery in progress. Reset to 000 after recovery.</td>
</tr>
<tr>
<td>010</td>
<td>A CI/CA split for a BWO data set is in progress. Do not start backup. If backup in progress, discard at end. This state can exist at open if the database manager abended during split. Database action depends on database manager. The data set might need restore and forward recovery or backout of changes if AIXs are present.</td>
</tr>
<tr>
<td>011</td>
<td>The database manager closed a BWO data set and a CI/CA split had occurred when it was previously open. Backup manager should reset it to 000 and serialize to back up, not a BWO candidate. The database manager should change this state to 110 at open.</td>
</tr>
<tr>
<td>100</td>
<td>A BWO data set has been opened by the database manager. Back up without serialization.</td>
</tr>
<tr>
<td>101</td>
<td>Data set has been restored and requires forward recovery before it can be used. Reset it to 001 before forward recovery.</td>
</tr>
<tr>
<td>110</td>
<td>A CI/CA split has occurred and completed on a BWO data set. This state can exist at open if the database manager abended. Back up without serialization. Reset it to 100 before backup.</td>
</tr>
<tr>
<td>111</td>
<td>An invalid state.</td>
</tr>
</tbody>
</table>

## Call for DFSMSdfp Share Attributes

The DFSMSdfp share attributes call (IGWLSHR) returns the DFSMSdfp share attributes currently in use.

### Format

The format of the IGWLSHR callable service is:

```plaintext
CALL IGWLSHR ,
  label (return_code , reason_code ,
  prob_det , share_attr_selector , share_attr_array_length ,
  share_attr_array )
```

### Parameters

**return_code**

Return code from IGWLSHR. The return code is also returned in register 15. Return codes are explained in "IGWASYS, IGWASMS, IGWABWO, GWLSHR Return and Reason Codes" on page 344. This is an output argument that must be defined as an integer.

**reason_code**

Reason code from IGWLSHR. The reason code is also returned in register 0. Reason codes are explained in "IGWASYS, IGWASMS, IGWABWO, GWLSHR Return and Reason Codes" on page 344. This is an output argument that must be defined as an integer.
Callable Services

.prob_det

Problem determination data. See [IGWASYS, IGWASMS, IGWABWO, IGWLSHR Return and Reason Codes] for more information about problem determination data. This is an output argument that must be defined as a two-element array of integers.

.share_attr_selector

Use to specify which DFSMSdfp share attributes are requested. Code a value of 1 to request the PDSE sharing protocol attributes. This is a required input argument that must be defined as an integer.

.share_attr_array_length

Use to specify the size of the share attributes array. This length represents the number of array elements in the share_attr_array. Code the value required for the chosen share_attr_selector value. The share_attr_array_length must minimally be 1 when the share_attr_selector is 1. This is a required input argument that must be defined as an integer.

.share_attr_array

Returns DFSMSdfp share attributes. This is an output argument. Define as an array of integers of length share_attr_array_length, where share_attr_array_length is the length required for the chosen share_attr_selector value. The array elements for the share_attr_selector value are returned as follows:

1 Status of PDSE sharing protocol. A value of 0 indicates PDSE support is unavailable; that is, the system supports the call, but SMS PDSE support is not active. If the system does not support this call (as with a previous release), then a return code of 36 is returned.

A value of 1 indicates normal PDSE sharing protocol in use. A value of 2 indicates extended PDSE sharing protocol in use.

2–4 Reserved elements; 0 is returned.

Return Codes

See [Table 56] for the IGWLSHR return and reason codes.

IGWASYS, IGWASMS, IGWABWO, IGWLSHR Return and Reason Codes

When IGWASYS, IGWASMS, IGWABWO, or IGWLSHR returns control to the calling program, it provides both a return code and a reason code. IGWASMS and IGWABWO can return additional data useful for problem determination in the prob_det array. IGWLSHR can return additional data regarding share_attr_selector and share_attr_array_length arguments. The following table identifies return code and reason code combinations, tells what each means, explains what and when additional problem determination data is returned, and recommends what action should be taken.

Table 56. IGWASYS, IGWASMS, IGWABWO, IGWLSHR Return and Reason Codes

<table>
<thead>
<tr>
<th>Return Code Dec (Hex)</th>
<th>Reason Code Dec (Hex)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (0)</td>
<td>0 (0)</td>
<td>The operation was successful.</td>
</tr>
<tr>
<td>4 (4)</td>
<td>4 (4)</td>
<td>The operation was successful, but the bwo_recov argument has no valid value for the data set specified in dname. This is because it was created under DFP 3.1.0, and no bwo_recov has been added to the data set. Add bwo_recov to the data set as appropriate.</td>
</tr>
</tbody>
</table>

**Call for Record-Level Sharing Query (IGWARLS)**

IGWARLS is used to query the information in the catalog for record-level sharing.

**Format**

The format of the IGWARLS call statement is:
Callable Services

```call
CALL IGWARLS , ( return_code , reason_code ,
prob_det , dsname_length , dsname , recovery_status ,
logstreamid_length , logstreamid , rls_recovery_timestamp_utc ,
rls_recovery_timestamp_local , vsam_quiesced , bwo )
```

Parameters

`return_code`
Return code from IGWARLS. The return code is also returned in register 15. Return codes are explained in "Return Codes" on page 347. This is an output argument. Define `return_code` as an integer.

`reason_code`
Reason code from IGWARLS. The reason code is also returned in register 0. Reason codes are explained in "Return Codes" on page 347. This is an output argument. Define `reason_code` as an integer.

`prob_det`
Problem determination data. See "Return Codes" on page 347 for more information about problem determination data. This is an output argument. Define `prob_det` as a two element array of integers.

`dsname_length`
Length, in bytes, of the data set name provided by the caller in `dsname`. The value can be a number from 1 to 44. This is a required input argument. Define `dsname_length` as an integer.

`dsname`
Name of the base cluster that the IGWARLS service will operate on. This is a required input argument. Define `dsname` as EBCDIC character data of length `dsname_length`.

`recovery_status`
Returns an indication as to whether the sphere is marked as requiring forward recovery.
- 0 - RLS recovery required is not pending for the VSAM sphere.
- 1 - RLS recovery required is pending.
`recovery_status` is an output argument that is defined as an integer.

`log_type`
The specification of the LOG= parameter on DEFINE CLUSTER is returned.
- 1 - LOG parameter undefined
- 2 - LOG=NONE
- 3 - LOG=UNDO
- 4 - LOG=ALL
`log_type` is an output argument that is defined as an integer.

`logstreamid_length`
Length, in bytes, of the LOGSTREAMID field. This is a required input parameter. Define `logstreamid_length` as an integer. The value of `logstreamid_length` should be at least 26 bytes.
**Callable Services**

**logstreamid**
The specification of the LOGSTREAMID on DEFINE CLUSTER is returned.
If the parameter is undefined, blanks are returned. The caller can determine
the size of the returned LOGSTREAMID field by scanning from right to left
looking for a non blank character or until the entire field has been scanned.

**logstreamid** is an output argument that is defined as an EBCDIC
character data field of length logstreamid_length.

**rls_recovery_timestamp_utc**
An output argument which represents the UTC time (formally known as
GMT) of the dump/copy in STCK format. The field is defined as an
eight-byte unsigned integer. Your program might regard this field as either
an integer or a character string.

**rls_recovery_timestamp_local**
An output argument which represents the local time of the dump/copy in
STCK format. The field is defined as an eight-byte unsigned integer. Your
program might regard this field as either an integer or a character string.

**vsam_quiesced**
An output argument which indicates whether the sphere is marked as
VSAM_QUIESCED.

• 0 - The sphere is not marked VSAM_QUIESCED.
• 1 - The sphere is marked VSAM_QUIESCED.

**vsam_quiesced** is an output argument, defined as an integer.

**bwo**
An output argument which indicates whether the value of the BWO
parameter on define cluster.

• 1 - BWO parameter is undefined.
• 2 - BWO = TYPECICS processing allowed.
• 3 - BWO = NO. BWO processing is not allowed.
• 4 - BWO = TYPEIMS processing allowed.
• 5 - BWO = TYPEOTHER processing allowed.

**Return Codes**
When IGWARLS returns control to the calling program, it provides both a return
code and a reason code. IGWARLS can return additional data useful for problem
determination in the prob_det array. **Table 57** identifies return code and reason code
combinations, tells what each means, explains what and when additional problem
determination data is returned, and recommends what action should be taken.

Callable Services

Example

The following example shows the RLS query call using LOAD and CALL statements:

```
LOAD EP=IGWARLS
LR R9,R0
CALL (R9),(RC1,RS1,PROB1,DSNLEN1,DSN1,RECSTAT,LOGTYPE,
LOGSTRML,LOGSTRM,RCVTMG,RCVTML,VSAMQUIS,BWO)
```

**Figure 34. Example of the IGWARLS Query Call Using LOAD and CALL Statements**

**Call for converting and comparing 28-bit cylinder addresses (IECTRKAD)**

IECTRKAD is a callable service to perform conversions and compares of 28-bit cylinder addresses. The track addresses are in the form $\text{CCCCcccH}$, where $\text{CCCC}$ is the 16 low order bits of the cylinder number and $\text{ccc}$ is the 12 high order bits of it.

Cobol, PL/I, and C programs can call IECTRKAD without having to write assembler routines to invoke TRKADDR.

The caller requirements of IECTRKAD are:
- Register 1 contains an address to a parameter list. Register 0 is not used.
- Register 13 points to a standard register 18-word save area and registers 14 and 15 have their standard usage.
- Calling program can be in either 24-or 32-bit addressing mode
- Calling program can be executing in any protection key and in either supervisor or problem state

The called routine, IECTRKAD, has the following characteristics:
- No executable macro other than CALL and LINK is provided to call IECTRKAD.
- The called routine resides in SYS1.CSSLIB and is shipped in distribution library ACSSLIB.
- User program can link edit with the called routine to invoke IECTRKAD.
- User program can use the LINK macro or the LOAD and CALL macros to invoke IECTRKAD.
- IECTRKAD processing will use the equivalent TRKADDR function and pass the result back accordingly.
Callable Services

- IECTRKAD is release independent; if you link or bind IECTRKAD with your program, it will run on earlier or later releases of z/OS. This includes releases before the first availability of IECTRKAD.

Format

You can adapt the assembler language syntax shown here to your computer language such as C, COBOL or PL/I:

```
label CALL IECTRKAD, (operation, cchh1, cchh2, number, returncode, reasoncode)
```

Parameters

Where the parameters are:

**operation**

Specifies the operation to perform. This parameter is the name of a field that contains character data of length 10. The allowable values are:

- **ABSTOREL**
  - calculates the relative track number on the volume from the passed cchh1 track address.

- **COMPARE**
  - compares the two track addresses passed in cchh1 and cchh2.

- **EXTRACTCYL**
  - extracts the 28-bit cylinder number from the passed cchh1 track address.

- **EXTRACTTRK**
  - extracts the 4-bit track number from the passed cchh1 track address.

- **NEXTTRACK**
  - increments the track address by one track and increments the cylinder number if necessary from the passed cchh1 track address.

- **NORMALIZE**
  - reverses the 16-bit and 12-bit portions of the cylinder number from the passed cchh1 track address. The CCCCcccH becomes ccccCCCC. This could be used to subsequently perform unsigned comparisons of track addresses.

- **NORMTOABS**
  - reverses the 12-bit and 16-bit portions of the cylinder from the track address passed in number. The cccCCCCcH becomes CCCCcccH. Use this to convert a normalized track address to an absolute 28-bit cylinder address.

- **RELTOABS**
  - converts a relative track number, passed in number, to a 28-bit cylinder address.
Callable Services

SETCYL
converts a relative cylinder number, passed in number, to a 28-bit cylinder address and sets the head portion to zero.

If you request an operation that is less than 10 characters, it must be padded on the right with blanks.

cchh1
Required parameter, cchh1, is a four-byte area containing a track address that nominally is in the form of CCHH. For all functions except RELTOABS and SETCYL this is input to the called routine. For RELTOABS, SETCYL, and NORMTOABS this is output from the called routine.

cchh2
Optional positional parameter, cchh2, is a four-byte area whose meaning depends on the operation specified by the first parameter. For all functions except COMPARE and NEXTTRACK this parameter is ignored.

For COMPARE processing, cchh2 contains the track address that is to be compared to the first cchh1 parameter.

For NEXTTRACK processing, cchh2, is the four-byte output area to contain the track address (CCHH) of the next logical track on the volume. If the input track number is 0 to 13, the output cylinder number will be the same and the output track number will be one greater than the input track number. If the input track number is 14, the output cylinder will be one higher than the cylinder number in cchh1 and the output track number will be 0. The called routine does not check for numeric overflow.

number
Optional positional parameter, number, is a four-byte integer whose meaning depends on the operation specified by the first parameter.

For ABSTOREL processing, number is the output area that will contain the relative track number on the volume.

For COMPARE processing, number is the output area that will contain the result of the comparison. Zero means the inputs are equal. Negative one means the first one is lower. Positive one means the first one is higher.

For EXTRACTCYL processing, number is the output area that will contain the 28-bit cylinder number with the four high order bits set to zero.

For EXTRACTTRK processing, number is the output area that will contain the four-bit track number with the 28 high order bits set to zero.

For NEXTTRACK processing, number is an ignored parameter. It can be 0 or any valid virtual address. Not checked by the called routine.

For NORMALIZE processing, number is the output area that will contain the normalized version of the input CCHH. The CCCCcccH becomes cccCCCCCH. The high order 28-bits are the cylinder number and the low order four bits are the track number. This allows your code to do a more efficient comparison of one track address with many track addresses. Normalize each and do unsigned comparisons.

For NORMTOABS processing, number is the input area that contains the normalized track address to be converted. The cccCCCCCH becomes CCCCCcccH. Use this to convert a normalized track address to an absolute 28-bit cylinder address.
Callable Services

For RELTOABS processing, number is the input area that contains the relative track number on the volume. For example the first two tracks on the second cylinder (cylinder 1) have relative track numbers of 15 and 16. The called routine converts the relative track number to a 28-bit nonlinear cylinder address with a 4-bit head value in the low order four bits in the cchh1 output area.

For SETCYL processing, number is the input area that contains the cylinder number on the volume in the low order 28-bits with the four high order bits set to zero. The called routine splits the 28-bits into the high order 12-bits and low order 16-bits, reverses them in the output field, cchh1, with the cylinder address in the high order 28-bits and the low order four bits to zero.

returncode

returncode is a 4-byte integer that contains the return code from IECTRKAD processing. returncode is also returned in register 15. The return codes that could be set include the following:

- 0 Successful.
- 4 Successful, but with exceptions
- 8 Request was unsuccessful because of invalid or incorrect input. Refer to thereasoncode for more detailed information

reasoncode

reasoncode is a 4-byte integer associated with a specific return code.
reasoncode is returned in Register 0.

No reason codes are supplied for return code 4:

The following reason codes are supplied for return code 8:

- 4 The H portion of a track address is not valid on a NEXTTRACK operation
- 8 The caller specified an invalid operation (the first parameter is not one of the supported operations)
- 12 The address of a required parameter is zero.

Character Data Representation Architecture (CDRA) APIs

The following CDRA APIs are included in the DFSMS product library. For more detailed description of both the APIs and their use, see Character Data Representation Architecture Reference and Registry (SC09-2190).

Chapter 10. Using the DESERV Exit

The DESERV exit was designed to support those programs which, before the binder, used SVC screening or replacement of the SVC table to trap SVC 21 (STOW) in order to monitor STOWs. DESERV provides an equivalent function to that obtained by SVC Screening or replacing the SVC table entry for SVC 21 (or SVC 12, BLDL). The DESERV exit can be used along with the SVC screening and SVCUPDTE facilities to monitor accesses and updates to PDS and PDSE directories.

The system calls the DESERV GET function when the following occurs:
- The binder is used to bind a program object or a load module and it is searching for member names to be included. (Note the linkage editor does not use DESERV).
- The system is searching for modules to load into storage while processing the ATTACH, LINK, LOAD or XCTL functions.

In these situations the system uses DESERV GET rather than issuing BLDL. However, in some situations DESERV GET issues BLDL to perform the directory search (the BLDL function does not issue DESERV calls). The system calls the DESERV PUT function when the following occurs:
- The binder is creating a program object in a PDSE (note the linkage editor does not use DESERV, nor does the binder use DESERV PUT when creating a load module in a PDS).
- An IEBCOPY job is loading a program object from an IEBCOPY unloaded data set.
- An IEBCOPY job is copying a member to a PDSE where one of the member's names is greater than 63 bytes long.

In these situations the system uses DESERV PUT rather than issuing STOW. The DESERV PUT and STOW code do not interact. STOW does not issue DESERV PUT nor does DESERV PUT issue STOW.

Currently the system does not use the RENAME or UPDATE functions. SMP/E is the only known user of the DELETE function. The rename, update and delete functions and the STOW code do not interact.

With SVC screening, an SVC screen table is associated with a task control block (TCB). The table marks specific SVC numbers as not valid. The table also defines the address of a routine that gets control when an SVC that is not valid is issued. Then it's possible for the screen routine to inhibit the function, perform the function itself, or temporarily disable the SVC screening and re-issue the SVC. This technique provides a front and back end mechanism for SVC routines.

With SVCUPDTE, an application can dynamically replace or delete SVC table entries for the system or obtain the SVC number of a routine at a specified entry point. One specific use of the replace function of SVCUPDTE would use a scenario like the following to replace an IBM supplied SVC routine.
1. Extract the SVC entry for SVC 18 (BLDL) from the SVC table.
2. Issue SVCUPDTE to install the vendor's version of the BLDL function.
3. When an SVC 18 is issued, the vendor's BLDL module gets control.
### DEserv Exit

4. The vendor's BLDL either performs the function and returns to the caller, or branch enters the IBM supplied BLDL code whose address was obtained earlier from the SVC table.

For more detail and explanation of the DEserv functions, see [z/OS DFSMS Using Data Sets](#) for their macros, see [z/OS DFSMS Macro Instructions for Data Sets](#).

DEserv provides a task level exit for an interface that is similar to SVC screening for the SVC routines BLDL and STOW. DEserv also provides a global exit for an interface that is similar to the SVCUPDTE replace option. For more information on using SVC Screening and SVCUPDTE, refer to [z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO](#) and [z/OS MVS Programming: Authorized Assembler Services Guide](#).

### Task Level Exit

The task level DEserv exit can be established for any TCB following the LPA's initialization. Once established for a task, the DEserv exit is given control for the DEserv functions that are issued under the TCB. The exit entry point is given control twice for each GET, PUT, RENAME, DELETE, or UPDATE invocation; once before DEserv executes and once immediately before the return from the DEserv function. The parameters passed to the exit indicate whether this call happens before or after the DEserv function executes.

If a DEserv FUNC=GET call is made for which there are no PDSEs in the concatenation, the DEserv code issues BLDL to search for the requested names. The task level exit is called in this case. However, if SVC screening is also active, the exit might perform one of the following tasks:

- Not process this DEserv call (that is, lets the SVC screen routine process the BLDL request) or
- Process this DEserv call with the pre- and post-processing exits, but also disable the SVC screening for BLDL in the pre-processing exit and enable the BLDL screening in the post-processing exit. A parameter passed to the exit indicates whether a BLDL will be or has been issued.

Just as with the SVC screening facility, the DEserv task level exit function enables the user to indicate that the exit should be propagated to subsequently attached tasks.

The first DEserv call for a task searches the TCB chain for a DEserv task level exit routine with propagate specified. DEserv searches the TCB chain following the originating TCB pointer (TCBOTC). If none exists, the task is marked to indicate that no DEserv task level exit exists. Therefore, for the propagate option to work, the exit routine must be established before issuing the ATTACH macro. This is roughly consistent with implementing SVC screening. The difference is that the SVC screening table is propagated at the time of the ATTACH, while the DEserv exit might not be propagated at ATTACH (for example, if the attached program is found in the job pack queue, no directory search (that is, DEserv GET) is done to find the module).
Global Exit

The global DESERV exit can be established for the system following the initialization of LPA. When establishing a global exit, obtain the DST (DESERV Screen Table) storage in common storage. The DST is used to identify a DESERV exit. Once established, the DESERV exit gets control anytime DESERV GET, PUT, RENAME, DELETE, or UPDATE functions are called. The exit entry point is given control twice for each invocation, once before DESERV is executed, and once immediately after the return from the DESERV function. The call to the exit indicates whether this call is before or after DESERV executes. The global exit routine must reside in commonly addressable storage.

If a DESERV FUNC=GET call is made for which there are no PDSEs in the concatenation, the DESERV code issues BLDL to search for the requested names. The global exit is called in this case. If both the SVCUPDTE facility and the DESERV global exit are used, before implementing the global DESERV exit consider the interactions of the DESERV global exit and the routine that is given control when the SVC is issued.

Interactions Between the Task Level and Global Exits

If both task level and global DESERV exits have been defined, there is a prescribed calling sequence. The task level exit is called first. If the task level exit indicates that the DESERV function should be terminated (via a return code 4 from the exit), DESERV returns immediately to its caller. However, the global exit is given control when the task level exit returned with return code 0. The global exit can indicate (via return code 4) that control should pass back immediately to the DESERV caller. In this case before returning to the DESERV caller, the task level exit is given control indicating that the DESERV function is complete. After returning from the task level exit, DESERV returns to the caller.

If the global exit returns with return code 0, the DESERV function executes, making the post-processing exit calls. The post processing exit calls are made first to the global exit and second to the task level processing exit. This sequence (the reverse of the pre-processing exit sequence) is chosen to simulate the return sequence that would have been seen if both SVC screen routine and updated SVC routine were in place. The following diagram illustrates the exit routine call sequence:
Establishing Multiple Task level or Multiple Global Exits

The system identifies a DESERV exit by a DST (DESERV Screen Table). The system maintains at most one task level DST for each task, and at most one DST for the system (which represents the global exit). However, multiple DESERV exits can be established. To support multiple exits of a given type (task or global), when a DESERV FUNC=EXIT is issued with EXIT_OPTION=REPLACE, DESERV returns the address of the DST that was replaced (or zero if no DST was replaced). Then it is the responsibility of the newly defined exit to pass control to the previously defined exit.

Issuing DESERV FUNC=EXIT (invocation environment)

<table>

</tr>
</tbody>
</table>

SERIALIZATION REQUIREMENTS: None. DESERV maintains serialization. Therefore the caller does not need to provide any ENQ-like serialization.
Invocation Syntax

The following figure illustrates the syntax for the DESERV EXIT function:

```
FUNCTION=EXIT

EXIT_SCOPE=GLOBAL or TASK

EXIT_OPTION=REPLACE or NOREPLACE or DELETE or QUERY

EXIT_DST=deserv_exit_screen_table RX-Type Address or (2-12)

MF=S, L, (E, N, label)

RETCODE=retcode

RSNCODE=rsncode
```

**FUNC=EXIT**
Requests the DESERV function which operates on a DESERV exit. This keyword is always required except when MF=E is coded with "NOCHECK" and no other keywords are coded or MF=L is coded with no other keywords. For the MF=E case, the FUNC keyword and other keywords specified on the MF=L DESERV macro invocation are assumed to have been coded completely.

**EXIT_SCOPE=GLOBAL or TASK**
Specifies whether the exit specified will be of a TASK level or of a GLOBAL level.

**EXIT_OPTION=REPLACE or NOREPLACE or DELETE or QUERY**
If EXIT_OPTION=REPLACE or NOREPLACE is coded, this specifies whether this invocation of the DESERV FUNC=EXIT should replace an existing DESERV EXIT (TASK or GLOBAL as specified by the EXIT_SCOPE parameter). EXIT_PREV_DST will return the existing exit or be set to zero if one does not exist.

If EXIT_OPTION=DELETE is coded, this indicates that the current exit is to be deleted (EXIT_OPTION=DELETE). In this case the EXIT_DST parameter specifies the address of the DST which is to be deleted. This address will be used as the compare value in a compare and swap operation, and only the currently active exit can be deleted. The DST address specified with the EXIT_PREV_DSTPTR parameter will be used as the swap value.

If EXIT_OPTION=QUERY is coded, this indicates that the current exit DST address is to be returned via the EXIT_PREV_DSTPTR parameter.

**EXIT_DST=deserv_exit_screen_table RX-Type Address or (2-12)**
Specifies the address of the DESERV Screen Table (DST). The screen table is mapped by DST DSECT of the IGWDES mapping macro. For an
EXIT_OPTION of either NOREPLACE or REPLACE, this parameter defines the DST and defines the exit routine address which becomes the currently active exit if the operation is successful. For an EXIT_OPTION of DELETE, this parameter defines the DST whose address is used as a compare value in a compare and swap operation when deleting the current DST (the address of the input DST is used as the compare value). If the compare fails, DESERV returns an error return and reason code. If EXIT_OPTION=QUERY is coded, this parameter is not required.

**EXIT_PREV_DSTPTR=addr_of_deserv_exit_screen_table** RX-Type Address or (2-12)

The EXIT_PREV_DSTPTR is an output parameter when an EXIT_OPTION of NOREPLACE, REPLACE or QUERY is specified, and an input parameter if an EXIT_OPTION of DELETE is specified.

For EXIT_OPTION=NOREPLACE or QUERY this parameter specifies a four byte field into which DESERV will return the address of the current DST (or zero if no DST exists).

For EXIT_OPTION=REPLACE, this parameter specifies a four byte field into which DESERV will return the address of the DST which was successfully replaced (or zero if no previous DST existed).

For EXIT_OPTION=DELETE, this parameter specifies a four byte field that points to the DST that DESERV restore as the current DST. This address is the swap value for the compare and swap operation.

**MF=S or L or {{E,{{(1-12) or label}{,COMPLETE or NOCHECK}}}} RX-Type Address or (1-12) - for MF=E second argument Default=S - if the MF keyword is not specified Default=COMPLETE - if MF=E is specified without the third argument (COMPLETE or NOCHECK).**

Specifies the format of the macro expansion.

The Standard form, S, checks all required keywords and keywords that are not valid. This form generates a complete inline expansion of the parameter list and code to call the Directory Entry Services routine. The standard form is for programs that are not reenterable, or for programs that do not change values in the parameter list.

L specifies the List form of the macro. This form generates a remote parameter list. Only keywords of argument type KEY or SYM can be coded. Registers are not valid because code generation does not occur, adcons are generated. Invalid keyword checking is done.

Keywords with defaults that are set by MF=L invocation are not reset to their default during MF=E invocation.

E specifies the Execute form of the macro. This form updates the remote parameter list (MF=L) and transfers control to the DESERV routine.

The second parameter for MF=E format is the address of the parameter list created by the MF=L DESERV invocation. This parameter must be specified as either an RX type of address (possibly the label from MF=L macro invocation) or a register enclosed in parentheses.

The third parameter, COMPLETE or NOCHECK, is optional. Default is COMPLETE. This argument specifies whether required keyword checking will be done. If MF=E is coded with the NOCHECK argument then no, some, or all allowed keywords can be specified, assuming that any missing keywords were coded on the MF=L macro invocation. If MF=E is coded with the COMPLETE argument or allowed to default, the parameter list will be zeroed out (except for
the parameter list header) This sets all defaults because the defaults for the
DESERV macro are 0. All required keywords must be specified.

```
RETCODE=retcode RX-Type Address or (2-12)
```

Specifies the address where the return code returned by DESERV will be
stored. Can not be specified on MF=L macro format. The default is not to store
the return code in virtual storage. The return code is always returned in register
15 without regard to whether RETCODE is coded.

```
RSNCODE=rsncode RX-Type Address or (2-12)
```

Specifies the address where the reason code returned by DESERV will be
stored. Can not be specified on MF=L macro format. The default is not to store
the return code in virtual storage. The return code is always returned in register
0 without regard to whether RETCODE is coded.

DESERV code is available and used by the system starting with DFSMSdfp Version
1.1. However, invoking the EXIT function requires that the appropriate PTF be
applied to the system to enable the support. Your program can test to determine if
the appropriate level of DFSMS™ or PTF is installed.

If the DESERV FUNC=EXIT interface is called on DFSMS without the support code
being available, DESERV returns an error return and reason code.

### Installing or Replacing the DESERV Exit

Your program, while operating in task mode, can establish DESERV exits by issuing
the DESERV macro with FUNC=EXIT and appropriate parameters.

<table>
<thead>
<tr>
<th>If EXIT_OPTION =</th>
<th>then:</th>
<th>and these parameters...</th>
</tr>
</thead>
<tbody>
<tr>
<td>REPLACE</td>
<td>The new exit definition replaces the most recently defined exit. The DST (DESERV Screen Table) address of the previously defined exit's DST is returned to the caller.</td>
<td>EXIT_DST and EXIT_PREV_DSTPTR must be specified.</td>
</tr>
<tr>
<td>NOREPLACE (with no exit currently existing)</td>
<td>The exit definition is activated. A value of zero is returned as the previous DST address.</td>
<td>See REPLACE.</td>
</tr>
<tr>
<td>NOREPLACE (with an exit currently existing)</td>
<td>The currently defined exit remains the active exit. The address of the currently defined DST is returned as the previous DST address.</td>
<td>See REPLACE.</td>
</tr>
</tbody>
</table>

**Note:** If EXIT_OPTION=REPLACE is specified the caller must expect that a previous DST address is returned. It is the responsibility of the caller to replace the old DST address when eventually disabling the new exit. Also the exit routine might need to be aware that there was a previous exit defined, and might choose to invoke the previously defined exit.

EXIT_DST defines the DST address. The DESERV FUNC=EXIT caller owns and manages storage for the DST. The DST can be encapsulated inside other application managed control blocks. This can help the exit routine determine the context of the application in which it was called. When the DST is used with a task level exit, the DST_FLAGS_PROP bit can be set on to indicate that this DST should
DESERV Exit

be propagated to tasks that are attached by this task. The propagate function is not supported for the global exit. The format of the DST is shown in Table 58.

Table 58. DESERV Screen Table Structure

<table>
<thead>
<tr>
<th>Offset</th>
<th>Length or Bit Pattern</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Reserved</td>
</tr>
<tr>
<td>16 (X'10')</td>
<td>4</td>
<td>DST_EXIT</td>
<td>Address of exit routine screen table (address)</td>
</tr>
</tbody>
</table>

EXIT_PREV_DSTPTR returns the address of the DST that was defined prior to this DESERV FUNC=EXIT call.

Deleting the DESERV Exit

An application that has established a DESERV exit can delete the currently active exit by issuing the DESERV macro with FUNC=EXIT. You can specify the following:

Table 59. Deleting the DESERV Exit

<table>
<thead>
<tr>
<th>For this parameter</th>
<th>specify this:</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXIT_SCOPE</td>
<td>(application dependent)</td>
</tr>
<tr>
<td>EXIT_OPTION</td>
<td>DELETE</td>
</tr>
<tr>
<td>EXIT_DST</td>
<td>Currently active DST to be deleted</td>
</tr>
<tr>
<td>EXIT_PREV_DSTPTR</td>
<td>The DST to become active</td>
</tr>
</tbody>
</table>

Note: The address of the DST must match that of the currently defined DST. If the addresses do not match, DESERV returns error return and reason codes to indicate the DELETE operation has failed and the active DST remains unaffected.

For a task related exit, the DESERV exit is implicitly deleted when the task ends. A global exit can only be explicitly deleted by issuing a DESERV FUNC=EXIT call.
Determining If a DESERV Exit Is Active

To determine if a DESERV exit is active issue the DESERV macro with FUNC=EXIT and choose the following options:

**Table 60. Determining If a DESERV Exit Is Active**

<table>
<thead>
<tr>
<th>For this parameter</th>
<th>choose this:</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXIT_OPTION</td>
<td>QUERY</td>
</tr>
<tr>
<td>EXIT_SCOPE</td>
<td>(application dependant)</td>
</tr>
<tr>
<td>EXIT_PREV_DSTPTR</td>
<td>The address of a 4 byte area into which the currently active DST address is returned (or zero if there is no currently defined DST address.)</td>
</tr>
</tbody>
</table>

Writing the DESERV Exit

A DESERV exit gets control once prior to any DESERV GET, PUT, RENAME, UPDATE or DELETE function processing, and once immediately prior to DESERV's return to the caller. A DESERV exit receives control in key 0 and supervisor state. Register 13 points to an 18-word key 0 register save area.

The DESX DSECT maps the input to the exit routines and is defined in the IGWDES macro. Register 1 points to the DESX on entry to the exit routine. The DESX structure is shown in Table 61.

DESERV Exit

Note that the DESERV return and reason codes, with the exception of the PUT codes, can be found in [z/OS DFSMS Using Data Sets]. See Figure 36 on page 377 for the PUT return and reason codes.

Parameters Related to the GET Function

If the DESERV exit gets control for a DESERV GET function invocation, DESX_DESP_PTR points to the DESERV parameter list. If the DESP field DESP_FUNC=X'01' (DESP_FUNC_GET), this indicates a GET function parameter list. See Table 62 on page 363 for the DESP structure for fields pertaining to a DESERV GET invocation.

DESERV GET will return information on selected members. This information is returned in a DESB structure. The DESB is mapped by the DESB DSECT in the IGWDES macro. If the storage for the DESB is provided by the DESERV GET, the DESP_AREA_PTR field contains the address of this storage. Alternatively the caller may request that DESERV GET not obtain the storage for the DESB. In this case the DESP_AREA_PTR field contains the address of a 4 byte area into which DESERV GET will return the address of a DESB. The DESB will be obtained in the subpool identified by DESP_SUBPOOL (or default to subpool zero). The flag DESP_SUBPOOL_FLG indicates whether the subpool was specified explicitly by the DESERV GET caller.

A DESERV GET invocation identifies the members to be searched for by a name list, a PDS format directory entry, or an SMDE. The DESP field DESP_GETTYPE defines the get type. If the get type is a PDSDE (the member to be searched for is defined by a PDS format directory entry), the DESP_PDSDE_PTR points to a directory entry as returned by the BLDL macro. The PDS2 DSECT in the IHAPDS macro maps this structure. The function of DESERV GET for a PDSDE get type depends on the type of library identified by the concatenation number in the PDS style directory entry. If the concatenation number identifies a PDS, the GET function is simply to convert the PDS style directory entry into a SMDE. If the concatenation number identifies a PDSE, the GET function is to connect to the member identified by the PDS2TTRP field, and to return the appropriate SMDE. In either case the SMDE is returned (if in the PDSE case the member actually exists) in the data portion of the output buffer (DESB, mapped below).

If the get type is name list, the DESL area points to the names to be searched for. The DESP_NAME_LIST_PTR points to the DESL and the DESL DSECT in the IGWDES macro maps it. A DESL is an array consisting of the number of entries the DESP field DESP_NAME_LIST2 defines. The DESL parameter list is shown in Table 63 on page 365.

If the get type is SMDE, the DESP_SMDE_PTR points to a system-managed directory entry (SMDE) as returned by DESERV GET. DESERV GET will cause a connection to the member identified by the SMDE. DESERV GET will return a copy of the SMDE in the output DESB. The SMDE returned will of course have updated connect token and connect id fields.

There are two input flags which control DESERV GET's view of the PDS or PDSE to be searched. If the DESP_C370LIB flag is on, a PDS may be viewed as a C370LIB. This means that if the PDS has a special member named @@DC370$, this member is treated as the "real" directory for the PDS. If the DESP_SYSTEM_DCB is on, this indicates that the caller (who must be authorized) has indicated that this DCB is "owned by the system" and is not on any DEB chain, therefore DEBCHK should not be done.

</tbody>
</table>

The DESERV GET caller will have built the DESL to point to variable length names. The DESN DSECT maps these names in the IGWDES macro. See Table 64 for the DESN parameter list.

Table 64. DESN Parameter List

<table>
<thead>

<td>DESN_VAL</td>
<td>Name data (character)</td>
<td></td>
</tr>
</tbody>
</table>

The DESP_CONN_INTENT field of the DESP indicates the connection intent requested by the caller. The connection intent only has an effect if the name is found in a PDSE. If the connection intent is DESP_CONN_INTENT_HOLD (X'01'), the effect is similar to a BDLI invocation (because the member is connected for HOLD which is not sufficient to read the member). If the connection intent is DESP_CONN_EXEC (X'02') or DESP_CONN_INTENT_INPUT (X'03'), the effect is similar to a FIND invocation (because the member is connected and sufficient...
control blocks are built so that the member can be read). The GET function does not currently support a connect intent of NONE.

The output from DESERV GET consists of flags and error codes in the DESL (if the get type is name list) as well as an SMDE (system managed directory entry) pointer. For a gettype of name list, the SMDE is pointed to by the DESL_SMDE_PTR field. For a gettype of PDSDE, the SMDE is in the DESB at the label DESB_DATA. The SMDE is mapped by the SMDE DSECT in the IGWSMDE macro and the PMAR DSECT in the IEWPMAR macro. The SMDE resides in the output buffer as provided by the caller of DESERV GET. The output buffer is mapped by the DESP DSECT of the IGWDES macro. The DESB structure is shown in Table 65.

The basic SMDE format is shown in Table 66.

</tbody>
</table>

If the SMDE represents a directory entry for a program (either a load module or a program object) the program's attributes are defined by the PMAR structure. The PMAR is a subfield of the SMDE and its offset is defined by the field SMDE_PMAR_OFF. Table 71 on page 369 shows the basic PMAR definition. Table 72 on page 371 and Table 73 on page 373 show the PMAR extensions for program objects (PMARL) and load modules (PMARR), respectively.

If the SMDE represents a data member of a PDS or a PDSE, the SMDE_USRD_OFF field indicates the offset into the SMDE for the user data of the directory entry.
Table 71. Directory Entry Name Section. Data is always present at offset SMDE_PMAR_OFF in an SMDE.

Parameters Related to the PUT Function

If the DESERV exit gets control for a DESERV put function invocation, DESX_DESP_PTR points to the DESERV parameter list. If the DESP field DESP_FUNC=X'04' (DESP_FUNC_PUT), this indicates a PUT function parameter list. Table 75 shows the fields of the DESP that pertain to the DESERV PUT invocation.

</tbody>
</table>
The DESD_FLAG_ALIAS identifies the entry in the DESD as a primary or an alias.

The DESERV exit is passed to the current return and reason code that is to be passed back to the DESERV caller. The exit (either the pre-processing or the post-processing) can cause DESERV to return a different return and reason code to the DESERV caller by returning with a return code of 4 in register 15. If the exit returns control to DESERV with a return code of 4 in register 15, the (possibly modified) values of DESX_RETURN_CODE and DESX_REASON_CODE are returned to the caller of DESERV. If the pre-processing exit returns a return code of 0 in register 15, processing continues. Whereas if the post-processing exit returns with a return code of 0 in register 15, the original values of DESX_RETURN_CODE and DESX_REASON_CODE (those that were passed as input to the exit) are returned to the DESERV caller.

The exit processing can include interrogation of the DESERV parameter list (DESP) or interrogation or modification of the other interface structures and buffers. The DESP will not be modified by the DESERV exit. The exit is passed the caller key DESP, but DESERV has already made a key 5 copy of the DESP that is used for DESERV processing. Therefore modifications to the caller key DESP would not
influence the DESERV processing. The DESERV interface structures are defined in the macro IGWDES. The macros IGWSMDE and IEPMAR define the directory entry format.

Parameters Related to the DELETE Function

If the DESERV exit gets control for a DESERV DELETE function invocation, DESX_DESP_PTR points to the DESERV parameter list. If the DESP field DESP_FUNC=X'07' (DESP_FUNC_DELETE), this indicates a DELETE function parameter list. Table 77 shows the fields of the DESP that pertain to the DESERV DELETE invocation.

</table>

The DESL points to the names to be deleted. The DESP_NAME_LIST_PTR points to the DESL and the DESL DSECT in the IGWDES macro maps it. A DESL is an array consisting of the number of entries the DESP field DESP_NAME_LIST2 defines. The DESL structure is shown in Table 63 on page 365.

### Parameters Related to the RENAME Function

If the DESERV exit gets control for a DESERV RENAME function invocation, DESX_DESP_PTR points to the DESERV parameter list. If the DESP field DESP_FUNC=X'08' (DESP_FUNC_RENAME), this indicates a RENAME function parameter list. Table 78 shows the fields of the DESP that pertain to the DESERV RENAME invocation.

DESERV Exit

The DESL points to the names that are to be renamed and to the new names. The DESP_NAME_LIST_PTR points to the DESL and the DESL DSECT in the IGWDES macro maps it. A DESL is an array consisting of the number of entries the DESP field DESP_NAME_LIST2 defines. The DESL structure is shown in Table 63 on page 365.

Parameters Related to the UPDATE Function

If the DESERV exit gets control for a DESERV UPDATE function invocation, DESX_DESP_PTR points to the DESERV parameter list. If the DESP field DESP_FUNC=X'09' (DESP_FUNC_UPDATE), this indicates an UPDATE function parameter list. Table 79 shows the fields of the DESP that pertain to the DESERV UPDATE invocation.

</tbody>
</table>

The DESL points to the SMDEs which are to be updated. The DESP_NAME_LIST_PTR points to the DESL and the DESL DSECT in the IGWDES macro maps it. A DESL is an array consisting of the number of entries the DESP field DESP_NAME_LIST2 defines. The DESL structure is shown in Table 63 on page 365.

### Entry Environment for Exit Routine

- **Interrupts:** Enabled
- **State and Key:** Supervisor state and key 0
- **ASC Mode:** P=H=S
- **AMODE, RMODE:** AMODE=31, RMODE=ANY
- **LOCKS:** No locks held

### Registers:

- **0** unpredictable
- **1** address of DESERV EXIT parameter list mapped by DSECT DESX in IGWDES.
- **2-12** unpredictable
- **13** eighteen word save area (key 0).
The exit is entered in TASK mode and the DESERV recovery environment is an ESTAE; therefore, the exit routine can issue SVCs, if required.

**Exit Environment for Exit routine**

**Interrupts:**
- Enabled

**State and Key:**
- Supervisor state and key 0

**ASC Mode:**
- P=H=S

**AMODE, RMODE:**
- AMODE=31, RMODE=ANY

**LOCKS:**
- No locks held

**Registers:**

Unless otherwise specified, all registers must be restored to their contents on entry.

**15 Return code**

For pre-processing exit:

- **R15 = 0** Continue processing of this DESERV call.
- **R15 = 4** Discontinue processing of this DESERV call. Control is immediately returned to the caller of DESERV with the return and reason codes as set by the exit in the DESX fields DESX_RETURN_CODE and DESX_REASON_CODE.

For post-processing exit:

- **R15 = 0** Continue processing of this DESERV call (that is, return to the caller of DESERV).
- **R15 = 4** Control is returned to the caller of DESERV with the return and reason codes as set by the exit in the DESX fields DESX_RETURN_CODE and DESX_REASON_CODE. Values for DESX_RETURN_CODE and DESX_REASON_CODE are described in the macro IGWDES. The reason code structure is such that the first two bytes are system component id and module id (that is, system diagnostic information). The low order two bytes contain the real reason code as indicated in the macro IGWDES. For additional return and reason codes for the GET, RENAME, DELETE, and UPDATE return and reason
Restriction: Any other return code from the exits causes DESERV code to take an SVC dump.

Registers on Entry to the DESERV Exit
When your DESERV exit gets control, the general-purpose registers have the following content:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>not applicable</td>
</tr>
<tr>
<td>1</td>
<td>address of DESX</td>
</tr>
<tr>
<td>2-12</td>
<td>not applicable</td>
</tr>
<tr>
<td>13</td>
<td>address of register save area</td>
</tr>
<tr>
<td>14</td>
<td>return address</td>
</tr>
<tr>
<td>15</td>
<td>address of DESERV exit entry point</td>
</tr>
</tbody>
</table>

Registers on Return from the DESERV Exit
When you return control to DESERV, the register contents must be set up as follows:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-14</td>
<td>restored to contents at entry</td>
</tr>
<tr>
<td>15</td>
<td>return code</td>
</tr>
</tbody>
</table>

DESERV Exit Return and Reason Codes

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00 (X'00')</td>
<td>Continue with DESERV function</td>
</tr>
<tr>
<td>04 (X'04')</td>
<td>Return immediately to the DESERV caller and return the return and reason codes as defined by DESX_RETURN_CODE and DESX_REASON_CODE respectively.</td>
</tr>
</tbody>
</table>
### DESERV Exit

#### DESERV FUNC=EXIT Return and Reason Codes

The formats of the return and reason codes are:

<table>
<thead>
<tr>
<th>Offset/length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>00 (X'00') 1 byte</strong></td>
<td>SMS Component code (X'27') indicates Common Adaptor (of which DESERV is a part)</td>
</tr>
<tr>
<td><strong>01 (X'01') 1 byte</strong></td>
<td>Module ID - used for problem diagnosis</td>
</tr>
<tr>
<td><strong>02 (X'02') 2 bytes</strong></td>
<td>Reason code - identifies the error. A program testing the DESERV reason code should only look at these last two bytes. The component id and module id should not be tested. They are reported for diagnostic purposes only.</td>
</tr>
</tbody>
</table>

The following are the two low order byte values for the reason codes that DESERV FUNC=EXIT might return (sorted by return code).

#### Table 80. Return and Reason Codes for the Exit DESERV Function

</tbody>
</table>

Additional Return and Reason Codes: For the GET, RENAME, DELETE, and UPDATE return and reason codes, refer to z/OS DFSMS Macro Instructions for Data Sets.

Example of the DESERV Exit

The following program segment establishes and deletes the task mode DESERV exit and thereby restores the previous task. The sample is generic enough to apply to either the global or the task level exit but shows here the task level support. When establishing a global exit, obtain the DST storage in common storage.
SAMPLE CSECT
USING *,12
STM 14,12,12(13)  SAVE REGISTERS
LR 12,15  ESTABLISH BASE REGISTER
LA 2,SAVE  ADDRESS REGISTER SAVE AREA
ST 2,8(13)  FORWARD CHAIN SAVE AREA
ST 13,SAVE+4  BACKWARD CHAIN SAVE AREA
LR 13,2  ESTABLISH SAVE AREA
.
.
.

* ESTABLISH THE TASK LEVEL EXIT
* BUILD THE DST TO REPRESENT MY TASK LEVEL EXIT
* LA 3,MY_DST  ADDRESSABILITY TO MY DST
USING DST,3  MAP DST
XC DST,DST  CLEAR MY DST STORAGE
MVC DST_ID,DST_ID_CONST  SET EYECATCHER IN DST
LA 15,DST_LEN_IV(,0)  GET LENGTH OF DST
ST 15,DST_LEN  SET LENGTH OF DST
MVI DST_LEV,DST_LEV_IV  SET LEVEL OF DST USED
OI DST_FLAGS,DST_FLAGS_PROP  SET FLAG TO PROPAGATE THIS EXIT TO ATTACHED TASKS.
MVC DST_EXIT_PTR,ADDR_DESEXIT  SET ADDRESS OF TASK EXIT

* CALL DESERV TO ENABLE MY TASK LEVEL EXIT
* THIS MODULE ASSUMES THAT IT IS RUNNING EITHER SUPERVISOR STATE OR SYSTEM KEY.
* DESERV FUNC=EXIT,
  EXIT_SCOPE=TASK,
  EXIT_OPTION=REPLACE,
  EXIT_DST=MY_DST,
  EXIT_PREV_DSTPTR=MY_PREV_DSTPTR,
  MF=S
.
.
.

* QUERY THE CURRENT DST ADDRESS, RETURNED IN CURRENT_DSTPTR.
* THERE IS NO NEED TO QUERY PRIOR TO DOING THE DELETE, THIS IS HERE JUST TO SHOW THE INVOCATION SYNTAX.
* DESERV FUNC=EXIT,
  EXIT_SCOPE=TASK,
  EXIT_OPTION=QUERY,
  EXIT_PREV_DSTPTR=CURRENT_DSTPTR,
  MF=S

Figure 37. Establishing and Deleting a Task Level DESERV Exit (Part 1 of 2)
DESERV Exit

Here the application would do something to cause a DESERV call to be done. An example of this type of thing would be attaching the binder as a subtask (the binder uses DESERV).

Delete the task level exit

```
DESERV FUNC=EXIT,
EXIT_SCOPE=TASK,
EXIT_OPTION=DELETE,
EXIT_DST=MY_DST,
EXIT_PREV_DSTPTR=MY_PREV_DSTPTR,
MF=S

* RESTORE REGISTERS AND RETURN
L 13,SAVE+4
LM 14,12,12(13)
SR 15,15 SET RETURN CODE
BR 14 RETURN TO CALLER
```

The following is a block used by this application. This block can be used by the exit. The exit also (smartly) finds the prev_dst_ptr field in my_block when it gives control to the previously established task level exit.

```
MY_BLOCK DS 0D MY APPLICATION BLOCK
MY_APPLICATION_STUFF DS CLB MY APPLICATION STUFF
MY_DST DS CL(DST_LEN_IV) MY DST IMBLED IN MY BLOCK
MY_PREV_DSTPTR DS F ADDRESS OF PREVIOUS TASK LEVEL
ADDR_DESEXIT DC A(DESEXIT) ADDRESS OF MY TASK LEVEL EXIT
DST_ID_CONST DC CLB'IGWDST ' DST EYECATCHER
CURRENT_DSTPTR DS F ADDRESS OF CURRENT TASK LEVEL
SAVE DS 1BF REGISTER SAVE AREA
END
```

Figure 37. Establishing and Deleting a Task Level DESERV Exit (Part 2 of 2)

The following program segment shows a sample DESERV exit. This is the exit established by the previous segment of code. This sample shows how to pass control to a previous exit. Note that this sample exit is not reentrant, so it assumes there is only one subtask.
DESEXIT CSECT
DESEXIT AMODE 31 Must be AMODE 31
DESEXIT RMODE ANY Could be RMODE 24 if required
*
* entry code to save registers and establish base register.
* USING *,12
  STM 14,12,12(13) SAVE REGISTERS
  LR 12,15 ESTABLISH BASE REGISTER
  LA 2,SAVE ADDRESS REGISTER SAVE AREA
  ST 2,8(13) FORWARD CHAIN SAVE AREA
  ST 13,SAVE+4 BACKWARD CHAIN SAVE AREA
  LR 13,2 ESTABLISH SAVE AREA
*
* Assume this exit is only interested in the output from GET functions.
* Therefore ignore entry for all other functions and only
* process the get function invocations where get processing is complete
*
  SLR 2,2 clear reg
  ST 2,EXIT_RC initialize return code
  LR 2,1 get the DESX address in reg 2
  USING DESX,2 map the DESX
  L 3,DESX_DST_PTR get address of DST
  LR 4,3 get address of DST
  LA 5,MY_DST-MY_BLOCK(,0) get offset to DST within MY_BLOCK
  SR 4,5 get the address of MY_BLOCK
  USING MY_BLOCK,4 map MY_BLOCK
*
* First give control to any previously established DESERV
* exits. If the value in PREV_DST_PTR is zero, then there was no
* previous DST (that is, no previous DESERV exit). PREV_DST_PTR was
* saved in MY_BLOCK by the SAMPLE CSECT that enabled this
* exit.
  SR 15,15 simulate previous exit's return code
  ICM 5,15,PREV_DST_PTR get previous DST address
  BZ NOPREVDST branch if zero, no previous DST
* There was a previous exit, to which you transfer control.
* First build a DESX then branch to the previous exit.
*
*
* Getmain dynamic storage for interfacing with the other exit
*
* GETMAIN RU,LV=DESX_LEN_IV,SP=230,KEY=0,LOC=(ANY)
  ST 1,MY_DESX_STG_PTR
  MVC 0(L'DESX,1),DESX copy the DESX that was input to this
* routine.
  ST 5,DESX_DST_PTR-DESX(,1) Set previous DST address in DESX
  L 15,DST_EXIT_PTR-DST(,5) get address of previous exit
  BALR 14,15 call the previous exit in 31 bit amode

Figure 38. Sample DESERV Exit Routine (Part 3 of 3)
Chapter 11. Managing Hierarchical File System Data Sets

A hierarchical file system (HFS) data set is a data set that contains a POSIX-compliant hierarchical file system, which is a collection of files and directories organized in a hierarchical structure that can be accessed using z/OS UNIX system services. You can use many of the standard BSAM, QSAM, BPAM, and VSAM interfaces to access data in z/OS UNIX HFS files. Most applications that use these access methods can access HFS files without reassembly or recomilation.

The contents of HFS data sets are structured like a tree, based on a root directory with various subdirectories. The files within an HFS data set are identified by their path and file names.

DFSMShsm can automatically back up HFS data sets if it is using DFSMSdss as its data mover, but it cannot back up individual files within an HFS data set.

Once you evaluate z/OS UNIX and decide to install it in your enterprise, you may proceed with the following planning tasks:

- Deciding which DASD devices will contain the HFS data sets
- Deciding how to control access to them
- Structuring the file systems
- Determining backup, restore, and expiration date policies
- Determining HFS naming policies (file names can be up to 255 characters long and path names can be up to 1023 characters)
- Defining data classes, management classes, and coding ACS routines and JCL statements for HFS data sets

Creating Hierarchical File System Data Sets

You specify HFS in the DSNTYPE parameter to allocate an HFS data set. You can also define a data class for HFS data sets. Both cataloged and uncataloged HFS data sets can reside on a single non-SMS-managed volume. A cataloged HFS data set can also be a multivolume if it resides on Storage Management Subsystem managed volumes. This type of data set can expand to as many as 255 extents of direct access storage device (DASD) space on multiple volumes (59 volumes maximum with 123 extents per volume).

RACF or an equivalent security product must be installed and active on your system to use z/OS UNIX or HFS data sets. z/OS UNIX maintains system security by verifying user identities and file access control information.

This information covers the following:

- Defining the Root File System
- Creating and Mounting the Root File System on page 396
- Creating Additional File Systems and Directories on page 396
- Adding and Mounting File Systems to the Root File System on page 396

Defining the Root File System

During installation of z/OS UNIX, a system programmer or storage administrator codes the ROOT statement in the BPXPRMxx member of SYS1.PARMLIB. This
Planning for HFS

identifies the HFS data set containing the root file system for the system to logically
mount when it starts z/OS UNIX system services.

ROOT FILESYSTEM('OMVS.ROOT')
TYPE(HFS)
MODE(RDWR)

The root file system is the starting point of the overall file structure. It consists of the
root directory and any related HFS files or subdirectories. After installation is
complete and the MVS system is running, you can create (allocate) an HFS data
set, which contains the root file system.

See z/OS MVS Initialization and Tuning Reference for information about member
BPXPRMxx.

Creating and Mounting the Root File System

Create an HFS data set to contain the root file system by running a job to allocate
the data set. During allocation, z/OS UNIX builds a basic root directory, which you
can alter to meet your specific needs. You specify DSNTYPE=HFS to designate an
HFS data set.

//STEP1 EXEC PGM=IEFBR14
//MKFS DD DSNAME=OMVS.ROOT,DISP=(NEW,CATLG),
// DSNTYPE=HFS,SPACE=(CYL,(1,1,1))

Tip: To make the HFS data set SMS-managed, use the ACS routines or specify the
STORCLAS parameter in the JCL. HFS data sets do not have to be
SMS-managed.

Write operations present the greatest exposure to file system damage. For this
reason the root file system should be small, minimizing the amount of write activity
to it, thus offering the least exposure to damage.

Additionally, if all users’ files are in file systems that are mounted on the root file
system, rather than defined as part of the root itself, and users are denied write
access to the root, the root is further protected from inadvertent damage. Damaged
user directories or files can be unmounted and replaced without causing z/OS UNIX
system services to fail.

Creating Additional File Systems and Directories

After allocating an HFS data set for the root file system and logging on as a TSO/E
user, you can define additional directories in the root file system using the MKDIR
command. For example, to create the /u/joe directory, issue:

MKDIR '/u'
MKDIR '/u/joe'

These directories can be used as mount points for additional mountable file
systems. You can use an IBM-supplied program that creates directories,
pseudo-TTY pairs, and device files. Interactive users and application programs can
then add files to those additional file systems.

The MKDIR command requires written permission on the parent directory of the
directory to be created.

Adding and Mounting File Systems to the Root File System

If you have appropriate authority, you can create other mountable file systems with
their own directory and data file structures, and mount them on a directory in the
root file system or in another file system. Each file system can be logically mounted to a directory (mount point) in another file system by using the TSO/E MOUNT command. Use the UNMOUNT command to unmount a file system. To create and mount additional file systems:

1. Allocate an additional HFS data set by using either the TSO/E ALLOCATE command as shown in the following example or a JCL DD statement similar to that shown in "Creating and Mounting the Root File System" on page 396.

   ALLOCATE DSNAME('OMVS.USER.JOE') NEW DSNTYPE(HFS) BLKSIZE(0)
   LRECL(8) RECFM(U) DSORG(PO) SPACE(1,1) CYLINDERS

   The new data set is allocated with an empty root directory.

2. Have an authorized user enter a TSO/E MOUNT command to logically mount the new file system in the directory of an existing file system.

   MOUNT FILESYSTEM('OMVS.USER.JOE') TYPE(HFS) MOUNTPOINT('/u/joe')

You can specify additional file systems to be logically mounted automatically every time z/OS UNIX is started by adding MOUNT commands to the BPXPRMxx member of SYS1.PARMLIB. The following restrictions apply to mounting file systems:

- The mount point must be a directory.
- Any files in the directory are not accessible while the file system is mounted.
- Only one mount can be active at any time for a mount point.
- A file system can be mounted on only one directory at a time.

You can also create special HFS files to perform the following tasks:

- Represent hardware devices (character special files).
- Allow the use of alias names for HFS files (symbolic links).
- Send data from one process to another so that the receiving process reads the data first-in-first-out (FIFO special files, also called named pipes). The term process as used here is defined as either a program that is created by the fork function, or a program that requests z/OS UNIX system services.

### Managing File System Size

File system size increases as users add files and extend existing files. Eventually, a file system can outgrow the space on its volume. In this case, the storage administrator or system programmer responsible for HFS data sets can either make more space available on the volume by moving individual HFS files to other file systems that have space available, or do one of the following:

- Move the entire file system to another set of volumes as follows:
  1. Have an authorized user enter a TSO/E UNMOUNT command to logically unmount the file system.
  2. Allocate an HFS data set with a different data set name on a volume, or set of volumes, that has adequate space available.
  3. Use the DFSMSdss DUMP function to logically dump the old file system.
  4. Use the DFSMSdss RESTORE function to restore the dumped file system with a new name to a volume, or set of volumes, that has sufficient space. If you want to maintain the original file system name, delete the existing file system first, and then restore it using DFSMSdss without renaming it.
- Remove files from the file system by either deleting them or by moving them to another file system. If it is impossible to remove the chosen files from a particular directory in the file system, it may be possible to remove other files from a different directory in the same file system. The objective is to reduce the size of the file system.
Planning for HFS

- Create a new file system on another volume, or set of volumes, and move some files from the full file system to the new file system. To avoid problems that can result from this approach, define symbolic links using the original names.
- Add another volume to the file system candidate volume list with the IDCAMS ALTER ADDVOLUMES command. The file system must be unmounted and remounted for the additional volumes to be usable by the HFS.
- The storage administrator or system programmer can monitor the space in a file system by mounting an HFS with parm FSFULL. For example, mount parm('FSFULL(70,10)') will cause HFS to issue message IGW023A when the file system is 70 percent full and then issues an additional IGW023I messages when the file system is 80 and 90 percent full.

The BPX1PCT callable service can be used to extend the file system (see "Using psctll (BPX1PCT) Physical File System Control for HFS" on page 401).

Managing File System Activity

If activity for a file system becomes so extensive that accesses are slow, you can do one of the following tasks:

- Move the file system to a volume that processes I/O more quickly, for example, a volume that has a faster channel or a cached storage control.
- Move a subtree from the full file system into a new file system on a different volume. Mount the new file system on the now-empty directory, which was the head of the subtree. This divides I/O activity between two volumes. To avoid failures from this action, define symbolic links using the original names.

Accessing HFS Data Set Attributes

Any application (for example, Interactive System Productivity Facility (ISPF) option 3.4I or DCOLLECT) that requests size information about HFS file system requires OMVS to service that request. This means that the user ID must be defined to OMVS and have Resource Access Control Facility (RACF) authority to access the data set. The HFS file system must be either mounted on this file system or mountable (that is, not already mounted READ/WRITE on another system).

Transporting a File System

You might also want to copy a data set to a storage medium that can be physically transported to another location. In order to do that, perform one of the following tasks:

- Use either the PAX, CPIO, or TAR shell commands to copy the file system in tape archive (TAR) format.
- Have an authorized user logically unmount the file system, allocate an HFS data set with a different data set name, and use the DFSMSdss dump utility to copy the old file system to the new data set.
Removing (Deleting) a File System

If you mount the file system (HFS data set) to a different file system or you want to delete it, first logically unmount it using the TSO/E UNMOUNT command against the HFS data set containing it. Then you can use either or both of the MOUNT commands (see “Adding and Mounting File Systems to the Root File System” on page 396).

You can eliminate the file system by using any of the following techniques:
- Use the DELETE command (IDCAMS or TSO).
- Execute an IEFBR14 job with DISP=(OLD,DELETE) specified for the HFS data set.
- ISPF option 3.x.
- Use the SCRATCH and UNCATLG commands of IEHPROGM.

Migrating a File System

If a file system is unmounted and remains so for a predetermined time, the system can migrate it to a lower priority storage medium. The system automatically recalls a migrated file system from migration storage if a mount command is issued for the file system.

If you plan to migrate HFS data sets, consider migrating them only to level 1 (DASD) storage. Recalling a data set that was migrated to tape could adversely affect performance because of the time required to physically mount the tape volume.

If the tape is in an automated library, then recalling it should be much faster than if the system has to request an operator to mount it.

Backing Up File Systems

DFSMShsm provides automatic backup facilities for HFS data sets. You can back up mountable file systems by periodically backing up the HFS data sets that contain them; the data sets can be restored if necessary. DFSMShsm is also used for migrating and restoring unmounted file systems.

You can manually back up a mountable file system, including the root file system, periodically with DFSMSdss data set dumps. To do this, issue the DFSMSdss DUMP command. This quiets activity against the specified HFS data set, then invokes backup processing. When the backup is complete, the file system is unquietsed and user activity can resume.

Retain periodic DFSMSdss data set dumps of file systems in case a program fails and damages files and directories. Keep this backup in another area or different building in case the computer site experiences physical damage.

There is no facility for automatically backing up individual files within an HFS data set. You can manually back up files with the PAX, CPIO, and TAR commands.

For more information on using DFSMSdss, refer to the DFSMSdss section of z/OS DFSMSdfp Storage Administration, SC26-7402.
**Recovering a Backed-Up File System**

If a file system is damaged, you can recover by replacing it with a saved version that was created from an earlier backup. To recover a backed up file system, you must perform the following tasks:

1. Notify all users to stop all activity on the damaged file system.
2. Have an authorized user enter the TSO/E UNMOUNT command with the IMMEDIATE option to logically unmount the damaged file system. If the unmount fails, reenter the UNMOUNT command with the FORCE option.
3. Use the DFSMSdss dump utility to restore the backed up file system to a replacement file system (HFS data set). You can do this simultaneously with the previous steps.
4. Have an authorized user enter a TSO/E MOUNT command to logically mount the replacement file system. Ensure that the MOUNT commands in the BPXPRMxx member in SYS1.PARMLIB are consistent with this MOUNT command.
5. Issue a broadcast message to all users or a message to all z/OS UNIX users when they invoke the shell, telling them that you have mounted a back-level file system and informing them of the mount point. Users must recreate and add any files added since the file system was backed up.

You might choose a more disruptive method to recover a backed up file system for the root file system. Refer to [z/OS UNIX System Services Planning](#), "Shutting Down z/OS Unix", for more information on how to perform a shutdown.

**HFS Deferred File System Synchronization**

Normal HFS disk hardening executes under a sync daemon that runs periodically to write out all file and metadata changes that have occurred since the last time the sync daemon ran. If a large number of files are created, modified, or deleted within the time span that is between the file system sync intervals, then with the next file system sync, these file changes are collected and the disk version of the file system is sync'ed with a greatly reduced number of media manager calls. This reduces the actual I/O activity.

The reduced I/O can have a dramatic effect on performance, because the default sync daemon interval is one minute. The sync daemon runs in the OMVS address space and is independent of any user request to the file system.

When the sync daemon runs, all the HFS changes are batched into one large I/O request that gets passed to the media manager. The intent is to perform one long I/O operation to the HFS on disk. However, even with optimal conditions, where the HFS resides on one volume and is contained within a single extent, it is necessary to have a few media manager calls during the disk hardening I/O operation. If the HFS has multiple extents or resides on multiple volumes, multiple channel programs must be built, because a single I/O operation cannot span multiple extents.

In addition to the sync daemon interval, HFS also supports the individual file sync (fsync). The fsync can be performed at any time by the application program. However, be aware that an fsync will result in the entire file system being sync'ed. It is very important to note that during the HFS file system sync operation, the sync task runs independently of the users that are currently accessing the HFS. When the sync task runs, it obtains an exclusive latch for the file system being sync'ed. This latch is held for the duration of the file system sync operation. While this latch
Planning for HFS

is held UNIX system services users of the HFS file system will not be able to
access the HFS. When the sync task runs, the HFS must:
1. Update all of the new or changed files’ metadata 
2. Delete structures for any removed files 
3. Update the internal HFS storage maps within the HFS attributes directory 
4. Call the media manager to perform the I/O operation that makes the changes to
the disk version of the HFS data set.

The I/O operation is synchronous, which means that HFS sync task will be
suspended for the duration of the media manager call. Normally, this file system
sync lockout condition is brief, lasting for a few seconds, and is rarely noticed by
the end user. However, in some situations the file system sync lockout could last
much longer. The duration of the lockout depends on the sync interval, the amount
of work that must be performed by the SYNC task, and the performance of the I/O
subsystem.

To minimize the effect on applications from the file system sync operations that take
a long time to complete, you can do one or more of the following:
1. Mount the affected HFS with a shorter sync interval. This will reduce overall
   HFS performance, but the sync lockout will not be as long.
2. Split the HFS into two or more smaller HFS data sets.
3. Avoid high impact commands such as "rm -R" on large directories.

How to specify a SYNC value

The default HFS SYNC daemon interval value is 60 seconds. You may override this
default by changing the SYNCDEFAULT option of the FILESYSTYPE parameter in
the BPXPRMxx member of SYS1.PARMLIB. Individual HFS data sets can have an
overriding SYNC value. This can be accomplished by specifying a SYNC value on
the ROOT parameter, or a SYNC value on the MOUNT parameter in the
BPXPRMxx member of SYS1.PARMLIB.

Refer to [z/OS MVS Initialization and Tuning Reference, SA22-7592](https://www.ibm.com/support/docview.wss?rs=900&context=LOS&context=IBMknowledgecenter& uid=swg27592000) for details on
how to specify FILESYSTYPE, ROOT, and MOUNT parameters. Additionally,
individual HFS data sets can be mounted by the user with the MOUNT command
that specifies a SYNC value.

Using pfsctl (BPX1PCT) Physical File System Control for HFS

The following information describes the use of pfsctl, BPX1PCT callable service, for
HFS.

The pfsctl callable service, BPX1PCT, conveys a command and an argument to a
physical file system. The meaning of the command and argument are specific to the
physical file system and are defined by the physical file system.

**Format:**

```
CALL BPX1PCT,(File_System_type,
    Command,
    Argument_length,
    Argument,
    Return_value,
    Return_code,
    Reason_code)
```

**File_System_type:**
Planning for HFS

Type: Character string  
Length: 8 bytes  
Character string: HFS

Command:
Type: Integer  
Length: Fullword

If the physical file system is an HFS data set, you can code one of these values:
- X'40000001' DisplayBufferLimits
- X'00000002' ChangeBufferLimits
- X'40000003' DisplayGlobalStats
- X'40000004' DisplayFSStats
- X'00000005' ExtendFS

These HFS-defined commands and the data areas for each are defined in GFUMPCTL, located in SYS1.MODGEN.

Argument Length: A 4-byte integer. See below for the valid values.

Argument: Structure as described below and in Table 82 on page 407, Table 83 on page 407, Table 84 on page 408, or Table 85 on page 409.

Return Value: Fullword

Return Code: A 4-byte integer that BPX1PCT sets to one of the values described in Table 81 on page 406.

Reason Code: A 4-byte integer that BPX1PCT sets to one of the values described in Table 81 on page 406.

If the physical file system is an HFS data set, then the following apply:
- "DisplayBufferLimits Command"
- "Output from TRKCALC" on page 305
- "ChangeBufferLimits Command" on page 403
- "DisplayGlobalStats Command" on page 403
- "DisplayFSStats Command" on page 404
- "BPX1PCT Return and Reason Codes" on page 406

DisplayBufferLimits Command

Function: The DisplayBufferLimits command returns the storage limits in the data area, specifically the VMAX and FMIN values for the HFS buffers currently in effect.

Command: X'40000001'

Argument Length: The argument length is the length of the data area. The data area must be at least the length of PCTL_BFRLIMITS_TYPE. See Table 82 on page 407.

Argument: PCTL_BFRLIMITS_TYPE

Usage Notes
1. The caller does not have to be authorized.
2. VMAX and FMIN values are both in megabytes (MB).
3. This command is equivalent to the confighfs shell command:
   confighfs -l

ChangeBufferLimits Command

**Function:** The ChangeBufferLimits command modifies the storage limits, specifically the VMAX and FMIN values, for HFS buffers as requested in the data area.

**Command:** `X’00000002’`

**Argument_length:**
The argument length is the length of the data area. The data area must be at least the length of `PCTL_BFRLIMITS_TYPE`. See Table 82 on page 407.

**Argument:** `PCTL_BFRLIMITS_TYPE`

**Usage Notes**
1. The following fields must be set within this structure:
   - The `PCTL_BL_ACTION` flag must be set.
   - Modify VMAX by setting the `PCTL_BL_VMAX` flag and specifying the new VMAX value in the field `PCTL_BL_VMAX_VAL`.
   - Modify FMIN by setting the `PCTL_BL_FMIN` flag and specifying the new FMIN value in the field `PCTL_BL_FMIN_VAL`.
2. The caller must be a superuser.
3. A request to modify both VMAX and FMIN can be made in one call.
4. The VMAX and FMIN values are in megabytes (MB).
5. This command is equivalent to the confighfs shell commands. The following confighfs command sets virtual storage maximum (VMAX) to n, where n is in MB:
   ```
   confighfs -v n
   ```
   The following confighfs command sets virtual storage minimum (FMIN) to n, where n is in MB:
   ```
   confighfs -f n
   ```

DisplayGlobalStats Command

**Function:** The DisplayGlobalStats command returns HFS global system level statistics in the data area.

**Command:** `X’40000003’`

**Argument_Length:**
The argument length is the length of the data area. The data area must be at least the length of `PCTL_GLOBALSTATS_TYPE`. See Table 83 on page 407.

**Argument:** `PCTL_GLOBALSTATS_TYPE`

**Usage Notes**
1. The caller does not have to be authorized.
2. This command is equivalent to the command:
   ```
   confighfs -q
   ```

Chapter 11. Managing Hierarchical File System Data Sets 403
DisplayFSStats Command

Function: The DisplayFSStats command returns HFS file system level statistics in the data area. The values returned for file system statistics are associated with the current mount of the specified file system.

Command: X'40000004'

Argument_Length: The argument length is the length of the data area. The data area must be the length of PCTL_FSSTATS_TYPE. See Table 84 on page 408.

Argument: PCTL_FSSTATS_TYPE
Usage Notes
1. The file system name must be supplied as input in the field PCTL_FS_NAME within the PCTL_FSSTATS_TYPE structure.
2. The caller does not have to be authorized.
3. This command is equivalent to the confighfs shell command:
   
   ```
   confighfs pathname
   ```

   where the pathname is an absolute or relative pathname that identifies the HFS.

ExtendFS Command

Function: The ExtendFS command attempts to extend (allocate additional disk space for) the specified file system by the requested amount as specified in the data area.

Command: X’00000005’

Argument_Length: The argument length is the length of the data area. The length of the data area must be at least the length of PCTL_EXTENDFS_TYPE. See Table 85 on page 409.

Argument: PCTL_EXTENDFS_TYPE

Usage Notes
- The following fields must be set within this structure:
- Set PCTL_EXT_FSNAME to the name of the file system to be extended.
- If your request is to allocate space on a new volume, set the PCTL_EXT_NEW_VOL flag on.
- Set PCTL_EXT_UNIT to one of the following units to extend:
  1. ExtendFS_UNIT_MB to indicate that the amount to extend is in megabytes (MB).
  2. ExtendFS_UNIT_TRK to indicate that the amount to extend is in tracks.
  3. ExtendFS_UNIT_CYL to indicate that the amount to extend is in cylinders.
- Set PCTL_EXT_AMT to the amount to be extended.
- The caller must be a superuser.
- If the flag PCTL_EXT_NEW_VOL = off, an attempt to obtain additional space is only made on the last volume of the HFS. The HFS will not be extended to a new volume.
- If the flag PCTL_EXT_NEW_VOL = on, an attempt to obtain additional space is only made on a new volume. In this case, candidate volumes must exist for the HFS, and the candidate volumes must have existed at the time of the current mount of the HFS.
- If a secondary space amount exists for the HFS, it is ignored.
- If the entire amount requested cannot be obtained, the operation fails.

This command is equivalent to the confighfs shell command:

```
confighfs -x size pathname To extend on the same volume
confighfs -xn size pathname To extend to a new volume
```

where size is the amount to be extended suffixed by the extend unit of M (megabytes), T (tracks), or C (cylinders) and pathname is an absolute or relative pathname that identifies the HFS.
Planning for HFS

BPX1PCT Return and Reason Codes

Using BPX1PCT for HFS returns a non-zero return code and reason code only if the return value is -1. Table 81 contains a list of return and reason codes returned by BPX1PCT for the HFS DisplayBufferLimits, ChangeBufferLimits, DisplayGlobalStats, DisplayFSStats, and ExtendFS commands.

Chapter 12. User Access to Subsystem Statistics, Status, and Counts Information

This information documents programming interfaces provided by IDCAMS.

Your program can call a system service that returns the information that the access method services LISTDATA command returns. This information is subsystem statistics, status and count information. To obtain this information, your program must be APF-authorized. Your program will call IDCSS01 with the LINK macro. You pass to IDCSS01 a three-word parameter list pointed to by register 1. If your program is not authorized and attempts to link to IDCSS01, the system issues ABEND with system code 047. The following shows an example of the IDCSS01 call:

```
ST R5,AddrSGARGL Set address of SSGARGL
LINK EP=IDCSSO1,PARAM=(,MyArgL,MyRetCode) Call LISTDATA
SR R15,R15 Prepare for ICM
ICM R15,B'0011',MyRetCode Obtain and test return code
BNZ ListDataFail Branch if call failed

MyArgL DC A(AddrSSGARGL) Address of SSGARGL address
AddrSGARGL DC A(0) Address of SSGARGL
MyRetcode DC H'0' Return code from service
IDCDF70 , Map the parameter list
```

Your program must point register 13 to a standard 18-word save area when calling IDCSS01.

Register 1 Parameter List

Word 1

must be zero.

Word 2

contains an address of a pointer to the argument list SSGARGL (detailed below), which IDCSS01 requires. Within this argument list is a field named SSGOADR, which points to the buffer area in which IDCSS01 returns subsystem statistics, status, or counts information. The buffer area may be obtained by the caller or may be left for IDCSS01 to obtain.

Word 3

points to an area to receive a 2-byte binary return code. Possible return codes are listed at the end of SSGARGL. IDCSS01 also returns this return code in the low order bytes of register 15.

Passed Argument List -- SSGARGL

The following describes SSGARGL. SSGARGL is the area pointed to by the word that Word 2 points to. Word 2 is part of the parameter list passed to IDCSS01. The caller must establish some fields; IDCSS01 establishes other fields. The caller must set an option flag to indicate whether information requested is status information (SSGRSS), counts information (SSGRPD), Space Efficient Volume status (SSGSEV), or Extent Pool Configuration status (SSGEPDC). If the caller passes SSGADDN, IDCSS01 establishes SSGAVOL and SSGUNIT.

If counts information is requested, the caller must indicate whether it applies to all subsystems (SSGALL), a specific subsystem (SSG1SS), or a specific device
(SSGDEV). In addition, the caller must either pass the ddname (through SSGADDN) of a DD statement that allocates a caching subsystem volume, or the caller must identify the volume and unit (through SSGAVOL and SSGUNIT) of a caching subsystem volume for which information is being requested.

If Space Efficient Volume status, or Extent Pool Configuration status is requested, the caller must follow the instruction described in the mapping for the space efficient volume status output buffer, or mapping for the extent pool configuration status output buffer described in later of this section.

**Note:** The SSGOLN may be larger than the data returned in the SSGBUFR buffer. To detect end of data, the following should be considered:

- If "current index into the SSGBUFR buffer" is within SSGNLN-4 bytes, then the full six bytes of SSGDAVOL being zero is the way to determine the premature “end of data”.
- If “current index into the SSGBUFR buffer” is beyond SSGOLN-4 bytes of the data, then they are at “end of data”.

The following list contains other fields that IDCSSO1 establishes:

Parameter List Extension.

Note: IDCSS01 will not reference fields contained in SSGARGLY unless the bit defined as SSGARGL3 is set to '1'.

Parameter List Extension number 3
Note: IDCSS01 will not reference fields contained in SSGARGLY unless the bit defined as SSGARGL3 is set to '1'.

Entire section added
caller set address of the MVS addr character in SSGAVOL and set offline (SSGOFI=ON). The Fixed Block (FB) SEVOL device status is returned when the reporting scope is single (SSGDEV=ON), the FB user request is active (SSGURFB=ON), FB LSS number is in SSGFBLSL, and FB device number is in SSGFBD. FB SEVOL status is available through CKD I/O device that resides in the same Storage Facility Image as FB SEVOL and resides in the same Even or Odd number LSS as even or odd FB LSS. SEVOL status is not supported when other statistics or status is requested by caller. Extent Pool Config (EPC) status is supported by caller and request return of status in SSGEPBUF pointed by SSGEPAR when request for EPC or Storage Facility Image oriented by I/O device in SSGADDN or SSGAVOL are made (SSGEP=ON). When Extent Pool ID (SSGEPID) is set as ‘FFFF’X by caller, EPC summary status is returned. When even numbered Extent Pool ID is specified in SSGEPID with the I/O device in the even LSS, detail status of EPC for the specified Extent Pool is returned. When odd numbered Extent Pool ID is specified with the I/O device in the odd LSS, detail status of EPC for the specified Extent Pool is returned. SSGURBMP is internal use only. When Extent Pool ID (SSGEPID) is set as ‘FFFF’X with SSGURBMP is ON, branch entry caller receives error. Whether ON or OFF of SSGURBMP does not make difference in EPC detail status for branch entry caller. EPC status report is not supported when other statistics or status is requested by caller.

.... 1.... SSGURFB
Request Fixed Block SEVOL status by turning SSGURFB flag ON.

.... 1.... SSGURBMP
IDCAMS internal use.
Refer SSGEPC bit description.

.... 1.... SSGEXRQ
By setting this attribute bit along with other request(s), caller supports and requests the return of extended length
statistics. The extended length is any set of statistics that is larger than the standard length of statistics. The extended length statistics will be returned if target storage facility supports it, otherwise the standard size statistics will be returned. Ignored this attribute bit for requests where the statistics do not support the extended length and where caller does not make any request.

Current request that supports the extended length is:

- Link performance statistics

Chapter 12. User Access to Subsystem Statistics, Status, and Counts Information
Mapping for the subsystem GET OUTPUT BUFFER for link performance statistics

Output buffer is a chain, anchored by SSGLPOAR, of link performance statistics tables. Each table entry represents data read from a single storage subsystem box. The statistics from a single box may be described with more than one table entry. The chain is a single threaded queue. Each chain element needs to be freed by the caller of this interface. Output buffer is built for storage boxes that support link performance statistics and are returned only if requested by caller (SSGLINKP) on a request for performance data (SSGRPD) for requests with scope of subsystem (SSGLSS) or all subsystems (SSGALL). The parameter list extension must also be passed as indicated with SSGARLG2.

<td>Fibre Channel Out of Order Data Count.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
This count is the number of times that an out of order frame is detected. The frame is either missing from a data sequence or it is received beyond the port’s sequence reassembly threshold.

192 (C0) UNSIGNED 4 SGLFOOA Fibre Channel Out of Order ACK Count.
This count is the number of times that an out of order ACK frame is detected. The frame is either missing from a data sequence or it is received beyond the port’s sequence reassembly threshold.

196 (C4) UNSIGNED 4 SGLFDPF Fibre Channel Duplicate Frame Count.
This count is the number of times a frame was received that has been detected as previously processed.

200 (C8) UNSIGNED 4 SGLFIRO Fibre Channel Invalid Relative Offset Count.
This count is the number of times that a frame was received with bad relative offset in the frame header.

204 (CC) UNSIGNED 4 SGLFSQT Fibre Channel Sequence Timeout Count.
This count is the number of times the port has detected a timeout condition on receiving sequence initiative for a fibre channel exchange.

208 (D0) UNSIGNED 4 SGLFBER Fibre Channel Bit Error Rate Count.
This count is the number of the bit error (invalid transmission word) bursts for the previous 5 minute counting window.

MAPPING FOR THE SUBSYSTEM GET OUTPUT BUFFER FOR RANK PERFORMANCE STATISTICS
Output buffer is a queue, anchored by SSGRSOAR, of rank performance statistics. Each queue element represents data read from a single storage subsystem box that describes sets of statistics. The queue is a single threaded queue. Each queue element needs to be freed by the caller of this interface. Output buffer built for storage subsystem boxes that support rank performance statistics and are returned only if requested by caller (SSGRANKP) on a request for performance data (SSGRPD) for requests with scope of subsystem (SSGISS) or all subsystems (SSGALL).

MAPPING FOR THE SPACE EFFICIENT VOLUME STATUS

Output buffer is a queue, anchored by SSGSEODR, of Space
Efficient Volume (SEVOL) status. Each queue element represents
status of the space efficient volume specified in the header.
The queue is a single threaded queue. Each queue element
needs to be freed by the caller of this interface.
Output buffer is built for SEVOL(s) when SEVOL status is
requested (SSGSEV=ON).
Caller sets the scope of SEVOL(s) by turning one of flag bit
that is the single device (SSGDEV), subsystem (SSG1SS),
or all subsystems (SSGALL). For a single SEVOL status request,
the SEVOL status can be obtain when the path of SEVOL is
available. For a subsystem (SSG1SS) and all systems (SSGALL)
scope, the SEVOL status is available when SEVOL is ONLINE.
When the scope is the single device (SSGDEV=ON) and
the Fix Block SEVOL is requested (SSGURFBD=ON), the status
of FB SEVOL oriented by LSS (SSGFBLSS) and Device
(SSGFBD) is reported. FB SEVOL status is not available
with the scope of the subsystem (SSG1SS=ON) or
the all subsystems (SSGALL=ON). FB SEVOL status is available
when LSS number of both the I/O device (SSGAVOL or SSGDNN) and
FB SEVOL are numbered in the same even or odd number.

Flag and variable combinations of SEVOL status request
are shown as below in the railroad chart format.

Mapping for the Extent Pool Configuration Status

Output Buffer
Output buffer is a queue, anchored by SSGEPQAR, of Extent Pool Configuration status. Each queue element represents the status of the Extent Pools defined in Storage Facility image. If the caller provide a Extent Pool ID ( SSGEPID has value between '0'X and 'FFFE'X ), then in addition to the summary status of Extent Pool, the detail status of that Extent Pool identified by Extent Pool ID is reported. Caller is responsible for freeing the output buffer.

The flag and variable combinations for EPC status is shown as below railroad chart.

Below variable defines scope

\[
\begin{align*}
&>> \text{SSGEPCE} \text{ SSGEPID=(} \text{FFFF}'X) \text{ } \rangle \rangle (A) \\
&> \text{SSGEPCE} \text{ SSGEPID=(} \text{0}'X \text{ to } \text{0FFFE}'X \text{ of even number}) \rangle \langle (B) \\
&> \text{SSGEPCE} \text{ SSGEPID=(} \text{1}'X \text{ to } \text{0FFFD}'X \text{ of odd number}) \rangle \langle (C)
\end{align*}
\]

\( (A) \) \langle (Even \ LSS \ I/O \ dev \ follows) \rangle \]; \( (B) \) \langle (Odd \ LSS \ I/O \ dev \ follows) \rangle \]

Following variable and flag represent I/O device

\[
\begin{align*}
&>> \text{SSGAVOL} \text{ SSGUNIT} \text{ SSGADDN} \text{ SSGOFFL} \rangle \rangle < \\
&>> \text{SSGAVOL} < \text{SSGOPF}
\end{align*}
\]

MAPPING FOR THE EXTENT POOL CONFIGURATION STATUS OUTPUT BUFFER

Mapping for the device performance statistics
output buffer
Output buffer is anchored by SSGOADR, of a device performance statistics output table. Output buffer needs to be freed by the caller of this interface. Output buffer is built for a device that supports device performance statistics and returned only if requested by caller for performance data (SSGRP0) for a request with scope of a device (SSGDEV).
The parameter list extension must also be passed as indicated with SSGARGL2.

20 (14) UNSIGNED 4 SSGDPRNI Search/Read Normal I/O Requests. The number of command chains which meet the following requirements.
- The chain is not part of a sequential operation.
- The chain did not include
a Define Extent command which specified Cache Fast Write Data.
- The chain contained at least one search or read command but no write commands.

24 (18) UNSIGNED 4 SSGPDRNH Search/Read Normal I/O Request Hits. The number of command chains which meet the following requirements.
- The chain is not part of a sequential operation.
- The chain did not include a Define Extent command which specified Cache Fast Write Data.
- The chain contained at least one search or read command but no write commands.
- The chain was completed without requiring access to any DDM.

28 (1C) UNSIGNED 4 SSGDPWNI Write Normal I/O Requests. The number of command chains which meet the following requirements.
- The chain is not part of a sequential operation.
- The chain did not include a Define Extent command which specified Cache Fast Write Data.
- The chain contained at least one write command.
- The chain was completed without requiring access to any DDM.

32 (20) UNSIGNED 4 SSGDFH DASD Fast Write I/O Request Hits. The number of command chains which meet the following requirements.
- The chain is not part of a sequential operation.
- The chain did not include a Define Extent command which specified Cache Fast Write Data.
- The chain contained at least one write command.
- The chain was completed without requiring access to any DDM.

36 (24) UNSIGNED 4 SSGDRSI Search/Read Sequential I/O Requests. The number of sequential mode command chains which meet the following requirements.
- The chain contained at least one search or read command but no write commands.

40 (28) UNSIGNED 4 SSGDPRSH Search/Read Sequential I/O Request Hits. The number of sequential mode command chains which meet the following requirements.
- The chain contained at least one search or read command but no write commands.
- The chain was completed without requiring access to any DDM.

44 (2C) UNSIGNED 4 SSGDPWSI Write Sequential I/O Requests. The number of sequential mode command chains which meet the
following requirements.
- The chain contained at least one write command.

48 (30) UNSIGNED 4 SSGDPWSH
Fast Write Sequential I/O Request Hits. The number of sequential write operations that did not require movement of data to or from a storage device before completion of the I/O operation.

52 (34) UNSIGNED 4 SSGDPRCF
Search/Read Cache Fast Write I/O Requests. The number of command chains which meet the following requirements.
- The chain included a Define Extent command which specified the Cache Fast Write Data attribute.
- The chain contained at least one search or read command but no write commands.
- Cache Fast Write Data must be activated for the subsystem.

56 (38) UNSIGNED 4 SSGDPRCH
Search/Read Cache Fast Write I/O Request Hits. The number of command chains which meet the following requirements.
- The chain included a Define Extent command which specified the Cache Fast Write Data attribute.
- The chain contained at least one search or read command but no write commands.
- Cache Fast Write Data must be activated for the subsystem.
- The chain was completed without requiring access to any DDM.

60 (3C) UNSIGNED 4 SSGDPFW
Cache Fast Write I/O Requests. The number of command chains which meet the following requirements.
- The chain included a Define Extent command which specified the Cache Fast Write Data attribute.
- The chain contained at least one write command.
- Cache Fast Write Data must be activated for the subsystem.
- The chain was completed without requiring access to any DDM.

64 (40) UNSIGNED 4 SSGPCFH
Cache Fast Write I/O Request Hits. The number of command chains which meet the following requirements.
- The chain included a Define Extent command which specified the Cache Fast Write Data attribute.
- The chain contained at least one write command.
- Cache Fast Write Data must be activated for the subsystem.
- The chain was completed without requiring access to any DDM.
- Inhibit Cache Loading I/O Request that operate with DASD (Set to zeros for 2107/1750)

68 (44) UNSIGNED 4 SSGDPCCL
Inhibit Cache Loading I/O
### Chapter 12. User Access to Subsystem Statistics, Status, and Counts Information

#### Description:
- **SGDPBIC**: Bypass Cache I/O Requests (Set to zeros for 2107/1750)
- **SGDPSDC**: Seq DASD to Cache Transfer Operations
- **SGDPDCC**: DASD to Cache Transfer Operation Count
- **SGDPCDC**: Cache to DASD Transfer Operation Count
- **SGDPFWD**: DASD Fast Write Operation Delayed Due to non-volatile storage Space constraints
- **SGDPNFW**: Normal 'DASD Fast Write' Write Operation Counts
- **SGDPSFW**: Sequential Access 'DASD Fast Write' Write Operation Counts
- **SGDPNRM**: Number of record cache Read misses
- **SGDPS2**: Device Status - Group 2
- **SGDPFWP**: Quick Write Promotes
- **SGDPDVD**: Flag byte
- **SGDPRVA**: Mask for reserved bits
- **SGDPZHV**: When set on, SSQDPZHR and SSQDPRZHR are valid.
- **SGDPRUNI**: Mask bits for Units Value after masking
- **SGDPSID**: SSID
- **SGDPITA**: Irregular Track Accesses
- **SGDPITH**: Irregular Track Access Hits
- **SGDPODC**: Operation Delayed Due To Cache Space Constraints

#### Details:
- The number of command chains which meet the following requirements:
  - The chain is not part of a sequential operation.
  - The chain did not include a Define Extent command which specified Cache Fast Write Data.
  - The chain contained at least one write command.
  - The chain was completed without requiring access to any DDM.

#### Notes:
- The format of the data in SSGDPDS2 is determined by the value in SSGDPFDR.
- The format of the data in SSGDPDS2 is determined by the Sense Subsystem Status in Byte 36.
- Note: The format of the data in SSGDPDS2 is identical to the data returned by the Sense Subsystem Status in Byte 36.
- **SGDPSDW**: Sequential Access 'DASD Fast Write' Write Operation Counts
- **SGDPFWP**: Quick Write Promotes
- **SGDPDVD**: Flag byte
- **SGDPRVA**: Mask for reserved bits
- **SGDPZHV**: When set on, SSQDPZHR and SSQDPRZHR are valid.
- **SGDPRUNI**: Mask bits for Units Value after masking
  - Unit of SSGDPPBR, SSGDPWRT, SSGDPBRD, SSGDPBWR, SSGDPRAT, and SSGDPWAT is 16 milliseconds.
  - Unit of SSGDPPBR, SSGDPWBR is 128 KB.
- **SGDPSDW**: Sequential Access 'DASD Fast Write' Write Operation Counts
- **SGDPFWP**: Quick Write Promotes
- **SGDPDVD**: Flag byte
- **SGDPRVA**: Mask for reserved bits
- **SGDPZHV**: When set on, SSQDPZHR and SSQDPRZHR are valid.
- **SGDPRUNI**: Mask bits for Units Value after masking
  - Unit of SSGDPPBR, SSGDPWRT, SSGDPBRD, SSGDPBWR, SSGDPRAT, and SSGDPWAT are valid
- **SGDPSID**: SSID
- **SGDPITA**: Irregular Track Accesses
- **SGDPITH**: Irregular Track Access Hits
- **SGDPODC**: Operation Delayed Due To Cache Space Constraints

### SSGDPDVD

**192 bytes**

**Type:** Unsigned 4

**Value:** SSGDPWAT

**Description:** Write Accumulated Time.

The accumulated response time for all write operations. See Increment Value in SSGDPDVD.

### SSGDPZHR

**196 bytes**

**Type:** Unsigned 4

**Value:** zHPF Read I/O Requests.

This count is the number of Transport Mode read command chains. The Read I/O Request will also be counted in one of the following counters:

- SSGDPRNI, Search/Read Normal I/O Requests
- SSGDPRSI, Search/Read Sequential I/O Requests
- SSGDPRCF, Search/Read Cache Fast Write I/O Requests

### SSGDPZHW

**200 bytes**

**Type:** Unsigned 4

**Value:** zHPF Write I/O Requests.

This count is the number of Transport Mode write command chains. The Write I/O Request will also be counted in one of the following counters:

- SSGDPWNI, Write Normal I/O Requests
- SSGDPSI, Write Sequential I/O Requests
- SSGDPFCF, Cache Fast Write I/O Requests

### SSGDPRVX

**204 bytes**

**Type:** Character 4

**Value:** Not used - zeros

**Description:**

Control Blocks

The following control blocks are described here:

- Data Extent Block (DEB) Fields for EXCP and EXCPVR.
- Data Facilities Area (DFA) Fields on page 439

Data Extent Block (DEB) Fields

The data extent block (DEB) fields shown here should only be used with EXCP and EXCPVR (see z/OS DFSMSdfp Diagnosis for all fields in the DEB).

Common Name: Data Extent Block
Macro ID: IEZDEB
DSECT Name:
- DEB (DSECT card precedes AVT section)
- DEBBASIC should be used for USING basic section.
- DEBDASD (DSECT name for direct access section)
- DEBACSMD (DSECT name for access method sections)
- DEBSUBNM (DSECT name for subroutine name section)
- DEBXTN (DSECT name for DEB extension)

Owning Component: Data Management, subcomponent OPEN/CLOSE/EOV
Eye-Catcher ID: None
Subpool and Key: 230 and key 5
Size: Variable (device and access method dependent sections)
Created by: OPEN
Pointed to by: DCBDEBAD field of the DCB data area.
DEBDEBAD field of the DEB data area (next DEB on the chain)
Serialization: LOCAL lock serializes the placing of a DEB on the TCB DEB chain and in the DEB table. OPEN/CLOSE/EOV processing is serialized by local lock and DEBCHK.
Function: The DEB is an extension of the information in the DCB. Each DEB is associated with a DCB, and the two point to each other. It contains information about the physical characteristics of the data set, and other information used by the control program.

</tr>
<tr>
<td>0(0)</td>
<td>ADDRESS</td>
<td>4</td>
<td>DEBCBAD</td>
<td>Address of a UCB associated with this extent. The following applies to DEBSUCBA, DEBSUCBB, DEBUCBAD and DEBUCBA: If the actual UCB is above the 16 MB line and the dynamic allocation nocapture option is not in effect, allocation normally captures the UCB to create a 24-bit address. When using EXCP and you specify the nocapture option of dynamic allocation but not the LOC=ANY option on the DCBE, then OPEN or EOV captures the UCB until a later EOV or close. In these cases the high order byte of this word contains the device modifier byte. If you specify nocapture on the dynamic allocation and the actual DASD or tape UCB address is above the line and the DCB is for BSAM, BPAM, QSAM or EXCP and the DCBE has specified LOC=ANY, then the system does not capture the UCB. In that case OPEN turns on the DEB31UCB bit to signify the 31-bit UCB address field is valid and that the device modifier byte is in DEBSDVMX or DEBDVMOD31. It may remain on for subsequent volumes even though they have actual 24-bit addresses in a four-byte field.</td>

Data Facilities Area (DFA) Fields

Except for DFADFVAD, all of the fields in the DFA are part of the intended programming interface.

**Common Name:** Data Facilities Area

**Macro ID:** IHADFA

**DSECT Name:** DFA

**Eye-Catcher ID:** DFAACRON

**Subpool and Key:** Nucleus resident and Key 0; Resident below 16MB

**Size:** 112 bytes

**Created by:** Assembled into nucleus

**Pointed to by:** CVT DFA field of the CVT

**Serialization:** N/A

**Function:** Maps the Data Facilities Area, which contains information that applies to DFSMS.

</table>

PRODUCT, VERSION, RELEASE, AND MODIFICATION LEVEL INFORMATION. BYTE 0 DEFINES A PRODUCT CODE. BYTES 1-3 DEFINE THE VERSION, RELEASE, AND MODIFICATION LEVELS OF THIS PRODUCT. A PRODUCT BYTE (DFAPROD) OF X'00' INDICATES DFP AS A PRODUCT. BYTES 1-3 OF DFARELS WILL ALSO BE X'00' IN THIS CASE. THE USER MAY CHOOSE TO CHECK DFAREL FOR THE RELEASE LEVEL OF THE DFP PRODUCT IN THIS CASE. IF DFAPROD IS NOT EQUAL TO X'00', DFAREL SHOULD NOT BE CHECKED AS IT WILL BE FROZEN AT THE LAST LEVEL OF DFP PRODUCT SHIPPED. A PRODUCT BYTE (DFAPROD) OF X'01' INDICATES DFSMS AS A PRODUCT BYTES 1-3 OF DFARELS WILL INDICATE THE VERSION, RELEASE AND MODIFICATION LEVELS OF THE DFSMS PRODUCT. A PRODUCT BYTE (DFAPROD) OF X'02' INDICATES OS/390. THIS VALUE INDICATES THIS LEVEL OF DFSMS IS OS/390 EXCLUSIVE. SINCE DFSMS LEVEL MIGHT NOT BE REFRESHED WITH EACH OS/390 RELEASE, THE VERSION, RELEASE, AND MODIFICATION FIELDS INDICATE THE LEVEL OF OS/390 IN WHICH THIS LEVEL OF DFSMS WAS FIRST SHIPPED. THE VERSION, RELEASE, AND MODIFICATION FIELDS ARE BINARY VALUES. (FOR EXAMPLE TEN WOULD BE X'0A').

Maintaining the System Image Library

This information describes how to maintain the system image library, SYS1.IMAGELIB. SYS1.IMAGELIB is a partitioned data set (a PDSE is not supported) containing universal character set (UCS), forms control buffer (FCB), and printer control information for DFSMSdfp–supported IBM printers in the following forms, depending on the type of printer:

- UCS images (also called modules)
- UCS image tables
- FCB images (also called modules)
- Control modules.

The system uses UCS images and image tables to relate a user-requested UCS to the corresponding print band/train. Most IBM standard UCS images are included in SYS1.IMAGELIB during system installation. Note that when you install a new release of DFSMS it replaces images that have the IBM-supplied names. If you modified or replaced any of these you might want to maintain a separate copy of them. The following table shows the standard character set images for the IBM 1403, 3203, and 3211 printers:

<table>
<thead>
<tr>
<th>Printer</th>
<th>Images</th>
</tr>
</thead>
<tbody>
<tr>
<td>1403 or 3203</td>
<td>AN, HN, PCAN, PCHN, PN, QN, QNC, RN, SN, TN, XN, YN</td>
</tr>
<tr>
<td>3211</td>
<td>A11, G11, H11, P11, T11</td>
</tr>
</tbody>
</table>

For detailed, printer-specific information, or to determine which print bands/trains are available, see the publications listed in the following table:

Notes to Table 90

1. The IBM 3203 Model 5 Printer is treated as a 3211 Printer by JES, except that the 3203 Model 5 does not support the 3211 indexing feature and ignores any indexing commands from JES. The 3203 Model 5 uses its own unique UCS images, but uses 3211 FCB images.

2. You can operate this printer as if it were a 4248 operating in 4248 native mode. In this case, use the 4248-related UCS sections of this chapter. The UCS information is contained in image tables.

3. You can operate this printer in native mode, in which case the UCS information is contained in image tables. You can also operate these printers in 3211 compatibility mode, in which case the UCS information is contained in UCS images; you should then use the 3211-related UCS sections of this chapter.

4. This printer uses the same image table as the 4248 printer. However, it does not support variable printer speeds or the horizontal copy feature and host stacker controls of the 4248 printer.

5. This printer uses the same FCB image as the 4248 Printer.

6. The image table is supplied by IBM. The contents of the 4245 image table are shown in Table 91 on page 451. The contents of the 4248 image table are shown in Table 92 on page 452.
7. 3800 Printing Subsystem control modules exist for:
   • Character arrangement tables
   • Graphics character modification tables
   • Copy modification tables
   • Library character sets
   • FCB images.

You can use the IEBIMAGE utility program to create and maintain these control modules. See [z/OS DFSMSdfp Utilities](https://www.ibm.com/support/knowledgecenter/SSEQ4Q_5.2.0/com.ibm.as400.ai.doc/aix001601.html) for details about IEBIMAGE. IEBIMAGE and SYS1.IMAGELIB are not used when the printer is running in page mode. In that case, PSF for z/O uses other types of modules from other libraries. See [3900 Product Description](https://www.ibm.com/support/knowledgecenter/SSEQ4Q_5.2.0/com.ibm.as400.ai.doc/aix001601.html) for more information.

8. Figure 42 on page 451 defines and describes the structure of a UCS image table entry.

---

**UCS Images in SYS1.IMAGELIB**

This information applies to the IBM 1403, 3203, and 3211 printers. SYS1.IMAGELIB contains UCS images for these printers. You can use the assembler and linkage editor to add a UCS image to those that reside in SYS1.IMAGELIB. The assembler does not generate executable code. It merely prepares DC statements, and the linkage editor puts them into SYS1.IMAGELIB. Observe the following rules when creating a new UCS image:

1. The member name must be 5 to 8 characters long; the first 4 characters must be the appropriate UCS prefix, as follows:

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>UCS1</td>
<td>1403 printer</td>
</tr>
<tr>
<td>UCS2</td>
<td>3211 printer (or 3211-compatible printer)</td>
</tr>
<tr>
<td>UCS3</td>
<td>3203 printer</td>
</tr>
</tbody>
</table>

   These first four characters must be followed by a character set code, one to four characters long. Any valid combination of letters and numbers under assembler language rules is acceptable. However, do not use the single letters U or C, because they are symbols for special conditions recognized by the system. Specify the assigned character set code on the DD statement or SETPRT macro to load the image into the UCS buffer.

   You can supply an alias name for a new image with the ALIAS statement. (For more information on the ALIAS statement, see [z/OS MVS Program Management: User’s Guide and Reference](https://www.ibm.com/support/knowledgecenter/SSEQ4Q_5.2.0/com.ibm.as400.ai.doc/aix001601.html).)

2. The first byte of the character set image load module specifies whether the image is a default. If a program issues an OPEN macro to a printer in which the UCS buffer has been loaded with a default image and the JCL does not specify a UCS name, the system uses the image in the buffer. If the buffer has not been loaded with a default image the system directs the operator to take action.

   Specify the following in the first byte for JES2:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00'</td>
<td>Indicates that the image is not to be used as a default.</td>
</tr>
<tr>
<td>X'40'</td>
<td>Indicates that the output is to be folded.</td>
</tr>
<tr>
<td>X'80'</td>
<td>Indicates a default image.</td>
</tr>
<tr>
<td>X'C0'</td>
<td>Indicates default image and folding.</td>
</tr>
</tbody>
</table>

   For non-JES2, specify:
Maintaining IMAGELIB

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00'</td>
<td>Indicates that the image is not to be used as a default.</td>
</tr>
<tr>
<td>X'80'</td>
<td>Indicates a default image.</td>
</tr>
</tbody>
</table>

3. The second byte of the load module indicates the number of lines (n) to be printed for image verification. See “Verifying the UCS Image” on page 458 for more information on image verification.

4. Each byte of the next n bytes indicates the number of characters to be printed on each verification line. For the 3211 Printer, the maximum number of characters printed per line is 48; the bytes of associative bits (see Rule 5, which follows) do not print during verification.

5. The UCS image itself must follow the previously described fields. The image must fill the number of bytes required by the printer; see the following table for image lengths. Note that, because of Assembler language syntax, you must code two apostrophes or two ampersands to represent a single apostrophe or a single ampersand, respectively, within a character set image.

<table>
<thead>
<tr>
<th>Printer</th>
<th>Image Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>1403</td>
<td>240 bytes</td>
</tr>
<tr>
<td>3203</td>
<td>304 bytes (240 characters followed by 64 bytes of associative bits)</td>
</tr>
<tr>
<td>3211</td>
<td>512 bytes (432 characters followed by 15 bytes of X'00', 64 bytes of associative bits, and 1 reserved byte of X'00')</td>
</tr>
</tbody>
</table>

You must code associative bits to prevent data checks when adding a UCS image to SYS1.IMAGELIB. See the appropriate printer publication for more information on coding associative bits.

See the following information:
- “Examples of UCS Image Coding”
- “UCS Image Alias Names” on page 450
- “UCS Image Tables in SYS1.IMAGELIB” on page 450
- “Alias Names in UCS Image Tables” on page 450
- “Adding or Modifying a UCS Image Table Entry” on page 454
- “Verifying the UCS Image” on page 458

Examples of UCS Image Coding

Figure 39 on page 447 shows an example of the JCL to add a 1403 UCS image, YN, to SYS1.IMAGELIB. Notes, which apply to all examples, follow Figure 41 on page 449.

Figure 40. Code to Add a 3203 UCS Image to SYS1.IMAGELIB

Notes: See Figure 41 on page 449 for the notes to this figure.
Figure 41 shows an example of the JCL to add a 3211 UCS image, A11, to SYS1.IMAGELIB.

In the sample code in the Figure 39 on page 447, Figure 40 on page 448, and Figure 41 be aware of the following:

- The RENT linkage editor attribute is required.
- For the 3203 and 3211 printers, to avoid data checks code the 64 bytes of associative bits. To determine how to code these bits for a particular image, see IBM 3203 Printer Component Description and Operator's Guide or IBM 3211 Printer, 3216 Interchangeable Train Cartridge, and 3811 Printer Control Unit Component Description and Operator's Guide.
- Executing the ASMHCL procedure does not generate executable code. The assembler/linkage editor merely places the UCS image into SYS1.IMAGELIB.
- The SPACE parameter is overridden here because the ASMHCL cataloged procedure has secondary allocation specified. You can specify use of the original secondary allocation amount by deleting the override.
UCS Image Alias Names

Alias names are provided for many of the IBM-supplied print bands and trains. For example, if the data set were printed on a 3211, a request for the 1403 TN train would assign the T11 train. The assigned alias names that follow the naming conventions currently used in SYS1.IMAGELIB are:

<table>
<thead>
<tr>
<th>Image</th>
<th>Alias</th>
</tr>
</thead>
<tbody>
<tr>
<td>UCS1AN</td>
<td>UCS1A11</td>
</tr>
<tr>
<td>UCS1HN</td>
<td>UCS1H11</td>
</tr>
<tr>
<td>UCS1PN</td>
<td>UCS1P11</td>
</tr>
<tr>
<td>UCS1TN</td>
<td>UCS1T11</td>
</tr>
<tr>
<td>UCS2A11</td>
<td>UCS2AN</td>
</tr>
<tr>
<td>UCS2H11</td>
<td>UCS2HN</td>
</tr>
<tr>
<td>UCS2P11</td>
<td>UCS2PN, UCS2RN, UCS2QN</td>
</tr>
<tr>
<td>UCS2T11</td>
<td>UCS2TN</td>
</tr>
</tbody>
</table>

The image and alias names are included in SYS1.IMAGELIB at system installation.

Some bands/trains, such as SN and G11, do not have aliases because neither has an equivalent band/train on the other printer. An installation can assign an alias, if it chooses. (For details about the ALIAS statement, see [z/OS MVS Program Management: User’s Guide and Reference](z/OS MVS Program Management: User’s Guide and Reference).) If you do not specify a name (or alias), you must specify an installation-defined SYSOUT class or a printer routing code to assign the data set to the correct printer. If JES is directed to print a data set on a printer for which the specified image does not exist, JES notifies the operator. The operator can then cause the data set to be printed with a valid band/train or redirect the data set to the proper printer. If an installation defines a new band/train, it can supply an alias name for it through the ALIAS statement when including the image in SYS1.IMAGELIB.

UCS Image Tables in SYS1.IMAGELIB

This section applies only to the IBM 3262 Model 5, 4245, 4248, and 6262 Model 14 printers. SYS1.IMAGELIB does not contain UCS images for these printers, but, instead, contains image tables. If you are running the printer in 3211 compatibility mode, UCS information is contained in image tables. Use the 3211-related sections of this chapter. The UCS image for each band is stored within the printer and is automatically loaded into the UCS buffer when you turn on machine power or install a new band. See Figure 42 on page 451 for the format of image table entries, and “Adding or Modifying a UCS Image Table Entry” on page 454 for information on how to add or modify an image table entry.

SYS1.IMAGELIB contains one UCS image table for each type of printer that supports image tables. An image table contains an entry for most installation-standard IBM-supplied bands. The 4245 image table is named UCS5. The shared 4248, 3262 Model 5, and 6262 Model 14 image table is named UCS6.

Alias Names in UCS Image Tables

The image tables also define alias names for most installation-standard print bands used on the IBM 4245 and 4248 printers. The IBM-supplied image tables do not provide alias names for the IBM 3262 Model 5 or 6262 Model 14 printers.
Some print bands, such as SN and KA22, do not have alias names because there is no equivalent band on other printers. You can add an alias name by adding or modifying an entry in the appropriate UCS image table. See "Adding or Modifying a UCS Image Table Entry" on page 454. A typical UCS image table entry is shown in Figure 42.

Notes to Figure 42:
1. This field is optional. The description data field is of variable length, up to a maximum of 32 bytes.
2. This field is optional for the 4245 Printer. For the 3262 Model 5, 4248, and 6262 Model 14, this field does not apply and is set to X'00'.

The contents of the UCS image table UCS5 (IGGUCS5 macro) for the 4245 Printer are shown in Table 91.

</tbody>
</table>

**Tip:** The image tables for the 4245 and 4248 printers include USA and Canada band IDs only. To support other national band IDs, modify the UCS image table. See Table 93 and “Adding or Modifying a UCS Image Table Entry” on page 454.

The 3262 Model 5 and 6262 Model 14 printers use the 4248 UCS image table, UCS6. However, IBM does not provide band names or aliases for either the 3262 Model 5 or 6262 Model 14 printer. To use 3262 Model 5 or 6262 Model 14 UCS images, add the names and aliases to UCS6. “Adding or Modifying a UCS Image Table Entry” on page 454 describes how to add entries to the UCS image table. For a list of the bands available for the 3262 Model 5, see Table 93. For a list of the bands available for the 6262 Model 14, see IBM 6262 Printer Print Band Manual and IBM 6262 Printer Model 014 User's Guide.

For Table 93, be aware of the following:
- You can define any 1- to 4-character name as aliases of the UCS6 Band names.
- `xx` designates switch settings that are ignored. Switch number 3 must be on if you are using a special order (RPQ) band.
- Note that `bb` here represents a space.

### Adding or Modifying a UCS Image Table Entry

To use a new UCS image name/alias with the 3262 Model 5, 4245, 4248, or 6262 Model 14 printers, add an entry for that image name/alias to the UCS image table. Use the assembler to create the image table object module, then link-edit the object module into SYS1.IMAGELIB, as shown in the following procedure. Similarly, to specify other images as defaults or change the description on an old image, change the image table.

To build new UCS table entries, or to change the format of old entries, use the following procedure. For examples of coding the IGGUCSIT macro, see Figure 43 on page 457 and Figure 44 on page 458.

1. To build a new UCS image table entry issue the IGGUCSIT macro, as described in the following text. If you are updating the image table as shown in the following examples, the linkage editor builds a new entry at the start of the table, even if you intended to replace an existing entry. When the system subsequently uses the table, it encounters the new entry first, thus the old one is effectively replaced.

2. Include the UCS image table source, using the IGGUCS5 or IGGUCS6 macro, both of which reside in SYS1.MODGEN.

3. Assemble the image table module (UCS5 or UCS6).

4. Link-edit the assembled module into SYS1.IMAGELIB.

**Requirement:** The RENT linkage editor attribute is required.
The format of the IGGUCSIT macro is:

```
IGGUCSIT MF=LIST,NAME=image_name,ALIAS=image_alias,

MF=LIST or DSECT
Specifies the form of the macro instruction.
LIST Produces a UCS image table entry based on the information supplied in other IGGUCSIT parameters. If LIST is selected or allowed to default, the NAME parameter must also be coded.
DSECT Produces a DSECT for a single UCS image table entry, similar to the sample entry shown in Figure 42 on page 451. If you code DSECT, all other parameters of IGGUCSIT are ignored.

LIST is the default.

NAME=image_name
Specifies the one to four character UCS image name.

ALIAS=image_alias
Specifies a one to four character alias name for the UCS image. If ALIAS is not specified, the image name coded in the NAME parameter will be entered in the UCS image table.

Exception: The 3262, 4248, and 6262 printers have no band IDs in common. Because these devices all use the UCS6 image table, select a unique alias name for each of these printer types. The alias must not appear in the image table more than once.

DEFAULT=YES or NO
Indicates whether the new UCS image is to be used as a default value.
YES Indicates that this UCS image is a default. Default images are used by the system for jobs that do not request a specific image.
NO Indicates that this UCS image should not be used as a default.

If the DEFAULT parameter is not specified, the new UCS image is not used as a default.

DESCR=description
Specifies descriptive information about the new UCS image. description can be up to 32 EBCDIC or hexadecimal characters long. You cannot use EBCDIC and hexadecimal characters in combination.
Maintaining IMAGELIB

Descriptive information is placed in the header line of the verification display, following the real UCS image name. If you omit the DESCR parameter, no description appears in the display. For more information on the verification display, see "Verifying the UCS Image" on page 458.

If VLENGTH is not specified for the 4245 Printer, the DESCR parameter is ignored.

**DEVICE=4245 or 4248**

Specifies the type of device for which an image table entry is to be created.

If you specify MF=LIST on the first invocation of the IGGUCSIT macro, DEVICE defaults to 4245. The default for subsequent invocations is the printer type that you specified (or the default) on the first invocation. Table entries with different DEVICE specifications are not allowed.

For the 3262 Model 5 or 6262 Model 14 printers, DEVICE=4248 should be specified to create the appropriate form of the image table entry.

**VLENGTH=(n1, n2, . . ., n)**

Specifies the lengths of each line in the UCS verification display. The length of each line must be specified separately, even if all lines are of the same length.

- $n_1$ is the length of print line 1;
- $n_2$ is the length of print line 2;
- $n$ is the length of the last print line.

To display the complete image, the sum of the verification line lengths should equal 350.

For details on the verification report, see "Verifying the UCS Image" on page 458.

The VLENGTH parameter is not valid for the 3262 Model 5, 4248, or 6262 Model 14 printers.

**FOLD=YES or NO**

Indicates whether the UCS image is to be folded.

- **YES** Indicates that the UCS image is to be folded. Allows printing only uppercase characters from either upper- or lowercase data codes. Folding continues until an UNFOLD command is received.
- **NO** Indicates that the UCS image is not to be folded. This is the default.

**Adding to the UCS Image Table**

In Figure 43 on page 457, the band name RPQ1 with description “RPQ BAND” is added to UC55. In the UCS verification display, 7 lines of 50 characters each are printed. Macro IGGUCS5 causes the UCS image table source (as distributed by IBM) to be included in the table entry.
When adding a new band ID to the 4245 UCS image table as shown in Figure 43, be aware of the following:

- The RENT linkage editor attribute is required.
- Executing the ASMHCL procedure does not generate executable code. The assembler/linkage editor places the updated UCS image table into SYS1.IMAGELIB.
- The SPACE parameter is overridden here because the ASMHCL cataloged procedure has a secondary allocation specified. Eliminating the override causes the original secondary allocation amount to be used.

In Figure 44 on page 458, the band name 40E1 DEFAULT BAND has been added to UCS6 and defined as a default band. An alias name, HN21, is also defined for band 40E1. Macro IGGMCS6 causes the UCS image table source (as distributed by IBM) to be included in the table entry.
Maintaining IMAGELIB

For Figure 44, be aware of the following:

- This method creates a duplicate entry for 40E1 that becomes the first entry in the table. Because the table is searched sequentially, the new entry is always found before the old entry, thus replacing the old entry.
- The RENT linkage editor attributes is required.
- Executing the ASMHCL procedure does not generate executable code. The assembler/linkage editor places the updated UCS image table into SYS1.IMAGELIB.
- The SPACE parameter is overridden because the ASMHCL cataloged procedure has a secondary allocation specified. Eliminating the override causes the original secondary allocation amount to be used.

Verifying the UCS Image

For the 1403 (with the UCS feature), 3203, 3211, 3262 Model 5, 4245, 4248, and 6262 Model 14 printers, you can print the UCS image for visual verification using either of the following parameters:

- In JCL: UCS=(character set code,VERIFY)
- In the SETPRT macro: UCS=(character set code,V).

These parameters have no effect for SYSOUT data sets.

You can also use these parameters for the 3262 Model 5, 4248, and 6262 Model 14 printers. However, because the UCS image cannot be read directly from the 3262 Model 5, 4248, or 6262 Model 14, only the header information is printed. The verification display header appears on the printer as follows:

```
UCS IMAGE VERIFICATION image_id [,FOLD] [description]
```

- **image_id** A one to four character name of the UCS image.
- **description** The descriptive information supplied for this UCS image in the UCS image table.
FCB Images in SYS1.IMAGELIB

Two standard FCB images, STD1 and STD2, are included in SYS1.IMAGELIB during system installation. The names of these standard images begin with the characters “FCB2”. You can define FCB images whose names begin with “FCB4” for the 4248, 3262 Model 5, and 6262 Model 14 Printers. These printers can use both the "FCB2"-prefixed images (referred to as 3211 format FCBs) and the “FCB4”-prefixed images. All other printers, except the 3800, can use only “FCB2”-prefixed images.

This section describes how you can create or replace “FCB2”-prefixed images. z/OS DFSMSdftp Utilities describes how you can use the IEBIMAGE utility program to create, update, or replace an “FCB4”-prefixed image for the 3262 Model 5, 4248, or 6262 Model 14 Printers. For details about the “FCB4”-prefixed images, see either IBM 6262 Printer Model 014 Product Description or IBM 4248 Printer Model 1 Description.

The 3262 Model 5, 4245, 4248, and 6262 Model 14 printers each load a default FCB image into the buffer when they are powered on. The 3262 Model 5 default FCB image is an 11-inch form with 6 lines per inch, a Channel 1 on the third print line, and a Channel 12 on line 64. The 4245 default FCB image is an 11-inch form with 6 lines per inch and a Channel 1 on the first print line. The 4248 default FCB image is the last FCB image loaded. The 6262 Model 14 default FCB image is either the last FCB image loaded and saved or the default shipped with the printer.

STD1 sets line spacing at 6 lines per inch for an 8½ inch form; STD2 is a default FCB image that sets line spacing at 6 lines per inch for an 11-inch form. Channels for both images are evenly spaced, with Channel 1 on the fourth line and Channel 9 on the last line. See Figure 45 on page 460 and Figure 46 on page 461 for the format of the standard STD1 and STD2 images.

The standard FCB image for the 3800 Printing Subsystem, STD3, is included in SYS1.IMAGELIB during system installation. All models of the 3800 use FCB images whose names begin with “FCB3”. Use the IEBIMAGE utility to create and modify FCB modules for the 3800 Printing Subsystem.
Maintaining IMAGELIB

Figure 45. Format of the Standard STD1 FCB Image
Adding an FCB Image to the Image Library

You can add a 3211-format FCB image to those that reside in SYS1.IMAGELIB, using the assembler and linkage editor. No executable code is generated; the assembler prepares DCs, and the linkage editor links them into SYS1.IMAGELIB.

The new FCB image must be structured according to the following rules:

1. The member name cannot exceed 8 bytes and must begin with the prefix FCB2. The characters that follow identify the FCB image and are referred to as the image identifier (ID). Any combination of valid assembler language characters can be used, with the exception of a single 'C' or 'U', because these are used by the system to recognize special conditions. To load the image into the FCB buffer, the image identifier must be specified in the FCB keyword of a DD statement or in the SETPRT macro.

2. The first byte of the FCB load module specifies whether the image is the default. (Default images are used by the system for jobs that do not request a specific image.) Specify the following in the first byte:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'80'</td>
<td>Indicates a default image</td>
</tr>
<tr>
<td>X'00'</td>
<td>Indicates a nondefault image</td>
</tr>
</tbody>
</table>

```
FCB2STD2 CSECT
DC X'80'    DEFAULT
DC AL1(66)  FCB IMAGE LENGTH = 66
DC X'000000' LINE 1, 2, 3
DC X'01'    LINE 4, CHANNEL 1
DC X'0000000000' LINE 5, 6, 7, 8, 9
DC X'02'    LINE 10, CHANNEL 2
DC X'0000000000' LINE 11, 12, 13, 14, 15
DC X'03'    LINE 16, CHANNEL 3
DC X'0000000000' LINE 17, 18, 19, 20, 21
DC X'04'    LINE 22, CHANNEL 4
DC X'0000000000' LINE 23, 24, 25, 26, 27
DC X'05'    LINE 28, CHANNEL 5
DC X'0000000000' LINE 29, 30, 31, 32, 33
DC X'06'    LINE 34, CHANNEL 6
DC X'0000000000' LINE 35, 36, 37, 38, 39
DC X'07'    LINE 40, CHANNEL 7
DC X'0000000000' LINE 41, 42, 43, 44, 45
DC X'08'    LINE 46, CHANNEL 8
DC X'0000000000' LINE 47, 48, 49, 50, 51
DC X'09'    LINE 52, CHANNEL 10
DC X'0000000000' LINE 53, 54, 55, 56, 57
DC X'0A'    LINE 58, CHANNEL 11
DC X'0000000000' LINE 59, 60, 61, 62, 63
DC X'0C'    LINE 64, CHANNEL 12
DC X'00'    LINE 65
DC X'19'    LINE 66, CHANNEL 9-END OF FCB IMAGE
END
```

Figure 46. Format of the Standard STD2 FCB Image

See the following information:

- [Adding an FCB Image to the Image Library](#)
- “Modifying an FCB Image” on page 463

Adding an FCB Image to the Image Library

You can add a 3211-format FCB image to those that reside in SYS1.IMAGELIB, using the assembler and linkage editor. No executable code is generated; the assembler prepares DCs, and the linkage editor links them into SYS1.IMAGELIB.

The new FCB image must be structured according to the following rules:

1. The member name cannot exceed 8 bytes and must begin with the prefix FCB2. The characters that follow identify the FCB image and are referred to as the image identifier (ID). Any combination of valid assembler language characters can be used, with the exception of a single 'C' or 'U', because these are used by the system to recognize special conditions. To load the image into the FCB buffer, the image identifier must be specified in the FCB keyword of a DD statement or in the SETPRT macro.

2. The first byte of the FCB load module specifies whether the image is the default. (Default images are used by the system for jobs that do not request a specific image.) Specify the following in the first byte:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'80'</td>
<td>Indicates a default image</td>
</tr>
<tr>
<td>X'00'</td>
<td>Indicates a nondefault image</td>
</tr>
</tbody>
</table>
3. The second byte of the load module indicates the number of bytes to be transferred to the control unit to load the FCB image. This count includes the byte, if used, for the print position indexing feature.

4. The third byte of the load module (the first byte of the FCB image) is either the print position indexing byte, or the lines-per-inch byte. The print position indexing byte is optional and, when used, precedes the lines-per-inch byte. The 3203 Model 5, 3262 Model 5, 4245, 4248, and 6262 Model 14 printers accept and discard the index byte if it is present, because they do not support the indexing feature. A description of the print position indexing feature and its use can be found in the publication *IBM 3211 Printer, 3216 Interchangeable Train Cartridge, and 3811 Printer Control Unit Component Description and Operator's Guide*.

The special index flag in the third byte contains X'80' plus a binary index value, from 1 to 32 (the default is 1). This index value sets the left margin: 1 indicates flush-left; any other value indicates a line indented the specified number of spaces.

The form image begins with the lines-per-inch (LPI) byte. The LPI byte defines the number of lines per inch (6 or 8) and also represents the first line of the page.

**Requirement:** Printers controlled by JES2 require a channel 1 identifier here.

Typically, the length of an FCB image is consistent with the length of the form it represents. For example, an 8½ inch form to be printed at 6 LPI has an FCB image that is 51 bytes long (8½ inches times 6 LPI).

The LPI byte appears as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'1n'</td>
<td>Sets 8 LPI</td>
</tr>
<tr>
<td>X'0n'</td>
<td>Sets 6 LPI</td>
</tr>
</tbody>
</table>

5. All remaining bytes (lines) must contain X'0n', except the last byte, which must be X'1n'. The letter n can be a hexadecimal value from 1 to C, representing a channel (one to 12), or it can be 0, which means no channel is indicated.

In *Figure 47 on page 463*, an FCB load module is assembled and added to SYS1.IMAGELIB. The image defines a print density of 8 lines per inch on an 11-inch form, with a right shift of 15 line character positions (1½ inches).
For Figure 47, be aware of the following:

- The RENT linkage editor attribute is required.
- Executing the ASMHCL procedure does not generate executable code. The assembler/linkage editor is used to place the FCB image into SYS1.IMAGELIB.
- The SPACE parameter is overridden here because the ASMHCL cataloged procedure has a secondary allocation specified. Eliminating the override causes the original secondary allocation amount to be used.

Modifying an FCB Image

To modify an FCB image in virtual storage before loading it into a forms control buffer, use the following sequence of macro instructions to read the FCB image into virtual storage.

1. An IMGLIB macro instruction, along with the OPEN parameter.
2. A BLDL macro instruction to determine if the FCB image is in the image library.
3. A LOAD macro instruction to load the image into virtual storage.
Maintaining IMAGELIB

4. After the image has been read in, issue the IMGLIB macro instruction with the CLOSE parameter and the address of the DCB built by the first IMGLIB macro.

A SETPRT macro instruction can be used to load the forms control buffer with the modified image. Printers other than the 3800 require the use of an FCB entry in an exit list, as described in z/OS DFSMS Using Data Sets.

The formats of the BLDL and SETPRT macros are given in z/OS DFSMS Macro Instructions for Data Sets; the format of the LOAD macro is given in z/OS MVS Programming: Assembler Services Guide and z/OS MVS Programming: Assembler Services Reference ABE-HSP.

The format of the IMGLIB macro is:

```
IMGLIB

label

OPEN

CLOSE, addr
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPEN</td>
<td>Opens SYS1.IMAGELIB and specifies that a DCB is to be built for it. The address of the DCB is returned in register 1.</td>
</tr>
<tr>
<td>CLOSE</td>
<td>Closes SYS1.IMAGELIB.</td>
</tr>
<tr>
<td>addr</td>
<td>Specifies the RX-type address of a word that points to the DCB. If coded in the form (reg), the register in parentheses contains the address of the DCB, not the address of the word.</td>
</tr>
</tbody>
</table>

Return Codes from IMGLIB

Return codes from the IMGLIB macro with the OPEN parameter are as follows:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (X'00')</td>
<td>Operation successful.</td>
</tr>
<tr>
<td>4 (X'04')</td>
<td>Either the volume containing SYS1.IMAGELIB is not mounted or a required catalog volume is not mounted.</td>
</tr>
<tr>
<td>8 (X'08')</td>
<td>Either SYS1.IMAGELIB does not exist on the volume to which the catalog points, or SYS1.IMAGELIB is not cataloged.</td>
</tr>
<tr>
<td>12 (X'0C')</td>
<td>An error occurred in reading the catalog or VTOC.</td>
</tr>
</tbody>
</table>

BLDL and LOAD are the only macros that can refer to the DCB built by the IMGLIB macro.

JES Support for the 3211 Indexing Feature

JES2 supports the 3211 indexing feature in two ways:
- Specification of the INDEX parameter on the /*OUTPUT card.
- The extended FCB image.

The system supplies two special FCBs: FCB26 for 6 lines per inch and FCB28 for 8 lines per inch (specified as FCB=6 and FCB=8, respectively). These FCBs contain a channel 1 indication in position 1, a special index flag in the third byte, and the number of lines per inch in the fourth byte of the image.
The special index flag in the third byte of FCB26 and FCB28 contains X'80' plus a binary index value, in the range 1 to 32 (default=1). The index value sets the left margin (1 indicates flush-left; other values cause indentation of the print line by N-1 positions).

If JES2 is to use any other FCB images, the images must specify channel 1 in position 1; otherwise, JES2 positions the forms in the printer incorrectly. (Because STD1 and STD2 do not specify channel 1 in position 1, they must be modified for JES2.)

If the third byte of any other FCB image (specifying the number of lines per inch) contains a data character other than X'80', JES2 uses that specification and supplies an index value of 1.

JES3 does not support the 3211 indexing feature, and any indexing commands from JES3 are ignored by the 3203 Model 5.
Using the extended address volume (EAV) migration assistance tracker

The EAV migration assistance tracker can help you find programs that you might need to change if you want to support extended address volumes (EAV). The EAV migration assistance tracker is an extension of the console ID tracking facility. It helps you:

- Identify select systems services by job and program name, where the invoking programs might require analysis for changes to use new services. The program calls are identified as informational instances for possible migration actions. They are not considered errors, because the services return valid information.

- Identify possible instances of improper use of returned information in programs, like parsing 28-bit cylinder numbers in output as 16-bit cylinder numbers. These instances are identified as warnings.

- Identify instances of programs that will either fail or run with an informational message if they run on an EAV. These are identified as programs in error. The migration assistance tracker flags programs with the following functions, when the target volume of the operation is non-EAV, and the function invoked did not specify the EADSCB=OK keyword:
  - OBTAIN
  - CVAFDIR
  - CVAFSEQ
  - CVAFDSM
  - CVAFFILT
  - CVAFVSM - Note that the CVAFVSM interface is an internal system function that is not documented externally for general use.
  - OPEN of VTOC
  - DCB OPEN of an EAS eligible data set

This allows the system programmer to identify programs in error by job and program name, without failing the programs. It also allows you to exclude programs that are not yet ready for evaluation.

Programs identified in this phase of migration assistance tracking will continue to fail if the system service is issued for an EAV if you do not specify the EADSCB=OK keyword for them.

The EAV migration assistance tracker can be manipulated with the following commands:

- The SETGTZ operator command, which is used to activate and deactivate the tracking facility.

- The DISPLAY GTZ,TRACKING operator command, which is used to display the current status of the tracking facility, along with any recorded instances of violations.

- The GTZxx dynamic parmlib member, which is used to list violations that have already been identified in order to prevent them from being recorded again.

See `console ID tracking facility in z/OS MVS Planning: Operations` for more information.

The following describe the instances identified and recorded by the EAV migration assistance tracker:

- "Information conventions for the EAV migration assistance tracker" on page 468
- "DFSMS instances tracked by the EAV migration assistance tracker" on page 469
Information conventions for the EAV migration assistance tracker

The information returned by the EAV migration assistance tracker describes the occurrence of an instance in text. Like the console ID tracking facility, the EAV migration assistance tracker returns tracking information and a tracking value. The tracking information can be from 1 to 28 characters in length and the system can set any EBCDIC value. The tracking value is four bytes of binary data associated with this instance. For DFSMS, these values include data to associate an instance to a specific DFSMS function and to define the reason for the instance being recorded. This standard allows for maximum flexibility in defining exclusion records that apply to DFSMS records.

The conventions for the tracking information and tracking value for a DFSMS instance follow.

Tracking information

The tracking information for a DFSMS instance might look as follows:

'SMS-I:3 LSPACE MSG= '

It can be broken down into several parts:
1. The first portion of the tracking information will be set to 'SMS-' to identify this as a DFSMS instance.
2. Appended to this is an error category, of "E" for error, "W" for warning, or "I" for informational, followed by a colon.
3. Appended to the colon is a numeric value that will identify the reason for the recorded instance. These values are
   • 1 - EAV migration: EADSCB=OK keyword was not specified on an invoking program where the target volume was non-EAV. The invoking program fails if the target volume is an EAV.
   • The invoking program would fail if the target volume was an EAV. The following section of the tracking information indicates the error that would have occurred. This instance is recorded in the tracker as an error message.
   • 2 - EAV migration. Formatted output display may contain 28-bit cylinder numbers. Program usage of these track addresses may need to be changed. Use macro TRKADDR for the comparison and manipulation of 28-bit cylinder numbers. This instance is recorded in the tracker as a warning message.
   • 3 - EAV migration. The new function is available on the invoking program. The identified program may want to exploit the available new function. This instance is recorded in the tracker as an informational message.
4. The remaining tracking information must be an EBCDIC value that describes the function executing when the tracker recorded the instance.

In the example above, the 'SMS-I:3 LSPACE MSG=' tracking information describes a DFSMS instance as an informational instance where new function is available that the invoking program might want to exploit. The function running when the tracker recorded this instance was LSPACE MSG=.

Tracking value

For DFSMS instances, the EAV migration assistance tracker sets the tracking value as follows:
• The system sets the low order byte of the track value to the same numeric value that identifies the reason for the instance.
EAV migration assistance tracker

- The remaining high order 3-bytes are left for the function recording the tracked instance. These 3-bytes are optional. For example, these values could be set to return and reason codes or parameter list flags.

Note that the tracking value must be set to a non-zero value in order for the SETCON TRACKING=ONWITHABEND to be applicable when an instance is recorded in the tracker. If the track value is 0 or 128 no ABEND will be issued when you specify tracking ONWITHABEND.

DFSMS instances tracked by the EAV migration assistance tracker

LSPACE (SVC 78)

An LSPACE request with the DATA=, MSG=, or XMSG= keywords was issued. Additional data from track-managed space is available with the EXPDATA= and XEXPMSG= keywords. When this instance occurs for any volume type, it will be recorded in the tracker as an informational message.

These five keywords are mutually exclusive.

LSPACE processing (IGC0007H) will set the following tracking information:

TRPL_TRACK_INFO =

'SMS-I:3 LSPACE retype'
  where,
    retype = DATA= or MSG= or XMSG=

TRPL_TRACK_DATA =

Byte 0-1
  Set to zero, not used.

Byte 2
  Set to the LSPACE parameter flag byte
  BIT 2 ON INDICATES THAT LSPACE WITH THE DATA= KEYWORD WAS SPECIFIED
  BIT 3 ON INDICATES THAT LSPACE WITH THE MSG= KEYWORD WAS SPECIFIED
  BIT 4 ON INDICATES THAT LSPACE WITH THE XMSG= KEYWORD WAS SPECIFIED

Byte 3
  Set to 03.
  DFSMS Tracking category 3: EAV Migration. Informational Message. New function is available. Additional data from track-managed space is available with the EXPDATA= and XEXPMSG= keywords.

TRPL_VIOLATORS_ADDR =

SET TO THE RESUME PSW OF THE RB THAT ISSUED SVC 78. TRACER CODE WILL DETERMINE JOB AND PROGRAM NAMES FROM THIS ADDRESS.

SAMPLE OUTPUT =

Using the extended address volume (EAV) migration assistance tracker 469
DEVTYPE (SVC 24)

A DEVTYPE request with DEVTAB or UCBLIST without INFOLIST, returns the number of cylinders on the volume. This is in a two-byte field at offset 8, which is too small if the volume has more than 65 520 cylinders. Consider using INFO=DASD which returns the number of cylinders in a four-byte field. When INFO=DASD is specified additional fields are now provided. They include (see mapping macro IHADVA):

- **DVAIXVLD BIT**
  - **DVACYLMG, DVAEADSCB, DVAолосZ valid**

- **DVACYLMG BIT**
  - Cylinder-managed space exists on this volume and begins at DVALCYL
  - in multicylinder units of DVAMCU.
  - DVAEADSCB is also set with this flag on. Valid when DVAIXVLD is set.

- **DVAEADSCB BIT**
  - Extended attribute DSCBs, Format 8 and 9 DSCBs, are allowed on this volume. Valid when DVAIXVLD is set.

- **DVAMCU 8-BIT UNSIGNED INTEGER**
  - Minimum allocation size in cylinders for cylinder-managed space. Each extent in this space must be a multiple of this value.
  - Also referred to as the multicylinder unit (MCU). This is the smallest unit of disk space in cylinders that can be allocated in cylinder-managed space. Valid when DVACYLMG is set.
  - This field is zero on releases before z/OS 1.10 or if the status is not yet known. In these two cases DVAMCU is not set.

- **DVALCYL 16-BIT UNSIGNED INTEGER**
  - First cylinder address divided by 4095 where space is managed in multicylinder units. Cyl-managed space begins at this address.
  - Valid when DVACYLMG is set. This field is zero on releases before z/OS 1.10 or if the status is not yet known. In these two cases DVAIXVLD is not set.

- **DVAVIRSZ 16-BIT UNSIGNED INTEGER**
  - Block size of the index data set.
  - Valid when DVAIXVLD is set on.
  - When valid and zero the volume has no working VTOC index. This field is zero on releases before z/OS 1.10 or if the status is not yet known. In these cases DVAIXVLD is not set.

When this instance occurs for any volume type, it will be recorded in the tracker as an informational message.

DEVTYPE processing (IGC0002D) will set the following tracking information:

```
TRPL_TRACK_INFO =
  'SMS-I:3 DEVTYPE'
TRPL_TRACK_DATA =
```

Accessibility

Publications for this product are offered in Adobe Portable Document Format (PDF) and should be compliant with accessibility standards. If you experience difficulties when using PDF files, you may view the information through the z/OS® Internet Library website or the z/OS Information Center. If you continue to experience problems, send an email to mhvrcfs@us.ibm.com or write to:

IBM® Corporation
Attention: MHVRCFS Reader Comments
Department H6MA, Building 707
2455 South Road
Poughkeepsie, NY 12601-5400
USA

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use software products successfully. The major accessibility features in z/OS enable users to:

- Use assistive technologies such as screen readers and screen magnifier software
- Operate specific or equivalent features using only the keyboard
- Customize display attributes such as color, contrast, and font size

Using assistive technologies

Assistive technology products, such as screen readers, function with the user interfaces found in z/OS. Consult the assistive technology documentation for specific information when using such products to access z/OS interfaces.

Keyboard navigation of the user interface

Users can access z/OS user interfaces using TSO/E or ISPF. Refer to z/OS TSO/E Primer, z/OS TSO/E User's Guide, and z/OS ISPF User's Guide Vol I for information about accessing TSO/E and ISPF interfaces. These guides describe how to use TSO/E and ISPF, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

z/OS information

z/OS information is accessible using screen readers with the BookServer or Library Server versions of z/OS books in the Internet library at:

http://www.ibm.com/systems/z/os/zos/bkserv/

One exception is command syntax that is published in railroad track format, which is accessible using screen readers with the Information Center, as described in "Dotted decimal syntax diagrams."

Dotted decimal syntax diagrams

Syntax diagrams are provided in dotted decimal format for users accessing the Information Center using a screen reader. In dotted decimal format, each syntax element is written on a separate line. If two or more syntax elements are always present together (or always absent together), they can appear on the same line, because they can be considered as a single compound syntax element.
Each line starts with a dotted decimal number; for example, 3 or 3.1 or 3.1.1. To hear these numbers correctly, make sure that your screen reader is set to read out punctuation. All the syntax elements that have the same dotted decimal number (for example, all the syntax elements that have the number 3.1) are mutually exclusive alternatives. If you hear the lines 3.1 USERID and 3.1 SYSTEMID, you know that your syntax can include either USERID or SYSTEMID, but not both.

The dotted decimal numbering level denotes the level of nesting. For example, if a syntax element with dotted decimal number 3 is followed by a series of syntax elements with dotted decimal number 3.1, all the syntax elements numbered 3.1 are subordinate to the syntax element numbered 3.

Certain words and symbols are used next to the dotted decimal numbers to add information about the syntax elements. Occasionally, these words and symbols might occur at the beginning of the element itself. For ease of identification, if the word or symbol is a part of the syntax element, it is preceded by the backslash (\) character. The * symbol can be used next to a dotted decimal number to indicate that the syntax element repeats. For example, syntax element *FILE with dotted decimal number 3 is given the format 3 \* FILE. Format 3* FILE indicates that syntax element FILE repeats. Format 3\* FILE indicates that syntax element * FILE repeats.

Characters such as commas, which are used to separate a string of syntax elements, are shown in the syntax just before the items they separate. These characters can appear on the same line as each item, or on a separate line with the same dotted decimal number as the relevant items. The line can also show another symbol giving information about the syntax elements. For example, the lines 5.1*, 5.1 LASTRUN, and 5.1 DELETE mean that if you use more than one of the LASTRUN and DELETE syntax elements, the elements must be separated by a comma. If no separator is given, assume that you use a blank to separate each syntax element.

If a syntax element is preceded by the % symbol, this indicates a reference that is defined elsewhere. The string following the % symbol is the name of a syntax fragment rather than a literal. For example, the line 2.1 %OP1 means that you should refer to separate syntax fragment OP1.

The following words and symbols are used next to the dotted decimal numbers:

- ? means an optional syntax element. A dotted decimal number followed by the ? symbol indicates that all the syntax elements with a corresponding dotted decimal number, and any subordinate syntax elements, are optional. If there is only one syntax element with a dotted decimal number, the ? symbol is displayed on the same line as the syntax element, (for example 5? NOTIFY). If there is more than one syntax element with a dotted decimal number, the ? symbol is displayed on a line by itself, followed by the syntax elements that are optional. For example, if you hear the lines 5 ?, 5 NOTIFY, and 5 UPDATE, you know that syntax elements NOTIFY and UPDATE are optional; that is, you can choose one or none of them. The ? symbol is equivalent to a bypass line in a railroad diagram.

- ! means a default syntax element. A dotted decimal number followed by the ! symbol and a syntax element indicate that the syntax element is the default option for all syntax elements that share the same dotted decimal number. Only one of the syntax elements that share the same dotted decimal number can specify a ! symbol. For example, if you hear the lines 2? FILE, 2.1! (KEEP), and 2.1 (DELETE), you know that (KEEP) is the default option for the FILE keyword.
In this example, if you include the FILE keyword but do not specify an option, default option KEEP will be applied. A default option also applies to the next higher dotted decimal number. In this example, if the FILE keyword is omitted, default FILE(KEEP) is used. However, if you hear the lines 2? FILE, 2.1, 2.1.1! (KEEP), and 2.1.1 (DELETE), the default option KEEP only applies to the next higher dotted decimal number, 2.1 (which does not have an associated keyword), and does not apply to 2? FILE. Nothing is used if the keyword FILE is omitted.

- * means a syntax element that can be repeated 0 or more times. A dotted decimal number followed by the * symbol indicates that this syntax element can be used zero or more times; that is, it is optional and can be repeated. For example, if you hear the line 5.1* data area, you know that you can include one data area, more than one data area, or no data area. If you hear the lines 3*, 3 HOST, and 3 STATE, you know that you can include HOST, STATE, both together, or nothing.

**Notes:**

1. If a dotted decimal number has an asterisk (*) next to it and there is only one item with that dotted decimal number, you can repeat that same item more than once.
2. If a dotted decimal number has an asterisk next to it and several items have that dotted decimal number, you can use more than one item from the list, but you cannot use the items more than once each. In the previous example, you could write HOST STATE, but you could not write HOST HOST.
3. The * symbol is equivalent to a loop-back line in a railroad syntax diagram.

- + means a syntax element that must be included one or more times. A dotted decimal number followed by the + symbol indicates that this syntax element must be included one or more times; that is, it must be included at least once and can be repeated. For example, if you hear the line 6.1+ data area, you must include at least one data area. If you hear the lines 2+, 2 HOST, and 2 STATE, you know that you must include HOST, STATE, or both. Similar to the * symbol, the + symbol can only repeat a particular item if it is the only item with that dotted decimal number. The + symbol, like the * symbol, is equivalent to a loop-back line in a railroad syntax diagram.
