XL C/C++
Run-Time Library Reference

This is a major revision of SA22-7821-08.

This edition applies to Version 1 Release 9 of z/OS (5694-A01), and to subsequent releases and modifications until otherwise indicated in new editions.

IBM welcomes your comments. A form for readers’ comments may be provided at the back of this document, or you may address your comments to the following address:

Chapter 3. Part 3. Library Functions

Names

Unsupported functions and external variables in AMODE 64.

Standards

Using C Include Files from C++

Built-in Functions

IEEE Binary Floating-Point

IEEE Decimal Floating-Point

External Variables

The __restrict__ macro

abort() — Stop a Program

abs(), absf(), absl() — Calculate Integer Absolute Value

accept() — Accept a New Connection on a Socket

accept_and_recv() — Accept Connection and Receive First Message

access() — Determine Whether a File Can be Accessed

acl_create_entry() — Add a New Extended ACL Entry to the ACL

acl_delete_entry() — Delete an Extended ACL Entry from the ACL

acl_delete_fd() — Delete an ACL by File Descriptor

acl_delete_file() — Delete an ACL by Filename

acl_first_entry() — Return to Beginning of ACL Working Storage

acl_free() — Release Memory Allocated to an ACL Data Object

acl_from_text() — Create an ACL from Text

acl_get_entry() — Get an ACL Entry

acl_get_fd() — Get ACL by File Descriptor

acl_get_file() — Get ACL by Filename

acl_init() — Initialize ACL Working Storage

acl_set_fd() — Set an ACL by File Descriptor

acl_set_file() — Set an ACL by Filename

acl_sort() — Sort the Extended ACL Entries
<table>

<td>Check WLM Scheduling Environment</td>
</tr>
<tr>
<td>chmod()</td>
<td>Change the Mode of a File or Directory</td>
</tr>
<tr>
<td>chown()</td>
<td>Change the Owner or Group of a File or Directory</td>
</tr>
<tr>
<td>chpriority()</td>
<td>Change the Scheduling Priority of a Process</td>
</tr>
<tr>
<td>chroot()</td>
<td>Change Root Directory</td>
</tr>
<tr>
<td>cimag(), cimagf(), cimagl()</td>
<td>Calculate the Complex Imaginary Part</td>
</tr>
<tr>
<td>clearenv()</td>
<td>Clear Environment Variables</td>
</tr>
<tr>
<td>clearerr()</td>
<td>Reset Error and End of File (EOF)</td>
</tr>
<tr>
<td>clock()</td>
<td>Determine Processor Time</td>
</tr>
<tr>
<td>clog(), clogf(), clogl()</td>
<td>Calculate the Complex Natural Logarithm</td>
</tr>
<tr>
<td>close()</td>
<td>Close a File</td>
</tr>
<tr>
<td>closedir()</td>
<td>Close a Directory</td>
</tr>
<tr>
<td>closelog()</td>
<td>Close the Control Log</td>
</tr>
<tr>
<td>clrmemf()</td>
<td>Clear Memory Files</td>
</tr>
<tr>
<td>__cnvblk()</td>
<td>Convert Block</td>
</tr>
<tr>
<td>collequiv()</td>
<td>Return a List of Equivalent Collating Elements</td>
</tr>
<tr>
<td>collorder()</td>
<td>Return List of Collating Elements</td>
</tr>
<tr>
<td>collrange()</td>
<td>Calculate the Range List of Collating Elements</td>
</tr>
<tr>
<td>colltostr()</td>
<td>Return a String for a Collating Element</td>
</tr>
<tr>
<td>compile()</td>
<td>Compile Regular Expression</td>
</tr>
<tr>
<td>confstr()</td>
<td>Get Configurable Variables</td>
</tr>
<tr>
<td>conj(), conjf(), conjl()</td>
<td>Calculate the Complex Conjugate</td>
</tr>
<tr>
<td>connect()</td>
<td>Connect a Socket</td>
</tr>
<tr>
<td>ConnectExportImport()</td>
<td>WLM Connect for Export or Import Use</td>
</tr>
<tr>
<td>ConnectServer()</td>
<td>Connect to WLM as a Server Manager</td>
</tr>
<tr>
<td>ConnectWorkMgr()</td>
<td>Connect to WLM as a Work Manager</td>
</tr>
<tr>
<td>__console()</td>
<td>Console Communication Services</td>
</tr>
<tr>
<td>__console2()</td>
<td>Enhanced Console Communication Services</td>
</tr>
<tr>
<td>ContinueWorkUnit()</td>
<td>Continue WLM Work Unit</td>
</tr>
<tr>
<td>__convert_id_np()</td>
<td>Convert Between DCE UUID and Userid</td>
</tr>
<tr>
<td>copysign(), copysignf(), copysignl()</td>
<td>Copy the Sign from one floating-point number to another</td>
</tr>
<tr>
<td>copysignd32(), copysignd64(), copysignd128()</td>
<td>Copy the Sign from one floating-point number to another</td>
</tr>
<tr>
<td>cos(), cosf(), cosl()</td>
<td>Calculate Cosine</td>

<tr>
<td>feholdexcept()</td>
<td>Save the Current Floating-Point Environment</td>
</tr>
<tr>
<td>feof()</td>
<td>Test End Of File (EOF) Indicator</td>
</tr>
<tr>
<td>feraiseccept()</td>
<td>Raise the Supported Floating-Point Exceptions</td>
</tr>
<tr>
<td>ferror()</td>
<td>Test for Read/Write Errors</td>
</tr>
<tr>
<td>fegetenv()</td>
<td>Set the Floating-Point Environment</td>
</tr>
<tr>
<td>fesetexceptflag()</td>
<td>Set the Floating-Point Status Flags</td>
</tr>
<tr>
<td>fesetround()</td>
<td>Set the Current Rounding Mode</td>
</tr>
<tr>
<td>fetch()</td>
<td>Get a Load Module</td>
</tr>
<tr>
<td>fetchep()</td>
<td>Share Writable Static</td>
</tr>
<tr>
<td>fetesecept()</td>
<td>Test the Floating-Point Status Flags</td>
</tr>
<tr>
<td>feupdateenv()</td>
<td>Save the Currently Raised Floating-Point Exceptions</td>
</tr>
<tr>
<td>fflush()</td>
<td>Write Buffer to File</td>
</tr>
<tr>
<td>ffs()</td>
<td>Find First Set Bit in an Integer</td>
</tr>
<tr>
<td>fgetc()</td>
<td>Read a Character</td>
</tr>
<tr>
<td>fgetpos()</td>
<td>Get File Position</td>
</tr>
<tr>
<td>fgets()</td>
<td>Read a String from a Stream</td>
</tr>
<tr>
<td>fgetwc()</td>
<td>Get Next Wide Character</td>
</tr>
<tr>
<td>fgetws()</td>
<td>Get a Wide-Character String</td>
</tr>
<tr>
<td>fileno()</td>
<td>Get the File Descriptor from an Open Stream</td>
</tr>
<tr>
<td>finite()</td>
<td>Determine the Infinity Classification of a Floating-Point Number</td>
</tr>
<tr>
<td>fldata()</td>
<td>Retrieve File Information</td>
</tr>
<tr>
<td>flocate()</td>
<td>Locate a VSAM Record</td>
</tr>
<tr>
<td>flockfile()</td>
<td>stdio Locking</td>
</tr>
<tr>
<td>floor(), floorf(), floorl()</td>
<td>Round Down to Integral Value</td>
</tr>
<tr>
<td>fmod32(), fmod64(), fmod128()</td>
<td>Round Down to Integral Value</td>
</tr>
<tr>
<td>fma(), fmaf(), fmal()</td>
<td>Multiply then Add</td>
</tr>
<tr>
<td>fmax(), fmaxf(), fmaxl()</td>
<td>Calculate the Maximum Numeric Value</td>
</tr>
<tr>
<td>fmaxd32(), fmaxd64(), fmaxd128()</td>
<td>Calculate the Maximum Numeric Value</td>
</tr>
<tr>
<td>fmin(), fminf(), fminl()</td>
<td>Calculate the Minimum Numeric Value</td>
</tr>
<tr>
<td>fmin32(), fmin64(), fmin128()</td>
<td>Calculate the Minimum Numeric Value</td>
</tr>
<tr>
<td>fmod(), fmodf(), fmodl()</td>
<td>Calculate Floating-Point Remainder</td>
</tr>
<tr>
<td>ftmpmsg()</td>
<td>Display a Message in the Specified Format</td>
</tr>
<tr>
<td>fnmatch()</td>
<td>Match Filename or Pathname</td>
</tr>
<tr>
<td>fopen()</td>
<td>Open a File</td>
</tr>
<tr>
<td>fork()</td>
<td>Create a New Process</td>
</tr>
<tr>
<td>fortrc()</td>
<td>Return FORTRAN Return Code</td>
</tr>
<tr>
<td>fpathconf()</td>
<td>Determine Configurable Pathname Variables</td>
</tr>
<tr>
<td>fpclassify()</td>
<td>Classifies an argument value</td>
</tr>
<tr>
<td>fp_clr_flag()</td>
<td>Reset Floating-Point Exception Status Flag</td>
</tr>
<tr>
<td>fp__raise_xcp()</td>
<td>Raise a Floating-Point Exception</td>
</tr>
<tr>
<td>fp__read_flag()</td>
<td>Return the Current Floating-Point Exception Status</td>
</tr>
<tr>
<td>fp__read_rnd()</td>
<td>Determine Rounding Mode</td>
</tr>
<tr>
<td>fprintf(), printf(), sprintf()</td>
<td>Format and Write Data</td>
</tr>
<tr>
<td>fp__swap_rnd()</td>
<td>Swap Rounding Mode</td>
</tr>
<tr>
<td>fputc()</td>
<td>Write a Character</td>
</tr>
<tr>
<td>fputs()</td>
<td>Write a String</td>
</tr>
<tr>
<td>fputwc()</td>
<td>Output a Wide-Character</td>
</tr>
<tr>
<td>fputws()</td>
<td>Output a Wide-Character String</td>
</tr>
<tr>
<td>fread()</td>
<td>Read Items</td>
</tr>
<tr>
<td>free()</td>
<td>Free a Block of Storage</td>
</tr>
<tr>
<td>freeaddrinfo()</td>
<td>free addrinfo storage</td>
</tr>
<tr>
<td>freopen()</td>
<td>Redirect an Open File</td>
</tr>
<tr>
<td>frexp(), frexpf(), frexpl()</td>
<td>Extract Mantissa and Exponent of the Floating-Point Value</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>frexp32(), frexp64(), frexp128()</td>
<td>Extract Mantissa and Exponent of the Decimal Floating-Point Value</td>
</tr>
<tr>
<td>fscanf(), scanf(), sscanf()</td>
<td>Read and Format Data</td>
</tr>
<tr>
<td>fseek()</td>
<td>Change File Position</td>
</tr>
<tr>
<td>fseeko()</td>
<td>Change File Position</td>
</tr>
<tr>
<td>fsetpos()</td>
<td>Set File Position</td>
</tr>
<tr>
<td>fstat()</td>
<td>Get Status Information about a File</td>
</tr>
<tr>
<td>fstatvfs()</td>
<td>Get File System Information</td>
</tr>
<tr>
<td>fsync()</td>
<td>Write Changes to Direct-Access Storage</td>
</tr>
<tr>
<td>ftell()</td>
<td>Get Current File Position</td>
</tr>
<tr>
<td>ftello()</td>
<td>Get Current File Position</td>
</tr>
<tr>
<td>ftw()</td>
<td>Set the Date and Time</td>
</tr>
<tr>
<td>ftok()</td>
<td>Generate an Interprocess Communication (IPC) key</td>
</tr>
<tr>
<td>ftell()</td>
<td>Truncate a File</td>
</tr>
<tr>
<td>ftw()</td>
<td>Change a File Tree</td>
</tr>
<tr>
<td>funlockfile()</td>
<td>stdio Locking</td>
</tr>
<tr>
<td>ftell()</td>
<td>Update a VSAM Record</td>
</tr>
<tr>
<td>fwide()</td>
<td>Set Stream Orientation</td>
</tr>
<tr>
<td>fwscanf(), swscanf(), wscanf()</td>
<td>Format and Write Wide Characters</td>
</tr>
<tr>
<td>fwrite()</td>
<td>Write Items</td>
</tr>
<tr>
<td>getaddrinfo()</td>
<td>Get address information</td>
</tr>
<tr>
<td>getc(), getchar()</td>
<td>Read a Character</td>
</tr>
<tr>
<td>getc_unlocked, getchar_unlocked, putc_unlocked, putchar_unlocked</td>
<td>Stdio With Explicit Client Locking</td>
</tr>
<tr>
<td>getclientid()</td>
<td>Get the Identifier for the Calling Application</td>
</tr>
<tr>
<td>__getclientid()</td>
<td>Get the PID Identifier for the Calling Application</td>
</tr>
<tr>
<td>getcontext()</td>
<td>Get User Context</td>
</tr>
<tr>
<td>__get_cpuid()</td>
<td>Retrieves the system CPUID</td>
</tr>
<tr>
<td>getcwd()</td>
<td>Get Pathname of the Working Directory</td>
</tr>
<tr>
<td>getdate()</td>
<td>Convert User Format Date and Time</td>
</tr>
<tr>
<td>getdtablesize()</td>
<td>Get the File Descriptor Table Size</td>
</tr>
<tr>
<td>getegid()</td>
<td>Get the Effective Group ID</td>
</tr>
<tr>
<td>geteuid()</td>
<td>Get the Effective User ID</td>
</tr>
<tr>
<td>getgid()</td>
<td>Get the Real Group ID</td>
</tr>
<tr>
<td>getgrent()</td>
<td>Get Group Database Entry</td>
</tr>
<tr>
<td>getgrgid()</td>
<td>Access the Group Database by ID</td>
</tr>
<tr>
<td>getgrgid_r()</td>
<td>Get Group Database Entry for a Group ID</td>
</tr>
<tr>
<td>getgrnam()</td>
<td>Access the Group Database by Name</td>
</tr>
<tr>
<td>getgrnam_r()</td>
<td>Search Group Database for a Name</td>
</tr>
<tr>
<td>getgroups()</td>
<td>Get a List of Supplementary Group IDs</td>
</tr>
<tr>
<td>gethostbyaddr()</td>
<td>Get a Host Entry by Address</td>
</tr>
<tr>
<td>gethostbyname()</td>
<td>Get a Host Entry by Name</td>
</tr>
<tr>
<td>gethostent()</td>
<td>Get the Next Host Entry</td>
</tr>
<tr>
<td>gethostname()</td>
<td>Get the Unique Identifier of the Current Host</td>
</tr>
<tr>
<td>gethostname()</td>
<td>Get the Name of the Host Processor</td>
</tr>
<tr>
<td>getibmopt()</td>
<td>Get IBM TCP/IP Image</td>
</tr>
<tr>
<td>getibmsockopt()</td>
<td>Get the Options Associated with a Bulk Mode Socket</td>
</tr>
<tr>
<td>getipc()</td>
<td>Query Interprocess Communications</td>
</tr>
</tbody>
</table>
globfree() — Free Storage Allocated by glob() ........................................ 901
gmtime() — Convert Time to Broken-Down UTC Time ................................... 902
gmtime_r() — Convert a Time Value to Broken-Down UTC Time ......................... 904
grantpt() — Grant Access to the Slave Pseudoterminal Device ......................... 906
hcreate() — Create Hash Search Tables .................................................. 907
hdestroy() — Destroy Hash Search Tables ................................................ 908
__heaprpt() — Obtain Dynamic Heap Storage Report .................................... 909
hsearch() — Search Hash Tables ............................................................. 911
htonl() — Translate Address Host to Network Long ...................................... 912
htons() — Translate an Unsigned Short Integer into Network Byte Order ............ 914
hypot(), hypotf(), hypotl() — Calculate the square root of the squares of two arguments ................................................................. 916
ibmsflush() — Flush the Application-side Datagram Queue ............................. 918
iconv() — Code Conversion ...................................................................... 920
iconv_close() — Deallocate Code Conversion Descriptor ................................. 924
iconv_open() — Allocate Code Conversion Descriptor ................................... 925
if_freenamet()} — free the memory allocated by if_nameindex() ...................... 929
if_indextoname() — map a network interface index to its corresponding name .... 930
if_nameindex() — return all network interface names and indexes .................. 931
if_nametoindex() — map a network interface name to its corresponding index .... 932
ilogb(), ilogbf(), ilogbl() — Integer Unbiased Exponent .............................. 933
ilogbd32(), ilogbd64(), ilogbd128() — Integer Unbiased Exponent .................. 935
imaxabs() — Absolute value for intmax_t ................................................... 937
imaxdiv() — quotient and remainder for intmax_t ....................................... 938
ImportWorkUnit() — WLM Import Service ............................................... 939
index() — Search for Character .................................................................. 941
inet6_opt_append() — Add an Option with Length “len” and Alignment “align” . 942
inet6_opt_find() — Search for an Option Specified by the Caller ................... 944
inet6_opt_finish() — Return the Updated Total Length of Extension Header .... 946
inet6_opt_get_val() — Extract Data Items in the Data Portion of the Option .... 947
inet6_opt_init() — Return the Number of Bytes for Empty Extension Header .... 949
inet6_opt_next() — Parse Received Option Headers Returning the Next Option ... 950
inet6_opt_set_val() — Insert Data Items into the Data Portion of the Option .... 952
inet6_rth_add() — Add an IPv6 Address to End of the Routing Header ........... 954
inet6_rth_getaddr() — Return Pointer to the IPv6 Address Specified ............. 955
inet6_rth_init() — Initialize an IPv6 Routing Header Buffer ......................... 956
inet6_rth_reverse() — Reverse the Order of the Addresses .......................... 957
inet6_rth_segments() — Return Number of Segments Contained in Header ...... 958
inet6_rth_space() — Return Number of Bytes for a Routing Header ............... 959
inet_addr() — Translate an Internet Address into Network Byte Order .......... 960
inet_lnaof() — Translate a Local Network Address into Host Byte Order ......... 962
inet_makeaddr() — Create an Internet Host Address .................................... 963
inet_netof() — Get the Network Number from the Internet Host Address ......... 965
inet_network() — Get the Network Number from the Decimal Host Address ...... 966
inet_ntoa() — Get the Decimal Internet Host Address ................................... 968
inet_ntop() — Convert Internet Address Format from Binary to Text ............... 970
inet_pton() — Convert Internet Address Format from Text to Binary ............... 972
initgroups() — Initialize the Supplementary Group ID List for the Process ......... 974
initstate() — Initialize Generator for random() ........................................ 975
insqee() — Insert an Element into a Doubly-linked List .................................. 976
ioctl() — Control Device ......................................................................... 977
__ipdbcs() — Retrieve the List of Requested DBCS Tables to Load .................. 997
__ipDomainName() — Retrieve the Resolver Supplied Domain Name ................ 998
__ipdspx() — Retrieve the Data Set Prefix Specified .................................. 999
__iphost() — Retrieve the Resolver Supplied Hostname ................................ 1000
__ipmsgc() — Determine the Case to Use for FTP Messages ......................... 1001
LeaveWorkUnit() — Leave a WLM Work Unit
__le_cib_get() — Get Condition Information Block
__le_condition_token_build() — Build a Language Environment Condition Token
__le_msg_add_insert() — Add Insert to a Language Environment Message
__le_msg_get() — Get a Language Environment Message
__le_msg_get_and_write() — Get and output a Language Environment Message
__le_msg_write() — Output a Language Environment Message to stderr
__le_debug_set_resume_mch() — Move the resume cursor to a predefined location represented by a machine state.
__le_traceback() — call chain traceback service
lfind() — Linear Search Routine
lgamma(), lgammaf(), lgammal() — Log Gamma Function
__librel() — Query Release Level
link() — Create a Link to a File
listen() — Prepare the Server for Incoming Client Requests
llabs() — Calculate Absolute Value of Long Long Integer
lldiv() — Compute Quotient and Remainder of Integral Division for Long Long Type
llround(), llroundf(), llroundl() — Round to the Nearest Integer
llroundd32(), llroundd64(), llroundd128() — Round to the Nearest Integer
lltoa() — Convert long long into a string
localdtconv() — Date/Time Formatting Convention Inquiry
localeconv() — Query Numeric Conventions
localtime() — Convert Time and Correct for Local Time
localtime_r() — Convert Time Value to Broken-Down Local Time
lockf() — Record Locking on Files
log(), logf(), logl() — Calculate Natural Logarithm
logb(), logbf(), logbl() — Unbiased Exponent
logbd32(), logbd64(), logbd128() — Unbiased Exponent
log32(), logd64(), logd128() — Calculate Natural Logarithm
__login() — Create a New Security Environment for Process
log1p(), log1pf(), log1pl() — Natural Log of x + 1
log10(), log10f(), log10l() — Calculate Base 10 Logarithm
log10d32(), log10d64(), log10d128() — Calculate Base 10 Logarithm
log2(), log2f(), log2l() — Calculate the Base-2 Logarithm
longjmp() — Restore Stack Environment
__longjmp() — Nonlocal Goto
lrand48() — Pseudo-Random Number Generator
lrint(), lrintf(), lrintl() and llrint(), llrintf(), llrintl() — Round the Argument to the Nearest Integer
lrintd32(), lrintd64(), lrintd128() — Round the Argument to the Nearest Integer
lround(), lroundf(), lroundl() — Round a Decimal Floating-point Number to its Nearest Integer
lroundd32(), lroundd64(), lroundd128() — Round a Floating-point Number to its Nearest Integer
lsearch() — Linear Search and Update
lseek() — Change the Offset of a File
lstat() — Get Status of File or Symbolic Link
l64a() — Convert Long to Base 64 String Representation
ltoa() — Convert long into a string
makecontext() — Modify User Context
malloc() — Reserve Storage Block
__malloc24() — Allocate 24–bit storage
malloc31() — Allocate 31-bit storage
map_init() — Designate a Storage Area for Mapping Blocks
map_service() — Set Memory Mapping Service
maxcoll() — Return Maximum Collating Element
maxdesc() — Get Socket Numbers to Extend Beyond the Default Range
mblen() — Calculate Length of Multibyte Character
mbrlen() — Calculate Length of Multibyte Character
mbrtowc() — Convert a Multibyte Character to a Wide Character
mbsinit() — Test State Object for Initial State
mbsrtowcs() — Convert a Multibyte String to a Wide-Character String
mbstowcs() — Convert Multibyte Characters to Wide Characters
mbtowc() — Convert Multibyte Character to Wide Character
m_create_layout() — Create and Initialize a Layout Object (Bidi data)
m_destroy_layout() — Destroy a Layout Object (Bidi data)
memccpy() — Copy Bytes in Memory
memchr() — Search Buffer
memcmp() — Compare Bytes
memcpy() — Copy Buffer
memmove() — Move Buffer
memset() — Set Buffer to Value
m_getvalues_layout() — Query Layout Values of a Layout Object (Bidi data)
mkdir() — Make a Directory
mkfifo() — Make a FIFO Special File
mknod() — Make a Directory or File
mkstemp() — Make a Unique Filename
mktemp() — Make a Unique Filename
mktime() — Convert Local Time
__mlockall() — Lock the Address Space of a Process
mmap() — Map Pages of Memory
modf(), modff(), modfl() — Extract Fractional and Integral Parts of Floating-Point Value
modfd32(), modfd64(), modfd128() — Extract Fractional and Integral Parts of Decimal Floating-Point Value
mount() — Make a File System Available
__mount() — Make a File System Available
mprotect() — Set Protection of Memory Mapping
mrand48() — Pseudo-Random Number Generator
m_setvalues_layout() — Set Layout Values of a Layout Object (Bidi data)
msgctl() — Message Control Operations
msgget() — Get Message Queue
msgcvt() — Message Receive Operation
__msgrcv_time() — Message Receive Operation With Timeout
msgsd() — Message Send Operations
msgxrcv() — Extended Message Receive Operation
msync() — Synchronize Memory with Physical Storage
m_transform_layout() — Layout Transformation for Character Strings (Bidi data)
m_unmap() — Unmap Pages of Memory
__must_stay_clean() — Enable or Query Clean
m_wtransform_layout() — Layout Transformation for Wide-Character Strings (Bidi data)
nan(), nanf(), nanl() — Return Quiet NaN
nand32(), nand64(), nand128() — Return Quiet NaN
nearbyint(), nearbyintf(), nearestintl() — Round the Argument to the Nearest Integer

Contents xvii
nearbyintd32(), nearbyintd64(), nearbyintd128() — Round the Argument to the Nearest Integer

nextafter(), nextafterf(), nextafterl() — Next Representable Double Float Floating-Point Value

nextafterd32(), nextafterd64(), nextafterd128() — Next Representable Decimal Floating-Point Value

nexttoward(), nexttowardf(), nexttowardl() — Calculate the Next Representable Value

nexttoward32(), nexttoward64(), nexttoward128() — Calculate the Next Representable Value

nextafterf(), nextafterl() — Next Representable Double Float 1292

nextafterd32(), nextafterd64(), nextafterd128() — Next Representable Decimal Floating-Point Value 1294

nexttoward(), nexttowardf(), nexttowardl() — Calculate the Next Representable Value 1296

nexttoward32(), nexttoward64(), nexttoward128() — Calculate the Next Representable Value 1299

nftw() — Traverse a File Tree 1301

nice() — Change Priority of a Process 1304

nlist() — Get Entries from a Name List 1305

nl_langinfo() — Retrieve Locale Information 1306

nrand48() — Pseudo-Random Number Generator 1307

ntohl() — Translate a Long Integer into Host Byte Order 1309

ntohs() — Translate an Unsigned Short Integer into Host Byte Order 1311

open() — Open a File 1313

opendir() — Open a Directory 1319

__opendir2() — Open a Directory 1322

openlog() — Open the System Control Log 1324

__open_stat() — Open a File and Get File Status Information 1326

__oserv() — Capture the WLM and Pthread Security Attributes 1329

__osname() — Get True Operating System Name 1333

__passwd() — Verify/Change User Password 1335

pathconf() — Determine Configurable Pathname Variables 1337

pause() — Suspend a Process Pending a Signal 1340

pclose() — Close a Pipe Stream to or from a Process 1342

perror() — Print Error Message 1344

__pid_affinity() — Add or Delete Process Affinity 1346

pipe() — Create an Unnamed Pipe 1348

__poe() — Port Of Entry information used in determining various levels of permission checking 1351

poll() — Monitor Activity on File Descriptors and Message Queues 1353

posix_openpt – open a pseudo-terminal device 1358

posix_openpt() — Open an unnumbered pseudo-terminal device 1360

pow(), powf(), powl() — Raise to Power 1362

powd32(), powd64(), powd128() — Raise to Power 1364

__pow_i() — Raise to a Power (R**I) 1366

__pow_ii() — Raise to a Power (I**I) 1367

pread() — Read From a File or Socket Without File Pointer Change 1368

printf() — Format and Write Data 1370

pselect() - Monitor Activity on Files/Sockets and Message Queues 1371

pthread_attr_destroy() — Destroy the Thread Attributes Object 1377

pthread_attr_getdetachstate() — Get the Detach State Attribute 1379

pthread_attr_getguardsize - Get guardsize attribute 1382

pthread_attr_getschedparam - Get scheduling parameter attributes 1384

pthread_attr_getstack - Get stack attribute 1386

pthread_attr_getstackaddr - Get stackaddr attribute 1388

pthread_attr_getstacksize() — Get the Thread Attribute Stacksize Object 1390

pthread_attr_getsynctype_np() — Get Thread Sync Type 1392

pthread_attr_getweight_np() — Get Weight of Thread Attribute Object 1393

pthread_attr_init() — Initialize a Thread Attribute Object 1395

pthread_attr_setdetachstate() — Set the Detach State Attribute Object 1397

pthread_attr_setguardsize - Set guardsize attribute 1399

pthread_attr_setschedparam - Set scheduling parameter attributes 1401
pthread_rwlock_trywrlock() — Attempt to Lock a Read/Write Lock Object for Writing ............................ 1528
pthread_rwlock_unlock() — Unlock a Read/Write Lock Object ...................................................... 1529
pthread_rwlock_wrlock() — Wait for a Lock on a Read/Write Lock Object for Writing .................... 1530
pthread_rwlockattr_destroy() — Destroy a Read/Write Lock Attribute Object ............................. 1531
pthread_rwlockattr_getpshared() — Get the Processed-Shared Read/Write Lock Attribute ..................... 1533
pthread_rwlockattr_init() — Initialize a Read/Write Lock Attribute Object ..................................... 1535
pthread_rwlockattr_setpshared() — Set the Process-Shared Read/Write Lock Attribute ...................... 1537
pthread_security_np() — Create or Delete Thread-level Security .................................................. 1539
pthread_self() — Get the Caller .......................................................................................................... 1542
pthread_setcancelstate() — Set Thread's Cancelability State Format ............................................. 1544
pthread_setcanceltype() — Set Thread's Cancelability Type Format .............................................. 1545
pthread_setconcurrency() — Set the Level of Concurrency ............................................................ 1546
pthread_setintr() — Set Thread's Cancelability State ........................................................................ 1547
pthread_setintrtype() — Set Thread's Cancelability Type .................................................................. 1550
pthread_set_limit_np() — Set Task and Thread Limits ...................................................................... 1553
pthread_setspecific() — Set the Thread-Specific Value for a Key .................................................... 1554
pthread_sigmask() — Examine or Change a Thread's Blocked Signals Format .................................. 1557
pthread_tag_np() — Set and Query Thread Tag Data ......................................................................... 1560
pthread_testcancel() — Establish a Cancelation Point ..................................................................... 1561
pthread_testintr() — Establish a Cancelability Point ........................................................................ 1562
pthread_yield() — Release the Processor to Other Threads ............................................................... 1564
ptsname() — Get Name of the Slave Pseudoterminal Device ............................................................ 1566
putc(), putchar() — Write a Character .................................................................................................. 1566
putenv() — Change or Add an Environment Variable ...................................................................... 1569
putenv(), putpmem() — Send a Message on a STREAM ..................................................................... 1570
puts() — Write a String ......................................................................................................................... 1574
pututxline() — Write Entry to utmpx Database ............................................................................. 1576
putw() — Put a Machine Word on a Stream ....................................................................................... 1578
putwc() — Output a Wide Character .................................................................................................. 1579
putwchar() — Output a Wide Character to Standard Output .......................................................... 1581
pwrite() — Write Data on a File or Socket Without File Pointer Change ............................................ 1583
qsort() — Sort Array ................................................................................................................................ 1585
quantized32(), quantized64(), quantized128() — Set the Exponent of X to the Exponent of Y ............ 1587
QueryMetrics() — Query WLM System Information ............................................................................ 1589
QuerySchEnv() — Query WLM Scheduling Environment ................................................................... 1591
QueryWorkUnitClassification() — WLM Query Enclave Classification Service ............................. 1593
raise() — Raise Signal ......................................................................................................................... 1595
rand() — Generate Random Number ................................................................................................... 1598
rand_r() — Pseudo-Random Number Generator ................................................................................ 1600
random() — A Better Random-Number Generator ........................................................................... 1601
read() — Read From a File or Socket .................................................................................................... 1602
readdir() — Read an Entry from a Directory ....................................................................................... 1608
__readdir() — Read Directory Entry and Get File Information ......................................................... 1611
readdir_r() — Read an Entry from a Directory ................................................................................... 1613
readlink() — Read the Value of a Symbolic Link ............................................................................. 1615
readv() — Read Data on a File or Socket and Store in a Set of Buffers ............................................. 1617
realloc() — Change Reserved Storage Block Size ............................................................................. 1620
realpath() — Resolve Pathname ........................................................................................................... 1623
re_compl() — Compile Regular Expression ....................................................................................... 1625
recv() — Receive Data on a File or Socket ......................................................................................... 1628
recvfrom() — Receive Messages on a Socket ..................................................................................... 1631
recvmsg() — Receive Messages on a Socket and Store in an Array of Message Headers .......................... 1635
re_exec() — Match Regular Expression ........................................ 1640
regcmp() — Compile Regular Expression .................................................. 1642
regcomp() — Compile Regular Expression ................................................. 1646
regerror() — Return Error Message ....................................................... 1649
regex() — Execute Compiled Regular Expression ........................................ 1651
regexec() — Execute Compiled Regular Expression ....................................... 1653
regfree() — Free Memory for Regular Expression ........................................ 1656
release() — Delete a Load Module ......................................................... 1657
remainder(), remainderf(), remainderl() — Computes the remainder x REM y ... 1659
remove() — Delete File ........................................................................... 1661
remque() — Remove an Element from a Doubly-linked List ......................... 1663
remquo(), remquof(), remquol() — Computes the remainder .......................... 1664
rename() — Rename File ........................................................................ 1666
res_init() — Domain Name Resolver Initialization ........................................ 1669
res_mkquery() — Make Resolver Query for Domain Name Servers (DNS) .... 1672
res_query() — Resolver Query for Domain Name Servers (DNS) .................... 1673
res_querydomain() — Build Domain Name and Resolver Query .................. 1675
res_search() — Resolver Query for Domain Name Servers (DNS) .................. 1677
res_send() — Send Resolver Query for Domain Name Servers (DNS) ............. 1679
reset_exception_handler() — Unregister an Exception Handler Routine ....... 1680
rewind() — Set File Position to Beginning of File ........................................ 1681
rewinddir() — Reposition a Directory Stream to the Beginning .................... 1683
rexec() — Execute Commands One at a Time on a Remote Host .................. 1685
rexec_af() — execute commands one at a time on a remote host .......................... 1688
rindex() — Search for Character .................................................................. 1688
rint(), rintf(), rintl() — Round to Nearest Integral Value ......................... 1689
rintd32(), rintd64(), rintd128() — Round to Nearest Integral Value ............ 1690
rmdir() — Remove a Directory .................................................................. 1692
round(), roundf(), roundl() — Round to the Nearest Integer ....................... 1695
round32(), roundd64(), round128() — Round to the Nearest Integer ............. 1696
rpmatch() — Test for a Yes/No Response Match .......................................... 1699
samequantumd32(), samequantumd64(), samequantumd128() — Determine if Exponents X and Y are the Same ................................................................. 1701
sbrk() — Change Space Allocation ............................................................. 1703
scalb() — Load Exponent ....................................................................... 1704
scalbn(), scalbnf(), scalbln(), scalbnf(), scalbln() — load exponent functions ......................................................................................................................... 1705
scalbd32(), scalbd64(), scalbd128() and scalblnd32(), scalblnd64() .......................... 1706
scalblnd32(), scalblnd64(), scalblnd128() — load exponent functions ......... 1708
scanf() — Read and Format Data .................................................................. 1710
sched_yield() — Release the Processor to Other Threads ......................... 1711
seed48() — Pseudo-Random Number Initializer ........................................... 1712
seekdir() — Set Position of Directory Stream ............................................... 1714
select(), pselect() — Monitor Activity on Files/Sockets and Message Queues 1715
selectex() — Monitor Activity on Files/Sockets and Message Queues ............ 1718
semctl() — Semaphore Control Operations ................................................ 1722
semget() — Get a Set of Semaphores ......................................................... 1731
semop() — Semaphore Operations .............................................................. 1734
__semop_timed() — Semaphore Operations With Timeout ............................ 1737
send() — Send Data on a Socket ................................................................. 1740
send_file() — Send File Data Over a Socket ................................................ 1743
sendmsg() — Send Messages on a Socket .................................................... 1747
sendto() — Send Data on a Socket .............................................................. 1752
__server_classify() — Set Classify Area Field ............................................. 1756

</tbody>
</table>

xxiv  z/OS V1R9.0 XL C/C++ Run-Time Library Reference
term() — Terminate MTF Subtasks ........................................ 2270
ttyname() — Get the Name of a Terminal .................................. 2272
tyname_r() — Find Pathname of a Terminal ................................. 2274
tyslot() — Find the Slot in the utmpx File of the Current User ........ 2275
t_unbind() — Disable a Transport Endpoint ................................ 2276
twalk() — Binary Tree Walk .................................................. 2277
tzset() — Set the Time Zone .................................................. 2279
ualarm() — Set the Interval Timer .......................................... 2280
__ucreate() — Create a Heap Using User-Provided Storage .............. 2283
__ufree() — Return Storage to a User-Created Heap ...................... 2285
__uheapreport() — Produce a Storage Report for a User-Created Heap 2286
ulimit() — Get/Set Process File Size Limits .............................. 2287
ulltoa() — Convert unsigned long into a string .......................... 2288
ultoa() — Convert unsigned long into a string .......................... 2289
__umalloc() — Allocate Storage from a User-Created Heap .............. 2290
umask() — Set and Retrieve File Creation Mask ......................... 2291
umount() — Remove a Virtual File System ................................ 2293
uname() — Display Current Operating System Name ..................... 2296
uncaught_exception() — Determine if an Exception is being Processed 2299
UnDoExportWorkUnit() — WLM Undo Export Service ..................... 2301
UnDoImportWorkUnit() — WLM Undo Import Service ..................... 2303
unexpected() — Handle Exception Not Listed in Exception Specification 2305
ungetc() — Push Character onto Input Stream ............................ 2307
ungetwc() — Push a Wide Character onto a Stream ....................... 2310
unlink() — Remove a Directory Entry .................................... 2312
unlockpt() — Unlock a Pseudoterminal Master/Slave Pair ............... 2314
unsetenv() — Delete an Environment Variable ............................ 2315
usleep() — Suspend Execution for an Interval ............................ 2316
utime() — Set File Access and Modification Times ....................... 2317
utimes() — Set File Access and Modification Times ...................... 2320
__utmpxname() — Change the utmpx Database Name ...................... 2322
utoa() — Convert unsigned int into a string ............................ 2323
va_arg(), va_copy(), va_end(), va_start() — Access Function Arguments 2324
valloc() — Page-Aligned Memory Allocator ................................ 2330
vfork() — Create a New Process ............................................ 2332
vfprintf() — Format and Print Data to Stream ............................ 2335
vfscanf(), vscanf(), vsscanf() — Format Input of a STDARG Argument List 2337
vfwprintf(), vswprintf(), vwprintf() — Format and Write Wide Characters of a stdarg Argument List .................. 2338

About this document

This document provides reference information about z/OS® XL C/C++ run-time library functions, macros, and header files.

**Note:** As of z/OS V1R7, the z/OS C/C++ compiler has been rebranded to z/OS XL C/C++.

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line (|) to the left of the change.

You may notice changes in the style and structure of some of the contents in this document; for example, headings that use uppercase for the first letter of initial words only, and procedures that have a different look and format. The changes are ongoing improvements to the consistency and retrievability of information in our documents.

How to read syntax diagrams

This section describes how to read syntax diagrams. It defines syntax diagram symbols, items that may be contained within the diagrams (keywords, variables, delimiters, operators, fragment references, operands) and provides syntax examples that contain these items.

Syntax diagrams pictorially display the order and parts (options and arguments) that comprise a command statement. They are read from left to right and from top to bottom, following the main path of the horizontal line.

Symbols

The following symbols may be displayed in syntax diagrams:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>➤➤</td>
<td>Indicates the beginning of the syntax diagram.</td>
</tr>
<tr>
<td>➤➤</td>
<td>Indicates that the syntax diagram is continued to the next line.</td>
</tr>
<tr>
<td>➤➤</td>
<td>Indicates that the syntax is continued from the previous line.</td>
</tr>
<tr>
<td>➤➤</td>
<td>Indicates the end of the syntax diagram.</td>
</tr>
</tbody>
</table>

Syntax items

Syntax diagrams contain many different items. Syntax items include:

- **Keywords** - a command name or any other literal information.
- **Variables** - variables are italicized, appear in lowercase, and represent the name of values you can supply.
- **Delimiters** - delimiters indicate the start or end of keywords, variables, or operators. For example, a left parenthesis is a delimiter.
- **Operators** - operators include add (+), subtract (-), multiply (*), divide (/), equal (=), and other mathematical operations that may need to be performed.
- **Fragment references** - a part of a syntax diagram, separated from the diagram to show greater detail.
- **Separators** - a separator separates keywords, variables or operators. For example, a comma (,) is a separator.
Note: If a syntax diagram shows a character that is not alphanumeric (for example, parentheses, periods, commas, equal signs, a blank space), enter the character as part of the syntax.

Keywords, variables, and operators may be displayed as required, optional, or default. Fragments, separators, and delimiters may be displayed as required or optional.

<table>
<thead>
<tr>
<th>Item type</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td>Required items are displayed on the main path of the horizontal line.</td>
</tr>
<tr>
<td>Optional</td>
<td>Optional items are displayed below the main path of the horizontal line.</td>
</tr>
<tr>
<td>Default</td>
<td>Default items are displayed above the main path of the horizontal line.</td>
</tr>
</tbody>
</table>

Syntax examples

The following table provides syntax examples.

<table>
<thead>
<tr>
<th>Item type</th>
<th>Syntax example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required item.</td>
<td>Required items appear on the main path of the horizontal line. You must specify these items.</td>
</tr>
<tr>
<td>Required choice.</td>
<td>A required choice (two or more items) appears in a vertical stack on the main path of the horizontal line. You must choose one of the items in the stack.</td>
</tr>
<tr>
<td>Optional item.</td>
<td>Optional items appear below the main path of the horizontal line.</td>
</tr>
<tr>
<td>Optional choice.</td>
<td>An optional choice (two or more items) appears in a vertical stack below the main path of the horizontal line. You may choose one of the items in the stack.</td>
</tr>
<tr>
<td>Default.</td>
<td>Default items appear above the main path of the horizontal line. The remaining items (required or optional) appear on (required) or below (optional) the main path of the horizontal line. The following example displays a default with optional items.</td>
</tr>
<tr>
<td>Variable.</td>
<td>Variables appear in lowercase italics. They represent names or values.</td>
</tr>
</tbody>
</table>
Table 1. Syntax examples  (continued)

<table>
<thead>
<tr>
<th>Item</th>
<th>Syntax example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repeatable item.</td>
<td><img src="#" alt="Diagram" /></td>
</tr>
</tbody>
</table>

An arrow returning to the left above the main path of the horizontal line indicates an item that can be repeated.

A character within the arrow means you must separate repeated items with that character.

An arrow returning to the left above a group of repeatable items indicates that one of the items can be selected, or a single item can be repeated.

Fragment.

The fragment symbol indicates that a labelled group is described below the main syntax diagram. Syntax is occasionally broken into fragments if the inclusion of the fragment would overly complicate the main syntax diagram.

z/OS XL C/C++ and related documents

This topic summarizes the content of the z/OS XL C/C++ documents and shows where to find related information in other documents.

---

**Softcopy documents**

The z/OS XL C/C++ publications are supplied in PDF and BookMaster® formats on the following CD: **z/OS Collection**, SK3T-4269. They are also available at [www.ibm.com/software/awdtools/czos/library/](http://www.ibm.com/software/awdtools/czos/library/).

To read a PDF file, use the Adobe® Reader. If you do not have the Adobe Reader, you can download it (subject to Adobe license terms) from the Adobe web site at [www.adobe.com](http://www.adobe.com).

**Note:** For further information on viewing and printing softcopy documents and using BookManager®, see **z/OS Information Roadmap**

---

**Softcopy examples**

Most of the larger examples in the following documents are available in machine-readable form:

- •  z/OS XL C/C++ Language Reference, SC09-4815
- •  z/OS XL C/C++ User’s Guide, SC09-4767
- •  z/OS XL C/C++ Programming Guide, SC09-4765

In the following documents, a label on an example indicates that the example is distributed as a softcopy file:
The label is the name of a member in the CBC.SCCNSAM data set. The labels begin with the form CCN or CLB. Examples labelled as CLB appear only in the z/OS XL C/C++ User's Guide, while examples labelled as CCN appear in all three documents, and are further distinguished by x following CCN, where x represents one of the following:

- R and X refer to z/OS XL C/C++ Language Reference, SC09-4815
- G refers to z/OS XL C/C++ Programming Guide, SC09-4765
- U refers to z/OS XL C/C++ User's Guide, SC09-4767

z/OS XL C/C++ on the World Wide Web

This page contains late-breaking information about the z/OS XL C/C++ product, including the compiler, the C/C++ libraries, and utilities. There are links to other useful information, such as the z/OS XL C/C++ information library and the libraries of other z/OS elements that are available on the Web. The z/OS XL C/C++ home page also contains links to other related Web sites.

Where to find more information

Please see z/OS Information Roadmap for an overview of the documentation associated with z/OS, including the documentation available for z/OS Language Environment.

Using LookAt to look up message explanations

LookAt is an online facility that lets you look up explanations for most of the IBM messages you encounter, as well as for some system abends and codes. Using LookAt to find information is faster than a conventional search because in most cases LookAt goes directly to the message explanation.

You can use LookAt from these locations to find IBM message explanations for z/OS elements and features, z/VM®, VSE/ESA™, and Clusters for AIX® and Linux™:

- Your z/OS TSO/E host system. You can install code on your z/OS systems to access IBM message explanations using LookAt from a TSO/E command line (for example: TSO/E prompt, ISPF, or z/OS UNIX System Services).
- Your Microsoft® Windows® workstation. You can install LookAt directly from the z/OS Collection (SK3T-4269) or the z/OS and Software Products DVD Collection (SK3T-4271) and use it from the resulting Windows graphical user interface (GUI). The command prompt (also known as the DOS > command line) version can still be used from the directory in which you install the Windows version of LookAt.
- Your wireless handheld device. You can use the LookAt Mobile Edition from [www.ibm.com/servers/eserver/zseries/ios/bkserv/lookat/lookatm.html](http://www.ibm.com/servers/eserver/zseries/ios/bkserv/lookat/lookatm.html) with a handheld device that has wireless access and an Internet browser (for example: Internet Explorer for Pocket PCs, Blazer or Eudora for Palm OS, or Opera for Linux handheld devices).
You can obtain code to install LookAt on your host system or Microsoft Windows 
workstation from:

- A CD-ROM in the z/OS Collection (SK3T-4269).
- The z/OS and Software Products DVD Collection (SK3T-4271).
- The LookAt Web site (click Download and then select the platform, release, 
collection, and location that suit your needs). More information is available in the 
LOOKAT.ME files available during the download process.

**Using IBM Health Checker for z/OS**

IBM Health Checker for z/OS is a z/OS component that installations can use to 
gather information about their system environment and system parameters to help 
identify potential configuration problems before they impact availability or cause 
outages. Individual products, z/OS components, or ISV software can provide checks 
that take advantage of the IBM Health Checker for z/OS framework. This book 
might refer to checks or messages associated with this component.

For additional information about checks and about IBM Health Checker for z/OS, 
users can obtain the IBM Health Checker for z/OS from the z/OS Downloads page 

SDSF also provides functions to simplify the management of checks. See [z/OS 

**Information updates on the web**

For the latest information updates that have been provided in PTF cover letters and 
Documentation APARs for z/OS, see the online document at: [http://publibz.boulder.ibm.com/cgi-bin/bookmgr_OS390/BOOKS/ZIDOCMST/CCONTENTS](http://publibz.boulder.ibm.com/cgi-bin/bookmgr_OS390/BOOKS/ZIDOCMST/CCONTENTS)

This document is updated weekly and lists documentation changes before they are 
incorporated into z/OS publications.
Summary of changes

Summary of changes
for SA22-7821-09
z/OS Version 1 Release 9

The book contains information previously presented in z/OS C/C++ Run-Time Library Reference, SA22-7821-08, which supports z/OS Version 1 Release 8.

New information

New functions:
- ceilid32(), ceilid64(), ceilid128()
- copysignd32(), copysignd64(), copysignd128()
- cosd32(), cosd64(), cosd128()
- __cospid32(), __cospid64(), __cospid128()
- expd32(), expd64(), expd128()
- fabsd32(), fabsd64(), fabsd128()
- fdimd32(), fdimd64(), fdimd128()
- fe_dec_getround(), fe_dec_setround()
- floord32(), floord64(), floord128()
- fmaxd32(), fmaxd64(), fmaxd128()
- frexp32(), frexp64(), frexp128()
- getipv4sourcefilter()
- getsourcelinear()
- ilogbd32(), ilogbd64(), ilogbd128()
- ldexpd32(), ldexpd64(), ldexpd128()
- __le_traceback()
- llroundd32(), llroundd64(), llroundd128()
- logbd32(), logbd64(), logbd128()
- logd32(), logd64(), logd128()
- log10d32(), log10d64(), log10d128()
- lrintd32(), lrintd64(), lrintd128(), llrintd32(), llrintd64(), llrintd128()
- lroundd32(), lroundd64(), lroundd128()
- modfd32(), modfd64(), modfd128()
- nand32(), nand64(), nand128()
- nearbyintd32(), nearbyintd64(), nearbyintd128()
- nextafterd32(), nextafterd64(), nextafterd128()
- nexttowardrd32(), nexttowardrd64(), nexttowardrd128()
- posix_openpt()
- powd32(), powd64(), powd128()
- pselect()
- pthread_atfork()
- pthread_attr_getguardsize()
- pthread_attr_getschedparam()
- pthread_attr_getstack()
- `pthread_attr_getstackaddr()`
- `pthread_attr_setguardsize()`
- `pthread_attr_setschedparam()`
- `pthread_attr_setstack()`
- `pthread_attr_setstackaddr()`
- `quantized32()`, `quantized64()`, `quantized128()`

- `samequantumd32()`, `samequantumd64()`, `samequantumd128()`
- `scalbnd32()`, `scalbnd64()`, `scalbnd128()`, `scalblnd32()`, `scalblnd64()`, `scalblnd128()`
- `setipv4sourcefilter()`
- `setsourcefilter()`
- `sind32()`, `sind64()`, `sind128()`
- `__sinpid32()`, `__sinpid64()`, `__sinpid128()`
- `sqrtd32()`, `sqrtd64()`, `sqrtd128()`
- `sockatmark()`
- `strtod32()`, `strtod64()`, `strtod128()`
- `truncd32()`, `truncd64()`, `truncd128()`
- `wcstod32()`, `wcstod64()`, `wcstod128()`

New headers:
- `netinet/tcp.h`
- `sys/select.h`

New feature test macros
- `_IEEEV1_COMPATIBILITY`
- `__STDC_WANT_DEC_FP__`
- `_UNIX03_THREADS`
- `_UNIX03_WITHDRAWN`

**Changed information**

Modified functions:
- `abs()`, `absf()`, `absl()`
- `aio_read()`, `aio_write()`
- `assert()`
- `bcmp()`
- `bcopy()`
- `brk()`
- `bzero()`
- `chroot()`
- `confstr()`
- `connect()`
- `cuserid()`
- `ecvt()`
- `__errno2()`
- fcvt()
- fegetenv()

- stdarg.h
- stdlib.h
- sys/___cpl.h
- sys/modes.h
- sys/ps.h
- sys/resource.h
- sys/socket.h
- sys/wait.h
- tgmath.h
- time.h
- uheap.h
- varargs.h
- wchar.h
- wcstol()
This document has been enabled for the following types of advanced searches in the online z/OS Library Center: examples.

You may notice changes in the style and structure of some content in this document — for example, headings that use uppercase for the first letter of initial words only, and procedures that have a different look and format. The changes are ongoing improvements to the consistency and retrievability of information in our documents.

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

Summary of changes for SA22-7821-08
z/OS Version 1 Release 8

The book contains information previously presented in z/OS C/C++ Run-Time Library Reference, SA22-7821-07, which supports z/OS Version 1 Release 7.

New information

New functions:
- flockfile(), ftrylockfile(), funlockfile()
- getc_unlocked(), getchar_unlocked(), putc_unlocked(), putchar_unlocked()

Changed information

The Enhanced ASCII Support section has been moved to Appendix B and modified to include the level of support for Preinitialized Environments for Authorized Programs.

Modified functions:
- fldata()
- flocate()
- fgetpos()
- fseek()
- fsetpos()
- ftell()
- ftello()
- fseeko()

Functions with Enhanced ASCII support added this release:
- flockfile(), ftrylockfile(), funlockfile()
- getc_unlocked(), getchar_unlocked(), putc_unlocked(), putchar_unlocked()

Modified header files:
- termios.h

Modified feature test macros:
• _SHARE_EXT_VARS

Modified External Variables:
• daylight
• getdate_err
• h_errno
• optarg
• opterr
• optind
• optopt
• t_errno
• timezone

Modified description:
• Changed External Variables in Chapter 3, Library Functions. See "External Variables" on page 110.

This document has been enabled for the following types of advanced searches in the online z/OS Library Center: examples.

You may notice changes in the style and structure of some content in this document — for example, headings that use uppercase for the first letter of initial words only, and procedures that have a different look and format. The changes are ongoing improvements to the consistency and retrievability of information in our documents.

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

Summary of changes
for SA22-7821-07
z/OS Version 1 Release 7

The book contains information previously presented in z/OS C/C++ Run-Time Library Reference, SA22-7821-06, which supports z/OS Version 1 Release 6.

New information

New functions:
• atoll()
• cabs(), cabsf(), cabsl()
• cacos(), cacosf(), cacosl()
• cacosh(), cacoshf(), cacoshl()
• carg(), cargf(), cargl()
• casin(), casinf(), casinl()
•casinh(), casinhf(), casinhl()
• catan(), catanf(), catanl()
• catanh(), catanhf(), catanhl()
• ccos(), ccosf(), ccosl()
• ccosh(), ccoshf(), ccoshl()
- cexp(), cexpf(), cexpl()
- cimag(), cimagf(), cimagl()

- inet6_rth_reverse()
- inet6_rth_segments()
- inet6_rth_getaddr()
- inet6_opt_init()
- inet6_opt_append()
- inet6_opt_finish()
- inet6_opt_set_val()
- inet6_opt_next()
• inet6_opt_find()
• inet6_opt_get_val()
• isnfinite()
• isgreater()
• isinf()
• isgreateerequal()
• isless()
• islessequal()
• islessgreater()
• isnormal()
• isunordered()
• llround(), llroundf(), llroundl()
• logbf(), logbl()
• llrint()
• lrint(), lrintf(), lrintl(), llrintf(), llrintl()
• lroundl()
• nan(), nanf(), nanl()
• nearbyint(), nearbyintf(), nearbyintl()
• nextafterf(), nextafterl()
• nexttowardl(), nexttowardlf(), nexttowardl()
• __pow_i()  
• __pow_ii()  
• pthread_setcancelstate()
• pthread_setcanceltype()
• pthread_testcancel()
• pthread_sigmask()
• pthread_setconcurrency()
• pthread_getconcurrency()
• pthread_key_delete()
• rintf(), rintl()
• round(), roundf(), roundl()
• scalbn(), scalbnf(), scalbnl()
• scalbln(), scalblnf(), scalblnl()
• sched_yield()
• signbit()
• strerror_r()
• strtof()
• strtoimax()
• strtol()
• strtoumax()
• unatexit()
• unsetenv()
• va_copy()
• vfscanf(), vscanf(), vsscanf()
• vfwprintf(), vwprintf()
- vfwscanf(), vwscanf(), vswscanf()
- wcstof()
- wcstomax()
- wcstold()
- wcstoumax()
- wctrans(), towctrans()

New header files:
- complex.h
- fenv.h
- stdbool.h
- stdint.h
- tgmath.h

New feature test macros files:
- _NOISOC99_SOURCE

**Changed information**

The Enhanced ASCII Support section has been moved to Appendix B and modified to include the level of support for Preinitialized Environments for Authorized Programs.

Modified functions:
- acoshf(), acoshl()
- asinhf(), asinhl()
- cbrtf(), cbrtl()
- __chattr()
- copysign()
- ecvt()
- exp2(), exp2f(), exp2l()
- expm1f(), expm1l(), expm1l()
- fcvt()
- fork()
- fprintf(), printf(), sprintf()
- fscanf(), scanf(), sscanf()
- gcvt()
- givesocket()
- hypotf(), hypotl()
- iswblank()
- lgammal()
- log1pf(), log1pl()
- perror()
- poll()
- popen()
- printf()
- pthread_create()
• remainderf(), remainderl()
• remquo(), remquof(), remquol()
• scalbn()
• selectex()
• strftime()
• strtof()
• strtol()
• strtoll()
• strtoz()
• swprintf()
• tgamma()l()
• vfork()
• vsprintf()
• wcscat()
• wcscoll()
• wcsncmp()
• wcscpy()
• wcsxspn()
• wcst ime()
• wcspbrk()
• wcspn()
• wcswcs()
• wcscat()
• wcscmp()
• wcscpy()
• wcsrchr()
• wcstod()
• wcstol()
• wcstoll()
• wcstoul()
• wcstoull()
• wcstoumax()
• wordexp()

Functions with Enhanced ASCII support added this release:
• atoll()
• fprintf(), wprintf()
• fscanf(), scanf()
• isblank()
• iswblank()
• strtof(), strto1d()
• strtoimax(), strto1max()
• strerror_r()
• unsetenv()
- `vfprintf()`, `vwprintf()`  
- `vfscanf()`, `vscanf()`, `vsscanf()`  
- `vfscanf()`, `vsprintf()`, `vwscanf()`  
- `wcstof()`, `wcstold()`  
- `wcstoll()`, `wcstoull()`  
- `wcstomax()`, `wcstoumax()`  

Modified header files:
- `float.h`  
- `inttypes.h`  
- `limits.h`  
- `locale.h`  
- `math.h`  
- `stdlib.h`  
- `time.h`  
- `wchar.h`  
- `wcstr.h`  

Modified feature test macros:
- `_ISOC99_SOURCE`  
- `_MSE_PROTOS`  
- `_OPEN_THREADS`

This document has been enabled for the following types of advanced searches in the online z/OS Library Center: examples.

Starting with z/OS V1R2, you may notice changes in the style and structure of some content in this document — for example, headings that use uppercase for the first letter of initial words only, and procedures that have a different look and format. The changes are ongoing improvements to the consistency and retrievability of information in our documents.

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.
Chapter 1. About IBM z/OS XL C/C++

The XL C/C++ feature of the IBM z/OS licensed program provides support for C and C++ application development on the z/OS platform.

z/OS XL C/C++ includes:
- A C compiler (referred to as the z/OS XL C compiler)
- A C++ compiler (referred to as the z/OS XL C++ compiler)
- Performance Analyzer host component, which supports the IBM C/C++ Productivity Tools for OS/390 product
- A set of utilities for C/C++ application development

Notes:
1. The Run-Time Library Extensions base element was introduced in z/OS V1R5. It includes the Common Debug Architecture (CDA) Libraries, the c89 utility, and, as of z/OS V1R6, the xlc utility. The Common Debug Architecture provides a consistent and common format for debugging information across the various languages and operating systems that are supported on the IBM System z™ platform. Run-Time Library Extensions also includes legacy libraries to support existing programs. These are the UNIX System Laboratories (USL) I/O Stream Library and USL Complex Mathematics Library. The IBM Open Class Library is not supported.
2. The Standard C++ Library is included with Language Environment libraries.
3. The z/OS XL C/C++ compiler works with the mainframe interactive Debug Tool product and WebSphere® Developer for System z, integrated with IBM Debug Tool for z/OS and IBM Debug Tool Utilities and Advanced Functions for z/OS.

IBM offers the C and C++ compilers on other platforms, such as the AIX, Linux, OS/400®, and z/VM operating systems. The C compiler is also available on the VSE/ESA platform.

Changes for z/OS V1R9

z/OS XL C/C++ has made the following performance and usability enhancements for the z/OS V1R9 release:

z/OS XL C support for system program development – METAL option
Prior to V1R9, z/OS XL C compiler-generated code required Language Environment for C run-time library functions and required the establishment of an overall execution context, including the heap storage and dynamic storage area. This dependency meant that the XL C compiler could only generate code to run in an environment where Language Environment services existed.

The METAL compiler option, which is provided with z/OS V1R9, generates code that does not have Language Environment run-time dependencies. In addition, language features are provided to embed small pieces of HLASM source within C statements. Most assembler macros can be used in this embedded HLASM code. Function prolog and epilog code can be provided for all functions that have extern scope. When applied together, these features can assist with writing programs suitable for use in an MVS™ system level environment, as well as for inter-operating with most programs written in HLASM. Any system services that the program needs can be obtained directly by calling Assembler Services.
z/OS XL C/C++ support for decimal floating-point formats (DFP)

z/OS V1R9 XL C/C++ supports the decimal floating-point formats in addition to the current hex and binary floating-point formats. The decimal formats are specified by the revised IEEE 754 Floating Point Standard. This support assists with avoiding potential rounding problems, which can result from using binary or hexadecimal floating-point types to handle decimal calculations.

z/OS XL C/C++ provides the following:

- Decimal type specifiers through the `_Decimal32`, `_Decimal64`, and `_Decimal128` reserved keywords
- Decimal literal support
- Conversion between decimal types and the other floating-point types

CDAHLASM utility to produce debug information

The CDAHLASM utility produces debug information in DWARF format and ADATA format. Debuggers can use the DWARF debug information to debug Metal C applications. The CDAASMC cataloged procedure is provided to execute this utility.

New compiler options

z/OS V1R9 XL C/C++ introduces the following new compiler options:

- ARMODE (C compiler only)
- ASMDATASIZE (C compiler only)
- ASSERT(RESTRICT)
- DFP
- EPILOG (C compiler only)
- GENASM (C compiler only)
- METAL (C compiler only)
- PROLOG (C compiler only)
- RESERVED_REG (C compiler only)

New compiler suboption

z/OS V1R9 XL C/C++ introduces the following new compiler suboption:

- TARGET(zOSV1R9)

New pragma directives

z/OS V1R9 XL C introduces the following new pragma directives:

- `#pragma epilog`
- `#pragma prolog`

Performance improvements

As an ongoing effort, improvements are provided in the generated code to take advantage of new instructions in the hardware architecture. You can benefit from these improvements by recompiling your existing source without code changes. Additional built-in functions are provided to help programs use selected hardware instructions directly. For information on these built-in functions, see the built-in functions described in Z/OS XL C/C++ Programming Guide.
The XL C/C++ compilers

The following sections describe the C and C++ languages and the z/OS XL C/C++ compilers.

The C language

The C language is a general purpose, versatile, and functional programming language that allows a programmer to create applications quickly and easily. C provides high-level control statements and data types as do other structured programming languages. It also provides many of the benefits of a low-level language.

The C++ language

The C++ language is based on the C language and includes all of the advantages of C listed above. In addition, C++ also supports object-oriented concepts, generic types or templates, and an extensive library. For a detailed description of the differences between z/OS XL C++ and z/OS XL C, refer to z/OS XL C/C++ Language Reference.

The C++ language introduces classes, which are user-defined data types that may contain data definitions and function definitions. You can use classes from established class libraries, develop your own classes, or derive new classes from existing classes by adding data descriptions and functions. New classes can inherit properties from one or more classes. Not only do classes describe the data types and functions available, but they can also hide (encapsulate) the implementation details from user programs. An object is an instance of a class.

The C++ language also provides templates and other features that include access control to data and functions, and better type checking and exception handling. It also supports polymorphism and the overloading of operators.

Common features of the z/OS XL C and XL C++ compilers

The XL C and XL C++ compilers, when used with the Language Environment element, offer many features to increase your productivity and improve program execution times:

- **Optimization support:**
  - Extra Performance Linkage (XPLINK) function calling convention, which has the potential for a significant performance increase when used in an environment of frequent calls between small functions. XPLINK makes subroutine calls more efficient by removing non-essential instructions from the main path.
  - Algorithms to take advantage of the zSeries® architecture to achieve improved optimization and memory usage through the OPTIMIZE and IPA compiler options.
  - The OPTIMIZE compiler option, which instructs the compiler to optimize the machine instructions it generates to try to produce faster-running object code and improve application performance at run time.
Interprocedural Analysis (IPA), to perform optimizations across procedural and compilation unit boundaries, thereby optimizing application performance at run time.

Additional optimization capabilities are available with the INLINE compiler option.

- DLLs (dynamic link libraries) to share parts among applications or parts of applications, and dynamically link to exported variables and functions at run time. DLLs allow a function reference or a variable reference in one executable to use a definition located in another executable at run time. You can use DLLs to split applications into smaller modules and improve system memory usage. DLLs also offer more flexibility for building, packaging, and redistributing applications.

- Full program reentrancy

With reentrancy, many users can simultaneously run a program. A reentrant program uses less storage if it is stored in the Link Pack Area (LPA) or the Extended Link Pack Area (ELPA) and simultaneously run by multiple users. It also reduces processor I/O when the program starts up, and improves program performance by reducing the transfer of data to auxiliary storage. z/OS XL C programmers can design programs that are naturally reentrant. For those programs that are not naturally reentrant, z/OS XL C programmers can use constructed reentrancy. To do this, compile programs with the RENT option and use the program management binder supplied with z/OS or the Language Environment prelinker and program management binder. The z/OS XL C++ compiler always uses the constructed reentrancy algorithms.

- Locale-based internationalization support derived from IEEE POSIX 1003.2-1992 standard. Also derived from X/Open CAE Specification, System Interface Definitions, Issue 4 and Issue 4 Version 2. This allows you to use locales to specify language/country characteristics for their applications.

- The ability to call and be called by other languages such as assembler, COBOL, PL/1, compiled Java™, and Fortran, to enable you to integrate z/OS XL C/C++ code with existing applications.

- Exploitation of z/OS and z/OS UNIX System Services technology. z/OS UNIX System Services is the IBM implementation of the open operating system environment, as defined in the XPG4 and POSIX standards.

- Support features in the following standards at the system level:
  - ISO/IEC 9899:1999
  - The core features of IEEE POSIX 1003.1a, Draft 6, July 1991
  - IEEE Portable Operating System Interface (POSIX) Part 2, P1003.2
  - The core features of IEEE POSIX 1003.4a, Draft 6, February 1992 (the IEEE POSIX committee has renumbered POSIX.4a to POSIX.1c)
  - X/Open CAE Specification, System Interfaces and Headers, Issue 4 Version 2
  - The core features of IEEE 754-1985 (R1990) IEEE Standard for Binary Floating-Point Arithmetic (ANSI), as applicable to the IBM System z environment.
  - X/Open CAE Specification, Networking Services, Issue 4

- Support for the Euro currency
z/OS XL C compiler-specific features

In addition to the features common to z/OS XL C and XL C++, the z/OS XL C compiler provides you with the following capabilities:

- The ability to write portable code that supports the following standards:
  - ISO/IEC 9899:1999
  - X/Open Specification Programming Languages, Issue 3, Common Usage C
  - FIPS-160
- System programming capabilities, which allow you to use z/OS XL C in place of assembler
- Extensions of the standard definitions of the C language to provide you with support for the z/OS environment, such as fixed-point (packed) decimal data support

z/OS XL C++ compiler-specific features

In addition to the features common to z/OS XL C and XL C++, the z/OS XL C++ compiler supports the Programming languages - C++ (ISO/IEC 14882:1998) standard. Also, it further conforms to the Programming languages - C++ (ISO/IEC 14882:2003(E)) standard, which incorporates the latest Technical Corrigendum 1.

Class libraries

z/OS V1R9 XL C/C++ uses the following thread-safe class libraries:

- Standard C++ Library, including the Standard Template Library (STL), and other library features of Programming languages - C++ (ISO/IEC 14882:1998) and Programming languages - C++ (ISO/IEC 14882:2003(E))

Note: As of z/OS V1R5, all application development using the C/C++ IBM Open Class Library (Application Support Class and Collection Class Libraries) is not supported. As of z/OS V1R9, the execution of applications using the C/C++ IBM Open Class Library is not supported. For additional information, see [IBM Open Class Library Transition Guide].

For new code and enhancements to existing applications, the Standard C++ Library should be used. The Standard C++ Library includes the following:

- Stream classes for performing input and output (I/O) operations
- The Standard C++ Complex Mathematics Library for manipulating complex numbers
- The Standard Template Library (STL) which is composed of C++ template-based algorithms, container classes, iterators, localization objects, and the string class

Utilities

The z/OS XL C/C++ compilers provide the following utilities:

- The xlc utility to invoke the compiler using a customizable configuration file.
- The c89 utility to invoke the compiler using host environment variables.
- The CXXFILT utility to map z/OS XL C++ mangled names to their original function names.
- The DSECT conversion utility to convert descriptive assembler DSECTs into z/OS XL C/C++ data structures.
- The makedepend utility to derive all dependencies in the source code and write these into the makefile. The make command will determine which source files to recompile, whenever a dependency has changed. This frees the user from manually monitoring such changes in the source code.
- The CDAHLASM utility, which produces debug information in DWARF (for Metal C applications) and ADATA formats. This utility uses the HLASM assembler to compile the source files produced by compiling Metal C code.

Language Environment utilities include:
- The object library utility (C370LIB; also known as EDCALIAS) to update partitioned data set (PDS and PDSE) libraries of object modules. The object library utility supports XPLINK, IPA, and LP64 compiled objects.
- The prelinker which combines object modules that comprise a z/OS XL C/C++ application to produce a single object module. The prelinker supports only object and extended object format input files, and does not support GOFF.

**Note:** IBM has stabilized the prelinker. Further enhancements will not be made to the prelinker utility. IBM recommends that you use the binder instead of the prelinker and linker.

**dbx**

You can use the dbx shell command to debug programs, as described in [z/OS UNIX System Services Programming Tools](http://www.ibm.com/servers/eserver/zseries/zos/unix/bpxa1dbx.html) and [z/OS UNIX System Services Command Reference](http://www.ibm.com/servers/eserver/zseries/zos/unix/bpxa1dbx.html).

**Language Environment element**

z/OS XL C/C++ exploits the C/C++ run-time environment and library of run-time services available with the Language Environment element provided with z/OS.

The Language Environment element consists of four language-specific run-time libraries, and Base Routines and Common Services, as shown in [Figure 1 on page 7](#). This element establishes a common run-time environment and common run-time services for language products, user programs, and other products.
The common execution environment is composed of data items and services that are included in library routines available to an application that runs in the environment. Language Environment services include:

- Services that satisfy basic requirements common to most applications. These include support for the initialization and termination of applications, allocation of storage, interlanguage communication (ILC), and condition handling.
- Extended services that are often needed by applications. z/OS XL C/C++ contains these functions within a library of callable routines, and includes interfaces to operating system functions and a variety of other commonly used functions.
- Run-time options that help in the execution, performance, and diagnosis of your application.
- Access to operating system services; z/OS UNIX System Services is available to you or your program through the z/OS XL C/C++ language bindings.
- Access to language-specific library routines, such as the z/OS XL C/C++ library functions.

**Note:** The Language Environment run-time option TRAP(ON) should be set when using z/OS XL C/C++. Refer to [z/OS Language Environment Programming Reference](#) for details on the Language Environment run-time options.

### AMODE 64 considerations

Throughout this document AMODE 64 restrictions are indicated with notes like this one for Hiperspace™:

**Restriction:** Hiperspace is not supported in AMODE 64.

Following are restrictions for AMODE 64:

- Hiperspace is not supported.
- The SPC facility is not supported.
- The following header files are not supported:
  - csp.h
  - ims.h
  - leawi.h
  - mtf.h
The following feature test macros are obsolete:
- _LARGE_FILES
- _LARGE_MEM
See the feature test macro description for more details.

The following feature test macros are not supported:
- __LIBASCII
- _OE_SOCKETS

The following functions are not supported:
- advance()
- brk()
- compile()
- __console()
- __csplist
- ctdli()
- fortrc()
- iscics()
- __openMvsRel()
- __pcblist
- pthread_quiesce_and_get_np()
- re_comp()
- re_exec()
- regcmp()
- regex()
- sbrk()
- sock_debug_bulk_perf0()
- sock_do_bulkmode()
- step()
- tsched()
- tsetsubt()
- tsyncro()
- tterm()
- valloc()

The following external variables are not supported:
- __loc1
- loc1
- loc2
- locs

Language Environment downward compatibility
Language Environment downward compatibility support is provided. Assuming that you have met the required programming guidelines and restrictions, described in the [z/OS Language Environment Programming Guide](#), this support enables you to...
develop applications on higher release levels of z/OS for use on platforms that are running lower release levels of z/OS. In XL C and XL C++, downward compatibility support is provided through the XL C/C++ TARGET compiler option. See TARGET in [z/OS XL C/C++ User’s Guide] for details on this compiler option.

For example, a company may use z/OS V1R9 with the Language Environment element on a development system where applications are coded, link-edited, and tested, while using any supported lower Language Environment release on their production systems where the finished application modules are used.

Downward compatibility support is not the roll-back of new function to prior releases of the operating system. Applications developed that exploit the downward compatibility support must not use any Language Environment function that is unavailable on the lower release of z/OS where the application will be used.

The downward compatibility support includes toleration PTFs for lower releases of z/OS to assist in diagnosing applications that do not meet the programming requirements for this support. (Specific PTF numbers can be found in the PSP buckets.)

The diagnosis assistance that will be provided by the toleration PTFs includes detection of an unsupported program object format. If the program object format is at a level which is not supported by the target deployment system, then the deployment system will produce an abend when trying to load the application program. The abend will indicate that the Data Facility Storage Management Subsystem (DFSMS™) software was unable to find or load the application program. Correcting this problem does not require the installation of any toleration PTFs. Instead, you will need to recreate the program object that is compatible with the older deployment system.

Language Environment downward compatibility support and the downward compatibility support that is provided by toleration PTFs does not change upward compatibility. That is, applications coded and link-edited with one Language Environment release will continue to run on later Language Environment releases without the need to recompile or re-link edit the application, independent of the downward compatibility support.

The current z/OS level header files and SYSLIB can be used (the user no longer has to copy header files and SYSLIB data sets from the deployment release).

**Note:** As of z/OS V1R3, the executables produced with the binder’s COMPAT=CURRENT setting will not run on lower levels of z/OS. You will have to explicitly override to a particular program object level, or use the COMPAT=MIN setting introduced in z/OS V1R3.

---

**About prelinking, linking, and binding**

When describing the process to build an application, this document refers to the *bind step*.

Normally, the program management binder is used to perform the bind step. However, in many cases the prelink and link steps can be used in place of the bind step. When they cannot be substituted, and the program management binder alone must be used, it will be stated. For more information, refer to Prelinking and linking Z/OS XL C/C++ programs and Binding Z/OS XL C/C++ programs in Z/OS XL C/C++ User’s Guide.
The terms *bind* and *link* have multiple meanings.

- With respect to building an application:

  In both instances, the program management binder is performing the actual processing of converting the object file(s) into the application executable module. Object files with longname symbols, reentrant writable static symbols, and DLL-style function calls require additional processing to build global data for the application.

  The term *link* refers to the case where the binder does not perform this additional processing, due to one of the following:
  - The processing is not required, because none of the object files in the application use constructed reentrancy, use long names, are DLL or are C++.
  - The processing is handled by executing the prelinker step before running the binder.

  The term *bind* refers to the case where the binder is required to perform this processing.

- With respect to executing code in an application:

  The *linkage definition* refers to the program call linkage between program functions and methods. This includes the passing of control and parameters. Refer to "Program Linkage" in *z/OS XL C/C++ Language Reference* for more information on linkage specification.

  Some platforms have a single linkage convention. z/OS has a number of linkage conventions, including standard operating system linkage, Extra Performance Linkage (XPLINK), and different non-XPLINK linkage conventions for C and C++.

**Notes on the prelinking process**

You cannot use the prelinker if you are using the XPLINK, GOFF, or LP64 compiler options. IBM recommends using the binder instead of the prelinker whenever possible.

The prelinker was designed to process long names and support constructed reentrancy in earlier versions of the C compiler on the MVS and OS/390® operating systems. The Language Environment prelinker provides output that is compatible with the linkage editor, which is shipped with the binder.

The *binder* is designed to include the functions of the prelinker, the linkage editor, the loader, and a number of APIs to manipulate the program object. Thus, the binder is a superset of the linkage editor. Its functionality provides a high level of compatibility with the prelinker and linkage editor, but provides additional functionality in some areas. Generally, the terms *binding* and *linking* are interchangeable. In particular, the binder supports:

- Inputs from the object module
- XOBJ, GOFF, load module and program object
- Auto call resolutions from z/OS UNIX archives and C370LIB object directories
- Long external names
- All prelinker control statements

**Notes:**

1. You need to use the binder for XPLINK objects.
2. As of z/OS V1R7, the Hierarchical File System (HFS) functionality has been stabilized and zSeries File System (zFS) is the strategic file system for z/OS UNIX System Services. The term *z/OS UNIX file system* includes both HFS and zFS.
For more information on the compatibility between the binder, and the linker and prelinker, see `z/OS MVS Program Management: User’s Guide and Reference`.

Updates to the prelinking, linkage-editing, and loading functions that are performed by the binder are delivered through the binder. If you use the Language Environment prelinker and the linkage editor (supplied through the binder), you have to apply the latest maintenance for the Language Environment element as well as the binder.

If you still need to use the prelinker and linkage editor, see `Prelinker and linkage editor options` in `z/OS XL C/C++ User’s Guide`.

**File format considerations**

You can use the binder in place of the prelinker and linkage editor but there are exceptions, which are file format considerations. For further information, on when you cannot use the binder, see `Binding z/OS XL C/C++ programs` in `z/OS XL C/C++ User’s Guide`.

**The program management binder**

The binder provided with z/OS combines the object modules, load modules, and program objects comprising an application. It produces a single z/OS output program object or load module that you can load for execution. The binder supports all C and C++ code, provided that you store the output program in a PDSE member or a z/OS UNIX System Services file.

If you cannot use a PDSE member or z/OS UNIX file, and your program contains C++ code, or C code that is compiled with any of the RENT, LONGNAME, DLL or IPA compiler options, you must use the prelinker. C and C++ code compiled with the GOFF or XPLINK compiler options cannot be processed by the prelinker.

Using the binder without using the prelinker has the following advantages:
- Faster rebinds when recompiling and rebinding a few of your source files
- Rebinding at the single compile unit level of granularity (except when you use the IPA compile-time option)
- Input of object modules, load modules, and program objects
- Improved long name support:
  - Long names do not get converted into prelinker generated names
  - Long names appear in the binder maps, enabling full cross-referencing
  - Variables do not disappear after prelink
  - Fewer steps in the process of producing your executable program

The Language Environment prelinker combines the object modules comprising a z/OS XL C/C++ application and produces a single object module. You can link-edit the object module into a load module (which is stored in a PDS), or bind it into a load module or a program object (which is stored in a PDS, PDSE, or z/OS UNIX file).

**z/OS UNIX System Services**

z/OS UNIX System Services provides capabilities under z/OS to make it easier to implement or port applications in an open, distributed environment. z/OS UNIX is available to z/OS XL C/C++ application programs through the C/C++ language bindings available with the Language Environment element.
Together, z/OS UNIX, the Language Environment element, and the z/OS XL C/C++
compilers provide an application programming interface that supports industry
standards.

z/OS UNIX provides support for both existing z/OS applications and new z/OS
UNIX applications through the following:

- C programming language support as defined by ISO C
- C++ programming language support as defined by ISO C++
- C language bindings as defined in the IEEE 1003.1 and 1003.2 standards;
  subsets of the draft 1003.1a and 1003.4a standards; \textit{X/Open CAE Specification:
  System Interfaces and Headers, Issue 4, Version 2}, which provides standard
  interfaces for better source code portability with other conforming systems; and
  \textit{X/Open CAE Specification, Network Services, Issue 4}, which defines the X/Open
  UNIX descriptions of sockets and X/Open Transport Interface (XTI)
- z/OS UNIX extensions that provide z/OS-specific support beyond the defined
  standards
- The z/OS UNIX Shell and Utilities feature, which provides:
  - A shell, based on the Korn Shell and compatible with the Bourne Shell
  - A shell, tcsh, based on the C shell, csh
  - Tools and utilities that support the \textit{X/Open Single UNIX Specification}, also
    known as \textit{X/Open Portability Guide (XPG) Version 4, Issue 2}, and provide
    z/OS support. The following is a partial list of utilities that are included:

  \begin{itemize}
  \item \texttt{ar} \hspace{1cm} Creates and maintains library archives
  \item \texttt{as} \hspace{1cm} Invokes HLASM to create assembler applications
  \item \texttt{BPXBATCH} \hspace{1cm} Allows you to submit batch jobs that run shell commands,
    scripts, or z/OS XL C/C++ executable files in z/OS UNIX files
    from a shell session
  \item \texttt{c89} \hspace{1cm} Uses host environment variables to compile, assemble, and
    bind z/OS UNIX, C/C++ and assembler applications
  \item \texttt{dbx} \hspace{1cm} Provides an environment to debug and run programs
  \item \texttt{gencat} \hspace{1cm} Merges the message text source files (usually \texttt{*.msg})
    into a formatted message catalog file (usually \texttt{*.cat})
  \item \texttt{iconv} \hspace{1cm} Converts characters from one code set to another
  \item \texttt{Id} \hspace{1cm} Combines object files and archive files into an output
    executable file, resolving external references
  \item \texttt{lex} \hspace{1cm} Automatically writes large parts of a lexical analyzer based on
    a description that is supplied by the programmer
  \item \texttt{localedef} \hspace{1cm} Creates a compiled locale object
  \item \texttt{make} \hspace{1cm} Helps you manage projects containing a set of interdependent
    files, such as a program with many z/OS source and object
    files, keeping all such files up to date with one another
  \item \texttt{xlc} \hspace{1cm} Allows you to invoke the compiler using a customizable
    configuration file
  \item \texttt{yacc} \hspace{1cm} Allows you to write compilers and other programs that parse
    input according to strict grammar rules
  \item Support for other utilities such as:
  \item \texttt{dspcat} \hspace{1cm} Displays all or part of a message catalog
  \end{itemize}

dspmsg  Displays a selected message from a message catalog
mkcatdefs  Preprocesses a message source file for input to the gencat utility
runcat  Invokes mkcatdefs and pipes the message catalog source data (the output from mkcatdefs) to gencat

- Access to the Hierarchical File System (HFS), with support for the POSIX.1 and XPG4 standards
- Access to the zSeries File System (zFS), which provides performance improvements over HFS, and also supports the POSIX.1 and XPG4 standards
- z/OS XL C/C++ I/O routines, which support using z/OS UNIX files, standard z/OS data sets, or a mixture of both
- Application threads (with support for a subset of POSIX.4a)
- Support for z/OS XL C/C++ DLLs

z/OS UNIX System Services offers program portability across multivendor operating systems, with support for POSIX.1, POSIX.1a (draft 6), POSIX.2, POSIX.4a (draft 6), and XPG4.2.

For application developers who have worked with other UNIX environments, the z/OS UNIX Shell and Utilities is a familiar environment for XL C/C++ application development. If you are familiar with existing MVS development environments, you may find that the z/OS UNIX System Services environment can enhance your productivity. Refer to the z/OS UNIX System Services User’s Guide for more information on the Shell and Utilities.

z/OS XL C/C++ applications with z/OS UNIX System Services C functions

All z/OS UNIX System Services C functions are available at all times. In some situations, you must specify the POSIX(ON) run-time option. This is required for the POSIX.4a threading functions, the POSIX system() function, and signal handling functions where the behavior is different between POSIX/XPG4 and ISO.

You can invoke a z/OS XL C/C++ program that uses z/OS UNIX C functions using the following methods:
- Directly from a shell.
- From another program, or from a shell, using one of the exec family of functions, or the BPXBATCH utility from TSO or MVS batch.
- Using the POSIX system() call.
- Directly through TSO or MVS batch without the use of the intermediate BPXBATCH utility. In some cases, you may require the POSIX(ON) run-time option.

Input and output

The z/OS XL C/C++ run-time library that supports the z/OS XL C/C++ compiler supports different input and output (I/O) interfaces, file types, and access methods. The Standard C++ Library provides additional support.

I/O interfaces

The z/OS XL C/C++ run-time library supports the following I/O interfaces:
C Stream I/O
This is the default and the ISO-defined I/O method. This method processes all input and output on a per-character basis.

Record I/O
The library can also process your input and output by record. A record is a set of data that is treated as a unit. It can also process VSAM data sets by record. Record I/O is a z/OS XL C/C++ extension to the ISO standard.

TCP/IP Sockets I/O
z/OS UNIX System Services provides support for an enhanced version of an industry-accepted protocol for client/server communication that is known as sockets. A set of C language functions provides support for z/OS UNIX sockets. z/OS UNIX sockets correspond closely to the sockets used by UNIX applications that use the Berkeley Software Distribution (BSD) 4.3 standard (also known as Berkeley sockets). The slightly different interface of the X/Open CAE Specification, Networking Services, Issue 4, is supplied as an additional choice. This interface is known as X/Open Sockets.

The z/OS UNIX socket application program interface (API) provides support for both UNIX domain sockets and Internet domain sockets. UNIX domain sockets, or local sockets, allow interprocess communication within z/OS, independent of TCP/IP. Local sockets behave like traditional UNIX sockets and allow processes to communicate with one another on a single system. With Internet sockets, application programs can communicate with each other in the network using TCP/IP.

In addition, the Standard C++ Library provides stream classes, which support formatted I/O in C++. You can code sophisticated I/O statements easily and clearly, and define input and output for your own data types. This helps improve the maintainability of programs that use input and output.

File types
In addition to conventional files, such as sequential files and partitioned data sets, the z/OS XL C/C++ run-time library supports the following file types:

Virtual Storage Access Method (VSAM) data sets
z/OS XL C/C++ has native support for the following VSAM data sets:

- Key-Sequence Data Sets (KSDS). Use KSDS to access a record through a key within the record. A key is one or more consecutive characters that are taken from a data record that identifies the record.
- Entry-Sequence Data Sets (ESDS). Use ESDS to access data in the order it was created (or in reverse order).
- Relative-Record Data Sets (RRDS). Use RRDS for data in which each item has a particular number (for example, a telephone system where a record is associated with each telephone number).

For more information on how to perform I/O operations on these VSAM file types, see “Performing VSAM I/O operations” in z/OS XL C/C++ Programming Guide.

Hierarchical File System files
z/OS XL C/C++ recognizes Hierarchical File System (HFS) file names. The name specified on the fopen() or freopen() call has to conform to certain rules. See “Opening Files” in z/OS XL C/C++ Programming Guide for the details of these rules. You can create regular HFS files, special character HFS files, or FIFO HFS files. You can also create links or directories.
Note: As of z/OS V1R7, the Hierarchical File System (HFS) functionality has been stabilized and zSeries File System (zFS) is the strategic UNIX System Services file system for z/OS.

Memory files
Memory files are temporary files that reside in memory. For improved performance, you can direct input and output to memory files rather than to devices. Since memory files reside in main storage and only exist while the program is executing, you primarily use them as work files. You can access memory files across load modules through calls to non-POSIX system() and C fetch(); they exist for the life of the root program. Standard streams can be redirected to memory files on a non-POSIX system() call using command line redirection.

Hiperspace expanded storage
Large memory files can be placed in Hiperspace expanded storage to free up some of your home address space for other uses. Hiperspace expanded storage or high performance space is a range of up to 2 GB of contiguous virtual storage space. A program can use this storage as a buffer (1 gigabyte(GB) = 2^{30} bytes).

zSeries File System
zSeries File System (zFS) is a z/OS UNIX file system that can be used in addition to the Hierarchical File System (HFS). zFS may provide performance gains in accessing files that are frequently accessed and updated. The I/O functions in the z/OS XL C/C++ run-time library support zFS.

Additional I/O features
z/OS XL C/C++ provides additional I/O support through the following features:
• Large file support, which enables I/O to and from z/OS UNIX System Services files that are larger than 2 GB (see "large file support" in z/OS XL C/C++ Language Reference)
• User error handling for serious I/O failures (SIGIOERR)
• Improved sequential data access performance through enablement of the DFSMS software support for 31-bit sequential data buffers and sequential data striping on extended format data sets
• Full support of PDSEs on z/OS (including support for multiple members opened for write)
• Overlapped I/O support under z/OS (NCP, BUFNO)
• Multibyte character I/O functions
• Fixed-point (packed) decimal data type support in formatted I/O functions
• Support for multiple volume data sets that span more than one volume of DASD or tape
• Support for Generation Data Group I/O

The System Programming C facility
The System Programming C (SPC) facility allows you to build applications that do not require dynamic loading of Language Environment libraries. It also allows you to tailor your application for better utilization of the low-level services available on your operating system. SPC offers a number of advantages:
• You can develop applications that can be executed in a customized environment rather than with Language Environment services. Note that if you do not use
Language Environment services, only some built-in functions and a limited set of z/OS XL C/C++ run-time library functions are available to you.

- You can substitute the z/OS XL C language in place of assembly language when writing system exit routines by using the interfaces that are provided by SPC.
- SPC lets you develop applications featuring a user-controlled environment in which a z/OS XL C environment is created once and used repeatedly for C function execution from other languages.
- You can utilize co-routines by using a two-stack model to write application service routines. In this model, the application calls on the service routine to perform services independent of the user. The application is then suspended when control is returned to the user application.

### Interaction with other IBM products

When you use z/OS XL C/C++, you can write programs that utilize the power of other IBM products and subsystems:

- **CICS Transaction Server for z/OS**
  You can use the CICS Command-Level Interface to write C/C++ application programs. The CICS Command-Level Interface provides data, job, and task management facilities that are normally provided by the operating system.

- **DB2 Universal Database™ for z/OS**
  DB2 programs manage data that is stored in relational databases. You can access the data by using a structured set of queries that are written in Structured Query Language (SQL).
  
  A DB2 program uses SQL statements that are embedded in the application program. The SQL translator (DB2 preprocessor) translates the embedded SQL into host language statements, which are then compiled by the z/OS XL C/C++ compilers. Alternatively, use the SQL compiler option to compile a DB2 program with embedded SQL without using the DB2 preprocessor. The DB2 program processes requests, then returns control to the application program.

- **Debug Tool**
  
  z/OS XL C/C++ supports program development by using the Debug Tool. This tool allows you to debug applications in their native host environment, such as CICS Transaction Server for z/OS, IMS, and DB2. Debug Tool provides the following support and function:
  - Step mode
  - Breakpoints
  - Monitor
  - Frequency analysis
  - Dynamic patching

  You can record the debug session in a log file, and replay the session. You can also use Debug Tool to help capture test cases for future program validation, or to further isolate a problem within an application.

  You can specify either data sets or z/OS UNIX System Services files as source files.

  For further information, see [www.ibm.com/software/awdtools/debugtool/](http://www.ibm.com/software/awdtools/debugtool/)

- **WebSphere Developer for System z**
  z/OS V1R7 XL C/C++ and later releases enable you to use WebSphere Developer for System z V7.0 to improve the efficiency of application development. For information on WebSphere Developer for System z, see: [http://www.ibm.com/software/awdtools/devzseries/](http://www.ibm.com/software/awdtools/devzseries/)

- **IBM C/C++ Productivity Tools for OS/390**
Note: Starting with z/OS V1R5, both the C/C++ compiler optional feature and
the Debug Tool product will need to be installed if you wish to use IBM
C/C++ Productivity Tools for OS/390. For more information on Debug Tool,
refer to www.ibm.com/software/awdtools/debugtool/.

With the IBM C/C++ Productivity Tools for OS/390 product, you can expand your
z/OS application development environment out to the workstation, while
remaining close to your familiar host environment. IBM C/C++ Productivity Tools
for OS/390 includes the following workstation-based tools to increase your
productivity and code quality:

– Performance Analyzer to help you analyze, understand, and tune your C and
  C++ applications for improved performance
– Distributed Debugger that allows you to debug C or C++ programs from the
  convenience of the workstation
– Workstation-based editor to improve the productivity of your C and C++
  source entry
– Advanced online help, with full text search and hypertext topics as well as
  printable, viewable, and searchable Portable Document Format (PDF)
  documents

Note: References to Performance Analyzer in this document refer to the IBM
OS/390 Performance Analyzer included in the IBM C/C++ Productivity
Tools for OS/390 product.

In addition, IBM C/C++ Productivity Tools for OS/390 includes the following host
components:

– Debug Tool
– Host Performance Analyzer

Use the Performance Analyzer on your workstation to graphically display and
analyze a profile of the execution of your host z/OS XL C or C++ application. Use
this information to time and tune your code so that you can increase the
performance of your application.

Use the Distributed Debugger to debug your z/OS XL C or C++ application
remotely from your workstation. Set a breakpoint with the simple click of the
mouse. Use the windowing capabilities of your workstation to view multiple
segments of your source and your storage, while monitoring a variable at the
same time.

Use the workstation-based editor to quickly develop C and C++ application code
that runs on z/OS. Context-sensitive help information is available to you when
you need it.

• IBM Fault Analyzer for z/OS
  The IBM Fault Analyzer helps developers analyze and fix application and system
  failures. It gathers information about an application and the surrounding
  environment at the time of the abend, providing the developer with valuable
  information needed for developing and testing new and existing applications. For
  more information, refer to: www.ibm.com/software/awdtools/faultanalyzer/

• Application Performance Analyzer for z/OS
  The Application Performance Analyzer for z/OS is an application program
  performance analysis tool that helps you to:
  – Optimize the performance of your existing application
  – Improve the response time of your online transactions and batch turnaround
times
  – Isolate performance problems in applications
For more information, refer to: www.ibm.com/software/awdtools/apa/.

- **ISPF Software Configuration and Library Manager facility (SCLM)**
  The ISPF Software Configuration and Library Manager facility (SCLM) maintains information about the source code, objects and load modules. It also keeps track of other relationships in your application, such as test cases, JCL, and publications. The SCLM Build function translates input to output, managing not only compilation and linking, but all associating processes required to build an application. This facility helps to ensure that your production load modules match the source in your production source libraries. For more information, refer to: www.ibm.com/software/awdtools/ispf/features/sclm-ov.html.

- **Graphical Data Display Manager (GDDM)**
  GDDM programs provide a comprehensive set of functions to display and print applications most effectively:
  - A windowing system that the user can tailor to display selected information
  - Support for presentation and keyboard interaction
  - Comprehensive graphics support
  - Fonts (including support for the double-byte character set)
  - Business image support
  - Saving and restoring graphic pictures
  - Support for many types of display terminals, printers, and plotters
  For more information, refer to: www.ibm.com/software/applications/gddm/.

- **Query Management Facility (QMF)**
  z/OS XL C supports the Query Management Facility (QMF), a query and report writing facility, which allows you to write applications through a callable interface. You can create applications to perform a variety of tasks, such as data entry, query building, administration aids, and report analysis. For more information, refer to: www.ibm.com/software/data/qmf/.

- **z/OS Java support**
  The Java language supports the Java Native Interface (JNI) for making calls to and from C/C++. These calls do not use ILC support but rather the Java-defined JNI, which is supported by both compiled and interpreted Java code. Calls to C or C++ do not distinguish between these two.

---

### Additional features of z/OS XL C/C++

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Long Long Data Type</strong></td>
<td>z/OS XL C/C++ supports long long as a native data type when the compiler option LANGLVL(LONGLONG) is turned on. This option is turned on by default by the compiler option LANGLVL(EXTENDED). As of z/OS V1R7, the XL C compiler supports long long as a native data type (according to the ISO/IEC 9899:1999 standard), when the LANGLVL(STDLC99) option or LANGLVL(EXTLC99) option is in effect.</td>
</tr>
<tr>
<td><strong>Multibyte Character Support</strong></td>
<td>z/OS XL C/C++ supports multibyte characters for those national languages such as Japanese whose characters cannot be represented by a single byte.</td>
</tr>
<tr>
<td><strong>Wide Character Support</strong></td>
<td>Multibyte characters can be normalized by z/OS XL C library functions and encoded in units of one length. These normalized characters are called wide characters. Conversions between multibyte and wide characters can be performed by string conversion functions such as wcstombs(), mbstowcs(), wcsrtombs(), and mbsrtowcs(), as well as the family of wide-character I/O functions. Wide-character data can be represented by the wchar_t data type.</td>
</tr>
</tbody>
</table>
### Feature Description

**Extended Precision Floating-Point Numbers**

`z/OS XL C/C++` provides three `z/Architecture®` floating-point number data types: single precision (32 bits), declared as `float`; double precision (64 bits), declared as `double`; and extended precision (128 bits), declared as `long double`.

Extended precision floating-point numbers give greater accuracy to mathematical calculations.

`z/OS XL C/C++` also supports IEEE 754 floating-point representation (base-2 or binary floating-point formats). By default, `float`, `double`, and `long double` values are represented in `z/Architecture` floating-point formats (base-16 floating-point formats). However, the IEEE 754 floating-point representation is used if you specify the `FLOAT(IEEE)` compiler option. For details on this support, see the description of the `FLOAT` option in `z/OS XL C/C++ User's Guide`.

As of `z/OS V1R9`, `XL C/C++` also supports IEEE 754 decimal floating-point representation (base-10 floating-point formats), with the types `_Decimal32`, `_Decimal64`, and `_Decimal128`, if you specify the `DFP` compiler option. For details on this support, see the description of the `DFP` option in `z/OS XL C/C++ User's Guide`.

**Command Line Redirection**

You can redirect the standard streams `stdin`, `stderr`, and `stdout` from the command line or when calling programs using the `system()` function.

**National Language Support**

`z/OS XL C/C++` provides message text in either American English or Japanese. You can dynamically switch between these two languages.

**Coded Character Set (Code Page) Support**

The `z/OS XL C/C++` compiler can compile `C/C++` source written in different EBCDIC code pages. In addition, the `iconv` utility converts data or source from one code page to another.

**Selected Built-in Library Functions**

For selected library functions, the compiler generates an instruction sequence directly into the object code during optimization to improve execution performance. String and character functions are examples of these built-in functions. No actual calls to the library are generated when built-in functions are used.

**Multi-threading**

Threads are efficient in applications that allow them to take advantage of any underlying parallelism available in the host environment. This underlying parallelism in the host can be exploited either by forking a process and creating a new address space, or by using multiple threads within a single process. For more information, refer to “Using Threads in z/OS UNIX Applications” in `z/OS XL C/C++ Programming Guide`.

**Packed Structures and Unions**

`z/OS XL C` provides support for packed structures and unions. Structures and unions may be packed to reduce the storage requirements of a `z/OS XL C` program or to define structures that are laid out according to COBOL or PL/I structure alignment rules.

**Fixed-point (Packed) Decimal Data**

`z/OS XL C` supports fixed-point (packed) decimal as a native data type for use in business applications. The packed data type is similar to the COBOL data type `COMP-3` or the PL/I data type `FIXED DEC`, with up to 31 digits of precision.

**Long Name Support**

For portability, external names can be mixed case and up to 32 K - 1 characters in length. For `C++`, the limit applies to the mangled version of the name.

**System Calls**

You can call commands or executable modules using the `system()` function under `z/OS`, `z/OS UNIX System Services`, and `TSO`. You can also use the `system()` function to call EXECs on `z/OS` and `TSO`, or shell scripts using `z/OS UNIX System Services`.

**Exploitation of Hardware**

Use the `ARCHITECTURE` compiler option to select the minimum level of machine architecture on which your program will run. Note that certain features provided by the compiler require a minimum architecture level. For more information, refer to the `ARCHITECTURE` compiler option in `z/OS XL C/C++ User's Guide`.

Use the `TUNE` compiler option to optimize your application for a specific machine architecture within the constraints imposed by the `ARCHITECTURE` option. The `TUNE` level must not be lower than the setting in the `ARCHITECTURE` option. For more information, refer to the `TUNE` compiler option in `z/OS XL C/C++ User's Guide`.

</tr>
</tbody>
</table>
Chapter 2. Header Files

This part describes each header file, explains its contents, and lists the functions that use the file. The function descriptions are described in Chapter 3, “Part 3. Library Functions,” on page 103.

The header files provided with the z/OS XL C/C++ Library contain macro and constant definitions, type definitions, and function declarations. Some functions require definitions and declarations from header files to work correctly. The inclusion of header files is optional, as long as the necessary statements from the header files are coded directly into the source.

The C/C++ header files are shipped in the CEE.SCEEH* data sets and in the /usr/include directory in the Hierarchical File System (HFS).

The following header files are not supported in AMODE 64:
- csp.h
- ims.h
- leawi.h
- mtf.h
- re_comp.h
- regexp.h
- spc.h

Use the \#include directive to select header files to include with your application, for example, \#include <stdio.h>.

For information about the \#include directive, see z/OS XL C/C++ Language Reference and z/OS XL C/C++ User's Guide.

Feature Test Macros

Many of the symbols that are defined in headers are “protected” by a feature test macro (FTM). These “protected” symbols are invisible to the application unless the user defines the feature test macro with \#define, using either of the following methods:
- In the source code before including any header files.
- On the compilation command.

Note that the LANG_LVL compiler option does not define or undefine these macros.

The following feature test macros are obsolete in AMODE 64:
- _LARGE_FILES
- _LARGE_MEM

See the feature test macro description for more details.

The following feature test macros are not supported in AMODE 64:
- __LIBASCII
- __OE_SOCKETS
Table 4 summarizes the relationships between the feature test macros and the standards. ‘Yes’ indicates that a feature test macro makes visible the symbols related to a standard.

Feature test macros that do not apply to POSIX standards are not listed in this table.

</tbody>
</table>

The following feature test macros (FTM) are supported:

_ALL_SOURCE

This feature test macro exposes the following namespaces: POSIX.1, POSIX.1a, POSIX.2, POSIX.4a draft 6, XPG4, and XPG4.2, as well as additions to z/OS UNIX drawn from Single UNIX Specification, Version 2.

In addition, defining _ALL_SOURCE makes visible a number of symbols which are not permitted under ANSI, POSIX or XPG4, but which are provided as an aid to porting C-language applications to z/OS UNIX System Services services. Extensions made visible with the following feature test macros are implicit in _ALL_SOURCE:

- _OPEN_SYS_DIR_EXT
- _OPEN_SYS_EXT
- _OPEN_SYS_IPC_EXTENSIONS
- _OPEN_SYS_MAP_EXTENDED
- _OPEN_SYSPTY_EXTENSIONS
- _OPEN_SYS_SOCKET_EXT
- _OPEN_SYS_SOCKET_EXT2
- _OPEN_SYS_SOCKET_IPV6

If _OPEN_THREADS is not explicitly defined in the application, _ALL_SOURCE will define _OPEN_THREADS 1 except when any of the following are present:
ALL_SOURCE_NO_THREADS

ALL_SOURCE does not expose functionality first introduced in Single UNIX Specification, Version 3 under macro definitions XOPEN_SOURCE 600 or_POSIX_C_SOURCE 200112L, although it does tolerate interfaces made visible by defining OPEN_THREADS to 2 or 3.

In order to stabilize the namespace, no future extensions, whether POSIX, XOPEN, or MVS, will expand the definition of ALL_SOURCE. Any future enhancement will require new, explicit feature test macros to add symbols to this namespace.

ALL_SOURCE_NO_THREADS

This feature test macro provides the same function as ALL_SOURCE, except it does not expose threading services (OPEN_THREADS).

IEEEV1_COMPATIBILITY

In 1999, the C/C++ Run-Time Library provided IEEE754 floating-point arithmetic support in support of IBM’s Java group. The Java language had a bit-wise requirement for its math library, meaning that all platforms needed to produce the same results as Sun Microsystems’ fdlibm (Freely Distributed LIBM) library. Therefore, Sun Microsystems’ fdlibm code was ported to the C/C++ Run-Time Library to provide IEEE754 floating-point arithmetic support. Subsequent to the C/C++ Run-Time Library’s 1999 release of IEEE754 floating-point math support, IBM’s Java group provided their own support of IEEE754 floating point arithmetic and no longer use the C/C++ Run-Time Library for this support.

Beginning in z/OS V1R9, a subset of the original fdlibm functions are being replaced by new versions that are designed to provide improved performance and accuracy. The new versions of these functions are replaced at the existing entry points. However, as a migration aid, IBM has provided new entry points for the original fdlibm versions. Applications that take no action will automatically use the updated functions. There are two methods for accessing the original functions.

This feature test macro provides an environment for the following C/C++ functions:

- do not include <math.h>
- include <math.h> and define the _FP_MODE_VARIABLE feature test macro

Either of the above will cause the application to be running in what is called “variable” mode with respect to floating-point math functions called within the compile unit. See z/OS XL C/C++ Programming Guide for more details on the environment variable.

The second method is through a feature test macro, described here, that can be used by applications that do include <math.h> and do not define the _FP_MODE_VARIABLE feature test macro.

If the application conforms to the rules of the second method, then the feature test macro can be used to access the original fdlibm versions of the following functions:
A recompile and relink of the application is required to access the original fdlibm versions.

_ISOC99_SOURCE

This feature test macro makes available all interfaces associated with ISO/IEC 9899:1999 except for interfaces requiring a compiler that is designed to support C99. This feature test macro also exposes the namespace normally exposed by the _MSE_PROTOS feature test macro, unless _NOISOC99_SOURCE is defined. The _ISOC99_SOURCE feature test macro is not required when a compiler that is designed to support C99 is used.

Note: If both _NOISOC99_SOURCE and _ISOC99_SOURCE are defined before inclusion of the first header, new C99 interfaces will not be exposed.

_LARGE_FILES

This feature test macro enables certain functions to operate on HFS files that are larger than 2 gigabytes in size. When this feature test macro is selected it must be used in conjunction with the compiler option, LANGLVL(LONGLONG) to activate the long long data type. The following functions will be activated to operate on HFS files of all sizes by expanding appropriate offset and file size values to a 64 bit value.

creat(), fcntl(), fgetpos(), fopen(), freopen(), fseek(), fseeko(), fsetpos(), fstat(), ftell(), ftello(), ftruncate(), getrlimit(), lockf(), lseek(), lstat(), mmap(), open(), read(), setrlimit(), stat(), truncate(), and write().

Restriction: This feature test macro is incompatible with the __LIBASCII feature test macro.

Note: This feature test macro is obsolete in AMODE 64. Large Files for HFS support is automatic in the LP64 programming model, therefore all behaviors with respect to Large Files for HFS are automatically included for AMODE 64 C/C++ applications.

_LARGE_MEM

This feature test macro is provided for AMODE 31 applications that need access to AMODE 64 values. Use of large memory support requires LANGLVL(LONGLONG).

Note: This feature test macro is obsolete in AMODE 64. Large memory support is automatic in the LP64 programming model, therefore all behaviors with respect to large memory are automatically included for AMODE 64 C/C++ applications.

__LIBASCII

This feature test macro provides an ASCII-like environment for the following C/C++ functions:

access(), asctime(), atof(), atoi(), atol(), chdir(), chmod(), chown(), creat(), ctime(), dllload(), dllqueryfn(), dynalloc(), ecvt(), execv(), execve(), execvp(), fctv(), fopen(), fopem()
For each application program using one or more of these functions, where the input/output is ASCII, add the following feature test macro:

- #define __LIBASCII
- Recompile using the CONV(ISO8859-1) option to cause the compiler to generate all strings defined in the source program in ASCII rather than EBCDIC format.

Restriction: This feature test macro is not supported in AMODE 64.

Restriction: Enhanced ASCII and __LIBASCII are independent, and should not be used together. Using Enhanced ASCII and __LIBASCII together is not supported.

Note: The libascii functions are as thread-safe as the run-time library with the exception of the getopt() function. The libascii getopt() function is not thread-safe. The second argument is changed for a short period of time from EBCDIC to ASCII and then back to EBCDIC. This feature test macro is incompatible with the _LARGE_FILES feature test macro.

_LONGMAP

Programs compiled with the LONGNAME compiler option and which use POSIX functions must define _LONGMAP when using the Prelinker outside of a z/OS UNIX shell environment.

_MSE_PROTOS

The _MSE_PROTOS feature test macro does the following:

1. Selects behavior for a multibyte extension support (MSE) function declared in wchar.h as specified by ISO/IEC 9899:1990/Amendment 1:1994 instead of behavior for the function as defined by CAE Specification, System Interfaces and Headers, Issue 4, July 1992 (XPG4), and

Note: Defining _ISOC99_SOURCE or using a compiler that is designed to support C99 also exposes this namespace provided that _NOISOC99_SOURCE is not also defined.

_NOISOC99_SOURCE
This feature test macro prevents exposure of new interfaces that are part of the C99 standard. This feature test macro must be defined before inclusion of the first header in order to prevent new C99 interfaces from being exposed.

**Note:** If both _NOISOC99_SOURCE and _ISOC99_SOURCE are defined before inclusion of the first header, new C99 interfaces will not be exposed.

_**OE_SOCKETS**_

This feature test macro defines a BSD-like socket interface for the function prototypes and structures involved. This can be used with _XOPEN_SOURCE_EXTENDED 1 and the XPG4.2 socket interfaces will be replaced with the BSD-like interfaces.

**Restriction:** This feature test macro is not supported in AMODE 64.

_**OPEN_DEFAULT**_

When defined to 0, and if no other feature test macro is defined, then all symbols will be visible. If in addition to _OPEN_DEFAULT only POSIX and/or XPG4 feature test macros are defined, then only the symbols so requested will be visible. Otherwise, additional symbols (for example, those visible when the LNLGLVL(EXTENDED) compiler options specified), may be exposed.

When defined to 1, this provides the base level of z/OS UNIX System Services services functionality, which is POSIX.1, POSIX.1a and POSIX.2.

_**OPEN_MSGQ_EXT**_

This feature test macro defines an interface which enables use of select(), selectex() and poll() to monitor message and file descriptors.

_**OPEN_SOURCE**_

When defined to 1, this defines all of the functionality that was available on MVS 5.1. This macro is equivalent to specifying _OPEN_SYS.

When defined to 2, this defines all of the functionality that is available on MVS 5.2.2, including XPG4, XPG4.2, and all of the z/OS UNIX System Services extensions.

When defined to 3, this macro is equivalent to specifying _ALL_SOURCE.

If _OPEN_THREADS is not explicitly defined in the application, _OPEN_SOURCE will define _OPEN_THREADS 1 except when any of the following are present:

- _ALL_SOURCE_NO_THREADS
- _UNIX03_THREADS
- _XOPEN_SOURCE 600

_**OPEN_SYS**_

When defined to 1, this indicates that symbols required by POSIX.1, POSIX.1a, POSIX.2 are made visible. Any symbols defined by the _OPEN_THREADS macro are allowed.

If _OPEN_THREADS is not explicitly defined in the application, _OPEN_SYS will define _OPEN_THREADS 1 except when any of the following are present:
Additional symbols can be made visible if any of the exposed standards explicitly allows the symbol to appear in the header in question or if the symbol is defined as a z/OS UNIX System Services services extension.

_OPEN_SYS_DIR_EXT

This feature test macro defines the interface and function prototypes for __opendir2() and __readdir2().

_OPEN_SYS_FILE_EXT

When defined to any value with #define, _OPEN_SYS_FILE_EXT indicates that symbols required for file conversion, file tagging, and file attributes manipulation functionality are made visible.

_OPEN_SYS_IPC_EXTENSIONS

This feature test macro defines z/OS UNIX System Services services extensions to the X/Open InterProcess Communications functions. When _OPEN_SYS_IPC_EXTENSIONS is defined, the POSIX.1, POSIX.1a, and the XPG4 symbols are visible. This macro should be used in conjunction with _XOPEN_SOURCE.

.OPEN_SYS_MUTEX_EXT

This feature test macro allows pthread condition variables and mutexes in shared memory. When this feature is defined, pthread_mutex_t and pthread_cond_t will grow significantly in size.

When either _XOPEN_SOURCE 600 or _UNIX03_THREADS are defined, the namespace includes all elements made visible by the _OPEN_SYS_MUTEX_EXT macro. In this case, _OPEN_SYS_MUTEX_EXT is redundant and does not need to be defined by the application.

.OPEN_SYS_PTY_EXTENSIONS

This feature test macro defines z/OS UNIX System Services services extensions to the X/Open Pseudo TTY functions. When _OPEN_SYS_PTY_EXTENSIONS is defined, the POSIX.1, POSIX.1a, XPG4, and XPG4.2 symbols are visible. This macro should be used in conjunction with _XOPEN_SOURCE_EXTENDED 1.

.OPEN_SYS_SOCK_EXT

This feature test macro defines the interface for function prototypes and structures for the extended sockets and bulk mode support.

.OPEN_SYS_SOCK_EXT2

This feature test macro defines the interface and function prototype for accept_and_recv().

.OPEN_SYS_SOCK_IPV6

When defined, indicates that symbols related to Internet Protocol Version 6 (IPv6) are made visible.

Defining _XOPEN_SOURCE to 600 will expose the IPv6 symbols required in Single Unix Specification, Version 3. However, these symbols only comprise a subset of the complete namespace associated with
OPEN_SYS_SOCK_IPV6. Although an application is allowed to define both macros, such an application may not be strictly conforming to Single UNIX Specification, Version 3.

OPEN_THREADS

When defined to 1, this indicates that symbols required by POSIX.1, POSIX.1a, and POSIX.4a (draft 6) are made visible.

When defined to 2, additional pthread functions introduced in z/OS V1R07 from Single UNIX Specification, Version 3 are made visible, along with those made visible when this is defined to 1. The following symbols are added to the namespace when OPEN_THREADS is defined to 2:

<table>
<thead>
<tr>
<th>Interfaces</th>
<th>Constants</th>
</tr>
</thead>
<tbody>
<tr>
<td>pthread_getconcurrency()</td>
<td>PTHREAD_CANCEL_ENABLE</td>
</tr>
<tr>
<td>pthread_setconcurrency()</td>
<td>PTHREAD_CANCEL_DISABLE</td>
</tr>
<tr>
<td>pthread_setcancelstate()</td>
<td>PTHREAD_CANCEL_DEFERRED</td>
</tr>
<tr>
<td>pthread_setcanceltype()</td>
<td>PTHREAD_CANCELASYNCHRONOUS</td>
</tr>
<tr>
<td>pthread_sigmask()</td>
<td></td>
</tr>
<tr>
<td>pthread_testcancel()</td>
<td></td>
</tr>
<tr>
<td>pthread_key_delete()</td>
<td></td>
</tr>
</tbody>
</table>

When defined to 3, all pthread functions required for the Threads option of Single UNIX Specification, Version 3 are exposed, although behavior and function signatures are still based on the POSIX.4a draft 6 specification. In addition to the symbols exposed by OPEN_THREADS 2, OPEN_THREADS 3 adds the following symbols to the namespace:

<table>
<thead>
<tr>
<th>Interfaces</th>
<th>Constants</th>
</tr>
</thead>
<tbody>
<tr>
<td>pthread_atfork()</td>
<td>PTHREAD_CANCEL_CANCELED</td>
</tr>
<tr>
<td>pthread_attr_getguardsize()</td>
<td>PTHREAD_COND_INITIALIZER</td>
</tr>
<tr>
<td>pthread_attr_getschedparam()</td>
<td>PTHREAD_CREATEDETACHED</td>
</tr>
<tr>
<td>pthread_attr_getstack()</td>
<td>PTHREAD_CREATEJOINABLE</td>
</tr>
<tr>
<td>pthread_attr_getstackaddr()</td>
<td>PTHREAD_EXPLICIT_SCHED</td>
</tr>
<tr>
<td>pthread_attr_setguardsize()</td>
<td></td>
</tr>
<tr>
<td>pthread_attr_setschedparam()</td>
<td></td>
</tr>
<tr>
<td>pthread_attr_setstack()</td>
<td></td>
</tr>
<tr>
<td>pthread_attr_setstackaddr()</td>
<td></td>
</tr>
</tbody>
</table>

Thread interfaces listed above and first exposed by OPEN_THREADS 2 or 3 are fully compliant with Single UNIX Specification, Version 3. However, the other threading interfaces in the library will not exhibit the new behavior or use function signatures changed in the new standard. Applications that define _UNIX03_THREADS or _XOPEN_SOURCE 600 will obtain threads support that complies fully with Single UNIX Specification, Version 3.

If OPEN_THREADS is defined with _XOPEN_SOURCE 600, OPEN_THREADS takes precedence and overrides the default threads behavior of _XOPEN_SOURCE 600. However, OPEN_THREADS and _UNIX03_THREADS are mutually exclusive.

Note: Feature test macros _OPEN_SYS, _OPEN_SOURCE, and _ALL_SOURCE incorporate OPEN_THREADS 1 by default, if OPEN_THREADS has not been explicitly defined in the application, except when any of the following are present:
_POSIX1_SOURCE
- When defined to 1, it has the same meaning as _POSIX_SOURCE.
- When defined to 2, both the POSIX.1a symbols and the POSIX.1 symbols are made visible. Additional symbols can be made visible if POSIX.1a explicitly allows the symbol to appear in the header in question.

_POSIX_C_SOURCE
- When defined to 1, it indicates that symbols required by POSIX.1 are made visible. Additional symbols can be made visible if POSIX.1 explicitly allows the symbol to appear in the header in question.
- When defined to 2, both the POSIX.1 and POSIX.2 symbols are made visible.
- When defined to 200112L, the Single UNIX Specification, Version 3 symbols are made visible, including POSIX.1 and POSIX.2. Since Version 3 is aligned with the ISO C standard (ISO/IEC 9899:1999), this definition of the feature test macro also exposes the C99 namespace.
- The _POSIX_C_SOURCE 200112L definition is available beginning with z/OS V1R9. Targeting earlier releases will result in an error during compile-time.
- Additional symbols can be made visible if POSIX.2 explicitly allows the symbol to appear in the header in question.

_POSIX_SOURCE
When defined to any value with #define, it indicates that symbols required by POSIX.1 are made visible. Additional symbols can be made visible if POSIX.1 explicitly allows the symbol to appear in the header in question.

_SHARE_EXT_VARS
This feature test macro provides access to POSIX and XPG4 external variables of an application from a dynamically loaded module such as a DLL. For those external variables that have a function to access a thread-specific value, it provides access to the thread-specific value of the external variable without having to explicitly invoke the function.

Individual variables can be externalized by using the feature test macros prefixed with _SHR_ and the feature test macros that are shown as follows. The entire set can be accessed by defining _SHARE_EXT_VARS.

**Note:** When an application is compiled with the XPLINK or LP64 option:
- The POSIX and XPG4 external variables will be resolved through the C run-time library side-deck in the SCEELIB data set and will be accessible from all dynamically loaded modules. See [z/OS XPLINK C/C++ Programming Guide](https://www.ibm.com/support/knowledgecenter/SST7XK_7.1.0/com.ibm.zos.v2r11.bx2e1005.mf000h00.htm) for more details.
- The _SHARE_EXT_VARS feature test macro, and the following feature test macros with the _SHR_ prefix, are only necessary for accessing the thread-specific values without having to explicitly invoke the function.

_SHR_DAYLIGHT
Header Files

To share access to the daylight external variable from a dynamically loaded module such as a DLL, define the _SHR_DAYLIGHT feature test macro and include time.h in your program source.

_SHR_ENVIRON

If you have declared char **environ in your program and want to access the environment variable array from a dynamically loaded module such as a DLL, define the _SHR_ENVIRON feature test macro and include stdlib.h in the program source.

_SHR_H_ERRNO

To share access to the h_errno external variable from a dynamically loaded module such as a DLL, define the _SHR_H_ERRNO feature test macro and include stdlib.h in your program source.

_SHR__LOC1

To share access to the __loc1 external variable from a dynamically loaded module such as a DLL, define _SHR__LOC1 feature test macro and include libgen.h in your program source.

_SHR_LOC1

To share access to the loc1 external variable from a dynamically loaded module such as a DLL, define _SHR_LOC1 feature test macro and include regexp.h in your program source.

_SHR_LOC2

To share access to the loc2 external variable from a dynamically loaded module such as a DLL, define _SHR_LOC2 feature test macro and include regexp.h in your program source.

_SHR_LOCS

To share access to the locs external variable from a dynamically loaded module such as a DLL, define _SHR_LOCS feature test macro and include regexp.h in your program source.

_SHR_OPTARG

To share access to the optarg external variable from a dynamically loaded module such as a DLL, define the _SHR_OPTARG feature test macro and include unistd.h or stdio.h in your program source.

_SHR_OPTERR

To share access to the opterr external variable from a dynamically loaded module such as a DLL, define the _SHR_OPTERR feature test macro and include unistd.h or stdio.h in your program source.

_SHR_OPTIND

To share access to the optind external variable from a dynamically loaded module such as a DLL, define _SHR_OPTIND feature test macro and include unistd.h or stdio.h in your program source.

_SHR_OPTOPT

To share access to the optopt external variable from a dynamically loaded module such as a DLL, define _SHR_OPTOPT feature test macro and include unistd.h or stdio.h in your program source.

_SHR_SIGNGAM
To share access to the signgam external variable from a dynamically loaded module such as a DLL, define the _SHR_SIGNGAM feature test macro and include math.h in your program source.

_SHR_T_ERRNO

To share access to the t_errno external variable from a dynamically loaded module such as a DLL, define the _SHR_T_ERRNO feature test macro and include xti.h in your program source.

_SHR_TIMEZONE

To share access to the timezone external variable from a dynamically loaded module such as a DLL, define the _SHR_TIMEZONE feature test macro and include time.h in your program source. To avoid name space pollution when _SHR_TIMEZONE is defined, the timezone variable must be referred to as _timezone.

_SHR_TZNAME

To share access to the tzname external variable from dynamically loaded module such as a DLL, define the _SHR_TZNAME feature test macro and include time.h in your program source.

__STDC_CONSTANT_MACROS

This feature test macro is required by C++ applications wishing to expose macros for integer constants as documented in <stdint.h>.

__STDC_FORMAT_MACROS

This feature test macro is required by C++ applications wishing to expose macros for format specifiers as documented in <inttypes.h>.

__STDC_WANT_DEC_FP_

This MACRO will be added to the C99 DFP specification (for C and C++). The user will define this MACRO when DFP support is wanted. It will cause all DFP-oriented definitions in <math.h> and other headers to be exposed if __IBM_DFP is defined.

__STDC_LIMIT_MACROS

This feature test macro is required by C++ applications wishing to expose limits of specified-width integer types and limits of other integer types as documented in <stdint.h>.

_UNIX03_SOURCE

This feature test macro exposes new Single UNIX Specification, Version 3 interfaces. It does not change the behavior of existing APIs, nor expose interfaces controlled by feature test macros such as __XOPEN_SOURCE_EXTENDED. Functions and behavior exposed by _UNIX03_SOURCE are a subset and not the complete implementation of the Single UNIX Specification, Version 3. To expose the full Single UNIX Specification, Version 3 implementation available in the C/C++ Run-time, see __XOPEN_SOURCE or __POSIX_C_SOURCE.

<table>
<thead>
<tr>
<th>Release</th>
<th>Interfaces Exposed with _UNIX03_SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS V1R06</td>
<td>dlclose(), dlerror(), dlopen(), dlsym()</td>
</tr>
</tbody>
</table>
Release | Interfaces Exposed with _UNIX03_SOURCE
--- | ---
z/OS V1R07 | sched_yield(), strerror_r(), unsetenv()
z/OS V1R08 | flockfile(), ftrylockfile(), funlockfile(),
getc_unlocked(), getchar_unlocked(),
putc_unlocked(), putchar_unlocked()
z/OS V1R09 | posix_openpt(), pselect(), sockatmark()

**Note:** This feature test macro does not expose any new pthread interfaces. See _OPEN_THREADS and _UNIX03_THREADS to expose pthread interfaces.

**_UNIX03_THREADS**

This feature test exposes all pthread functions, function signatures, and behaviors required for the Threads option of Single UNIX Specification, Version 3. The macro is available for compiles targeting z/OS V1R9 or later.

Defining _UNIX03_THREADS exposes the content covered by feature test macro _OPEN_SYS_MUTEX_EXT, so that the latter is redundant and need not be defined with _UNIX03_THREADS.

It is not necessary to define this feature test macro, if _XOPEN_SOURCE is defined to 600. Unless _OPEN_THREADS is defined, _XOPEN_SOURCE 600 will make available the same interfaces and behaviors as _UNIX03_THREADS.

_UNIX03_THREADS and _OPEN_THREADS are mutually exclusive.

**_UNIX03_WITHDRAWN**

Defining this feature test macro exposes any language elements, previously in the Legacy Feature Group or marked obsolescent, that have been removed from Single UNIX Specification, Version 3. These elements would not otherwise be visible in the namespace exposed by compiling with _XOPEN_SOURCE 600 or POSIX_C_SOURCE 200112L.

The following withdrawn symbols are exposed when _UNIX03_WITHDRAWN is defined:

<table>
<thead>
<tr>
<th>Functions</th>
<th>Constants</th>
</tr>
</thead>
<tbody>
<tr>
<td>brk()</td>
<td>CLOCK_TICKS</td>
</tr>
<tr>
<td>chroot()</td>
<td>IUCLC</td>

</tr>
</tbody>
</table>

### Constants

<table>
<thead>
<tr>
<th>Constants</th>
</tr>
</thead>
<tbody>
<tr>
<td>__loc1</td>
</tr>
</tbody>
</table>

---

**_VARARG_EXT_**

This feature test macro allows users of the va_arg, va_end, and va_start macros to define the va_list type differently.

**_XOPEN_SOURCE**

This feature test macro defines the functionality defined in the XPG4 standard dated July 1992.

When defined to 500, this feature test macro makes available certain key functions that are associated with Single UNIX Specification, Version 2.

When defined to 600, this feature test macro exposes the complete implementation of the Single UNIX Specification, Version 3, including the namespace defined by _POSIX_C_SOURCE 200112L as well as namespaces associated with the X/Open System Interface (XSI) extension and these options and option groups:

- File Synchronization
- Memory Mapped Files
- Memory Protection
- Realtime Signals Extension
- Thread Stack Address Attribute
- Thread Stack Size Attribute
- Thread Process-Shared Synchronization
- Thread-Safe Functions
- Threads
- Encryption Option Group
- Legacy Option Group
- XSI Streams Option Group

The use of _XOPEN_SOURCE 600 exposes namespaces covered by several other feature test macros, and as such, makes those macros redundant. The following need not be defined when _XOPEN_SOURCE 600 is defined:

<table>
<thead>
<tr>
<th>Headers</th>
</tr>
</thead>
<tbody>
<tr>
<td>_ISOC99_SOURCE</td>
</tr>
<tr>
<td>_POSIX_C_SOURCE</td>
</tr>
<tr>
<td>_LARGE_FILES</td>
</tr>
<tr>
<td>_UNIX03_THREADS</td>
</tr>
<tr>
<td>_OPEN_SYS_MUTEX_EXT</td>
</tr>
<tr>
<td>_UNIX03_SOURCE</td>
</tr>
<tr>
<td>_POSIX_SOURCE</td>
</tr>
<tr>
<td>_XOPEN_SOURCE_EXTENDED</td>
</tr>
</tbody>
</table>

If _OPEN_THREADS is defined with _XOPEN_SOURCE 600, _OPEN_THREADS takes precedence and overrides Single UNIX Specification, Version 3 threads behavior. Whenever _OPEN_THREADS is in effect, the _OPEN_SYS_MUTEX_EXT extensions are also dropped, unless the application explicitly defines this macro.

The _XOPEN_SOURCE 600 definition is available beginning with z/OS V1R9. Targeting earlier releases will result in an error during compile-time.
Full support of Single UNIX Specification, Version 3 requires use of a C99 compliant compiler. Most of the namespace is available to older compilers, but some elements of Version 3 (e.g. <complex.h>,<tgmath.h>) will not be visible. Applications must use a C99 compliant compiler or compile with LANGLVL(LONGLONG) to obtain large file support when defining _XOPEN_SOURCE 600.

_XOPEN_SOURCE_EXTENDED
When defined to 1, this defines the functionality defined in the XPG4 standard plus the set of “Common APIs for UNIX-based Operating Systems”, April, 1994, draft.

aio.h
The aio.h header file contains definitions for asynchronous I/O operations. It declares these functions:

<table>
<thead>
<tr>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>aio_read()</td>
</tr>
<tr>
<td>aio_write()</td>
</tr>
<tr>
<td>aio_cancel()</td>
</tr>
<tr>
<td>aio_suspend()</td>
</tr>
<tr>
<td>aio_error()</td>
</tr>
<tr>
<td>aio_return()</td>
</tr>
</tbody>
</table>

Usage note
There are several sockets oriented extensions to asynchronous I/O available with the BPX1AIO callable service, such as asynchronous accept(), asynchronous forms of all five pairs of read and write type operations, and receiving I/O completion notifications via an ECB, exit program, or through a message queue. The <aio.h> header contains all the structure fields, constants, and prototypes necessary to use BPX1AIO from a C program. These extensions are exposed when the __AIO_OS390 feature test macro is defined. The BPX1AIO stub resides in SYS1.CSSLIB and must be bound with your program. For a more detailed description of asynchronous I/O services, see BPX1AIO in z/OS UNIX System Services Programming.

arpa/inet.h
The arpa/inet.h header file contains definitions for internet operations.

arpa/nameser.h
The arpa/nameser.h header file contains the definitions used to support the construction of queries and the inspection of answers received from a Domain Name Server available in a network. It also contains the macros GETSHORT(), PUTSHORT(), GETLONG(), and PUTLONG() that are used to construct or inspect DNS requests.

assert.h
The assert.h header file defines the assert() macro that allows you to insert diagnostics into your code. You must include assert.h when you use assert().

cassert
The cassert header file contains definitions for C++ for enforcing assertions when functions execute. Include the standard header into a C++ program to effectively include the standard header <assert.h> within the std namespace.
namespace std {
#include <assert.h>
};

_Ccsid.h

The _Ccsid.h header file declares functions, symbols and data types used in CCSID to codeset name conversion.

cctype

The cctype header file contains definitions for C++ for classifying characters. Include the standard header into a C++ program to effectively include the standard header <ctype.h> within the std namespace.
namespace std {
#include <ctype.h>
};

ceecedct.h

The ceeedct.h header file contains C declarations of the Language Environment condition tokens.

cerrno

The cerrno header file contains definitions for C++ for testing error codes reported by library functions. Include the standard header into a C++ program to effectively include the standard header <errno.h> within the std namespace.
namespace std {
#include <errno.h>
};

cfloat

The cfloat header file contains definitions for C++ for testing floating-point type properties. Include the standard header into a C++ program to effectively include the standard header <float.h> within the std namespace.
namespace std {
#include <float.h>
};

cics.h

The cics.h header file declares the iscics() function, which verifies whether cics is running.

ciso646

The ciso646 header file contains definitions for C++ for programming in ISO646 variant character sets. Include the standard header into a C++ program to effectively include the standard header <iso646.h> within the std namespace.
namespace std {
#include <iso646.h>
};
Header Files

climits

The climits header file contains definitions for C++ for testing integer type properties. Include the standard header into a C++ program to effectively include the standard header <limits.h> within the std namespace.

namespace std {
    #include <limits.h>
};

clocale

The locale header file contains definitions for C++ for adapting to different cultural conventions. Include the standard header into a C++ program to effectively include the standard header <locale.h> within the std namespace.

namespace std {
    #include <locale.h>
};
cmath

The cmath header file contains definitions for C++ for computing common mathematical functions. Include the standard header into a C++ program to effectively include the standard header <math.h> within the std namespace.

namespace std {
    #include <math.h>
};
collate.h

The collate.h header includes declarations of functions that allow retrieval of information regarding the current locale’s collating properties. It declares these functions:

class()    collequiv()    collorder()    collrange()    colltostr()
getmccoll() getwmccoll()  ismccollel()    maxcoll()       strtocoll()

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this book. For still more information, see the chapter, “Internationalization: Locales and Character Sets” in z/OS XL C/C++ Programming Guide.

complex.h

The complex.h header file contains function declarations for all the complex math functions listed below.

cabs()      cabsf()       cabsl()      cacos()      cacosf()      cacosl()
cacosh()    cacoshf()    cacoshl()    cacos()      cacosl()      cacosf()      carg()      cargf()      cargl()
csinh()    csinhf()    csinhl()    csin()      csinf()      csinl()      cctan()    cctanh()    cctanhf()    cctanhl()    cctan()    cctanf()    cctanl()
ccos()      ccosh()      ccoshf()    ccoshl()    ccos()      ccosl()      ccosf()      carg()      cargf()      cargl()
ccexp()      cexpf()      cexpl()      cimag()    cimagf()    cimagl()      cpow()      cpowf()      cpowl()
Macros

complex
   expands to _Complex, where _Complex is a type specifier.

_Complex_I
   expands to const float _Complex with the value of the imaginary unit

I
   expands to _Complex_I

Compile Requirement

Use of this header requires a compiler that is designed to support C99.

Restriction: This header is not supported for C++ applications.

Note: The UNIX System Laboratories (USL) Complex Mathematics Class Library
also contains a header file that is called complex.h and it is used only for
C++ applications.

cpio.h

The cpio.h header file contains CPIO archive values.

csetjmp

The csetjmp header file contains definitions for C++ for executing nonlocal goto
statements. Include the standard header into a C++ program to effectively include
the standard header <setjmp.h> within the std namespace.

namespace std {
   #include <setjmp.h>
};

csignal

The csignal header file contains definitions for C++ for controlling various
exceptional conditions. Include the standard header into a C++ program to
effectively include the standard header <signal.h> within the std namespace.

namespace std {
   #include <signal.h>
};
csp.h

Restriction: This header file is not supported in AMODE 64.

The csp.h header file declares the __csplist macro, which obtains the CSP
parameter list.
These macros are not supported under z/OS UNIX System Services services and they are not supported for C++ applications.

**cstdarg**

The cstdarg header file contains definitions for C++ for accessing a varying number of arguments. Include the standard header into a C++ program to effectively include the standard header <stdarg.h> within the std namespace.

```cpp
namespace std {
#include <stdarg.h>
};
```

**cstddef**

The cstddef header file contains definitions for C++ for defining several useful types and macros. Include the standard header into a C++ program to effectively include the standard header <stddef.h> within the std namespace.

```cpp
namespace std {
#include <stddef.h>
};
```

**cstdio**

The cstdio header file contains definitions for C++ for performing input and output. Include the standard header into a C++ program to effectively include the standard header <stdio.h> within the std namespace.

```cpp
namespace std {
#include <stdio.h>
};
```

**cstdlib**

The cstdlib header file contains definitions for C++ for performing a variety of operations. Include the standard header into a C++ program to effectively include the standard header <stdlib.h> within the std namespace.

```cpp
namespace std {
#include <stdlib.h>
};
```

**cstring**

The cstring header file contains definitions for C++ for manipulating several kinds of strings. Include the standard header into a C++ program to effectively include the standard header <string.h> within the std namespace.

```cpp
namespace std {
#include <string.h>
};
```

**ctest.h**

The ctest.h header file contains declarations for the functions that involve debugging and diagnostics. The diagnostic functions are:

- `cdump()`
- `csnap()`
- `ctest()`
- `ctrace()`
ctime

The ctime header file contains definitions for C++ for converting between various time and date formats. Include the standard header into a C++ program to effectively include the standard header <time.h> within the std namespace.

```cpp
namespace std {
#include <time.h>
};
```

cctype.h

The cctype.h header file declares functions used in character classification. The functions declared are:

- isalnum()
- isalpha()
- isblank()
- iscntrl()
- isdigit()
- isgraph()
- islower()
- isprint()
- ispunct()
- isspace()
- isupper()
- isxdigit()
- tolower()
- toupper()

_XOPEN_SOURCE

- isascii()
- toascii()
- _tolower()
- _toupper()

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this book. For still more information, see the chapter, "Internationalization: Locales and Character Sets" in z/OS XL C/C++ Programming Guide.

cwchar

The cwchar header file contains definitions for C++ for manipulating wide streams and several kinds of strings. Include the standard header into a C++ program to effectively include the standard header <wchar.h> within the std namespace.

```cpp
namespace std {
#include <wchar.h>
};
```

cwctype

The cwctype header file contains definitions for C++ for classifying wide characters. Include the standard header into a C++ program to effectively include the standard header <wctype.h> within the std namespace.

```cpp
namespace std {
#include <wctype.h>
};
```

decimal.h

The decimal.h header file is not supported under z/OS C++ applications.

The decimal.h header file contains declarations for those built-in functions that perform fixed-point decimal operations. The functions declared are:

- decabs()
- decchk()
- decfix()
The header file also contains definitions of constants that specify the ranges of the decimal data types.

### dirent.h

The dirent.h header file contains constants, prototypes, and typedef definitions for POSIX directory access functions. It declares the following functions:

- `_OPEN_SYS_DIR_EXT
  - __opendir2() __readdir2()
- __POSIX_SOURCE
  - closedir() opendir() readdir() rewinddir()
- __XOPEN_SOURCE
  - seekdir() telldir()
- __XOPEN_SOURCE 500
  - readdir_r()

This header file can be used by C++ POSIX(OFF) functions. See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information.

### dlfcn.h

The dlfcn.h header file declares the following macros for use in the construction of a dlopen() mode argument:

**RTLD_LAZY**
Relocations are performed at an implementation-defined time.

**RTLD_NOW**
Relocations are performed when the object is loaded.

**RTLD_GLOBAL**
All symbols are available for relocation processing of other modules.

**RTLD_LOCAL**
All symbols are not made available for relocation processing by other modules.

- dlclose() dleerror() dlsym() dlopen()
Use this header file when using these functions to import functions and variables from a DLL.

**dynit.h**

The dynit.h header file contains information for dynamic allocation routines. Specifically, it contains declarations of the dynalloc() and dynfree() functions, the definition of the dyninit() macro, declarations of related structures, and definitions of related constants.

**env.h**

The env.h header file is used to declare the setenv() and clearenv() functions, which are used in POSIX programs to set and clear environment variables. The env.h header file requires the _POSIX1_SOURCE 2 feature test macro.

**errno.h**

The errno.h header file defines the symbolic constants that are returned in the external variable errno.

The errno.h header file also defines errno, which is a modifiable lvalue having type int. If you intend to test the value of errno after library function calls, first set it to 0, because the library functions do not reset the value to 0.
strerror() or perror() functions can be used to print the description of the message associated with a particular errno.

To test for the explicit error, use the macro names defined in errno.h, rather than specific values of these macros. Doing so will ensure future compatibility and portability.

erro.h also declares the __errno2() prototype.

exception

The exception header file defines several types and functions related to the handling of exceptions.

namespace std {
    class exception;
    class bad_exception;
    typedef void (*terminate_handler)();
    typedef void (*unexpected_handler)();
    terminate_handler set_terminate(terminate_handler ph) throw();
    unexpected_handler set_unexpected(unexpected_handler ph) throw();
    void terminate();
    void unexpected();
    bool uncaught_exception();
};

bad_exception

class bad_exception : public exception {
};

The class describes an exception that can be thrown from an unexpected handler. The value returned by what() is an implementation-defined C string. None of the member functions throw any exceptions.

exception

class exception {
public:
    exception() throw();
    exception(const exception& rhs) throw();
    exception& operator=(const exception& rhs) throw();
    virtual ~exception() throw();
    virtual const char *what() const throw();
};

The class serves as the base class for all exceptions thrown by certain expressions and by the Standard C++ library. The C string value returned by what() is left unspecified by the default constructor, but may be defined by the constructors for certain derived classes as an implementation-defined C string. None of the member functions throw any exceptions.

terminate_handler
typedef void (*terminate_handler)();

The type describes a pointer to a function suitable for use as a terminate handler.

unexpected_handler
typedef void (*unexpected_handler)();
The type describes a pointer to a function suitable for use as an unexpected handler.

**fcntl.h**

The fcntl.h header file declares the following POSIX functions for creating, opening, rewriting, and manipulating files.

```c
_POSIX_SOURCE
creat() fcntl() open()
```

**features.h**

The features.h header file contains definitions for feature test macros. For information on feature test macros, see “Feature Test Macros” on page 21.

**fenv.h**

The fenv.h header contains the following data types, macros and functions. This header is supported under IEEE Binary Floating-Point only and is required to define the feature test macro __ISOC99_SOURCE or requires the compiler that is designed to support C99 to expose the functionality. The decimal floating-point macros, prefixed by FE_DEC_ and _FE_DEC_, are used by the fe_dec_getround and fe_dec_setround functions to get and set the rounding mode of decimal floating-point operations. Decimal floating-point functionality additionally requires the __STDC_WANT_DEC_FP__ feature test macro to be defined.

**Data types**

- `fenv_t` represents the entire floating-point environment.
- `fexcept_t` represents the floating-point status flags collectively.

**Macros**

- `FE_DIVBYZERO` defines the divide by zero exception
- `_FE_DEC_AWAYFROMZERO` rounds away from zero
- `FE_DEC_DOWNWARD` rounds towards minus infinity
- `_FE_DEC_PREPAREFORSHORTER` rounds to prepare for shorter precision
- `FE_DEC_TONEAREST` rounds to nearest
- `FE_DEC_TONEARESTFROMZERO` rounds to nearest, ties away from zero
- `_FE_DEC_TONEARESTTOWARDZERO` rounds to nearest, ties toward zero
- `FE_DEC_TOWARDZERO` rounds toward zero
FE_DEC_UPWARD rounds toward plus infinity
FE_INEXACT defines the inexact exception
FE_INVALID defines the invalid exception
FE_OVERFLOW defines the overflow exception
FE_UNDERFLOW defines the underflow exception
FE_ALL_EXCEPT defines the bitwise OR of all the exception macros.
FE_DOWNWARD rounds towards minus infinity
FE_TONEAREST rounds to nearest
FE_TOWARDZERO rounds toward zero
FE_UPWARD rounds towards plus infinity
FE_DFL_ENV defines the floating-point environment as it was available at program start up

Functions

feclearexcept() fegetenv() fegetexceptflag() fegetround() feholdexcept()
feraiseexcept() fesetenv() fesetexceptflag() fesetround() fetestexcept()
feupdateenv() fe_dec_getround() fe_dec_setround()

float.h

The float.h header file contains definitions of constants listed in ANSI 2.2.4.2.2, that describe the characteristics of the internal representations of the three floating-point data types, float, double, and long double. The definitions are:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FLT_ROUNDS</td>
<td>The rounding mode for floating-point addition.</td>
</tr>
<tr>
<td>FLT_RADIX</td>
<td>The radix for z/OS XL C applications. The FLT_RADIX value depends on the compile option FLOAT. FLOAT(HEX) gives value 16. FLOAT(IEEE) gives value 2.</td>
</tr>
<tr>
<td>FLT_MANT_DIG DBL_MANT_DIG</td>
<td>The number of hexadecimal digits stored to represent the significant of a fraction.</td>
</tr>
<tr>
<td>LDBL_MANT_DIG</td>
<td>The number of decimal digits, q, such that any floating-point number with q decimal digits can be rounded into a floating-point number with p radix FLT_RADIX digits and back again, without any change to the q decimal digits.</td>
</tr>
<tr>
<td>FLT_DIG DBL_DIG LDBL_DIG</td>
<td></td>
</tr>
</tbody>
</table>
Table 6. Definitions in float.h (continued)

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FLT_MIN_EXP</td>
<td>The minimum negative integer such that FLT_RADIX raised to that power minus 1 is a normalized floating-point number.</td>
</tr>
<tr>
<td>DBL_MIN_EXP</td>
<td>The minimum negative integer such that 10 raised to that power is in the range of normalized floating-point numbers.</td>
</tr>
<tr>
<td>LDBL_MIN_EXP</td>
<td>The maximum integer such that FLT_RADIX raised to that power minus 1 is a representable finite floating-point number.</td>
</tr>
<tr>
<td>FLT_MIN_10_EXP</td>
<td>The minimum negative integer such that 10 raised to that power is in the range of normalized floating-point numbers.</td>
</tr>
<tr>
<td>DBL_MIN_10_EXP</td>
<td>The maximum integer such that 10 raised to that power is in the range of representable finite floating-point numbers.</td>
</tr>
<tr>
<td>LDBL_MIN_10_EXP</td>
<td>The maximum integer such that 10 raised to that power is in the range of representable finite floating-point numbers.</td>
</tr>
<tr>
<td>FLT_MAX_EXP</td>
<td>The maximum integer such that FLT_RADIX raised to that power minus 1 is a representable finite floating-point number.</td>
</tr>
<tr>
<td>DBL_MAX_EXP</td>
<td>The maximum integer such that 10 raised to that power is in the range of representable finite floating-point numbers.</td>
</tr>
<tr>
<td>LDBL_MAX_EXP</td>
<td>The maximum integer such that 10 raised to that power is in the range of representable finite floating-point numbers.</td>
</tr>
<tr>
<td>FLT_MAX_10_EXP</td>
<td>The maximum integer such that 10 raised to that power is in the range of representable finite floating-point numbers.</td>
</tr>
<tr>
<td>DBL_MAX_10_EXP</td>
<td>The maximum integer such that 10 raised to that power is in the range of representable finite floating-point numbers.</td>
</tr>
<tr>
<td>LDBL_MAX_10_EXP</td>
<td>The maximum integer such that 10 raised to that power is in the range of representable finite floating-point numbers.</td>
</tr>
<tr>
<td>FLT_MAX</td>
<td>The maximum representable finite floating-point number.</td>
</tr>
<tr>
<td>DBL_MAX</td>
<td>The maximum representable finite floating-point number.</td>
</tr>
<tr>
<td>LDBL_MAX</td>
<td>The maximum representable finite floating-point number.</td>
</tr>
<tr>
<td>FLT_EPSILON</td>
<td>The difference between 1.0 and the least value greater than 1.0 that is representable in the given floating-point type.</td>
</tr>
<tr>
<td>DBL_EPSILON</td>
<td>The difference between 1.0 and the least value greater than 1.0 that is representable in the given floating-point type.</td>
</tr>
<tr>
<td>LDBL_EPSILON</td>
<td>The difference between 1.0 and the least value greater than 1.0 that is representable in the given floating-point type.</td>
</tr>
<tr>
<td>DECIMAL_DIG</td>
<td>The minimum number of decimal digits needed to represent all the significant digits for type long double.</td>
</tr>
<tr>
<td>FLT_EVAL_METHOD</td>
<td>Describes the evaluation mode for floating point operations. This value is 1, which evaluates all operations and constants of types float and double to type double and that of long double to type long double.</td>
</tr>
<tr>
<td>DEC_EVAL_METHOD</td>
<td>The decimal floating-point evaluation format.</td>
</tr>
</tbody>
</table>

The float.h header file also contains constants that describe the characteristics of the internal representations of the three decimal floating-point data types, _Decimal32, _Decimal64, and _Decimal128. The prefixes DEC32_, DEC64_, and DEC128_ are used to denote the types _Decimal32, _Decimal64, and _Decimal128, respectively.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEC32_MANT_DIG</td>
<td>The number of digits in the coefficient.</td>
</tr>
<tr>
<td>DEC64_MANT_DIG</td>
<td>The number of digits in the coefficient.</td>
</tr>
<tr>
<td>DEC128_MANT_DIG</td>
<td>The number of digits in the coefficient.</td>
</tr>
<tr>
<td>DEC32_MIN_EXP</td>
<td>The minimum exponent.</td>
</tr>
<tr>
<td>DEC64_MIN_EXP</td>
<td>The minimum exponent.</td>
</tr>
<tr>

#### fmtmsg.h

The fmtmsg.h header file contains message display structures.

#### fnmatch.h

The fnmatch.h header file contains filename matching types.

#### fpxcp.h

The fpxcp.h header file declares floating-point exception interfaces.

#### __ftp.h

The __ftp.h header file contains definitions for FTP resolver functions.

#### ftw.h

The ftw.h header file contains file tree traversal constants.

#### glob.h

The glob.h header file contains pathname pattern matching types.

#### grp.h

The grp.h header file declares functions used to access group databases.

- _POSIX_SOURCE
  - getgrgid()
  - getgrnam()
- _OPEN_SYS
  - initgroups()
  - setgroups()
 HEADER FILES

_XOPEN_SOURCE_EXTENDED 1

setgrent()  endgrent()  getgrent()

iconv.h

The iconv.h header file declares the iconv_open(), iconv(), and iconv_close() functions that deal with code conversion.

__Ieee754.h

The _Ieee754.h header file declares IEEE 754 interfaces.

ims.h

Restriction: This header file is not supported in AMODE 64.

The ims.h header file declares the ctdli() function that invokes IMS facilities. The function is *not* supported from an z/OS UNIX System Services services program running POSIX(ON).

inttypes.h

The following macros are defined in inttypes.h. Each expands to a character string literal containing a conversion specifier which can be modified by a length modifier that can be used in the *format* argument of a formatted input/output function when converting the corresponding integer type. These macros have the general form of PRI (character string literals for the fprintf() and fwprintf() family of functions) or SCN (character string literals for the fscanf() and fwsprintf() family of functions), followed by the conversion specifier, followed by a name corresponding to a similar type name in <inttypes.h>. In these names, the suffix number represents the width of the type. For example, PRIdFAST32 can be used in a format string to print the value of an integer of type int_fast32_t.

This header defines the type imaxdiv_t.

Note: Requires long long to be available.
imaxdiv_t is a structure type that is the type of the value returned by the imaxdiv() function. It is functionally equivalent to lldiv_t.

Compile requirement:

In the following list all macros with the suffix MAX or 64 require long long to be available.

<table>
<thead>
<tr>
<th>PRIi8</th>
<th>PRIi16</th>
<th>PRIi32</th>
<th>PRIi64</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

Chapter 2. Header Files  49
Example
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>
int main(void)
{
    int8_t i = 40;
    printf("Demonstrating the use of the following macros:\n");
    printf("Using PRId8, the printed value of 40 \"is \%" PRId8\"\n", i);
    printf("Using PRIiFAST8, the printed value of 40 \"is \%" PRIiFAST8\"\n", i);
    printf("Using PRIoLEAST8, the printed value of 40 \"is \%" PRIoLEAST8 \"\n", i);
    return 0;
}

Output:

Demonstrating the use of the following macros:
Using PRId8, the printed value of 40 is 40
Using PRIiFAST8, the printed value of 40 is 40
Using PRIoLEAST8, the printed value of 40 is 50

Compile requirement:

In the following list all macros with the suffix MAX or 64 require long long to be available.

Macros for printf family for unsigned integers:

<table>
<thead>
<tr>
<th>PRio8</th>
<th>PRio16</th>
<th>PRio32</th>
<th>PRio64</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>PRIxFAST8</td>
<td>PRIxFAST16</td>
<td>PRIxFAST32</td>
<td>PRIxFAST64</td>
</tr>
<tr>
<td>PRIxMAX</td>
<td>PRIxFAST8</td>
<td>PRIxFAST32</td>
<td>PRIxFAST64</td>
</tr>
<tr>
<td>PRIxPTR</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```c
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void) {
    uint32_t i = 24000;
    printf("Demonstrating the use of the following macros:\n");
    printf("Using PRIuPTR, the address of the variable "
 "is %" PRIuPTR "\n", i);
    printf("Using PRIxFAST32, the printed value of 24000 "
 "is %" PRIxFAST32 "\n", i);
    printf("Using PRIxLEAST32, the printed value of 24000 "
 "is %" PRIxLEAST32 "\n", i);
    return 0;
}
```

Output:

Demonstrating the use of the following macros:
Using PRIuPTR, the address of the variable is 538874544
Using PRIxFAST32, the printed value of 24000 is 5DC0
Using PRIxLEAST32, the printed value of 24000 is 5dc0

**Compile requirement:**

In the following list all macros with the suffix MAX or 64 require long long to be available.

Macros for fscanf family for signed integers:

<table>
<thead>
<tr>
<th>SCNd8</th>
<th>SCNd16</th>
<th>SCNd32</th>
<th>SCNd64</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCNdLEAST8</td>
<td>SCNdLEAST16</td>
<td>SCNdLEAST32</td>
<td>SCNdLEAST64</td>
</tr>
<tr>
<td>SCNdFAST8</td>
<td>SCNdFAST16</td>
<td>SCNdFAST32</td>
<td>SCNdFAST64</td>
</tr>
<tr>
<td>SCNdMAX</td>
<td>SCNdPTR</td>
<td>SCNi8</td>
<td>SCNi16</td>

<tr>
<td>SCNiLEAST8</td>
<td>SCNiLEAST16</td>
<td>SCNiLEAST32</td>
<td>SCNiLEAST64</td>
</tr>
<tr>
<td>SCNiFAST8</td>
<td>SCNiFAST16</td>
<td>SCNiFAST32</td>
<td>SCNiFAST64</td>
</tr>
<tr>
<td>SCNiMAX</td>
<td>SCNiPTR</td>
<td>SCNi8</td>
<td>SCNi16</td>
</tr>
</tbody>
</table>

Example

```c
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void) {
    int32_t i;
    printf("Enter decimal value ");
    scanf("%" SCNdFAST32, i);
    printf("Print result: %" PRIdFAST32 "\n", i);
    return 0;
}
```

Output:

Enter decimal value 23
Print result: 23
Compile requirement:

</tbody>
</table>

Example

```c
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    intmax_t i;
    printf("Enter hex value ");
    scanf("%" SCNxMAX, i);
    printf("Print result: %" PRIxMAX "\n", i);
    return 0;
}
```

Output:

Enter hex value 0x32
Print result: 00000000000000000032

**iso646.h**

The header file iso646.h allows the user to use the following macros in place of the associated operator.

<table>
<thead>
<tr>
<th>Macros</th>
<th>Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>and</td>
<td>&amp;&amp;</td>
</tr>
<tr>
<td>and_eq</td>
<td>&amp;=</td>
</tr>
<tr>
<td>bitand</td>
<td>&amp;</td>
</tr>
<tr>
<td>bitor</td>
<td></td>
</tr>
<tr>
<td>compl</td>
<td>~</td>
</tr>
<tr>
<td>not</td>
<td>!</td>
</tr>
<tr>
<td>not_eq</td>
<td>!=</td>
</tr>
</tbody>
</table>
The langinfo.h header file contains the declaration for the \texttt{nl\_langinfo()} function. The header file also defines the macros that, in turn, define constants used to identify the information queried by \texttt{nl\_langinfo()} in the current locale. The following macros are defined:

Table 7. Item Values defined in langinfo.h

<td>String for formatting time in 12-hour clock format</td>
</tr>
<tr>
<td>THOUSEP</td>
<td>Separator for thousands</td>
</tr>
<tr>
<td>YESEXPR</td>
<td>Affirmative response expression</td>
</tr>
<tr>
<td>YESSTR</td>
<td>Affirmative response string</td>
</tr>
</tbody>
</table>

**Note:**

- The YESSTR and NOSTR constants are kept for historical reasons. They were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3.

- If it is necessary to continue using these constants in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

For more information about the effect of locale, see `setlocale()`, `locale.h`, or look up the individual functions in this book. For still more information, see the chapter, “Internationalization: Locales and Character Sets” in `z/OS XL C/C++ Programming Guide`.

---

**lc_core.h**

The `lc_core.h` header file contains locale-related data structures.

**lc_sys.h**

The `lc_sys.h` header file contains definitions used by the `localedef` utility for building references to locale methods in ASCII locales.
The __le_api.h header file declares the following AMODE 64 C functions in Language Environment:

- __le_cib_get()
- __le_condition_token_build()
- __le_msg_add_insert()
- __le_msg_get()
- __le_msg_get_and_write()
- __le_msg_write()
- __le_set_debug_resume_mch()

Restrictions:

- This header is supported in AMODE 64 only. For AMODE 31, the leawi.h header file should be used.

leawi.h

Restriction: This header file is not supported in AMODE 64. For AMODE 64, the __le_api.h header file should be used.

The leawi.h header file contains internal macros. The header file is required for applications that use Language Environment Application Writer Interfaces (LE AWI).

libgen.h

The libgen.h header file contains definitions for pattern matching functions.

limits.h

The limits.h header file contains symbolic names that represent standard values for limits on resources, such as the maximum value for an object of type char.

Table 8. Definitions of Resource Limits

</tr>
</tbody>
</table>

localdef.h

The localdef.h header file defines data structures for locale objects which are loaded by setlocale(). The data structures in localdef.h are not a supported programming interface.

---

Header Files

The localdef.h header file defines data structures for locale objects which are loaded by setlocale(). The data structures in localdef.h are not a supported programming interface.
locale.h

The locale.h header file contains declarations for the localeconv() and setlocale() library functions, which retrieve values from the current locale, and for the setlocale() function, used to query or change locale settings for internationalized applications.

The locale.h file declares the `lconv` structure. Table 9 below shows the elements of the `lconv` structure and the defaults for the C locale.

### Table 9. Elements of `lconv` Structure

<table>
<thead>
<tr>
<th>Element</th>
<th>Purpose of Element</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>char *decimal_point</td>
<td>Decimal-point character used to format non-monetary quantities.</td>
<td>“.”</td>
</tr>
<tr>
<td>char *thousands_sep</td>
<td>Character used to separate groups of digits to the left of the decimal-point character in formatted non-monetary quantities.</td>
<td>“”</td>
</tr>
<tr>
<td>char *grouping</td>
<td>String indicating the size of each group of digits in formatted non-monetary quantities. The value of each character in the string determines the number of digits in a group. A value of CHAR_MAX indicates that there are no further groupings. 0 indicates that the previous element is to be used for the remainder of the digits.</td>
<td>“”</td>
</tr>
<tr>
<td>char *int_curr_symbol</td>
<td>International currency symbol for the current locale. The first three characters contain the alphabetic international currency symbol. The fourth character (usually a space) is the character used to separate the international currency symbol from the monetary quantity.</td>
<td>“”</td>
</tr>
<tr>
<td>char *currency_symbol</td>
<td>Local currency symbol of the current locale.</td>
<td>“”</td>
</tr>
<tr>
<td>char *mon_decimal_point</td>
<td>Decimal-point character used to format monetary quantities.</td>
<td>“.”</td>
</tr>
<tr>
<td>char *mon_thousands_sep</td>
<td>Separator for digits in formatted monetary quantities.</td>
<td>“”</td>
</tr>
<tr>
<td>char *mon_grouping</td>
<td>String indicating the size of each group of digits in formatted monetary quantities. The value of each character in the string determines the number of digits in a group. A value of CHAR_MAX indicates that there are no further groupings. 0 indicates that the previous element is to be used for the remainder of the digits.</td>
<td>“”</td>
</tr>
<tr>
<td>char *positive_sign</td>
<td>String indicating the positive sign used in monetary quantities.</td>
<td>“”</td>
</tr>
<tr>
<td>char *negative_sign</td>
<td>String indicating the negative sign used in monetary quantities.</td>
<td>“”</td>
</tr>
<tr>
<td>char int_frac_digits</td>
<td>The number of displayed digits to the right of the decimal place for internationally formatted monetary quantities.</td>
<td>UCHAR_MAX</td>
</tr>
<tr>
<td>char frac_digits</td>
<td>Number of digits to the right of the decimal place in monetary quantities.</td>
<td>UCHAR_MAX</td>
</tr>
</tbody>
</table>

<td>Value indicating the position of the negative_sign for a negative formatted monetary quantity. For a list of valid values, see Table 10 on page 59.</td>
<td>UCHAR_MAX</td>
</tr>
<tr>
<td>char *left_parenthesis</td>
<td>Negative-valued monetary symbol. <strong>Note:</strong> This element is an IBM-specific extension.</td>
<td>**</td>
</tr>
<tr>
<td>char *right_parenthesis</td>
<td>Negative-valued monetary symbol. <strong>Note:</strong> This element is an IBM-specific extension.</td>
<td>**</td>
</tr>
<tr>
<td>char *debit_sign</td>
<td>Debit_sign character string. <strong>Note:</strong> This element is an IBM-specific extension.</td>
<td>**</td>
</tr>
<tr>
<td>char *credit_sign</td>
<td>Credit_sign character string. <strong>Note:</strong> This element is an IBM-specific extension.</td>
<td>**</td>
</tr>
<tr>
<td>char int_p_cs_precedes</td>
<td>For international formatting, value indicating the placement of the currency symbol in a nonnegative, monetary quantity. For a list of valid values, see Table 10 on page 59.</td>
<td>UCHAR_MAX</td>
</tr>
<tr>
<td>char int_n_cs_precedes</td>
<td>For international formatting, value indicating the placement of the currency symbol in a negative, monetary quantity. For a list of valid values, see Table 10 on page 59.</td>
<td>UCHAR_MAX</td>
</tr>
<tr>
<td>char int_p_sep_by_space</td>
<td>For international formatting, value indicating the use of white space in a nonnegative, monetary quantity. For a list of valid values, see Table 10 on page 59.</td>
<td>UCHAR_MAX</td>
</tr>
<tr>
<td>char int_n_sep_by_space</td>
<td>For international formatting, value indicating the use of white space in a negative, monetary quantity. For a list of valid values, see Table 10 on page 59.</td>
<td>UCHAR_MAX</td>
</tr>
</tbody>
</table>
Table 9. Elements of iconv Structure (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Purpose of Element</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>char int_p_sign_posn</td>
<td>For international formatting, value indicating the position of the positive sign for a nonnegative monetary quantity. For a list of valid values, see Table 10.</td>
<td>UCHAR_MAX</td>
</tr>
<tr>
<td>char int_n_sign_posn</td>
<td>For international formatting, value indicating the position of the negative sign for a negative monetary quantity. For a list of valid values, see Table 10.</td>
<td>UCHAR_MAX</td>
</tr>
</tbody>
</table>

For a list of valid values, see Table 10.

Table 10. Monetary Formatting Values

<table>
<thead>
<tr>
<th>Element</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>cs_precedes</td>
<td>0  The currency_symbol succeeds the value for the formatted monetary quantity;</td>
</tr>
<tr>
<td></td>
<td>1  The currency_symbol precedes the value for the formatted monetary quantity</td>
</tr>
<tr>
<td>sep_by_space</td>
<td>0  No space separates the currency_symbol from the formatted monetary quantity;</td>
</tr>
<tr>
<td></td>
<td>1  If currency_symbol and sign string are adjacent, a space separates them from the value. Otherwise, the currency symbol and value are separated by a space.</td>
</tr>
<tr>
<td></td>
<td>2  If currency_symbol and sign string are adjacent, a space separates them from each other. Otherwise, the sign string and value are separated by a space.</td>
</tr>
<tr>
<td>sign_posn</td>
<td>0  Parentheses surround the quantity and currency_symbol;</td>
</tr>
<tr>
<td></td>
<td>1  The sign string precedes the quantity and currency_symbol;</td>
</tr>
<tr>
<td></td>
<td>2  The sign string succeeds the quantity and currency_symbol;</td>
</tr>
<tr>
<td></td>
<td>3  The sign string immediately precedes currency_symbol;</td>
</tr>
<tr>
<td></td>
<td>4  The sign string immediately succeeds currency_symbol;</td>
</tr>
<tr>
<td></td>
<td>5  Substitute debit_sign or credit_sign for negative_sign or positive_sign, respectively.</td>
</tr>
</tbody>
</table>

Note: This value is an IBM-specific extension.

The locale.h file declares the dtconv structure:

```c
struct dtconv {
    char *abbrev_month_names[12]; /* Abbreviated month names */
    char *month_names[12]; /* full month names */
    char *abbrev_day_names[7]; /* Abbreviated day names */
    char *day_names[7]; /* full day names */
    char *date_time_format; /* date and time format */
    char *date_format; /* date format */
    char *time_format; /* time format */
    char *am_string; /* AM string */
    char *pm_string; /* PM string */
    char *time_format_ampm; /* long date format */
    char *iso_std8601_2000; /* ISO 8601:2000 std date format */
};
```

Note: This structure is an IBM-specific extension.
The locale.h file also contains macro definitions for use with the setlocale() function:

<table>
<thead>
<tr>
<th>LC_ALL</th>
<th>LC_COLLATE</th>
<th>LC_CTYPE</th>
<th>LC_MONETARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>LC_NUMERIC</td>
<td>LC_TIME</td>
<td>LC_TOD</td>
<td>NULL</td>
</tr>
<tr>
<td>LC_MESSAGES</td>
<td>LC_SYNTAX</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The aspects of a program related to national language or to cultural characteristics (such as time zone, currency symbols, and sorting order of characters) can be customized at run time using different locales, to suit users' requirements at those locales. The methods for doing so are discussed in the internationalization chapter of the z/OS XL C/C++ Programming Guide.

**math.h**

The math.h header file contains function declarations for all the floating-point math functions:

No feature test macro required.

**Notes:**
- `nan()`, `nanf()`, and `nanl()` functions are supported under IEEE only.
- For the C99 math functions, it is required to define the feature test macro `_ISO_C99_SOURCE` or requires a compiler that is designed to support C99 to expose the functionality.
Special Behavior for C++

For C++ applications, each of the base functions in the following list is also overloaded for float, double, and long double. For example:

- float sqrt(float)
- double sqrt(double)
- long double sqrt(long double)

```
_XOPEN_SOURCE
erf()

_XOPEN_SOURCE_EXTENDED
acosh() asinh() atanh() cbrt() expm1()
ilogb() logb() log1p() nextafter() remainder()
rint() scalb()

__STDC_WANT_DEC_FP__
```

For C++ applications, the following functions are overloaded for _Decimal32, _Decimal64, and _Decimal128:

```

<table>
<thead>
<tr>
<th>abs()</th>
<th>ceil()</th>
<th>copysign()</th>
<th>cos()</th>
<th>exp()</th>
</tr>
</thead>
<tbody>
<tr>
<td>fabs()</td>
<td>fdim()</td>
<td>floor()</td>
<td>fmax()</td>
<td>fmin()</td>
</tr>
<tr>
<td>frexp()</td>
<td>ilogb()</td>
<td>ldexp()</td>
<td>lrint()</td>
<td>lround()</td>
</tr>
<tr>
<td>log()</td>
<td>log10()</td>
<td>logb()</td>
<td>lrint()</td>
<td>lround()</td>
</tr>
</tbody>
</table>
```

---

Chapter 2. Header Files 61
modf()  nearbyint()  nextafter()  nexttoward()  pow()
rint()  round()  scalbn()  scalbln()  sin()
sqrt()  trunc()

For example:
• _Decimal32 ceil(_Decimal32)
• _Decimal64 ceil(_Decimal64)
• _Decimal128 ceil(_Decimal128)

Object-like macros

Note: The floating point macros and the macros INFINITY and NAN are supported under IEEE only.

DEC_INFINITY
A constant expression of type _Decimal32 representing infinity.

DEC_NAN
A quiet decimal floating NaN for the type _Decimal32.

HUGE_VAL_D32
A constant expression of type _Decimal32 representing +infinity.

HUGE_VAL_D64
A constant expression of type _Decimal64 representing +infinity.

HUGE_VAL_D128
A constant expression of type _Decimal128 representing +infinity.

HUGE_VALF
A very large positive number that expands to a float expression

HUGE_VALL
A very large positive number that expands to a long double expression.

INFINITY
A constant expression of type float representing positive infinity.

NAN
A constant expression of type float representing a quiet NaN.

FP_INFINITE
The value of the macro fpclassify for an argument that is plus or minus infinity. This expands to an integer constant expression.

FP_NAN
The value of the macro fpclassify for an argument that is not-a-number (NaN). This expands to an integer constant expression.

FP_NORMAL
The value of the macro fpclassify for an argument that is finite and normalized. This expands to an integer constant expression.

FP_SUBNORMAL
The value of the macro fpclassify for an argument that is finite and denormalized. This expands to an integer constant expression.

FP_ZERO
The value of the macro fpclassify for an argument that is positive or negative. This expands to an integer constant expression.
FP_FAST_FMA
Indicates that the fma function generally executes about as fast as, or faster than, a multiply and an add of double operands.

FP_FAST_FMAF
This is the float version of FP_FAST_FMA.

FP_FAST_FMAL
This is the long double version of FP_FAST_FMA.

Note: Decimal floating-point does not support FP_FAST_FMAD32, FP_FAST_FMAD64, and FP_FAST_FMAD128.

FP_ILOGB0
The value returned by ilogb() if its argument is zero.

FP_ILOGBNAN
The value returned by ilogb() if its argument is a NaN.

MATH_ERRNO
This is defined as value 1 (one) and is used for testing the value of the macro math_errhandling to determine whether a math function reports an error by storing a nonzero value in errno.

MATH_ERREXCEPT
This is defined as value 2 and is used for testing the value of the macro math_errhandling to determine whether a math function reports an error by raising an invalid floating point exception.

math_errhandling
This macro expands to an expression that has type int and the value MATH_ERRNO, MATH_ERREXCEPT, or the bitwise OR of both. This implementation defines this macro as MATH_ERRNO.

Function-like macros

fpclassify() isfinite() isnan() isgreater() isgreaterequal()
isless() islessequal() islessgreater() isnormal() isnunordered()signbit()

The header file includes declarations for the built-in functions abs() and fabs(). For information about built-in functions, see "Built-in Functions" on page 107.

The math.h header file declares the macro HUGE_VAL, which expands to a positive double constant expression, not necessarily representable as a float. Similarly, the macros HUGE_VALF and HUGE_VALL are respectively float and long double analogs of HUGE_VAL.

For all mathematical functions, a domain error occurs when an input argument is outside the range of values allowed for that function. If a domain error occurs, errno is set to the value of EDOM.

A range error occurs if the result of the function cannot be represented in a float, double, long double, _Decimal32, _Decimal64, or _Decimal128 value. If the magnitude of the result is too large (overflow), the function returns the positive or negative value of the macro HUGE_VAL, HUGE_VALF, HUGE_VALL, HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128, as applicable, and sets errno to ERANGE. If the result is too small (underflow), the function returns 0.
float_t and double_t are floating-point types whose type depends on the value of FLT_EVAL_METHOD. FLT_EVAL_METHOD is 1 which implies both float_t and double_t are double.

Note: Decimal floating-point does not support FP_FAST_FMAD32, FP_FAST_FMAD64, and FP_FAST_FMAD128.

memory.h

The memory.h header file contains declarations for memory operations.

monetary.h

The monetary.h header file contains the declaration for the strfmon() function.

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this book. For still more information, see the chapter, “Internationalization: Locales and Character Sets” in z/OS XL C/C++ Programming Guide.

msgcat.h

The msgcat.h header file contains message catalog structures and definitions. The data structures in msgcat.h are not a supported programming interface.

mtf.h

Restriction: This header file is not supported in AMODE 64.

The mtf.h header file contains declarations for the multitasking facility (MTF) functions:

\[ \text{tinit()} \quad \text{tsched()} \quad \text{tsyncro()} \quad \text{tterm()} \]

\[ \text{tsched()} \] is a built-in function.

This header file also contains definitions of macros for certain return values from the above functions.

This header file is supported only under z/OS C applications. The functions are not supported under z/OS UNIX System Services services.

_Nascii.h

The _Nascii.h header file contains the externals for the correspondence table and functions that support bimodal application development.

ndbm.h

The ndbm.h header file contains definitions for ndbm database operations.

netdb.h

The netdb.h header file contains definitions for network database operations.
net/if.h

The net/if.h header file contains network interface structures and definitions.

net/rtroute.h

The net/rtroute.h header file contains network routing structures and definitions.

netinet/icmp6.h

The netinet/icmp6.h header file defines structures and constants for ICMPv6 header options.

The following structures are exposed with this header file:
- icmp6_hdr
- nd_router_solicit
- nd_router_advert
- nd_neighbor_solicit
- nd_neighbor_advert
- nd_redirect
- nd_opt_hdr
- nd_opt_prefix_info
- nd_opt_rd_hdr
- nd_opt_mtu
- mld_hdr
- icmp6_router_renum
- rr_pco_match
- rr_pco_use
- rr_result

The following definitions are associated with the icmp6_hdr structure:
- icmp6_data32
- icmp6_data16
- icmp6_data8
- icmp6_pptr
- icmp6_mtu
- icmp6_id
- icmp6_seq
- icmp6_maxdelay

The following definitions are associated with ICMPv6 Type and Code values:
- ICMP6_DST_UNREACH
- ICMP6_PACKET_TOO_BIG
- ICMP6_TIME_EXCEEDED
- ICMP6_PARAM_PROB
- ICMP6_INFOMSG_MASK
- ICMP6_ECHO_REQUEST
- ICMP6_ECHO_REPLY
The following definitions are associated with the nd_router_solicit structure:
- ND_ROUTER_SOLICIT
  - nd_rs_type
  - nd_rs_code
  - nd_rs_cksum
  - nd_rs_reserved

The following definitions are associated with the nd_router_advert structure:
- ND_ROUTER_ADVERT
  - nd_ra_type
  - nd_ra_code
  - nd_ra_cksum
  - nd_ra_curhoplimit
  - nd_ra_flags_reserved
  - ND_RA_FLAG_MANAGED
  - ND_RA_FLAG_OTHER
  - nd_ra_router_lifetime

The following definitions are associated with the nd_neighbor_solicit structure:
- ND_NEIGHBOR_SOLICIT
  - nd_ns_type
  - nd_ns_code
  - nd_ns_cksum
  - nd_ns_reserved

The following definitions are associated with the nd_neighbor_advert structure:
- ND_NEIGHBOR_ADVERT
  - nd_na_type
  - nd_na_code
  - nd_na_cksum
  - nd_na_flags_reserved
  - ND_NA_FLAG_ROUTER
  - ND_NA_FLAG_SOLICITED
  - ND_NA_FLAG_OVERRIDE

The following definitions are associated with the nd_redirect structure:
The following definitions are associated with the nd_opt_hdr structure:
- ND_OPT_SRC_LINKADDR
- ND_OPT_TGT_LINKADDR
- ND_OPT_PREFIX_INFORMATION
- ND_OPT_REDIRECTED_HEADER
- ND_OPT_MTU

The following definitions are associated with nd_opt_prefix_info structure:
- ND_OPT_PI_FLAG_ONLINK
- ND_OPT_PI_FLAG_AUTO

The following definitions are associated with the mld_hdr structure:
- MLD_LISTENER_QUERY
- MLD_LISTENER_REPORT
- MLD_LISTENER_REDUCTION
  - mld_type
  - mld_code
  - mld_cksum
  - mld_maxdelay
  - mld_reserved

The following definitions are associated with the icmp6_router_renum structure:
- ICMP6_ROUTER_RENUMBERING
  - rr_type
  - rr_code
  - rr_cksum
  - rr_seqnum
  - ICMP6_RR_FLAGS_TEST
  - ICMP6_RR_FLAGS_REQRESULT
  - ICMP6_RR_FLAGS_FORCEAPPLY
  - ICMP6_RR_FLAGS_SPECSITE
  - ICMP6_RR_FLAGS_PREVDONE

The following definitions are associated with the rr_pco_match structure:
- RPM_PCO_ADD
- RPM_PCO_CHANGE
- RPM_PCO_SETGLOBAL

The following definitions are associated with the rr_pco_use structure:
- ICMP6_RR_PCOUSE_RAFLAGS_ONLINK
- ICMP6_RR_PCOUSE_RAFLAGS_AUTO
The following definitions are associated with the rr_result structure:
- ICMP6_RR_RESULT_FLAGS_OOB
- ICMP6_RR_RESULT_FLAGS_FORBIDDEN

**netinet/in.h**

The netinet/in.h header file contains definitions for the internet protocol family.

The following structure definition is supported for IPv6:
- struct ip6_mtuinfo{};

The following functions are supported for IPv6:
- inet6_rth_space()
- inet6_rth_init()
- inet6_rth_add()
- inet6_rth_reverse()
- inet6_rth_segments()
- inet6_rth_getaddr()
- inet6_opt_init()
- inet6_opt_append()
- inet6_opt_finish()
- inet6_opt_set_val()
- inet6_opt_next()
- inet6_opt_find()
- inet6_opt_get_val()

The following macros are supported for IPv6:
- IN6_IS_ADDR_LINKLOCAL
- IN6_IS_ADDR_LOOPBACK
- IN6_IS_ADDR_MC_GLOBAL
- IN6_IS_ADDR_MC_LINKLOCAL
- IN6_IS_ADDR_MC_NODELOCAL
- IN6_IS_ADDR_MC_ORGLOCAL
- IN6_IS_ADDR_MC_SITELOCAL
- IN6_IS_ADDR_MULTICAST
- IN6_IS_ADDR_SITELOCAL
- IN6_IS_ADDR_UNSPECIFIED
- IN6_IS_ADDR_V4COMPAT
- IN6_IS_ADDR_V4MAPPED

**Structures:**

```c
struct ip_mreq{
    struct in_addr imr_multiaddr;
    struct in_addr imr_interface;
};
```

**Socket options:**
Multicast filter support is accessed by defining feature test macro
\_OPEN_SYS_SOCKET_EXT3. The feature test also exposes symbols in
sys/socket.h

- `setipv4sourcefilter()`
- `getipv4sourcefilter()`
- `setsourcefilter()`
- `getsourcefilter()`

**Structure:**

Multicast filter support is accessed by defining feature test macro
\_OPEN_SYS_SOCKET_EXT3. The feature test also exposes symbols in
sys/socket.h

```
struct ip_mreq{}
struct ip_mreq_source{}
struct group_req{}
struct group_source_req{}
```

**netinet/ip6.h**

The netinet/ip6.h header file defines structures and constants for IPv6 header options.

The following structures are exposed with this header file:
- `ip6_hdr`
- `ip6_hbh`
- `ip6_dest`
- `ip6_rthdr`
- `ip6_rthdr0`
- `ip6_frag`
- `ip6_opt`
- `ip6_opt_jumbo`
- `ip6_opt_nsap`
- `ip6_opt_tunnel`
- `ip6_opt_router`

The following definitions are associated with the `ip6_hdr` structure:
- `ip6_vcf`
- `ip6_flow`
- `ip6_plen`
- `ip6_nxt`
The following definitions are associated with the extension header structure:
- IP6F_OFF_MASK
- IP6F_RESERVED_MASK
- IP6F_MORE_FRAG

The following definitions are associated with the option header structure:
- IP6OPT_TYPE
- IP6OPT_TYPE_SKIP
- IP6OPT_TYPE_DISCARD
- IP6OPT_TYPE_FORCEICMP
- IP6OPT_TYPE_ICMP
- IP6OPT_MUTABLE
- IP6OPT_PAD1
- IP6OPT_PADN
- IP6OPT_JUMBO
- IP6OPT_NSAP_ADDR
- IP6OPT_TUNNEL_LIMIT
- IP6OPT_ROUTER_ALERT
- IP6OPT_JUMBO_LEN
- IP6_ALERT_MLD
- IP6_ALERT_RSVP
- IP6_ALERT_AN

**netinet/tcp.h**

The netinet/tcp.h header contains definitions for the Internet Transmission Control Protocol (TCP).

**new**

The <new> header file defines several types and functions that control allocation and freeing of storage under program control.

Some of the functions declared in this header are replaceable. The implementation supplies a default version. A program can, however, define a function with the same signature to replace the default version at link time. The replacement version must satisfy the requirements of the function.

```c
namespace std {
    typedef void (*new_handler)();
    class bad_alloc;
    class nothrow_t;
    extern const noexcept nothrow_t noexcept;
    // FUNCTIONS
    new_handler set_new_handler(new_handler ph) throw();
};
// OPERATORS
void operator delete(void *p) throw();
```
void operator delete(void *, void *) throw();
void operator delete(void *p, const std::nothrow_t&) throw();
void operator delete[](void *p) throw();
void operator delete[](void *, void *) throw();
void operator delete[](void *p, const std::nothrow_t&) throw();
void *operator new(std::size_t n) throw(std::bad_alloc);
void *operator new(std::size_t n, const std::nothrow_t&) throw();
void *operator new[](std::size_t n, void *p) throw();
void *operator new[](std::size_t n) throw(std::bad_alloc);
void *operator new[](std::size_t n, const std::nothrow_t&) throw();
void *operator new[](std::size_t n, void *p) throw();

The <new> header file supercedes the new.h header, which remains for compatibility as a wrapper to <new>.

bad_alloc
class bad_alloc : public exception {
  
};
The class describes an exception thrown to indicate that an allocation request did not succeed. The value returned by what() is an implementation-defined C string. None of the member functions throw any exceptions.

ewline_handler
typedef void (*new_handler)();
The type points to a function suitable for use as a new handler.

nothrow
extern const noexcept_t noexcept;
The object is used as a function argument to match the parameter type noexcept_t.

nothrow_t
class noexcept_t {};
The class is used as a function parameter to operator new to indicate that the function should return a null pointer to report an allocation failure, rather than throw an exception.

new.h

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header <new>. However, new.h remains for compatibility as a wrapper for TARGET releases of z/OS V1R2 and later.

For compilations with a TARGET release before z/OS V1R2, the new.h header file declares the set_new_handler() function, which is used for z/OS C++ exception handling (try, throw, and catch). This header file also declares array and non-array version of the allocation operator new and the deallocation operator delete.

nlist.h

The nlist.h header file declares the nlist() function.
Header Files

**nl_types.h**

The `nl_types.h` header file defines the following types:

- **nl_item** int used as manifest constant by `nl_langinfo()`
- **nl_catd** pointer to a catalog descriptor structure

The header also contains these constants:

- **NL_SETD**
- **NL_CAT_LOCALE**

The following functions are prototyped:

- `catclose()`
- `catgets()`
- `catopen()`

No feature test macro is required for `nl_item`.

To expose the other definitions in this header, compile with the `_XOPEN_SOURCE` feature test macro defined.

For more information about the effect of locale, see `setlocale()`, `locale.h`, or look up the individual functions in this book. For still more information, see the chapter, “Internationalization: Locales and Character Sets” in [Z/OS XL C/C++ Programming Guide](https://www.ibm.com/support/knowledgecenter/en/SSLTBW_2.2.0/com.ibm.zos.r19d.ibm_zos_cReturnedFrom.html).

**poll.h**

The `poll.h` header file contains definitions for the `poll()` function.

**pthread.h**

The `pthread.h` header file contains function declarations and mappings for threading interfaces and defines a number of constants used by those functions. The header includes the `sched.h` header. When `_UNIX03_THREADS` is defined, `pthread.h` also includes the `time.h` header. For `_OPEN_THREADS` applications, `pthread.h` defines the `timespec` structure.

There is a lot of overlap in the namespaces identified by the `_OPEN_THREADS` and `_UNIX03_THREADS` feature test macros. There are, however, behavioral differences between functions of the same name exposed by `_OPEN_THREADS` (POSIX.4a Draft 6) and by `_UNIX03_THREADS` (Single UNIX Specification, Version 3). See the individual function descriptions for specific details.

- **_OPEN_THREADS 1**
  - `pthread_attr_destroy()`
  - `pthread_attr_getdetachstate()`
  - `pthread_attr_getinitstate()`
  - `pthread_attr_init()`
  - `pthread_attr_setdetachstate()`
  - `pthread_attr_setstacksize()`
  - `pthread_cancel()`
  - `pthread_cleanup_pop()`
  - `pthread_cleanup_push()`
  - `pthread_condattr_destroy()`
  - `pthread_condattr_init()`
  - `pthread_cond_broadcast()`
  - `pthread_cond_destroy()`
  - `pthread_cond_init()`
  - `pthread_cond_signal()`
  - `pthread_cond_timedwait()`
  - `pthread_cond_wait()`
  - `pthread_create()`

The pthread.h header defines the following constants:

```c
__COND_DEFAULT
__COND_NODEBUG
__DETACHED
__HEAVY_WEIGHT
__MEDIUM_WEIGHT
__MUTEX_NODEBUG
__MUTEX_NONRECURSIVE
__MUTEX_RECURSIVE
__UNDETACHED
NO_PRIO_INHERIT

PTHREAD_CANCEL_ASYNCHRONOUS
PTHREAD_CANCEL_DEFERRED
PTHREAD_CANCEL_DISABLE
PTHREAD_CANCEL_ENABLE
PTHREAD_CANCELED
PTHREAD_COND_INITIALIZER
PTHREAD_CREATE_DETACHED
PTHREAD_CREATE_JOINABLE
PTHREAD_EXPLICIT_SCHED
PTHREAD_INHERIT_SCHED

_OPEN_SYS

pthread_attr_getsynctype_np()
pthread_attr_getweight_np()
pthread_attr_setsynctype_np()
pthread_attr_setweight_np()
pthread_condattr_getkind_np()
pthread_condattr_setkind_np()
pthread_join_d4_np()
pthread_mutexattr_getkind_np()
pthread_mutexattr_setkind_np()
pthread_security_np()
pthread_tag_np()

_OPEN_SYS_MUTEX_EXT

pthread_condattr_getpshared()
pthread_condattr_setpshared()
Furthermore, pthread.h defines these macros:

- PTHREAD_MUTEX_DEFAULT
- PTHREAD_MUTEX_ERRORCHECK
- PTHREAD_MUTEX_NORMAL
- PTHREAD_MUTEX_INITIALIZER
- PTHREAD_MUTEX_RECURSIVE
- PTHREAD_RWLOCK_INITIALIZER
- __THDQ_LENGTH
- _OPEN_THREADS 2
- PTHREAD_CANCEL_ENABLE
- PTHREAD_CANCEL_DISABLE
- PTHREAD_CANCEL_DEFERRED
- PTHREAD_CANCEL_ASYNCHRONOUS

**pwd.h**

The pwd.h header file declares functions that access the user database through a password structure. The header file also defines the passwd structure.

- _POSIX_SOURCE
  - getpwnam()
  - getpwuid()
- _XOPEN_SOURCE_EXTENDED 1
  - endpwent()
  - getpwent()
  - setpwent()

**re_comp.h**

The re_comp.h header file contains regular expression matching functions for re_comp().

**Note:**

This header is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use regcomp(), regexec(), regerror() and regfree() functions and the header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions.

Applications conforming to Single UNIX Specification, Version 3 must not include the <re_comp.h> header file.
regex.h

The regex.h header file contains definitions for the following regular expression functions.

regcomp()  regerror()  regexec()  regfree()

The regex.h header file declares the regex_t type, which can store a compiled regular expression.

The regex.h header file declares the following macros:

- Values of the cflags parameter of the regcomp() function: REG_EXTENDED, REG_ICASE, REG_NEWLINE, REG_NOSUB
- Values of the subflags parameter of the regexec() function: REG_NOTBOL, REG_NOTEOL
- Values of the errcode parameter of the regerror() function: REG_*.

regexp.h

The regexp.h header file contains regular expression declarations.

Note:

This header is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use regcomp(), regexec(), regerror() and regfree() functions and the header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions.

Applications conforming to Single UNIX Specification, Version 3 must not include the <regexp.h> header file.

resolv.h

The resolv.h header file contains the __res_state structure and the definitions to support the IP Address Resolution functions commonly called the Resolver. It contains the prototypes for the following functions — dn_comp(), dn_expand(), dn_find(), dn_skipname(), res_init(), res_mkquery(), res_query(), res_querydomain(), res_search(), and res_send() — which are used to communicate with a Domain Name Server (DNS).

rexec.h

The rexec.h header file declares the rexec() and rexec_af() functions.

sched.h

The sched.h header file declares functions to manipulate and examine process execution scheduling.

_UNIXX03_SOURCE

sched_yield()
When compiled with SUSV3 thread support (_UNIX03_THREADS or _XOPEN_SOURCE 600), sched.h defines the following symbols:

| SCHED_FIFO | SCHED_OTHER | SCHED_RR |

and the sched_param structure.

search.h

The search.h header file contains definitions for searching tables.

setjmp.h

The setjmp.h header file contains function declarations for longjmp() and setjmp(), which use the system stack to affect the program state. It also defines one buffer type, jmp_buf, that the setjmp() and longjmp() functions use to save and restore the program state.

_POSIX_SOURCE

setjmp.h declares functions siglongjmp() and sigsetjmp() and defines a buffer type sigjmp_buf used by siglongjmp() and sigsetjmp().

_XOPEN_SOURCE_EXTENDED 1

setjmp.h declares the functions _longjmp() and _setjmp(). See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information about using POSIX support.

signal.h

The signal.h header file defines the following values.

- Functions:
  - raise()
  - signal()

- Macros:
  - SIG_DFL
  - SIG_ERR
  - SIG_IGN
  - SIG_PROMOTE

- Signals:
  - SIGABND
  - SIGABRT
  - SIGFPE
  - SIGILL
  - SIGINT
  - SIGIOERR
  - SIGSEGV
  - SIGTERM
  - SIGUSR1
  - SIGUSR2

- The type sig_atomic_t, which is the largest integer type the processor can load or store automatically in the presence of asynchronous interrupts.

The following functions are supported only in a POSIX program. You must specify the POSIX(ON) run-time option for these functions. See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information.

- kill()
- sigaction()
- __sigactionset()
- sigaddset()
- sigdelset()
- sigemptyset()
- sigfillset()
- sigismember()
- siglongjmp()
- sigpending()
The following values are available in z/OS UNIX System Services services only:

- **Signals:**

  | SIGALRM | SIGCHLD | SIGCONT | SIGHUP | SIGKILL |
  | SIGPIPE | SIGQUIT | SIGSTOP | SIGTSTP | SIGIO   |
  | SIGTTOU | SIGTTIN | SIGCLD  | SIGDCE  | SIGCLD  |

- The structures `sigaction`, `__sigactionset_t`, `__sigactionset_s`, `sigset_t`, and `pid_t`.
- **options** arguments for `sigprocmask()`: SIG_BLOCK, SIG_UNBLOCK, and SIG_SETMASK.
- Flags for the `sa_flags` field, available in z/OS UNIX System Services services only: SA_NOCLDSTOP and _SA_OLD_STYLE.

**_XOPEN_SOURCE_EXTENDED 1:**

- **Signals:**

  | SIGBUS | SIGPOLL | SIGPROF | SISYS | SIGURG |
  | SIGXCPU | SIGXFSSZ | SIGVTALRM | SIGWINCH | SIGWINCH |

- **Functions:**

  | bsd_signal() | killpg() | sigaltstack() | sighold() | sigignore() |
  | siginterrupt() | sigpause() | sigrealse() | sigset() | sigstack() |

*Note:* `bsd_signal()` has been marked obsolescent in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `sigaction()` function is preferred for portability.

**_OPEN_THREADS 2:**

- **Functions:**

  | pthread_sigmask() |

**_UNIX03_THREADS:**

- **Functions:**

  | pthread_kill() |

---

**spawn.h**

The `spawn.h` header file contains `spawn()` constants and inheritance structure.

---

**spc.h**

**Restriction:** This header file is not supported in AMODE 64.

This header file is supported only for z/OS C applications.

The `spc.h` header file contains declarations for the functions available in the system programming environment, as described in "using the System Programming C..."
The functions are:

- edcxregs
- edcxusr
- edcxusr2
- __xhotc()
- __xhotl()
- __xhott()
- __xhotu()
- __xregs()
- __xsacc()
- __xsrvc()
- __xusr()
- __xusr2()
- __24malc()
- __4kmalc()

The spc.h header file also declares these functions, used for the allocation of storage and writing of strings, (which are described in Chapter 3, “Part 3. Library Functions”)

- calloc()
- free()
- malloc()
- realloc()
- sprintf()

### stdarg.h

The stdarg.h header file defines macros used to access arguments in functions with variable-length argument lists:

- va_arg()
- va_copy()
- va_start()
- va_end()

The stdarg.h header file also defines the structure va_list.

### stdbool.h

The <stdbool.h> header defines the following macros:

- bool expands to _Bool
- __bool_true_false_are_defined expands to 1
- false expands to 0
- true expands to 1

Restriction: This header is not supported for C++ applications.

### stddef.h

The stddef.h header file contains definitions of the commonly used pointers, variables, and types, from the typedef statements, as listed below:

- ptdiff_t
  The signed long type of the result of subtracting two pointers.

- size_t
  typedef for the type of the value returned by sizeof.

- wchar_t
  typedef for a wide-character constant.

stddef.h defines the macros NULL and offsetof. NULL is a pointer that never points to a data object. The offsetof macro expands to the number of bytes between a structure member and the start of the structure. The offsetof macro has the form offsetof(structure_type, member)
The stddef.h header file contains the same information as found in `<stddef.h>`.

The stdint.h header defines integer types, limits of specified width integer types, limits of other integer types and macros for integer constant expressions.

**Note:** For the exact width integer types, minimum width integer types and limits of specified width integer types we support bit sizes $N$ with the values 8, 16, 32, and 64.

The following exact width integer types are defined.
- int$N_t$
- uint$N_t$

The following minimum-width integer types are defined.
- int_least$N_t$
- uint_least$N_t$

The following fastest minimum-width integer types are defined. These types are the fastest to operate with among all integer types that have at least the specified width.
- int_fast$N_t$
- uint_fast$N_t$

The following greatest-width integer types are defined. These types hold the value of any signed/unsigned integer type.

**Note:** Requires long long to be available.
- intmax_t
- uintmax_t

The following integer types capable of holding object pointers are defined.
- intptr_t
- uintptr_t

**Object-like macros for limits of integer types**

**Note:** For the exact width integer limits, minimum width integer limits and limits of specified width integer types we support bit sizes $N$ with the values 8, 16, 32, and 64.

Macros for limits of exact width integer types.
- INT$N$_MAX
- INT$N$_MIN
- UINT$N$_MAX

Macros for limits of minimum width integer types.
- INT_LEAST$N$_MAX
- INT_LEAST$N$_MIN
• UINT_LEAST\_MAX

Macros for limits of fastest minimum width integer types,
• INT\_FAST\_MAX
• INT\_FAST\_MIN
• UINT\_FAST\_MAX

Macros for limits of greatest width integer types.

**Note:** Requires long long to be available.
• INTMAX\_MAX
• INTMAX\_MIN
• UINTMAX\_MAX

Macros for limits of pointer integer types.
• INTPTR\_MAX
• INTPTR\_MIN
• UINTPTR\_MAX

Macros for limits of ptrdiff_t.
• PTDIFF\_MAX
• PTDIFF\_MIN

Macros for limits of sig\_atomic\_t.
• SIG\_ATOMIC\_MAX
• SIG\_ATOMIC\_MIN

Macro for limit of size\_t.
• SIZE\_MAX

Macros for limits of wchar\_t.
• WCHAR\_MAX
• WCHAR\_MIN

Macros for limits of wint\_t.
• WINT\_MAX
• WINT\_MIN

**Function-like macros for integer constants**

**Note:** For the following macro for minimum width integer constants, we support *bit sizes* \(N\) with the values 8, 16, 32, and 64.

Macros for minimum width integer constants.
• INTN\_C(value)
• UINTN\_C(value)

Example:
```c
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>
```
int main(void)
{
    uint32_t a = UINT32_C(1234);
    printf("%u\n", a);
}

Output
1234

Here is an example of how the compiler expands the macro

```
+ uint32_t a = 1234U;
```

Macros for greatest width integer constants

**Note:** Requires long long to be available.
- INTMAX_C(value)
- UINTMAX_C(value)

Example:

```c
/* long long required */
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    intmax_t a = INTMAX_C(45268724);
    printf("%jd\n", a);
}

Output
45268724
```

Here is an example of how the compiler expands the macro with the LP64 compiler option:

```
+ intmax_t a = 45268724L;
```

Otherwise the compiler expands to:

```
+ intmax_t a = 45268724LL;
```

### stdio.h

The stdio.h header file declares functions that deal with standard input and output. One of these functions, fdopen(), is supported only in a POSIX program. See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information.

The stdio.h header file also declares these functions:

- clearerr()
- clrmemf()
- fclose()
- fdelrec()
- feof()
Defined Types in stdio.h

The FILE type is defined in stdio.h. Stream functions use a pointer to the FILE type to get access to a given stream. The system uses the information in the FILE structure to maintain the stream. The C standard streams stdin, stdout, and stderr are also defined in stdio.h.

The type fpos_t is defined in stdio.h for use with fgetpos() and fsetpos().

The types __S99parms, __S99rbx_t, and __S99emparms_t are defined in stdio.h for use with the svc99() function.

The type fldata_t is defined in stdio.h for use with the fldata() function.

The types __amrc_type and __amrc2_type are defined in stdio.h for use in determining error information when I/O functions fail.

Macros Defined in stdio.h

You can use these macros as constants in your programs, but you should not alter their values.

BUFSIZ Specifies the buffer size to be used by the setbuf() library function when you are allocating buffers for stream I/O. This value is the expected size of the user’s buffer supplied to setbuf(). If a larger buffer is required, for example, if blocksize is larger than BUFSIZ, or if special buffer attributes are required, z/OS XL C/C++ applications will not use the user’s buffer.

EOF The value returned by an I/O function when the End Of File (EOF) (or in some cases, an error) is found.

FOPEN_MAX The maximum number of files that can be open simultaneously.

FILENAME_MAX The maximum number of characters in a filename. Can be used in the size specification of an array (for example, to hold the filename returned by fldata()).

L_tmpnam The size of the longest temporary name that can be generated by the tmpnam() function.

L_ctermid Maximum size of a character array for ctermid() output. This macro is supported only in a POSIX program. See z/OS XL C/C++ applications with z/OS UNIX System Services C functions on page 13 for more information.

NULL A pointer which never points to a data object.

TMP_MAX The maximum number of unique file names that can be generated by the tmpnam() function.
The macros SEEK_CUR, SEEK_END, and SEEK_SET expand to integral constant expressions and can be used as the third argument to fseek().

The macros _IOFBF, _IOLBF, and _IONBF expand to integral constant expressions with distinct values suitable for use as the third argument to setvbuf() function.

The following macros expand to integer constant expressions suitable for interpreting values returned by fldata(), in the fldata_t structure.

__APPEND  __BINARY  __DISK  __DUMMY  __ESDS  __ESDS_PATH  __DISK  __ESDS  __DISK  __ESDS
__KSDS  __KSDS_PATH  __MEMORY  __HIPERSPACE  __NORLS  __NOTVSAM  __OTHER  __PRINTER  __READ  __RECORD  __RBA_EQ  __RBA_EQ_BWD  __TAPE  __TDQ  __TERMINAL  __TEXT  __UPDATE  __WRITE

The following macros expand to integer constant expressions suitable for use as the fourth argument to the flocate() function.

__KEY_EQ  __KEY_EQ_BWD  __KEY_FIRST  __KEY_GE  __KEY_LAST  __RBA_EQ  __RBA_EQ_BWD

The following macros expand to integer constant expressions suitable for use as the argument to the function clrmemf().

__CURRENT  __CURRENT_LOWER  __LOWER

The following macros expand to integer constant expressions suitable for use to determine the last operation reported in the __amrc_type structure. All these macros are described in z/OS XL C/C++ Programming Guide.

__BSAM_BLDL  __BSAM_CLOSE  __BSAM_CLOSE_T  __BSAM_POINT  __CANNOT_EXTEND  __CDBC_SI_TRUNCATE  __CDBC_SO_TRUNCATE  __CBCHECK  __CELMMSGF_WRITE  __CELMSGF_WRITE  __CICS_WRITEQ_TD  __HSP_CREATE  __HSP_DELETE  __HSP_EXTEND  __HSP_READ  __INTERCEPT_READ  __IO_CATALOG  __IO_DEVTYPE  __IO_INIT  __IO_LOCATE  __IO_OBTAIN  __IO_RDJFCB  __IO_RENAME  __IO_SCRATCH  __IO_TRKCALC  __IO_UNCATALOG  __LFS_CLOSE  __LFS_FSTAT  __LFS_LSEEK  __LFS_OPEN  __LFS_READ  __NOSEEK_REWIND  __OS_CLOSE  __OS_OPEN  __QSAM_FREEPOOL  __QSAM_GET  __QSAM_PUT  __QSAM_RELSE  __QSAM_TRUNC  __SVC99_ALLOC  __SVC99_ALLOC_NEW  __SVC99_UNALLOC  __TGET_READ  __TPUT_WRITE  __VSAM_CLOSE  __VSAM_ENDREQ  __VSAM_ERASE  __VSAM_GENCB  __VSAM_GET  __VSAM_MODCB  __VSAM_OPEN_ESDS  __VSAM_OPEN_KSDS  __VSAM_OPEN_ESDS_PATH  __VSAM_OPEN_KSDS_PATH  __VSAM_OPEN_FAIL  __VSAM_OPEN_RRDS
The stdlib.h header file contains declarations for the following functions:

- **abort()**
- **abs()**[^1][^3]
- **alloca()**[^1]
- **atexit()**
- **atof()**
- **atoi()**
- **atol()**
- **bsearch()**
- **calloc()**
- **cds()**[^1]
- **clearenv()**
- **cs()**[^1]
- **csid()**
- **div()**[^3]
- **exit()**
- **fetch()**[^2]
- **fetchep()**[^2]
- **free()**
- **getenv()**
- **getenv()**
- **labs()**
- **ldiv()**
- **llabs()**
- **lldiv()**
- **__librel()**
- **malloc()**
- **mblen()**
- **mbstowcs()**
- **mbtowc()**
- **qsort()**
- **rand()**
- **realloc()**
- **release()**[^2]
- **rpmatch()**
- **setenv()**
- **srand()**
- **system()**
- **unatexit()**
- **wcsid()**
- **wcstombs()**
- **wctomb()**
- **strto32()**[^4]
- **strto64()**[^4]
- **strtol()**
- **strtol()**
- **strtoll()**
- **strtoul()**
- **strtoull()**
- **system()**
- **strtod128()**[^4]

[^1]: Built-in function.
[^2]: Not supported under C++ applications.
[^3]: Special Behavior for C++: For C++ applications, the functions abs() and div() are also overloaded for the type long.
[^4]: The __STDC_WANT_DEC_FP__ feature test macro is required to expose decimal floating-point functionality.

Two type definitions are added to stdlib.h for the Compare and Swap functions cs() and cds(). The structures defined are __cs_t and __cds_t.

The type size_t is declared in the header file. It is used for the type of the value returned by sizeof. The type wchar_t is declared and used for a wide character constant. For more information on the types size_t and wchar_t, see "stddef.h" on page 79.

The stdlib.h declares div_t and ldiv_t, which define the structure types that are returned by div() and ldiv().

The stdlib.h file also contains definitions for the following macros:

- **NULL**
  The NULL pointer constant (also defined in stddef.h).
- **EXIT_SUCCESS**
  Used by the atexit() function.
- **EXIT_FAILURE**
  Used by the atexit() function.
- **RAND_MAX**
  Expands to an integer representing the largest number that the RAND function can return.
- **MB_CUR_MAX**
  Expands to an integer representing the maximum...
number of bytes in a multibyte character. This value is dependent on the current locale.

If MB_CUR_MAX is set to 1, multibyte functions will behave as if all multibyte characters are one byte long; wide-character functions are not supported and full DBCS support is not provided. If MB_CUR_MAX is 4, all DBCS support provided by the library is enabled.

string.h

The string.h header file declares the string manipulation functions and their built-in versions:

No feature test macro required.

memchr()[1]  memcmp()[1]  memcpy()[1]  memmove()  memset()[1]
strcat()[1]  strchr()[1]  strcmp()[1]  strcoll()  strcpy()[1]
strcsn()  sterr()  strlen()[1]  strncat()[1]  strncmp()[1]
strncpy()[1]  strpbrk()  strrt()  strspn()  strstr()
strtok()  strxfrm()

_UNIX03_SOURCE

sterror_r

_XOPEN_SOURCE

memccpy()

_XOPEN_SOURCE_EXTENDED 1

strdup()

The string.h header file also defines the macro NULL and the type size_t. For more information see “stddef.h” on page 79.

strings.h

The strings.h header file contains definitions for string operations.

stropts.h

The stropts.h header file declares the following functions:

fattach()  fdetach()  getmsg()  getpmsg()
ioctl()  isastream()  putmsg()  putpmsg()
syslog.h

The syslog.h header file contains definitions for system error logging.

sys/acl.h

The sys/acl.h header enables users to manipulate ACLs. It also declares the following functions:

- acl_create_entry()
- acl_delete_entry()
- acl_delete_fd()
- acl_delete_file()
- acl_first_entry()
- acl_free()
- acl_from_text()
- acl_init()
- acl_get_entry()
- acl_get_fd()
- acl_get_file()
- acl_get_fd()
- acl_get_file()
- acl_init()
- acl_to_text()
- acl_update_entry()

sys/__cpl.h

The sys/__cpl.h header contains definition for the __cpl() function. It also defines the following constants:

<table>
<thead>
<tr>
<th>Symbolic Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPL_QUERY</td>
<td>Request data from available Coupling Facilities</td>
</tr>
<tr>
<td>CPL_CFSIZER</td>
<td>Request a structure size</td>
</tr>
<tr>
<td>CPL_CFSIZER_W_LVL</td>
<td>Request a structure size with the level of the CF</td>
</tr>
</tbody>
</table>

sys/file.h

The sys/file.h header file defines file manipulation constants.

sys/__getipc.h

The sys/__getipc.h header file contains definitions to get interprocess communication information.

sys/ioctl.h

The sys/ioctl.h header file contains system I/O definitions and structures.

sys/ipc.h

The sys/ipc.h header file contains definitions for the interprocess communication access structure.

sys/layout.h

The sys/layout.h header file contains declarations for supporting bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

sys/mman.h

The sys/mman.h header file contains memory management declarations.
sys/__messag.h

The sys/__messag.h header file contains definitions for the __console() function.

sys/mntent.h

This header file is supported only in an _OPEN_SYS program. See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information.

The sys/mntent.h header file declares the w_getmntent() function and it defines the structures mnte2 and w_mntent, along with some related constants.

sys/modes.h

The sys/modes.h header file contains several macro definitions:
- Defined constant masks and bits for values of type mode_t, such as the st_mode field of the stat struct
- A defined constant mask for the st_genvalue field of the stat struct
- Function-like macros for testing values of the st_mode field of the stat struct.

Under z/OS XL C support, these definitions are included in sys/stat.h to make sys/stat.h conform with POSIX.

sys/msg.h

The sys/msg.h header file contains definitions for message queue structures.

sys/ps.h

The sys/ps.h header file declares the w_getpsent() function that provides process data and defines the structure w_pspoc along with some related constants.

It requires the _OPEN_SOURCE 1 feature test macro.

sys/resource.h

The sys/resource.h header file contains definitions for XSI resource operations, including declarations, constants, and structures used by the following functions:
- getpriority()
- getrlimit()
- getrusage()
- setpriority()
- setrlimit()

sys/select.h

The sys/select.h header file contains definitions for select types.

sys/sem.h

The sys/sem.h header file contains definitions for the semaphore facility.
**sys/server.h**

The sys/server.h header file contains definitions for using WorkLoad Manager services.

**sys/shm.h**

The sys/shm.h header file contains definitions for the shared memory facility.

**sys/socket.h**

The sys/socket.h header file contains sockets definitions.

The structure sockaddr_storage is exposed by defining the feature test macro _OPEN_SYS_SOCK_IPV6 or _OPEN_SYS_SOCK_EXT3.

**sys/stat.h**

The sys/stat.h header file declares the following functions related to z/OS UNIX System Services files and their access:

- chaudit()
- chmod()
- creat()
- fchaudit()
- fchmod()
- fstat()
- lstat()
- mkdir()
- mkfifo()
- mknod()
- __mount()
- mount()
- __open_stat()
- stat()
- umask()
- umount()

**sys/statfs.h**

The sys/statfs.h header file declares the w_statfs() function that provides file system status and the w_statfs structure. It requires the _OPEN_SYS feature test macro.

**sys/statvfs.h**

The sys/statvfs.h header file contains definitions for file system status.

**sys/time.h**

The sys/time.h header file contains definitions for time types.

**sys/timeb.h**

The sys/timeb.h header file contains additional definitions for date and time.

**sys/times.h**

The sys/times.h header file declares the times() function that gets processor times for use by processes. It requires the _POSIX_SOURCE feature test macro.

**sys/ttydev.h**

The sys/ttydev.h header file defines constants used by the terminal I/O functions.
The `sys/types.h` header file defines a collection of `typedef` symbols and structures.

sys/uio.h

The sys/uio.h header file contains definitions for vector I/O operations.

sys/un.h

The sys/un.h header file contains definitions for UNIX-domain sockets.

sys/__ussos.h

The sys/__ussos.h header file contains the _SET_THLIIPADDR() macro, which sets a client’s IP address for security facility authorization (SAF).

sys/utsname.h

The sys/utsname.h header file declares the utsname structure and the uname() function, which returns the name of the current operating system. It requires the _POSIX_SOURCE feature test macro.

sys/wait.h

The sys/wait.h header file declares the following functions, used for holding processes.

_POSIX_SOURCE
wait()  waitpid()

_XOPEN_SOURCE_EXTENDED 1
waitid()  wait3()

Note: wait3() has been withdrawn in Single UNIX Specification, Version 3.

sys/__wlm.h

The sys/__wlm.h header file contains definitions for WorkLoad Manager functions.

tar.h

The tar.h header file contains definitions for the tar utility.
Header Files

terminat.h

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header <exception>. However, terminat.h remains for compatibility as a wrapper for TARGET releases of z/OS V1R2 and later.

For compilations with a TARGET release before z/OS V1R2, the terminat.h header file, which is used for z/OS XL C++ exception handling, declares the terminate() and set_terminate() functions.

termios.h

The termios.h header file contains constants, prototypes, and typedef definitions of POSIX terminal I/O functions. It includes the __termcp structure, and declares the following functions:

cfgetispeed()  cfgetospeed()  cfsetispeed()  cssetospeed()  tcdrain()
tcflow()  tcflush()  tcgetattr()  __tcgetcp()  tcgetsid()
tcsendbreak()  tcsetattr()  __tcsetcp()  __tcsettables()

These functions are supported only in a POSIX program. See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information.

The termios.h header file also contains constants, prototypes and typedef definitions for the w_ioctl() function.

tgmath.h

The header tgmath.h includes the headers math.h and complex.h and defines a number of type-generic macros. This requires the compiler that is designed to support C99.

Use of the macro invokes a function whose corresponding real type and type domain are determined by the arguments for the generic parameters. If there is more than one real floating type argument, usual arithmetic conversions are applied to the real floating type arguments so that they have compatible types. Then,

- If any argument has type _Decimal128, the type determined is _Decimal128.
- Otherwise, if any argument has type _Decimal64, the type determined is _Decimal64.
- Otherwise, if any argument has type _Decimal32, the type determined is _Decimal32.
- Otherwise, if any argument has type long double, the type determined is long double.
- Otherwise, if any argument has type double or is of integer type, the type determined is double.
- Otherwise, if none of the above the type determined is float.

All the functions in math.h and complex.h have their corresponding type generic macros in this header where if for a function in math.h, there is a corresponding c prefixed function in complex.h, then the corresponding type generic macro has the same name as the one in math.h. The macros are:

acos  acosh  asin  asinh  atan  atan2
atanh  carg  cbrt  ceil  cimag  conj

copysign  cos  cosh  cproj  creal  erf

erfc  exp  exp2  expm1  fabs  fdim

group  exp  exp2  expm1  fabs  fdim

hypot  ilogb  ldexp  lgamma  lrint  lround

log  log10  log1p  log2  logb  lrint

lround  nearbyint  nextafter  nexttoward  pow  remainder

remquo  rint  round  scalbln  scalbn  sin

sinh  sqrt  tan  tanh  tgamma  trunc

quantize()  samequantum()
- Types `clock_t`, `time_t`, and `size_t`.
- The NULL pointer constant. For more information on NULL and the type `size_t`, see `stddef.h` on page 79.
- The macro `CLK_TCK`, which is the number of clock ticks per second, is kept for historical reasons. It was used in connection with the return value of the `clock()` function. `CLK_TCK` has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `sysconf(_SC_CLK_TCK)` instead of the `CLK_TCK` macro.

However, if it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

### Table 19. Fields of `tm` Structure

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tm_sec</code></td>
<td>Seconds (0-60)</td>
</tr>
<tr>
<td><code>tm_min</code></td>
<td>Minutes (0-59)</td>
</tr>
<tr>
<td><code>tm_hour</code></td>
<td>Hours (0-23)</td>
</tr>
<tr>
<td><code>tm_mday</code></td>
<td>Day of month (1-31)</td>
</tr>
<tr>
<td><code>tm_mon</code></td>
<td>Month (0-11; January = 0)</td>
</tr>
<tr>
<td><code>tm_year</code></td>
<td>Year (current year minus 1900)</td>
</tr>
<tr>
<td><code>tm_wday</code></td>
<td>Day of week (0-6; Sunday = 0)</td>
</tr>
<tr>
<td><code>tm_yday</code></td>
<td>Day of year (0-365; January 1 = 0)</td>
</tr>
<tr>
<td><code>tm_isdst</code></td>
<td>Zero if Daylight Saving Time is not in effect; positive if Daylight Saving Time is in effect; negative if the information is not available.</td>
</tr>
</tbody>
</table>

The time functions are affected by the current locale selected. The `LC_CTYPE` category affects the behavior of the `strftime()`, `strptime()`, and `wcsftime()` functions. The `LC_TOD` category affects the behavior of the `gmtime()`, `mktime()`, and `localtime()` functions.

### typeinfo

The typeinfo header file defines several types associated with the type-identification operator typeid, which yields information about both static and dynamic types.

```cpp
namespace std {
    class type_info;
    class bad_cast;
    class bad_typeid;
};
```

type_info

The class describes type information generated within the program by the implementation. Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoded values, and collating order for types are all unspecified and may differ between program executions.
An expression of the form typeid x is the only way to construct a (temporary) typeinfo object. The class has only a private copy constructor. Since the assignment operator is also private, you cannot copy or assign objects of class typeinfo either.

class type_info {
public:
    virtual ~type_info();
    bool operator==(const type_info& rhs) const;
    bool operator!=(const type_info& rhs) const;
    bool before(const type_info& rhs) const;
    const char *name() const;
private:
    type_info(const type_info& rhs);
    type_info& operator=(const type_info& rhs);
};

type_info::operator!=
bool operator!=(const type_info& rhs) const;
The function returns !(this == rhs).

type_info::operator==
bool operator==(const type_info& rhs) const;
The function returns a nonzero value if this and rhs represent the same type.

type_info::before
bool before(const type_info& rhs) const;
The function returns a nonzero value if this precedes rhs in the collating order for types.

type_info::name
const char *name() const;
The function returns a C string which specifies the name of the type.

bad_cast
class bad_cast : public exception {
};

The class describes an exception thrown to indicate that a dynamic cast expression, of the form:
    dynamic_cast<type>(expression)

generated a null pointer to initialize a reference. The value returned by what() is an implementation-defined C string. None of the member functions throw any exceptions.

bad_typeid
class bad_typeid : public exception {
};

The class describes an exception thrown to indicate that a typeid operator encountered a null pointer. The value returned by what() is an implementation-defined C string. None of the member functions throw any exceptions.
Header Files

typeinfo.h

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header <typeinfo>. While this header represents function that did not previously exist on the z/OS and OS/390 operating systems, it is being provided now for compatibility as a wrapper to <typeinfo>.

The typeinfo.h header file contains definitions for types associated with the type-identification operator typeid, which yields information about both static and dynamic types.

ucontext.h

The ucontext.h header file contains the prototypes and definitions needed by the following functions:

getcontext() setcontext() makecontext() swapcontext()

uheap.h

The uheap.h header file contains the prototypes and definitions needed by the following functions:

__ucreate() __umalloc() __ufree() __uheapreport()

ulimit.h

The ulimit.h header file contains definitions for ulimit commands.

unexpect.h

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header <exception>. However, unexpect.h remains for compatibility as a wrapper for TARGET releases of z/OS V1R2 and later.

For compilations with a TARGET release before z/OS V1R2, the unexpect.h header file, which is used for z/OS XL C++ exception handling, declares the unexpected() and set_unexpected() functions.

unistd.h

The unistd.h header file declares a number of implementation-specific functions:

__atoe() __atoe_l() __check_resource_auth_rnp() __convert_id_rnp() __etoa() __etoa_l() __isPosixOn() __smf_record() __wsinit() __a2e_l() __a2e_s() __e2a_l() __e2a_s() XPLINK

There are also a large number of POSIX and UNIX functions declared, shown below with the minimum feature test macro needed to expose them:

access() alarm() chdir() chown() close() ctermid() dup() dup2()
The unistd.h header file also defines many symbols to represent configuration variables and implementation features provided. Some of these are used at compile time, while others are used to interrogate the system during run-time, using sysconf(), confstr(), pathconf(), or fpathconf().

The unistd.h header file also defines many symbols to represent configuration variables and implementation features provided. Some of these are used at compile time, while others are used to interrogate the system during run-time, using sysconf(), confstr(), pathconf(), or fpathconf().

The unistd.h header file also defines many symbols to represent configuration variables and implementation features provided. Some of these are used at compile time, while others are used to interrogate the system during run-time, using sysconf(), confstr(), pathconf(), or fpathconf().
utmpx.h

The utmpx.h header file contains user accounting database definitions.

varargs.h

The varargs.h header file contains definitions for handling variable argument lists.

Note:

This header is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the <stdarg.h> header to support variable argument list functionality compatible with IEEE Std 1003.1-2001.

Applications conforming to Single UNIX Specification, Version 3 must not include the header file.

variant.h

The variant.h header file declares the getsyntx() function, which returns LC_SYNTAX characters. It also contains the declaration of the variant structure:

```c
struct variant {
    char *codeset; /* code set of the current locale */
    char backslash; /* encoding of \ */
    char right_bracket; /* encoding of ] */
    char left_bracket; /* encoding of [ */
    char right_brace; /* encoding of } */
    char left_brace; /* encoding of { */
    char circumflex; /* encoding of ^ */
    char tilde; /* encoding of ~ */
    char exclamation mark; /* encoding of ! */
    char number sign; /* encoding of # */
    char vertical line; /* encoding of | */
    char dollar sign; /* encoding of $ */
    char commercial at; /* encoding of @ */
    char grave accent; /* encoding of ` */
};

struct variant *getsyntx(void);
```

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this book. For still more information, see the chapter, “Internationalization: Locales and Character Sets” in z/OS XL C/C++ Programming Guide.

wchar.h

The wchar.h header file contains the declaration for the supported subset of the ISO/C Multibyte Support extensions introduced in ISO/IEC 9899:1990/Amendment 1:1993(E) extensions. The following functions are declared in wchar.h:

- btowc()
- fgetwc()
- fgetws()
- fputwc()
- fputws()
- fwide()
- fwprintf()
- fwscanf()
- getwc()
- getwchar()
- mbstowc()
- mbsinit()
- mbrtowcs()
- putwc()
- putwchar()
- swprintf()
- swscanf()
- ungetwc()
- vwprintf()
- vfwprintf()
- vwscanf()
You don’t need to include stdio.h and stdarg.h to use the header file. The header file wchar.h contains definitions of the following types:

- `mbstate_t`  
  Conversion-state information needed when converting between sequences of multibyte characters and wide characters.

- `size_t`  
  typedef for the type of the value returned by `sizeof`.

- `wchar_t`  
  typedef for a wide-character constant.

- `win_t`  
  An integral type unchanged by integral promotions that can hold any value corresponding to members of the extended character set, as well as WEOF (see below).

- `FILE`  
  The `FILE` structure type is defined in both stdio.h and wchar.h. Stream functions use a pointer to the `FILE` type to get access to a given stream. The system uses the information in the `FILE` structure to maintain the stream. The C standard streams `stdin`, `stdout`, and `stderr` are also defined in stdio.h.

- `va_list`  
  This type is defined in both stdarg.h and wchar.h.

The header file wchar.h also contains definitions of the following constants:

- `NULL`  
  A pointer that never points to a data object.

- `WEOF`  
  Expands to a constant expression of type `win_t`, whose value does not correspond to any member of the extended character set. It indicates End Of File (EOF).

- `WCHAR_MIN`  
  Defines the lower limit of the `wchar_t` type.

- `WCHAR_MAX`  
  Defines the upper limit of the `wchar_t` type.

You can perform wide-character input/output on the streams described in the ISO/IEC 9899:1990 standard, subclause 7.9.2. This standard expands the definition of a stream to include an orientation for both text and binary streams. For more information about DBCS orientation, see the section on Double-Byte Characters Sets in the `z/OS XL C/C++ Programming Guide`.

The wide-character string functions are also declared in wcstr.h for compatibility with previous releases of C/370, although wcstr.h may be withdrawn in the future.
Header Files

For more information about the effect of locale, see setlocale(), locale.h, or look up the individual functions in this book. For still more information, see the chapter, “Internationalization: Locales and Character Sets” in z/OS XL C/C++ Programming Guide.

wcstr.h

The wcstr.h header file declares the following multibyte functions:

wcscat()  wcschr()  wcscmp()  wcscpy()  wcscspn()
wcslen()  wcsncat()  wcsncmp()  wcsncpy()  wcspbrk()
wcsrchr()  wcsspn()  wcswcs()  wcslen()  wcsncat()  wcsncmp()  wcsncpy()  wcspbrk()

wcstr.h also defines the types size_t, NULL, wchar_t, and wint_t.

The wide-character string functions are also declared in wchar.h for compatibility with previous releases of C/370. wcstr.h may be withdrawn in future releases of the z/OS XL C/C++ product.

wcstr.h is a non-standard header provided for compatibility with previous releases of C/370. Functions in wcstr.h are exposed by compiling with LANGLVL(EXTENDED).
The wcstr.h header may be withdrawn in future releases of the z/OS XL C/C++ product. The wide character functions in wcstr.h are also declared in the wchar.h header, which is the standard interface.

wctype.h

The wctype.h header declares functions that deal with wide character properties. The following are declared as functions and are also defined as macros:

iswalnum()  iswalpha()  iswblank()  iswctrl()  iswctype()
iswdigit()  iswgraph()  iswlower()  iswprint()  iswpunct()
iswspace()  iswupper()  iswxdigit()  towlower()  towupper()
wctype()

The following are declared as prototypes only:
towctrans()  wctrans()  wctype()  towctrans()  wctrans()  wctype()

The wctype.h header defines the types wctrans_t, wctype_t and wint_t. The wctype.h defines the macro WEOF, which expands to a constant expression of type wint_t, whose value does not correspond to any member of the extended character set. The macro WEOF indicates End Of File (EOF).

wordexp.h

The wordexp.h header file contains definitions for word expansion types.

xti.h

The xti.h header file declares the following under the _XOPEN_SOURCE_EXTENDED 1 feature test macro:
## Symbolic constants

Table 20. Symbolic Constants defined in xti.h

Header Files
Chapter 3. Part 3. Library Functions

This part describes the z/OS XL C/C++ Run-Time Library functions, including the built-in library functions used by the z/OS XL C/C++ compilers.

Names

Identifiers (function names, macros, types) defined by the various standards in the headers are reserved. Also reserved are:

- Identifiers that begin with an underscore and either an uppercase letter or another underscore.
- Identifiers that end with "_.t".

Do not use these reserved identifiers for any purpose other than those defined in the documentation.

All identifiers other than the ISO C identifiers comprise the user’s name space. You are free to use any of these names. However, a number of names in the z/OS XL C/C++ Run-Time Library encroach on the user’s name space. This is a result of our desire to provide names that are meaningful and easy to remember, or to support industry-defined names, for example: fetchep() or pthread_cancel(). The header files cause these names to be renamed into reserved names and these in turn are mapped onto the external entry point names that usually are operating-system specific.

If you want to use names in the z/OS XL C/C++ Run-Time Library which are in the user’s name space as defined, just include the appropriate header. If you cannot include the appropriate header because it would bring in other names that collide with your own private names, but you still want to use some of the functions defined there, you can refer to these functions by their reserved internal names. These reserved names are unique, not longer than 8 characters, and usually start with a double underscore.

The IBM z/OS XL C/C++ compiler automatically maps all underscores and lowercase letters in external identifiers in source code to ‘@’ characters and uppercase characters in the object deck. Thus, to refer to the fetchep() function without including the stdlib.h header, you can use its reserved internal name __ftchep(), which is then automatically mapped to the external entry point @@FTCHEP. For C++ functions, you must ensure C by declaring the functions as extern "C".

Functions that are mapped this way have the external entry point listed in the function description in this part under the heading, “External Entry Point”.

See also the following sections in z/OS XL C/C++ Language Reference for more information on external names:

- "#pragma csect"
- "#pragma map"
- “External Name Mapping”

See also the following sections in z/OS XL C/C++ User’s Guide:

- “Prelinking a C Application”
- The LONGNAME compiler option

See also “Naming Conventions” in “Using Environment Variables”, in z/OS XL C/C++ Programming Guide for details about external names.
Unsupported functions and external variables in AMODE 64

All program examples in this book have been tested to work in 32-bit mode. Some examples may not work in AMODE 64. As examples are updated for AMODE 64, a statement of AMODE 64 support will be added to the description of the example.

The following functions are not supported in AMODE 64:
- advance()
- brk()
- compile()
- __console()
- __csplist
- ctdli()
- fortc()
- iscics()
- __openMvsRel()
- __pcblist
- pthread_quiesce_and_get_np()
- re_comp()
- re_exec()
- regcmp()
- regex()
- sbrk()
- sock_debug_bulk_perf0()
- sock_do_bulkmode()
- step()
- tinit()
- tsched()
- tsetsubt()
- tsyncro()
- tterm()
- valloc()

The following external variables are not supported in AMODE 64:
- __loc1
- loc1
- loc2
- locs

Standards

Each function description begins with a table to indicate the standards/extensions, language support, and dependencies. See the table below for more details:

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>C only</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>ISO C Amendment</td>
<td>C++ only</td>
<td>OS/390 V2R6</td>

</tr>
<tr>
<td>C/C++ DFP</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

By indicating a standard, we refer to the origin of the function, not necessarily the compliance. For example, functions that are enriched by features from XPG4 have XPG4 listed.

These are the standards referred to:

- **Standards/extensions**
  3. *POSIX*
    - *POSIX.2* refers to IEEE Portable Operating System Interface (POSIX) Part 2, P1003.2 draft 12.
    - *POSIX.4a* refers to a subset of IEEE POSIX 1003.4a, Draft 6, Feb. 26, 1992.
Library Functions

7. RFC2553 refers to the Basic Socket Interface Extensions for IPv6 (draft-ietf-ipngwg-rfc2253bis-05.txt, dated February 2002).

**Note:** Not all of the support described in this draft is available on z/OS.

8. RFC2292 refers to the Advanced Sockets API for IPv6 (draft-ietf-ipngwg-rfc2292bis-06.txt, dated February 25, 2002).

**Note:** Not all of the support described in this draft is available on z/OS.

12. **Extensions** refers to one of the following:
   a. SAA refers to the IBM Systems Application Architecture Common Programming Interface (SAA CPI) Level 2 definition of the C language.
   b. **C Library** refers to the functions that are extensions to the run-time library, before the Language Environment product.
   c. **Language Environment** refers to functions that are extensions to the conventional standards.
   d. **z/OS UNIX System Services** refers to functions that provide z/OS UNIX System Services support beyond the defined standards.

13. C/C++ DFP refers to:
   a. ISO/IEC TR24732 -- Extensions for the programming language C to support decimal floating point arithmetic.
   b. ISO/IEC TR24733 -- Extensions for the programming language C++ to support decimal floating point arithmetic.

- **Language support**
  - C or C++ refers to whether the function is supported for the z/OS XL C compiler, the z/OS XL C++ compiler, or both.

- **Dependencies**
  Some functions have the following dependencies identified. If the dependencies are not met, then the function fails, and returns an errno of EMVSNSRRTL. Functions defined by the standards that cannot fail, will cause abnormal termination and return Language Environment condition CEE5001.
  - POSIX(ON) **required** refers to whether the enclave can run with the POSIX semantics.

POSIX is an application characteristic that is maintained at the enclave level. After you have established the characteristic during enclave initialization, you cannot change it.

When you set POSIX to ON, you can use functions that are unique to POSIX, such as pthread_create().

One of the effects of POSIX(ON) is the enablement of POSIX signal handling semantics, which interact closely with the z/OS Language Environment condition handling semantics. Where ambiguities exist between ANSI and POSIX semantics, the POSIX run-time setting indicates the POSIX semantics to follow. For more information about running POSIX programs, please see "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13.
These standards do have some overlap, as illustrated in Figure 2.

![Figure 2. Overlap of C Standards and Extensions](image)

The C library contains several functions that are extensions to the SAA CPI Level 2 definition. These library functions are available only if the LANGLEVEL(EXTENDED) compile-time option is in effect. As indicated, some of the stub routines for the extensions are available if you specify LANGLEVEL(ANSI). They are made available for compatibility with Version 1; they may not be available in the future. (Within run-time libraries, a stub routine is a routine that contains the minimum lines of code required to locate a given routine at run time.)

Many of the symbols that are defined in headers are “protected” by a feature test macro. For information on the relationships between feature test macros and the standards, see “Feature Test Macros” on page 21.

### Using C Include Files from C++

If you need to use an old C header file in a C++ program, use extern, like this:

```c
extern "C" {
  #include "myhdr.include"
}
```

### Built-in Functions

Built-in functions are ones for which the compiler generates inline code at compile time. Every call to a built-in function eliminates a run-time call to the function having the same name in the dynamic library.

Built-in functions are used by application code, while it is running, without reference to the dynamic library. Although built-in functions increase the size of a generated application slightly, this should be offset by the improved performance resulting from reducing the overhead of the dynamic calls. Built-in functions can be used with the System Programming C (SPC) Facilities to generate free-standing C applications.

**Restriction:** The SPC facility is not supported in AMODE 64.
Table 21 shows all of the built-in functions. In the listing of library functions, each built-in function is labelled as such.

Table 21. Built-in Library Functions

</tbody>
</table>

The built-in versions of these functions are accessed by preprocessor macros defined in the standard header files. They are not used unless the appropriate header file (such as decimal.h, math.h, stdlib.h, or string.h) is included in the source file.

Your program will use the built-in version of a standard function only if you include the associated standard header file. However, decfix(), decabs(), and decchk() are implemented only as built-in functions. They are not available without including the header file.

If you are using the standard header file, but want to use the function in the dynamic library instead of the built-in function, you can force a call to the dynamic library by putting parentheses around the function name in your source code:

`(memcpy)(buf1, buf2, len)`

The built-in functions are documented in "Built-in Functions" on page 107 in z/OS XL C/C++ Programming Guide.

If you will never use the built-in version, you can also use `#undef` with the function name. For example, `#undef memcpy` causes all calls to memcpy in the compilation unit to make a dynamic call to the function rather than using the built-in version.

**IEEE Binary Floating-Point**

Starting with OS/390 V2R6 (including the Language Environment and C/C++ components), support has been added for IEEE binary floating-point (IEEE floating-point) as defined by the ANSI/IEEE Standard 754-1985, IEEE Standard for Binary Floating-Point Arithmetic.

**Notes:**

1. You must have OS/390 Release 6 or higher to use the IEEE Binary Floating-Point instructions. In Release 6, the base control program (BCP) is enhanced to support the new IEEE Binary Floating-Point hardware in the IBM S/390 Generation 5 Server. This enables programs running on OS/390 Release 6 to use the IEEE Binary Floating-Point instructions and 16 floating-point registers. In addition, the BCP provides simulation support for all the new floating-point hardware instructions. This enables applications that make light use of IEEE Binary Floating-Point, and can tolerate the overhead of software simulation, to execute on OS/390 V2R6 without requiring an IBM S/390 Generation 5 Server.

2. The terms *binary floating point* and *IEEE binary floating point* are used interchangeably. The abbreviations BFP and HFP, which are used in some function names, refer to binary floating point and hexadecimal floating point respectively.
3. Under Hexadecimal Floating-Point format, the rounding mode is set to round toward 0. Under IEEE Binary Floating-Point format, the rounding mode is to round toward the nearest integer.

The z/OS XL C/C++ compiler provides a FLOAT option to select the format of floating-point numbers produced in a compile unit. The FLOAT option allows you to select either IEEE Binary Floating-Point or hexadecimal floating-point format. For details on the z/OS XL C/C++ support, see the description of the FLOAT option in z/OS XL C/C++ User's Guide. In addition, two related sub-options have been introduced, ARCH(3) and TUNE(3). The two sub-options support the new G5 processor architecture, and IEEE binary floating-point data. Refer to the ARCHITECTURE and TUNE compiler options in z/OS XL C/C++ User's Guide for details.

The C/C++ run-time library interfaces, which formerly supported only hexadecimal floating-point format, have been changed in OS/390 V2R6 to support both IEEE Binary Floating-Point and hexadecimal floating-point formats. These interfaces are documented in the z/OS XL C/C++ Run-Time Library Reference.

The primary documentation for the IEEE Binary Floating-Point support is contained in z/Architecture Principles of Operation and z/OS XL C/C++ User’s Guide.

IEEE binary floating point support provides interoperability and portability between platforms. It is anticipated that the support will be most commonly used for new and ported applications and in emerging environments, such as Java. Customers should not migrate existing applications that use hexadecimal floating point to binary floating point, unless there is a specific reason.

IBM does not recommend mixing floating-point formats in an application. However, for applications which must handle both formats, the C/C++ run-time library does offer some support. Reference information for IEEE Binary Floating-Point can also be found in z/OS XL C/C++ Language Reference.

---

**IEEE Decimal Floating-Point**

Starting with z/OS V1R9 (including the Language Environment and C/C++ components), support has been added for IEEE decimal floating-point as defined by the ANSI/IEEE Standard P754/D0.15.3, IEEE Standard for Floating-Point Arithmetic.

Note:

1. You must have z/OS V1R9 or higher to use IEEE decimal floating-point, the hardware must have the Decimal Floating Point Facility installed and the __STDC_WANT_DEC_FP__ feature test macro must be defined.
2. The abbreviation DFP refers to IEEE Decimal Floating-Point.
3. IEEE decimal floating-point is not supported in a CICS environment.

The z/OS XL C/C++ compiler provides a DFP option to include support for IEEE Decimal Floating-Point numbers. For details on the z/OS XL C/C++ support, see the description of the DFP option in z/OS XL C/C++ User's Guide. New C/C++ run-time library interfaces, which support IEEE Decimal Floating Point numbers have been added for z/OS V1R9 and other existing interfaces have been updated to support DFP. These interfaces are documented in the z/OS XL C/C++ Run-Time Library Reference. The primary documentation for the IEEE decimal floating-point support is contained in “z/Architecture Principles of Operating Systems” and z/OS XL C/C++ User’s Guide.
Library Functions

4. When one or more input values for a Decimal Floating Point (DFP) library function are not in the preferred Densely Packed Decimal (DPD) encoding, it is not defined whether or not the output values are converted to the preferred DPD coding. Applications should not rely on the current behavior of library functions regarding the DPD recoding of output values.

External Variables

The POSIX 1003.1 and X/Open CAE Specification 4.2 (XPG4.2) require that the C system header files define certain external variables. Additional variables are defined for use with POSIX or XPG4.2 functions. If you define one of the POSIX or XPG4 feature test macros and include one of these headers, the external variables will be defined in your program. These external variables are treated differently compared with other global variables in a multithreaded environment (values are thread-specific) and across a call to a fetched module (values are propagated).

To access the global variable values the following must be specified during C/C++ compiles and z/OS bind:

Non-XPLINK (non-thread-safe)

C code must be compiled with the RENT or DLL option (C++ code needs no additional options). The SCEEOBJ autocall library must be specified during the bind.

Non-XPLINK (thread-safe)

No additional options are required for either C or C++. The _SHARE_EXT_VARS feature test macro, or the necessary _SHR_prefix feature test macros must be used.

Equivalently, the necessary thread-specific functions can be called directly (as documented below under each external variable).

XPLINK (non-thread-safe)

No additional options (besides XPLINK) are required for either C or C++. The C run-time library side-deck, member CELHS003 of the SCEELIB data set, must be included during the bind.

(c89/cc/c++ automatically include this side-deck when the XPLINK link edit option (for example, c89 -Wl,XPLINK ...) is used.)

XPLINK (thread-safe)

No additional options (besides XPLINK) are required for either C or C++. The C run-time library side-deck, member CELHS003 of the SCEELIB dataset, must be included during the bind.

The _SHARE_EXT_VARS feature test macro, or the necessary _SHR_prefix feature test macros must be used. Equivalently, the necessary thread-specific functions can be called directly (as documented in the later sections under each external variable).

LP64 (non-thread-safe)

No additional options (besides LP64 ) are required
for either C or C++. The C run-time library side-deck, member CELQS003 of the SCEELIB dataset, must be included during the bind.

The _SHARE_EXT_VARS feature test macro, or the necessary _SHR_ prefixed feature test macros must be used.

Equivalently, the necessary thread-specific functions can be called directly (as documented in the later sections under each external variable).

**LP64 (thread-safe)**

No additional options (besides LP64) are required for either C or C++. The C run-time library side-deck, member CELQS003 of the SCEELIB dataset, must be included during the bind. (c89/cc/c++ automatically include this side-deck when the LP64 link edit option (for example, c89 -Wl, LP64 ...) is used.)

The _SHARE_EXT_VARS feature test macro, or the necessary _SHR_ prefixed feature test macros must be used.

Equivalently, the necessary thread-specific functions can be called directly (as documented in the later sections under each external variable).

**errno**

When a run-time library function fails, the function may do any of the following to identify the error:

- Set errno to a documented value.
- Set errno to a value that is not documented. You can use strerror() or perror() to get the message associated with the errno.
- Not set errno.
- Clear errno.

See also *errno.h*.

**daylight**

Daylight savings time flag set by tzset(). Note that other time zone sensitive functions such asctime(), localtime(), mktime(), and strftime() implicitly call tzset().

**Note:** Use the __dlght() function to access the thread-specific value of daylight. See also *time.h*.

**getdate_err**

The variable is set to the value below when an error occurs in the getdate() function.

1. The DATEMASK environment variable is NULL or undefined.
2. The template file cannot be opened for reading.
3. Failed to get file status information.
4. The template file is not a regular file.
5. An error is encountered while reading the template file.
7. There is no line in the template that matches the input.
**Library Functions**

Any changes to errno are unspecified.

**Note:** Use the `__gderr()` function to access the thread-specific value of `getdate_errno`. See also `time.h`.

**h_errno**

An integer which holds the specific error code when the network name server encounters an error. The network name server is used by the `gethostbyaddr()` and `gethostbyname()` functions.

**Note:** Use the `__h_errno()` function to access the thread-specific value of `h_errno`. See also `netdb.h`.

**__loc1**

_Be restricted:_ This external variable is not supported in AMODE 64

A global character pointer which is set by the `regex()` function to point to the first matched character in the input string. Use the `__loc1()` function to access the thread-specific value of `__loc1`.

**Note:**

This variable is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the interfaces supported by the `<regex.h>` header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions.

If it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro `__UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3. See also `libgen.h`.

**loc1**

_Be restricted:_ This external variable is not supported in AMODE 64.

A pointer to characters matched by regular expressions used by `step()`. The value is not propagated across a call to a fetched module.

**Note:**

This variable is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not
supported as part of Single UNIX Specification, Version 3. New applications
should use the interfaces supported by the <regex.h> header, which provide
full internationalized regular expression functionality compatible with IEEE
Std 1003.1-2001 Regular Expressions. See also regexp.h.

**loc2**

**Restriction:** This external variable is not supported in AMODE 64

A pointer to characters matched by regular expressions used by step(). The value is
not propagated across a call to a fetched module.

**Note:**

This variable is kept for historical reasons. It was part of the Legacy Feature
in Single UNIX Specification, Version 2, but has been withdrawn and is not
supported as part of Single UNIX Specification, Version 3. New applications
should use the interfaces supported by the <regex.h> header, which provide
full internationalized regular expression functionality compatible with IEEE
Std 1003.1-2001 Regular Expressions. See also regexp.h.

**locs**

**Restriction:** This external variable is not supported in AMODE 64

Used by advance() to stop regular expression matching in a string. The value is not
propagated across a call to a fetched module. See also regexp.h.

**Note:**

This variable is kept for historical reasons. It was part of the Legacy Feature
in Single UNIX Specification, Version 2, but has been withdrawn and is not
supported as part of Single UNIX Specification, Version 3. New applications
should use the interfaces supported by the <regex.h> header, which provide
full internationalized regular expression functionality compatible with IEEE
Std 1003.1-2001 Regular Expressions.

**optarg**

Character pointer used by getopt() for options parsing variables.

**Note:** Use the __opargf() function to access the thread-specific value of optarg.

**Note:** This variable has been removed from stdio.h by Single UNIX Specification,
Version 3 and is exposed for Version 3 only in unistd.h. See also stdio.h
and unistd.h.

**opterr**

Error value used by getopt().

**Note:** Use the __operrf() function to access the thread-specific value of opterr.

**Note:** This variable has been removed from stdio.h by Single UNIX Specification,
Version 3 and is exposed for Version 3 only in unistd.h. See also stdio.h
and unistd.h.
Library Functions

**optind**

Integer pointer used by getopt() for options parsing variables.

**Note:** Use the `__opindf()` function to access the thread-specific value of `optind`.

**Note:** This variable has been removed from stdio.h by Single UNIX Specification, Version 3 and is exposed for Version 3 only in unistd.h. See also `stdio.h` and `unistd.h`.

**optopt**

Integer pointer used by getopt() for options parsing variables.

**Note:** Use the `__opoptf()` function to access the thread-specific value of `optopt`.

**Note:** This variable has been removed from stdio.h by Single UNIX Specification, Version 3 and is exposed for Version 3 only in unistd.h. See also `stdio.h` and `unistd.h`.

**signgam**

Storage for sign of lgamma(). This function defaults to thread-specific. See also `math.h`.

**stderr**

Standard Error stream. The external variable will be initialized to point to the enclave-level stream pointer for the standard error file. There is no multithreaded function. See also `stdio.h`.

**stdin**

Standard Input stream. The external variable will be initialized to point to the enclave-level stream pointer for the standard input file. There is no multithreaded function. See also `stdio.h`.

**stdout**

Standard Output stream. The external variable will be initialized to point to the enclave-level stream pointer for the standard output file. There is no multithreaded function. See also `stdio.h`.

**t_errno**

An integer which holds the specific error code when a failure occurs in one of the X/Open Transport Interface (XTI) functions. Use the `__t_errno()` function to access the thread-specific value of `t_errno`.

**Note:** Use the `__t_errno()` function to access the thread-specific value of `t_errno`. See also `xti.h`.

**timezone**

Long integer difference from UTC and standard time as set by tzset(). Note that other time zone sensitive functions such as ctime(), localtime(), mktime(), and strftime() implicitly call tzset().

**Note:** Use the `__tzone()` function to access the thread-specific value of `timezone`. See also `time.h`.
tzname

Character pointer to unsized array of timezone strings used by tzset() and ctime(). The *tzname variable contains the Standard and Daylight Savings time zone names. If the TZ environment variable is present and correct, tzname will be set from TZ. Otherwise tzname will be set from the LC_TOD locale category. See the tzset() function for a description. There is no multithreaded function. See also time.h.

The __restrict__ macro

The restrict keyword is being made available in the form of a macro named __restrict__ which can be used for coding before the availability of a compiler that is designed to support C99. Once the compiler support is available, only a recompile will be necessary. Applications need to include <features.h> before using the __restrict__ macro.

<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

void abort(void);
```

General Description

Causes an abnormal program termination and returns control to the host environment. The `abort()` function flushes all buffers and closes all open files. Be aware that abnormal termination will *not* run the `atexit()` list functions.

If the `abort()` function is called and the user has a handler for `SIGABRT`, then `SIGABRT` is raised; however, `SIGABRT` is raised again when the handler associated with the default action is returned. The code path only passes through the user’s handler once, even if the handler is reset. The same thing occurs if `SIGABRT` is ignored; abnormal termination occurs.

The `abort()` function will not result in program termination if `SIGABRT` is caught by a signal handler, and the signal handler does not return. You can avoid returning by “jumping” out of the handler with `setjmp()` and `longjmp()`. In z/OS XL C programs, you can jump out of the handler with `sigsetjmp()` and `siglongjmp()`.

For more information see the process termination sections in the chapter “Using Run-Time User Exits” in the z/OS XL C/C++ Programming Guide.

Special Behavior for POSIX C Programs

To obtain access to the special POSIX behavior for `abort()`, the POSIX run-time option must be set ON.

Calls to `abort()` raise the `SIGABRT` signal, using `pthread_kill()`, so that the signal is directed to the same thread. A `SIGABRT` signal generated by `abort()` cannot be blocked.

Under POSIX, the handler can use `siglongjmp()` to restore the environment at a place in the code where a `sigsetjmp()` was previously issued. In this way, an application can avoid the process for termination. See “z/OS XL C/C++ applications with z/OS UNIX System Services C functions” on page 13 for more information about using POSIX support.

Special Behavior for C++
If abort() is called from a z/OS XL C++ program, the program will be terminated immediately, without leaving the current block. Functions passed to atexit(), and destructors for static and local (automatic) objects, will not be called.

By default, the z/OS XL C++ function terminate() calls abort().

**Returned Value**

The abnormal termination return code for z/OS is 2000.

**Example**

**CELEBA01**

```c
/* CELEBA01

This example tests for successful opening of the file myfile.
If an error occurs, an error message is printed and the program ends with a call to the abort() function.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{

    FILE *stream;
    unlink("myfile.dat");
    if ((stream = fopen("myfile.dat", "r")) == NULL)
    {
        printf("Could not open data file\n");
        abort();
        printf("Should not see this message\n");
    }
}
```

_Decimal32 abs(_Decimal32 x); /* C++ only */
_Decimal64 abs(_Decimal64 x); /* C++ only */
_Decimal128 abs(_Decimal128 x); /* C++ only */
```

General Description

The functions abs(), absf(), and absl() return the absolute value of an argument n.

For the integer version of abs(), the minimum allowable integer is INT_MIN+1. (INT_MIN is a macro that is defined in the limits.h header file.) For example, with the z/OS XL C/C++ compiler, INT_MIN+1 is -2147483648.

For the double, float, and long double versions of abs(), the minimum allowable values are DBL_MIN+1, FLT_MIN+1, and LDBL_MIN+1, respectively. (The floating-point macro constants are defined in the float.h header file.)

If the value entered cannot be represented as an integer, the abs(), absf(), and absl() functions return the same value.

Notes:

- These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE Binary Floating-Point " on page 108 for more information about IEEE Binary Floating-Point.

Note:
Special Behavior for C++:

For C++ applications, abs() is also overloaded for the types long, float, and long double.

Returned Value

The returned value is the absolute value, if the absolute value is possible to represent.

Otherwise the input value is returned.

There are no errno values defined.

Example

CELEBA02

/

CELEBA02

This example calculates the absolute value of an integer x and assigns it to y.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
  int x = -4, y;
  y = abs(x);
  printf("The absolute value of %d is %d.\n", x, y);
}

Output

The absolute value of -4 is 4.

accept

accept() — Accept a New Connection on a Socket

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

**X/Open**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int accept(int socket, struct sockaddr *__restrict__ address, socklen_t *__restrict__ address_len);
```

**Berkeley Sockets**

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int accept(int socket, struct sockaddr *address, int *address_len);
```

General Description

The `accept()` call is used by a server to accept a connection request from a client. When a connection is available, the socket created is ready for use to read data from the process that requested the connection. The call accepts the first connection on its queue of pending connections for the given socket `socket`. The `accept()` call creates a new socket descriptor with the same properties as `socket` and returns it to the caller. If the queue has no pending connection requests, `accept()` blocks the caller unless `socket` is in nonblocking mode. If no connection requests are queued and `socket` is in nonblocking mode, `accept()` returns −1 and sets the error code to EWOULDBLOCK. The new socket descriptor cannot be used to accept new connections. The original socket, `socket`, remains available to accept more connection requests.

Parameter Description

- **socket**
  - The socket descriptor.

- **address**
  - The socket address of the connecting client that is filled in by `accept()` before it returns. The format of `address` is determined by the domain that the client resides in. This parameter can be NULL if the caller is not interested in the client address.

- **address_len**
  - Must initially point to an integer that contains the size in bytes of the storage pointed to by `address`. On return, that integer contains the size required to represent the address of the connecting socket. If this value is larger than the size supplied on input, then the information contained in sockaddr is truncated to the length supplied on input. If `address` is NULL, `address_len` is ignored.

The `socket` parameter is a stream socket descriptor created with the `socket()` call. It is usually bound to an address with the `bind()` call. The `listen()` call marks the
socket as one that accepts connections and allocates a queue to hold pending connection requests. The listen() call places an upper boundary on the size of the queue.

The address parameter is a pointer to a buffer into which the connection requester's address is placed. The address parameter is optional and can be set to be the NULL pointer. If set to NULL, the requester's address is not copied into the buffer. The exact format of address depends on the addressing domain from which the communication request originated. For example, if the connection request originated in the AF_INET domain, address points to a sockaddr_in structure, or if the connection request originated in the AF_INET6 domain, address points to a sockaddr_in6 structure. The sockaddr_in and sockaddr_in6 structures are defined in netinet/in.h. The address_len parameter is used only if the address is not NULL. Before calling accept(), you must set the integer pointed to by address_len to the size of the buffer, in bytes, pointed to by address. On successful return, the integer pointed to by address_len contains the actual number of bytes copied into the buffer. If the buffer is not large enough to hold the address, up to address_len bytes of the requester's address are copied. If the actual length of the address is greater than the length of the supplied sockaddr, the stored address is truncated. The sa_len member of the store structure contains the length of the untruncated address.

Note:

- This call is used only with SOCK_STREAM sockets. There is no way to screen requesters without calling accept(). The application cannot tell the system the requesters from which it will accept connections. However, the caller can choose to close a connection immediately after discovering the identity of the requester.
- The accept() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII Support" on page 2495 for details.

A socket can be checked for incoming connection requests using the select() call.

Special Behavior for C++

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED feature test macro.

Returned Value

If successful, accept() returns a nonnegative socket descriptor.

If unsuccessful, accept() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>If during an accept call that changes identity, the UID of the new identity is already at MAXPROCUID, the accept call fails.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The socket parameter is not within the acceptable range for a socket descriptor.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using address and address_len would result in an attempt to copy the address into a portion of the caller's address space into which information cannot be written.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal interrupted the accept() call before any connections were available.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>listen() was not called for socket descriptor socket.</td>
</tr>
</tbody>
</table>
## accept

- **EIO** There has been a network or transport failure.
- **EMFILE** An attempt was made to open more than the maximum number of file descriptors allowed for this process.
- **EMVSERR** Two consecutive accept calls that cause an identity change are not allowed. The original identity must be restored (close() the socket that caused the identity change) before any further accepts are allowed to change the identity.
- **ENFILE** The maximum number of file descriptors in the system are already open.
- **ENOBUS** Insufficient buffer space is available to create the new socket.
- **ENOTSOCK** The `socket` parameter does not refer to a valid socket descriptor.
- **EOPNOTSUPP** The socket type of the specified socket does not support accepting connections.
- **EWOULDBLOCK** The socket descriptor `socket` is in nonblocking mode, and no connections are in the queue.

### Example

The following are two examples of the accept() call. In the first, the caller wishes to have the requester's address returned. In the second, the caller does not wish to have the requester's address returned.

```c
int clientsocket;  
int s;  
struct sockaddr clientaddress;  
int address_len;  
int accept(int s, struct sockaddr *addr, int *address_len);  
/* socket(), bind(), and listen() have been called */  
/* EXAMPLE 1: I want the address now */  
address_len = sizeof(clientaddress);  
clientsocket = accept(s, &clientaddress, &address_len);  
/* EXAMPLE 2: I can get the address later using getpeername() */  
clientsocket = accept(s, (struct sockaddr *)0, (int *)0);  
```

</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open

```c
#define _OPEN_SYS_SOCKET_EXT2
#include <sys/socket.h>

int accept_and_recv(int socket, int *accept_socket,
                     struct sockaddr *remote_address,
                     socklen_t *remote_address_len,
                     struct sockaddr *local_address,
                     socklen_t *local_address_len,
                     void *buffer, size_t length);
```

General Description

The `accept_and_recv()` function extracts the first connection on the queue of pending connections. It either reuses the specified socket (if `accept_socket` is not -1) or creates a new socket with the same socket type, protocol, and address family as the listening socket (if `accept_socket` is -1). It then returns the first block of data sent by the peer and returns the local and remote socket addresses associated with the connection.

The function takes the following arguments:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `socket`        | Specifies a socket that was created with `socket()`, has been bound to an address with `bind()`, and has issued a successful call to `listen()`.
| `accept_socket` | Pointer to an int which specifies the socket on which to accept the incoming connection. The socket must not be bound or connected. Use of this parameter lets the application reuse the accepting socket. It is possible that the system may choose to reuse a different socket than the one the application specified by this argument. In this case, the system will set `*accept_socket` to the socket actually reused. A value of -1 for `*accept_socket` indicates that the accepting socket should be assigned by the system and returned to the application in this parameter. It is recommended that a value of -1 be used on the first call to `accept_and_recv()`. For more details, see "Application Usage" on page 124. |
| `remote_address`| Either a NULL pointer or a pointer to a `sockaddr` structure where the address of the connecting socket will be returned. |
| `remote_address_len` | Points to a `socklen_t` item. On input, this item specifies the length of the supplied `sockaddr` structure. On output, this item contains the length of the stored address. |
accept_and_recv

local_address Either a NULL pointer or a pointer to a sockaddr structure where the address of the local socket will be returned.

local_address_len Points to a socklen_t item. On input, this item specifies the length of the supplied sockaddr structure. On output, this item contains the length of the stored address.

buffer Either a NULL pointer, or a pointer to a buffer where the message should be stored. If this is a NULL pointer, no receive is performed, and accept_and_recv() completes when the incoming connection is received.

length Specifies the length in bytes of the buffer pointed to by the buffer argument.

If *accept_socket is not -1, the incoming connection will be accepted on the socket specified by *accept_socket. The system may choose to reuse a different socket. If it does, the system will change *accept_socket to reflect the socket actually used.

If remote_address is not a NULL pointer, the address of the peer for the accepted connection is stored in the sockaddr structure pointed to by remote_address, and the length of this address is stored in the object pointed to by remote_address_len. If local_address is not a NULL pointer, the address of the local socket associated with this connection is stored in the sockaddr structure pointed to by local_address, and the length of this address is stored in the object pointed to by local_address_len.

If the actual length of the address is greater than the length of the supplied sockaddr structure, the stored address will be truncated.

Nonblocking mode is not supported for this function. If O_NONBLOCK is set on the socket file descriptor, the function will return with -1 and errno will be set to EOPNOTSUPP. If the listen queue is empty of connection requests and O_NONBLOCK is not set on the socket file descriptor, accept_and_recv() will block and will not return until an incoming connection is received. In addition, if buffer is not NULL, accept_and_recv will not return until the first block of data on the connection has been received.

Note: The accept_and_recv() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII Support " on page 2495 for details.

Application Usage

On the first call to accept_and_recv(), it is recommended that the application set the socket pointed to by accept_socket to -1. This will cause the system to assign the accepting socket. The application then passes the assigned value into the next call to accept_and_recv() (by setting accept_socket = socket_ptr).

To take full advantage of the performance improvements offered by the accept_and_recv() function, a process/thread model different from the one where a parent accepts in a loop and spins off child process threads is needed. The parent/process thread is eliminated. Multiple worker processes/threads are created, and each worker process/thread then executes the accept_and_recv() function in a loop. The performance benefits of accept_and_recv() include fewer buffer copies, recycled sockets, and optimal scheduling.
Returned Value

If successful, accept_and_recv() returns the number of bytes actually stored in the buffer pointed to by the `buffer` argument.

If unsuccessful, accept_and_recv() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int access(const char *pathname, int how);
```

General Description

Determines how an HFS file can be accessed. When checking to see if a process has appropriate permissions, access() looks at the real user ID (UID) and group ID (GID), not the effective IDs.

`pathname` is the name of the file whose accessibility you want to test. The `how` argument indicates the access modes you want to test. The following symbols are defined in the unistd.h header file for use in the `how` argument:

- F_OK Tests whether the file exists.
- R_OK Tests whether the file can be accessed for reading.
- W_OK Tests whether the file can be accessed for writing.
- X_OK Tests whether the file can be accessed for execution.

You can take the bitwise inclusive-OR of any or all of the last three symbols to test several access modes at once. If you are using F_OK to test for the file’s existence, you cannot use OR with any of the other symbols.

Returned Value

If the specified access is permitted, access() returns 0.

If the given file cannot be accessed in the specified way, access() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The process does not have appropriate permissions to access the file in the specified way, or does not have search permission on some component of the <code>pathname</code> prefix.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of <code>how</code> is incorrect.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in the symbolic links.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td><code>pathname</code> is longer than <code>PATH_MAX</code> characters. The <code>PATH_MAX</code> value is determined using <code>pathconf()</code>.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>There is no file named <code>pathname</code>, or the <code>pathname</code> argument is an empty string.</td>
</tr>
</tbody>
</table>
access

ENOTDIR Some component of the *pathname* prefix is not a directory.

EROF S The argument *how* has specified write access for a file on a read-only file system.

Returned Value for POSIX C Programs

The following *errno* values behave differently when a program is running with POSIX(ON):

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELOOP</td>
<td>A loop exists in the symbolic links. This error is issued if the number of symbolic links detected in the resolution is greater than POSIX_SYMLOOP (a value defined in the limits.h header file).</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td><em>pathname</em> is longer than PATH_MAX characters, or some component of <em>pathname</em> is longer than NAME_MAX, when _POSIX_NO_TRUNC (defined in the unistd.h header file) is in effect. The PATH_MAX and NAME_MAX values are determined using pathconf().</td>
</tr>
</tbody>
</table>

See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information about using POSIX support.

Example

CELEBA03

```c
/* CELEBA03

The following example determines how a file is accessed.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#undef _POSIX_SOURCE
#include <unistd.h>

main() {
    char path[]="/";
    if (access(path, F_OK) != 0)
        printf("'%s' does not exist!
", path);
    else {
        if (access(path, R_OK) == 0)
            printf("You have read access to '%%s'\n", path);
        if (access(path, W_OK) == 0)
            printf("You have write access to '%%s'\n", path);
        if (access(path, X_OK) == 0)
            printf("You have search access to '%%s'\n", path);
    }
}
```

Output

From a non-superuser:

You have read access to '/'
You have search access to '/'

acl_create_entry

acl_create_entry() — Add a New Extended ACL Entry to the ACL

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_create_entry(lacl_t *acl_p, acl_entry_t entry_p, int version);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The acl_create_entry() function creates a new extended ACL entry in the ACL pointed to by the contents of the pointer argument acl_p. The contents of the acl_entry are specified by entry_p. ACL working storage is allocated as needed. The first call to acl_get_entry() following the call to acl_create_entry() will obtain the first extended ACL entry in the ACL, as ordered by the system.

The version tells the function the version of ACL entry. See [“sys/acl.h” on page 87](#) for details.

Returned Value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_create_entry() function returns -1 and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Argument acl_p does not point to a pointer to an ACL structure. Argument entry_d does not point to a valid extended ACL entry.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>The ACL working storage requires more memory than is available.</td>
</tr>
</tbody>
</table>

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_delete_entry(lacl_t acl_d, acl_entry_t entry_d);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See z/OS UNIX System Services Planning for details.

The acl_delete_entry() function removes the extended ACL entry indicated by entry_d in the ACL pointed to by argument acl_d. The first call to acl_get_entry() following the call to acl_delete_entry() will obtain the first extended ACL entry in the ACL, as ordered by the system.

Returned Value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_delete_entry() function returns -1 and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Argument acl_d does not point to a pointer to an ACL structure. Argument entry_d does not point to a valid extended ACL entry or not within the given ACL structure.</td>
</tr>
</tbody>
</table>

acl_delete_fd

acl_delete_fd() — Delete an ACL by File Descriptor

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_delete_fd (int fd, int type_d);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See z/OS UNIX System Services Planning for details.

The acl_delete_fd() function deletes the type_d ACL. That means that all extended ACL entries are deleted for type_d ACL. A file/dir subject must match the owner of the directory/file or the subject must have appropriate privileges.

The effective UID of the process must match the owner of the directory/file or the process must have appropriate privileges. If the type_d is the directory/file default and the object referred to by fd is not a directory, then the function will fail. An attempt to delete an ACL from a file that does not have that ACL is not considered an error.

Upon successful completion, the acl_delete_fd() will delete the type ACL associated with the file referred by argument fd. If unsuccessful, the type ACL associated with the file object referred by argument fd will not be changed.

Returned Value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_delete_fd() function returns -1 and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>

<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_delete_file(const char *path_p, int type_d);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See z/OS UNIX System Services Planning for details.

The acl_delete_file() function deletes the type_d ACL. That means that all extended ACL entries are deleted for type_d ACL. A file/directory always has base ACL entries so they cannot be deleted. The effective UID of the process must match the owner of the directory/file or the process must have appropriate privileges.

If the type_d is the directory/file default and the object referred to by fd is not a directory, then the function will fail. An attempt to delete an ACL from a file that does not have that ACL is not considered an error.

Upon successful completion, the acl_delete_file() will delete the type ACL associated with the file referred by argument path_p. If unsuccessful, the type ACL associated with the file object referred by argument path_p will not be changed.

Returned Value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_delete_file() function returns -1 and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Argument type_d is not a valid ACL type.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>The length of the pathname argument exceeds PATH_MAX, or a pathname component is longer than NAME_MAX and <code>{_POSIX_NO_TRUNC}</code> is in effect for that file. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. PATH_MAX and NAME_MAX values can be determined by using pathconf().</td>
</tr>
</tbody>
</table>
acl_delete_file

ENOENT The named object does not exist or the path_p argument points to an empty string.

ENOTDIR The type specified was directory/file default but the argument path_p is not a directory or a component of the path prefix is not a directory.

</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_from_text (const char *buf_p, short OpType, acl_all_t ptr, char **ret);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The acl_from_text() function converts the text form of an ACL referred to by `buf_p` into the acl_t form of an ACL. It parses both the extended and base ACL entries.

If successful, the structure that `ptr` points to will be updated with ACL entries for the 3 types of ACLs. The structure members that `ptr` points to must either be NULL or point to a valid acl_t structure. If the structure member is not NULL, ACL entries contained in `buf_p` will be merged in. New storage for those structure members may be allocated as needed and in that case passed-in storage will be freed, so structure members may point to a different storage than the one originally supplied.

If `ptr` is NULL, the acl_from_text will fail. If the `buf_p` has no ACL entries (such as empty string, only empty lines, etc), acl_from_text() will fail with errno set to EINVAL and `ret` will point to the null terminator in `buf_p`.

Working storage is allocated for the individual ACLs structures as needed and need to be freed using acl_free().

If the function is unsuccessful due to error encountered in parsing, ret will contain the address of beginning of extended/base ACL entry where the error was found in `buf_p` and errno will be set to EINVAL. Otherwise `ret` will be NULL.

The text form of the ACL referred to by `buf_p` may be incomplete or may be a non-valid ACL as defined by acl_valid(). The `buf_p` must be null terminated. The first call to acl_get_entry() following the call to acl_from_text() obtains the first entry in the ACL as ordered by the system.

For OpType =ACL_DELETE, the extended ACL entries will be updated with the flag bit to be removed from the ACL when acl_set_fd() or acl_set_file() is called. The base ACL entries are parsed but not put into the structure that `ptr` points to since you cannot delete base ACL entries.

The `buf_p` cannot have a mixture of ACL entry delimiters (newline and comma). All ACL entries in the buf must use the same delimiter, either a newline or comma. For
a mixture of delimiters, acl_from_text() will fail with errno set to EINVAL and ret parameter will point to the delimiter in error.

 acl_all_t :
 index 0 access acl
 index 1 file default acl
 index 2 directory default acl

Valid text input format based on OpType:
tag     fdefault, default (access if nothing is specified)
type    user, group, other
id      uid, gid, username, groupname
perm    rwx ( or '-' for no permission), octal (0-7) , +/^ (where + is turn on and ^ is turn off)

Pound sign (#) is used to designate a comment. When the input is separated by commas, everything past # is treated as a comment. When the input is separated by a newline, everything after # till the newline is considered a comment. Comments are ignored and are not stored in the buffer.

ACL_ADD  tag:type:id:perm // extended ACL entry
         type::perm // base ACL entry
ACL_MODIFY same as ACL_ADD
ACL_DELETE tag::id // extended ACL entry

Note: The extended ACL entries must have the type (group or user) and the id (uid/gid). The base ACL entries do not have a value for the id field. The id field or the lack of one is what distinguishes the base ACL entry from the extended ACL entry. The base ACL entries do not have the tag fields since they only apply to access ACL.

The acl_from_text() allows for trailing ACL entry separator (newline or comma). For relative permission settings, only one of '+' or '^' is allowed per ACL entry. When using relative permissions you must have at least one of r, w, or x. For example: +rw or ^rwx.

Returned Value

Upon successful completion, the function returns a zero.

If any of the following conditions occur, the acl_from_text() function returns -1 and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Argument buf_p cannot be translated into an ACL.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>The ACL working storage requires more memory than is available.</td>
</tr>
<tr>
<td>E2BIG</td>
<td>The number of base ACL entries exceeded allowable 3.</td>
</tr>
</tbody>
</table>

The ret will contain the address in buf_p where the error was found.

<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_get_entry (acl_t acl_d, acl_entry_t *entry_p);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The acl_get_entry() function obtains a descriptor to the next extended ACL entry of the ACL indicated by argument acl_d. Upon successful execution, the acl_get_entry() function returns a descriptor for the extended ACL entry via entry_p. Argument acl_d must refer to a valid acl_t structure.

The first call to acl_get_entry() following a call to acl_first_entry(), acl_from_text(), acl_get_fd(), acl_get_file(), acl_set_fd(), acl_set_file(), or acl_valid() obtains the first extended ACL entry in the ACL, as ordered by the system. Subsequent calls to acl_get_entry() obtain successive extended ACL entries, until the last entry is obtained. After the last extended ACL entry has been obtained from the acl_d the value NULL is returned via entry_p.

To determine if ACL has any base ACL entries, check acl_d->lacl_base, which gives the number of base ACL entries present. Then the process can access the base ACL entries directly in the acl_d. (For example: acl_d->lacl_base_entries[0].acle_type is the type field of the first base ACL entry.)

Returned Value

If the function successfully obtains a pointer to the extended ACL entry, the function returns a value of one. If the last extended ACL entry in the ACL has already been returned by a previous call to acl_get_entry() or if ACL has no extended ACL entries, the function returns a value of zero.

If any of the following conditions occur, the acl_get_entry() function returns -1 and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Argument acl_d does not point to an ACL structure.</td>
</tr>
</tbody>

<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_get_fd (int fd, acl_type_t type_d, lacl_t acl_d, int *num);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See z/OS UNIX System Services Planning for details.

The acl_get_fd() function retrieves an ACL based on type_d argument for an object associated with the file descriptor fd. The ACL is retrieved into the supplied working storage pointed to by acl_d. For the type_d = ACL_ACCESS, acl_get_fd() will get both the base ACL entries and extended ACL entries. (The base ACL entries only apply to the ACL_ACCESS ACL.)

The working storage should be allocated using the acl_init() function. If the buffer is not big enough, the acl_get_fd() will fail with errno=E2BIG and num will be filled with the number of ACLs in the ACL pointed to by fd. The user can get a bigger acl_t structure buffer using the num value and reissue the acl_get_fd().

If the object associated with the file descriptor does not have the specified ACL, then an ACL containing zero ACL entries will be returned. If the argument fd refers to an object other than a directory and the value of type_d is a directory/file default, then the function will fail.

The first call to acl_get_entry() following the call to acl_get_fd() obtains the first extended ACL entry in the ACL as ordered by the system.

The result of acl_get_fd() can be used to set that same ACL using acl_set_fd() or acl_set_file() using OpType = ACL_ADD.

Returned Value

Upon successful completion, the function returns zero.

If any of the following conditions occur, the acl_get_fd() function returns a value of NULL and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The required access to the file referred to by fd is denied.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The fd argument is not a valid file descriptor.</td>
</tr>
</tbody>
</table>
EINVAL  Argument type_d is not a valid ACL type. Argument acl_d does not point to an ACL structure.

ENOTDIR  The type specified was directory/file default but the argument fd does not refer to a directory.

E2BIG    The supplied buffer is too small for all extended ACL entries. num value has the number of ACL entries that need to fit in the buffer.

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_get_file(const char *path_p, acl_type_t type_d, acl_t acl_d, int *num);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See z/OS UNIX System Services Planning for details.

The acl_get_file() function retrieves an ACL based on `type_d` argument for an object associated with the object via file name. The ACL is retrieved into the specified working storage pointed to by `acl_d`. For the `type_d` = ACL_ACCESS, acl_get_file() will get both the base ACL entries and extended ACL entries. The base ACL entries only apply to the ACL_ACCESS ACL.

The working storage should be allocated using the acl_init() function. If the buffer is not big enough, the acl_get_fd() will fail with errno=E2BIG and `num` will be filled with the number of ACLs in the ACL pointed to by `fd`. The user can get a bigger acl_t structure buffer using the num value and reissue the acl_get_fd().

If the object associated with the file descriptor does not have the specified ACL, then an ACL containing zero ACL entries will be returned. If the argument `fd` refers to an object other than a directory and the value of `type_d` is a directory/file default, then the function will fail.

The first call to acl_get_entry() following the call to acl_get_fd() obtains the first extended ACL entry in the ACL as ordered by the system. The result of acl_get_fd() can be used to set that same ACL using acl_set_fd() or acl_set_file() using OpType = ACL_ADD.

Returned Value

Upon successful completion, the function returns zero.

If any of the following conditions occur, the acl_get_file() function returns a value of NULL and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.</td>
</tr>
</tbody>
</table>
EINVAL Argument type_d is not a valid ACL type. Argument acl_d does not point to an ACL structure.

ENAMETOOLONG The length of the pathname argument exceeds PATH_MAX, or a pathname component is longer than NAME_MAX and {_POSIX_NO_TRUNC} is in effect for that file. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. PATH_MAX and NAME_MAX values can be determined by using pathconf().

ENOENT The named object does not exist or the path_p argument points to an empty string.

ENOTDIR The type specified was directory/file default but the argument path_p is not a directory or a component of the path prefix is not a directory.

E2BIG The supplied buffer is too small for all extended ACL entries. Num value has the number of ACL entries that need to fit in the buffer.

<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

lacl_t acl_init(int count);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See z/OS UNIX System Services Planning for details.

The acl_init() function allocates and initializes working storage for an ACL of at least `count` extended ACL entries. A pointer to the working storage is returned. The working storage allocated to contain the ACL must be freed by a call to acl_free(). The working storage contains an ACL with no ACL entries. The count must be greater than 0.

The acl_init() function initializes fields in the `lacl_t` it returns. When those fields are destroyed (for example, using memset or overwriting storage), the results are unpredictable. To re-use the buffer, acl_entry_delete() all extended ACL entries and set `lacl_base` = 0 or acl_free() the existing buffer and acl_init() for a new one.

Returned Value

Upon successful completion, the function returns a pointer to the working storage.

If any of the following conditions occur, the acl_init() function returns NULL and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>The <code>lacl_t</code> to be returned requires more memory than is available.</td>
</tr>
<tr>

acl_set_fd() — Set an ACL by File Descriptor

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_set_fd (int fd, acl_type_t type_d, lacl_t acl_d, short OpType,
    acl_entry_t *entry_p);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access
to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS
file systems. You must know whether your security product supports ACLs and what
rules are used when determining file access. See z/OS UNIX System Services
Planning for details.

The acl_set_fd() function associates the type_d ACL with the object referred to by
fd. The effective UID of the subject must match the owner of the object or the
subject must have appropriate privileges.

If the type_d is the directory/file default and the object referred to by fd is not a
directory, then the function will fail.

The acl_set_fd() function will succeed only if the ACL is valid as defined by the
acl_valid() function.

Upon successful completion, acl_set_fd() will set the ACL of the object. For type_d
= ACL_ACCESS, acl_set_fd() will also set the base ACL entries. The base ACL
entries only apply to ACL_ACCESS ACL type, so for any other type the base ACL
entries are ignored.

The OpType determines whether the ACL is updated or replaced.

<table>
<thead>
<tr>
<th>OpType</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACL_ADD</td>
<td>replace the whole ACL with the given extended and base ACL entries</td>
</tr>
</tbody>
</table>
| ACL_MODIFY  | update the ACL with the given extended and/or base ACL entries (if
    individual extended ACL entries are marked for deletion, then
    ACL_MODIFY removes them)                                               |
| ACL_DELETE  | delete from the ACL the specified extended ACL entries; marks the
    individual extended ACL entries for deletion (cannot delete base
    ACL entries)                                                          |

If OpType is ACL_MODIFY, the setting will modify the existing extended ACL entries
and add new ones if they do not exist. Both ACL entry’s mask and value are used
to determine ACL entry’s permission to set.
If `OpType` is ACL_ADD, the existing ACL is replaced by the new one. Only extended ACL entry’s value is used to determine permissions to set. The object’s previous ACL will no longer be in effect. If the object had no ACL, a new one is added for both ACL_MODIFY and ACL_ADD.

Similarly, for `OpType` = ACL_ADD, base ACL entries are replaced with the new values specified (mask field is ignored). All three base ACL entries (ACL_USER, ACL_GROUP, and ACL_OTHER) must be specified. For `OpType` = ACL_MODIFY, the base ACL entries are modified with the specified values (both mask and value fields are used).

For `OpType` = ACL_MODIFY only the base ACL entries to be changed need to be specified. The `OpType` = ACL_DELETE does not apply to base ACL entries since they cannot be removed. Every file always has base ACL entries.

If the acl_set_fd() is unsuccessful, the ACL of the object referred to by argument `fd` is not changed.

The ordering of entries within ACL referred to by `acl_d` may be changed. The first call to acl_get_entry() following the call to acl_set_fd() obtains the first extended ACL entry in the ACL as ordered by the system.

### Returned Value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_set_file() function returns a value of -1 and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.</td>
</tr>
<tr>
<td>E2BIG</td>
<td>The ACL has more extended ACL entries than is allowed.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>The named object does not exist or the <code>path_p</code> argument points to an empty string.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Argument <code>acl_d</code> does not point to a valid ACL structure.</td>
</tr>
<tr>
<td>ENOSPC</td>
<td>The directory or file system that would contain the new ACL cannot be extended or the file system is out of space.</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>The <code>type_d</code> specified was directory/file default but the argument <code>path_p</code> does not refer to a directory.</td>
</tr>
</tbody>
</table>
| ENAMETOOLONG | The length of the pathname argument exceeds PATH_MAX, or a pathname component is longer than NAME_MAX and \(_\_POSIX_NO_TRUNC\) is in effect for that file. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. PATH_MAX and NAME_MAX values can be determined by using `pathconf()`.
| EMVSERR    | Other internal RACF error (more information in `errno2`) |

The function will return -2 and set errno to EINVAL if the base ACL entry is not unique or is not a valid type or for ACL_ADD, there are less than 3 base ACL entries. The `entry_p` will be NULL.
The function will return -3 and set errno to EINVAL if the extended ACL entry is not unique or is not a valid type. The `entry_p`, if not NULL, will point to the extended ACL entry in error.

acl_set_file

**acl_set_file() — Set an ACL by Filename**

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

### Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_set_file (char *path_p, acl_type_t type_d, lacl_t acl_d, short OpType,
                  acl_entry_t *entry_p);
```

### General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See `z/OS UNIX System Services Planning` for details.

The `acl_set_file()` function associates the `type_d` ACL with the object referred to by file name `path_p`. The effective UID of the subject must match the owner of the object or the subject must have appropriate privileges.

If the `type_d` is the directory/file default and the object referred to by file name `path_p` is not a directory, then the function will fail.

The `acl_set_file()` function will succeed only if the ACL is valid as defined by the `acl_valid()` function.

Upon successful completion, `acl_set_file()` will set the ACL of the object. For `type_d` = ACL_ACCESS, `acl_set_file()` will also set the base ACL entries. The base ACL entries only apply to ACL_ACCESS ACL type, so for any other type the base ACL entries are ignored.

The **OpType** determines whether the ACL is updated or replaced.

<table>
<thead>
<tr>
<th>OpType</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACL_ADD</td>
<td>replace the whole ACL with the given extended and base ACL entries</td>
</tr>
<tr>
<td>ACL_MODIFY</td>
<td>update the ACL with the given extended and/or base ACL entries (if individual extended ACL entries are marked for deletion, then ACL_MODIFY removes them)</td>
</tr>
<tr>
<td>ACL_DELETE</td>
<td>delete from the ACL the specified extended ACL entries; marks the individual extended ACL entries for deletion (cannot delete base ACL entries)</td>
</tr>
</tbody>
</table>

If **OpType** is ACL_MODIFY, the setting will modify the existing extended ACL entries and add new ones if they do not exist. Both ACL entry’s mask and value are used to determine ACL entry’s permission to set.
If `OpType` is `ACL_ADD`, the existing ACL is replaced by the new one. Only extended ACL entry’s value is used to determine permissions to set. The object’s previous ACL will no longer be in effect. If the object had no ACL, a new one is added for both `ACL_MODIFY` and `ACL_ADD`.

Similarly, for `OpType = ACL_ADD`, base ACL entries are replaced with the new values specified (mask field is ignored). All three base ACL entries (ACL_USER, ACL_GROUP, and ACL_OTHER) must be specified. For `OpType = ACL_MODIFY`, the base ACL entries are modified with the specified values (both mask and value fields are used).

For `OpType = ACL_MODIFY` only the base ACL entries to be changed need to be specified. The `OpType = ACL_DELETE` does not apply to base ACL entries since they cannot be removed. Every file always has base ACL entries.

If the `acl_set_file()` is unsuccessful, the ACL of the object referred to by argument `path_p` is not changed.

The ordering of entries within ACL referred to by `acl_d` may be changed. The first call to `acl_get_entry()` following the call to `acl_set_file()` obtains the first extended ACL entry as ordered by the system.

**Returned Value**

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the `acl_set_file()` function will return a value of -1 and set errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCESS</td>
<td>Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.</td>
</tr>
<tr>
<td>E2BIG</td>
<td>The ACL has more extended ACL entries than are allowed.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>The named object does not exist or the <code>path_p</code> argument points to an empty string.</td>
</tr>
<tr>

<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_sort(lacl_t acl_d);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See z/OS UNIX System Services Planning for details.

The acl_sort() function sorts the extended ACL entries in the following orders:
- ACL_USER lowest to highest uid
- ACL_GROUP lowest to highest gid

Returned Value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_sort() returns -1 and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>

</tr>
</tbody>
</table>

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

char * acl_to_text (const lacl_t acl_d, ssize_t *len_p, acl_type_t type_d,
                     char delim);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The acl_to_text() function translates the extended ACL entries in an ACL pointed to by argument acl_d into a NULL terminated character string. This function allocates any memory necessary to contain the string and returns a pointer to the string. The memory allocated to contain the string must be freed. If the pointer len_p is not NULL, then the function returns the full length of the string (not including the NULL terminator) in the location pointed to by len_p. The delim parameter determines the delimiter used to separate the ACL entries (usually newline or comma).

The mask field in the base and extended ACL entry is ignored and only the ACL entry value field is used to display the ACL entry permissions.

For acl_d with no extended ACL entries, acl_to_text() returns NULL. When acl_to_text() cannot convert uid/gid to username/groupname, it leaves the uid/gid in the string.

The format of the text string:

```
<acl_entry>delim<acl_entry> ... <acl_entry>
```

where acl_entry may be:

- base_acl_tag::permissions
- user:user_name::permissions
- group:group_name::permissions
- default:user_name::permissions

base_acl_entry:

- user, group, or other

permissions:

rw (with '-' for no permission)
default:
- file default
- directory default

Returned Value

Upon successful completion, the function returns a pointer to the text form of an ACL.

If any of the following conditions occur, the acl_to_text() returns NULL and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Argument acl_d does not point to a valid ACL structure. The ACL referenced by acl_d contains one or more improperly formed ACL entries, or for some other reason cannot be translated into the string form of ACL.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>The character string to be returned requires more memory than is available.</td>
</tr>
</tbody>
</table>

acl_update_entry() — Update the Extended ACL Entry

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_update_entry(lacl_t acl_d, acl_entry_t entry_s, acl_entry_t entry_d
                     int version);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See z/OS UNIX System Services Planning for details.

The acl_update_entry() function updates the extended ACL entry `entry_s` with the values from `entry_d`. The version tells the function the version of ACL entry. See "sys/acl.h" on page 87 for ACL entry mapping.

Returned Value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the acl_create_entry() function returns -1 and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Argument <code>entry_s</code> or <code>entry_d</code> do not point to a valid extended ACL entry. Argument <code>acl_d</code> does not point to a valid ACL structure.</td>
</tr>
</tbody>
</table>

acl_valid() — Validate an ACL

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_valid (lACL_t acl_d, acl_entry_t *entry_p);
```

General Description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the HFS, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See z/OS UNIX System Services Planning for details.

The acl_valid() function checks the access ACL, file default ACL, or directory default ACL referred to by the argument `acl_d` for validity.

The ACL_USER, ACL_GROUP, and ACL_OTHER can only exist once in base ACL entries. The ACL_OTHER only applies to base ACL entries.

The tag type (user, group) must contain valid values for the extended ACL entries. The qualifier field (uid, gid) must be unique among all extended ACL entries of the same ACL except for the extended ACL entries that are mapped for deletion (see ACL entry mapping in "sys/acl.h" on page 87 for more information). The ordering of base and/or extended ACL entries within ACL referred by the `acl_d` may be changed.

The first call to acl_get_entry() following the call to acl_valid() obtains the first extended ACL entry in the ACL as ordered by the system.

Returned Value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the location referred to by `entry_p` will be undefined and the acl_valid() function returns -1 and sets errno to the corresponding value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Argument acl_d does not point to an ACL structure.</td>
</tr>
</tbody>
</table>

If any of the following conditions occur, the acl_valid() function will set the location referred to by `entry_p` to one of the ACL entries in error, return -2 and set errno to the appropriate value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The ACL contains extended ACL entries that are not unique or is not a valid ACL entry type.</td>
</tr>
</tbody>
</table>
acl_valid

If any of the following conditions occur, the acl_valid() function will return -3 and set errno to the appropriate value.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The ACL contains base ACL entries that are not unique or is not a valid ACL entry type. Only one base ACL entry of the same tag type (ACL_USER, ACL_GROUP, ACL_OTHER) may exist.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

Format

```
#include <math.h>

double acos(double x);
float acos(float x);    /* C++ only */
long double acos(long double x); /* C++ only */
float acosf(float x);
long double acosl(long double x);
```

General Description

Calculates the arccosine of x, expressed in radians, in the range 0 to pi.

The value of x must be between -1 and 1 inclusive.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE Binary Floating-Point " on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

**Special Behavior for C/370**

If x is less than -1 or greater than 1, the function sets errno to EDOM and returns 0. If the correct value would cause underflow, zero is returned and the value ERANGE is stored in errno.

**Special Behavior for XPG4.2**

If successful, the function returns the arccosine of x, in the range [0,pi] radians.

If the value of x is not in the range [-1,1], the function returns 0.0 and sets errno to the following value. No other errors will occur.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EDOM</td>
<td>The value x is not in the range [-1,1].</td>
</tr>
</tbody>
</table>

**Special Behavior for IEEE**

If successful, the function returns the arccosine of the argument x.

If x is less than -1 or greater than 1, the function sets errno to EDOM and returns NaNQ (Not a Number Quiet). No other errors will occur.
acos, acosf, acosl

Example

CELEBA04
/* CELEBA04

This example prompts for a value for x.
It prints an error message if x is greater than 1 or
less than −1; otherwise, it assigns the arccosine of
x to y.

*/
#include <stdio.h>
#include <stdlib.h>
#include <math.h>
#define MAX 1.0
#define MIN -1.0

int main(void)
{
    double x, y;

    printf( "Enter x\n" );
    scanf( "%lf", &x );

    /* Output error if not in range */
    if ( x > MAX )
        printf( "Error: %.f too large for acos\n", x );
    else if ( x < MIN )
        printf( "Error: %.f too small for acos\n", x );
    else {
        y = acos( x );
        printf( "acos( %.f ) = %.f\n", x, y );
    }
}

Output

Expected result if 0.4 is entered:
Enter x
acos( 0.400000 ) = 1.159279

#include <math.h>

double acosh(double x);
```

C99

```c
#define _ISOC99_SOURCE
#include <math.h>

float acoshf(float x);
long double acoshl(long double x);
```

General Description

The acosh functions compute the (nonnegative) arc hyperbolic cosine of \( x \). A domain error occurs for arguments less than 1.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>

<td>X</td>
<td>X</td>
</tr>
<tr>
<td>acoshf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>acoshl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

If successful, acosh() returns the hyperbolic arccosine of its argument \( x \).

If the value of \( x \) is less than 1.0, then the function returns 0.0 and sets errno to EDOM.

Special Behavior for IEEE

If successful, the function returns the hyperbolic arccosine of its argument \( x \).

If \( x \) is less than 1.0, the function sets errno to EDOM and returns NaNQ.

advance() — Pattern Match Given a Compiled Regular Expression

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <regexp.h>

int advance(const char *string, const char *expbuf);

extern char *loc2, *locs;
```

General Description

Restriction: This function is not supported in AMODE 64.

The `advance()` function attempts to match an input string of characters with the compiled regular expression which was obtained by an earlier call to `compile()`.

The first parameter `string` is a pointer to a string of characters to be checked for a match.

`expbuf` is the pointer to the regular expression which was previously obtained by a call to `compile()`.

The external variable `loc2` will point to the next character in `string` after the last character that matched the regular expression.

The external variable `locs` can be optionally set to point to some point in the input regular expression string to cause the `advance()` function to exit its back up loop.

Note: The external variables `cirf`, `sed`, and `nbra` are reserved.

During the pattern matching operation, when `advance()` encounters a `*` or `{}` sequence in the regular expression, it will advance its pointer to the string to be matched as far as possible and will recursively call itself trying to match the rest of the string to the rest of the regular expression. As long as there is no match, `advance()` will back up along the string until it finds a match or reaches the point in the string that initially matched the `*` or `{}`. It is sometime desirable to stop this backing up before the initial point in the string is reached. If the external character pointer `locs` is equal to the point in the string at some time during the back up process, `advance()` will break out of the loop that backs up and will return 0 (a failure indication).

Notes:

1. The application must provide the proper serialization for the `compile()`, `step()`, and `advance()` functions if they are run under a multithreaded environment.
2. The `compile()`, `step()`, and `advance()` functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as
part of Single UNIX Specification, Version 3. New applications should use the
newer functions fnmatch(), glob(), regcomp() and regexec(), which provide full
internationalized regular expression functionality compatible with IEEE Std

Returned Value
If the initial substring of string matches the regular expression in expbuf, advance() returns nonzero.
If there is no match, advance() returns 0.
If there is a match, advance() sets an external character pointer, loc2, as a side
effect. The variable loc2 points to the next character in string after the last character
that matched the regular expression.

__ae_correstbl_query() — Return Coded Character Set ID Type (ASCII/EBCDIC)

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

```c
#include <_Nascii.h>
__argument_t __ae_correstbl_query(void *search_argument, int src_arg_type,
   _AE_correstbl_t **ebcdic_entry_ptr,
   _AE_correstbl_t **ascii_entry_ptr);
```

General Description

The __ae_correstbl_query() function is a method by which the user can obtain coded character set id (CCSID), type, and correspondence information from the EBCDIC/ASCII Correspondence and CCSID/Codeset Name Lookup Table, CEL4CTBL.

The user must provide the following:

**Argument** | **Description**
--- | ---
*search_argument | A Codeset Name or CCSID search argument.
src_arg_type | Specifies whether search_argument is a Codeset Name or a CCSID, using one of the defined values from <_Nascii.h>:
- _AE_CODESET_SRCH_ARG
- _AE_CCSID_SRCH_ARG

**ebcdic_entry_ptr** | The address of an _AE_correstbl_t pointer for storing the EBCDIC table entry.

**ascii_entry_ptr** | The address of an _AE_correstbl_t pointer for storing the ASCII table entry.

The function will then populate the supplied pointers with the address of _AE_correstbl_t structures containing the requested codeset's table entry as well as the address of the corresponding codeset's entry. However, not every EBCDIC codeset in the table has a corresponding ASCII encoding and vice versa. When a corresponding codeset does not exist, the pointer value returned in that argument is zero.

For consistency, the first _AE_correstbl_t pointer address argument will be populated with the EBCDIC entry address, and the second _AE_correstbl_t pointer will be populated with the ASCII entry address, regardless of which was the requested codeset and which was the corresponding codeset.

The __argument_t return value for __ae_correstbl_query() indicates the EBCDIC or ASCII type of the provided codeset.
**__ae_correstbl_query**

**Returned Value**

If successful, __ae_correstbl_query() returns either:

- __AE_EBCDIC_TYPE, when the requested entry is EBCDIC.
- __AE_ASCII_TYPE, when the requested entry is ASCII.

If unsuccessful, because the correspondence table cannot be loaded or the provided Codeset Name or CCSID is not valid, __ae_correstbl_query() returns __AE_UNKNOWN_TYPE.

aio_cancel() — Cancel an Asynchronous I/O Request

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_cancel(int fildes, struct aiocb *aiocbp);
```

General Description

The `aio_cancel()` function attempts to cancel one or more asynchronous I/O requests currently outstanding against file descriptor `fildes`. The `aiocbp` argument points to an `aiocb` structure for a particular request to be canceled or is NULL to cancel all outstanding cancelable requests against `fildes`.

Normal asynchronous notification occurs for asynchronous I/O operations that are successfully canceled. The associated error status is set to `ECANCELED` and the return status is set to −1 for the canceled requests.

For requests that cannot be canceled, the normal asynchronous completion process takes place when their I/O completes. In this case the `aiocb` is not modified by `aio_cancel()`.

An asynchronous operation is cancelable if it is currently blocked or becomes blocked. Once an outstanding request can be completed it is allowed to complete. For example, an `aio_read()` will be cancelable if there is no data available at the time that `aio_cancel()` is called.

`fildes` must be a valid file descriptor, but when `aiocbp` is not NULL `fildes` does not have to match the file descriptor with which the asynchronous operation was initiated. For maximum portability, though, it should match.

The `aio_cancel()` function always waits for the request being canceled to either complete or be canceled. When control returns from `aio_cancel()`, the program may safely free the original request’s aiocb and buffer. If a signal was specified on the original request, the signal handler for that request’s I/O complete notification may run before, during, or after control returns from `aio_cancel()`, so coordination may be necessary between the signal handler and the caller of `aio_cancel()`. This is particularly unpredictable when `aio_cancel()` is called from a different thread than the original request, unless the original thread no longer exists.

Canceling all requests on a given descriptor does not stop new requests from being made or otherwise effect the descriptor. The program may start again or close the descriptor depending on why it issued the cancel.

An individual request can only be canceled once. Subsequent attempts to explicitly cancel the same request will fail with `EALREADY`.

Chapter 3. Part 3. Library Functions 167
aio_cancel

Returned Value

aio_cancel() returns one of the following values:

- `AIO_CANCELED` if the requested operations were canceled.
- `AIO_NOTCANCELED` if at least one of the requested operations cannot be canceled because it is in progress.

In this case, the state of the other operations, if any, referenced in the call to `aio_cancel()` is not indicated by the return value of `aio_cancel()`. The application can determine the status of these operations by using `aio_error()`.

- `AIO_ALLDONE` if all of the operations have already completed. This is returned when there are no outstanding requests found that match the criteria specified. This is also the result returned when a file associated with `fd` does not support the asynchronous I/O function because there are no outstanding requests to be found that match the criteria specified.
- `−1` if there was an error. `aio_cancel()` sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EALREADY</td>
<td>The operation to be canceled is already being canceled.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The <code>fd</code> argument is not a valid file descriptor.</td>
</tr>
</tbody>
</table>

aio_error() — Retrieve Error Status for an Asynchronous I/O Operation

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_error(const struct aiocb *aiocbp);
```

General Description

The `aio_error()` function returns the error status associated with the `aiocb` structure referenced by the `aiocbp` argument. The error status for an asynchronous I/O operation is the `errno` value that would be set by the corresponding `read()`, or `write()` operation. If the operation has not yet completed, then the error status will be equal to `EINPROGRESS`.

Returned Value

If the asynchronous I/O operation has completed successfully, `aio_error()` returns 0.

If the asynchronous I/O operation has completed unsuccessfully, `aio_error()` returns the error status as described for `read()`, or `write()`.

If the asynchronous I/O operation has not yet completed, then `EINPROGRESS` is returned.

`aio_error()` does not set `errno`.

When the `errno` is returned is not `EINPROGRESS` and not zero, the `errno2` set by either `read()` or `write()` can be retrieved by using the `__errno2()` function.

**aio_read**

**aio_read() — Asynchronous Read from a Socket**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_read(struct aiocb *aiocbp);
```

**General Description**

The `aio_read()` function initiates an asynchronous read operation as described by the `aiocb` structure (the asynchronous I/O control block).

The `aiocbp` argument points to the `aiocb` structure. This structure contains the following members:

- `aio_fildes`: file descriptor
- `aio_offset`: file offset
- `aio_buf`: location of buffer
- `aio_nbytes`: length of transfer
- `aio_reqprio`: request priority offset
- `aio_sigevent`: signal number and value
- `aio_lio_opcode`: operation to be performed

The operation reads up to `aio_nbytes` from the socket or file associated with `aio_fildes` into the buffer pointed to by `aio_buf`. The call to `aio_read()` returns when the request has been initiated or queued to the file or device (even when the data cannot be delivered immediately).

Asynchronous I/O is currently only supported for sockets. The `aio_offset` field may be set but it will be ignored.

With a stream socket an asynchronous read may be completed when the first packet of data arrives and the application may have to issue additional reads, either asynchronously or synchronously, to get all the data it wants. A datagram socket has message boundaries and the operation will not complete until an entire message has arrived.

The `aiocbp` value may be used as an argument to `aio_error()` and `aio_return()` functions in order to determine the error status and return status, respectively, of the asynchronous operation. While the operation is proceeding, the error status retrieved by `aio_error()` is EINPROGRESS; the return status retrieved by `aio_return()` however is unpredictable.
If an error condition is encountered during the queueing, the function call returns without having initiated or queued the request.

When the operation completes asynchronously the program can be notified by a signal as specified in the `aio_sigevent` structure. It is significantly more efficient to receive these notifications with `sigwaitinfo()` or `sigtimedwait()` than to let them drive a signal handler. At this time the return and error status will have been updated to reflect the outcome of the operation. The sigevent structure's notification function fields are not supported. If a signal is not desired the program can occasionally poll the aiocb with `aio_error()` until the result is no longer `EINPROGRESS`.

Be aware that the operation may complete, and the signal handler may be delivered, before control returns from the call to `aio_read()`. Even when the operation does complete this quickly the return value from the call to `aio_read()` will be zero, reflecting the queueing of the I/O request not the results of the I/O itself.

An asynchronous operation may be canceled with `aio_cancel()` before its completion. Canceled operations complete with an error status of `ECANCELED` and any specified signal will be delivered. Due to timing, the operation may still complete naturally, either successfully or unsuccessfully, before it can be canceled by `aio_cancel()`.

If the file descriptor of this operation is closed, the operation will be deleted if it has not completed or is not just about to complete. Signals specified for deleted operations will not be delivered. `Close()` will wait for asynchronous operations in progress for the descriptor to be deleted or completed.

You may use `aio_suspend()` to wait for the completion of asynchronous operations.

Sockets must be in blocking state or the operation may fail with `EWOULDBLOCK`.

If the control block pointed by `aiocbp` or the buffer pointed to by `aio_buf` becomes an illegal address before the asynchronous I/O completion, then the behavior of `aio_read()` is unpredictable.

If the thread that makes the `aio_read()` request terminates before the I/O completes the `aiocb` structure will still be updated with the return and error status, and any specified signal will be delivered to the process in which the thread was running. If thread related storage was used on the request the results are quite unpredictable.

Simultaneous asynchronous operations using the same `aiocbp`, asynchronous operations using a non-valid `aiocbp`, or any system action, that changes the process memory space while asynchronous I/O is outstanding to that address range, will produce unpredictable results.

Simultaneous `aio_read()` operations on the same socket should not be done in general. With stream sockets, the I/O complete notifications may not be delivered in the same order as the bytes to which they refer, and so the byte stream may appear out of order. With UDP sockets, each datagram will complete one `aio_read()` operation, but IBM recommends against doing multiple `aio_read()`s for UDP sockets because this can cause significantly more system overhead as data arrives than a single outstanding request would.

There are several sockets oriented extensions to asynchronous I/O available with the BPX1AIO callable service, such as asynchronous accept() and asynchronous forms of the four other read type operations: `recvfrom()`, `recvmsg()`, `recv()`, and...
readv(). Also, the I/O Completion notification might be received via an ECB, an exit program or through a message queue. The aio.h header contains all the structure fields, constants, and prototypes necessary to use BPX1AIO from a C program. These extensions are exposed when the _AIO_OS390 feature flag is #defined. BPX1AIO calls may be mixed with aio_xxxx calls and any of the regular socket functions. For a more detailed description of asynchronous I/O services, see [z/OS UNIX System Services Programming: Assembler Callable Services Reference]

The aio_lio_opcode field is set to LIO_READ by the function aio_read().

_POSIX-PRIORITIZED_IO is not supported. The aio_reqprio field may be set but it will be ignored.

_POSIX_SYNCHRONIZED_IO is not supported.

Returned Value

If successful, aio_read() returns 0 to the calling process.

If unsuccessful, aio_read() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The requested asynchronous I/O operation was not queued due to system resource limitations.</td>
</tr>
<tr>
<td>ENOSYS</td>
<td>The file associated with aio_fildes does not support the aio_read() function.</td>
</tr>
</tbody>
</table>

Each of the following conditions may be detected synchronously at the time of the call to aio_read(), or asynchronously. If any of the conditions below are detected synchronously, aio_read() returns −1 and sets the errno to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to −1, and the error status of the asynchronous operation will be set to the corresponding value.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The aio_fildes argument is not a valid file descriptor open for reading.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>aio_sigevent contains an non-valid value.</td>
</tr>
<tr>
<td>EWOULDBLOCK</td>
<td>The file associated with aio_fildes is in nonblocking state and there is no data available.</td>
</tr>
</tbody>
</table>

In the case where the aio_read() function successfully queues the I/O operation but the operation is subsequently canceled or encounters an error, the return status of the asynchronous operations is set to −1, and the error status of the asynchronous operation will be set to the error status normally set by the read() function call, or to the following value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECANCELED</td>
<td>The requested I/O was canceled before the I/O completed due to an explicit call to aio_cancel().</td>
</tr>
</tbody>
</table>

</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_return(const struct aiocb *aiocbp);
```

General Description

The aio_return() function returns the return status associated with the aiocb structure referenced by the aiocbp argument. The return status for an asynchronous I/O operation is the value that would be set by the corresponding read() or write() operation. While the operation is proceeding, the error status retrieved by aio_error() is EINPROGRESS; the return status retrieved by aio_return() however is unpredictable. The aio_return() function may be called to retrieve the return status of a given asynchronous operation; once aio_error() has returned with 0.

Returned Value

If the asynchronous I/O operation has completed successfully, aio_return() returns the status as described for read() or write().

If the asynchronous I/O operation has not yet completed, then the return status is unpredictable.

aio_return() does not set errno.

<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_suspend(const struct aiocb *const list[], int nent, const struct timespec *timeout);
```

General Description

The `aio_suspend()` function suspends the calling thread when the `timeout` is a NULL pointer until at least one of the asynchronous I/O operations referenced by the `list` argument has completed, or until a signal interrupts the function. Or, if `timeout` is not NULL, it is suspended until the time interval specified by `timeout` has passed. If the time interval indicated in the `timespec` structure pointed to by `timeout` passes before any of the I/O operations referenced by `list`, then `aio_suspend()` returns without suspending the calling thread.

The `list` argument is an array of pointers to asynchronous I/O control blocks (AIOCBs). The `nent` argument indicates the number of elements in the array. Each `aiocb` structure pointed to will have been used in initiating an asynchronous I/O request. This array may contain NULL pointers, which are ignored. If this array contains pointers that refer to `aiocb` structures that have not been used in submitting asynchronous I/O or `aiocb` structures that are not valid, the results are unpredictable.

Returned Value

If successful, `aio_suspend()` returns 0.

If unsuccessful, `aio_suspend()` returns −1. The application may determine which asynchronous I/O completed by scanning the associated error and return status using `aio_error()` or `aio_return()`, respectively. `aio_suspend()` sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>No asynchronous I/O indicated in the list referenced by <code>list</code> completed in the time interval indicated by <code>timeout</code>.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal interrupted the <code>aio_suspend()</code> function. Note that, since each asynchronous I/O operation may possibly provoke a signal when it completes, this error return may be caused by the completion of one (or more) of the very I/O operations being awaited.</td>
</tr>
</tbody>
</table>
ENOSYS  z/OS UNIX System Services does not support the aio_suspend() function.

Usage Notes:

1. The AIOCBs represented by the list of AIOCB pointers must reside in the same storage key as the key of the invoker of aio_suspend. If the AIOCB Pointer List or any of the AIOCBs represented in the list are not accessible by the invoker an EFAULT may occur.
2. AIOCB pointers in the list with a value of zero will be ignored.
3. A timeout value of zero (seconds+nanoseconds) means that the aio_suspend() call will not wait at all. It will check for any completed asynchronous I/O requests. If none are found it will return with a EAGAIN. If at least one is found aio_suspend() will return with success.
4. A timeout value of a timespec with the tv_sec field set with INT_MAX, as defined in <limits.h>, will cause the aio_suspend service to wait until a asynchronous I/O request completes or a signal is received.

If the Macro _AIO_OS390 is defined then the following may also apply.
5. The number of pointers to AIOCBs that use application supplied event control block (ECB) pointers for invocations of asynchronous I/O is limited to 253. There is no limit when not using the _AIO_OS390 Feature Test Macro. See z/OS UNIX System Services Programming: Assembler Callable Services Reference under the BPX1AIO for information on supplying user-defined ECBs in the AIOCB data area.
6. The AIOCBs passed to aio_suspend() must not be freed or reused by other threads in the process while this service is still in progress. This service may use the AIOCBs even after the asynchronous I/O completes. This restriction excludes multiple threads from doing aio_suspend() on the same AIOCB at the same time. Modifying the AIOCB during an aio_suspend() will produce unpredictable results.
7. The use of these extensions will require macros from SYS1.CSSLIB. Make sure that it is included in the SYSLIB concatenation during the compile.

aio_write() — Asynchronous Write to a Socket

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_write(struct aiocb *aiocbp);
```

General Description

The `aio_write()` function initiates an asynchronous write as described by the `aiocb` structure (the asynchronous I/O control block).

The `aiocbp` argument points to the `aiocb` structure. This structure contains the following members:

- `aio_fildes`: file descriptor
- `aio_offset`: file offset
- `aio_buf`: location of buffer
- `aio_nbytes`: length of transfer
- `aio_reqprio`: request priority offset
- `aio_sigevent`: signal number and value
- `aio_lio_opcode`: operation to be performed

The operation will write `aio_nbytes` from the buffer pointed to by `aio_buf` to the socket or file associated with `aio_fildes`. The call to `aio_write()` returns when the request has been initiated or queued to the file or device (even when the data cannot be delivered immediately).

Asynchronous I/O is currently only supported for sockets. The `aio_offset` field may be set but it will be ignored.

The `aiocbp` value may be used as an argument to `aio_error()` and `aio_return()` functions in order to determine the error status and return status, respectively, of the asynchronous operation. While the operation is proceeding, the error status retrieved by `aio_error()` is `EINPROGRESS`; the return status retrieved by `aio_return()` however is unpredictable.

If an error condition is encountered during the queueing, the function call returns without having initiated or queued the request.

When the operation completes asynchronously the program can be notified by a signal as specified in the `aio_sigevent` structure. It is significantly more efficient to receive these notifications with `sigwaitinfo()` or `sigtimedwait()` than to let them drive a signal handler. At this time the return and error status will have been updated to reflect the outcome of the operation. The `sigevent` structure’s notification function...
fields are not supported. If a signal is not desired the program can occasionally poll
the aiocb with aio_error() until the result is no longer EINPROGRESS.

Be aware that the operation may complete, and the signal handler may be
delivered, before control returns from the call to aio_read(). Even when the
operation does complete this quickly the return value from the call to aio_read() will
be zero, reflecting the queueing of the I/O request not the results of the I/O itself.

An asynchronous operation may be canceled with aio_cancel() before its
completion. Canceled operations complete with an error status of ECANCELED and
any specified signal will be delivered. Due to timing, the operation may still
complete naturally, either successfully or unsuccessfully, before it can be canceled
by aio_cancel().

If the file descriptor of this operation is closed, the operation will be deleted if it has
not completed or is not just about to complete. Signals specified for deleted
operations will not be delivered. Close() will wait for asynchronous operations in
progress for the descriptor to be deleted or completed.

You may use aio_suspend() to wait for the completion of asynchronous operations.

Sockets must be in blocking state or the operation may fail with EWOULDBLOCK.

If the control block pointed by aiocbp or the buffer pointed to by aio_buf becomes
an illegal address before the asynchronous I/O completion, then the behavior of
aio_read() is unpredictable.

If the thread that makes the aio_read() request terminates before the I/O completes,
the aiocb structure will still be updated with the return and error status, and any
specified signal will be delivered to the process in which the thread was running. If
thread related storage was used on the request the results are quite unpredictable.

Simultaneous asynchronous operations using the same aiocbp, attempting
asynchronous operations using a non-valid aiocbp, or any system action, that
changes the process memory space while asynchronous I/O is outstanding to that
address range, will produce unpredictable results.

Simultaneous aio_write() operations on the same stream socket should not be done
because the data may be transmitted on the network out of order. With UDP
sockets each aio_write defines a single datagram and there is no implied order of
arrival in UDP. Beware, though, of sending too many datagrams. If there is network
congestion or the receiver is slow you can tie up a large amount of system storage
with uncontrolled aio_writes, and eventually they may start to fail with ENOBUFS.

There are several sockets oriented extensions to asynchronous I/O available with
the BPX1AIO callable service, such as asynchronous accept() and asynchronous
forms of the four other write type operations: sendto(), sendmsg(), send(), and
writev(). Also, the I/O Completion notification might be received via an ECB, an exit
program or through a message queue. The aio.h header contains all the structure
fields, constants, and prototypes necessary to use BPX1AIO from a C program.
These extensions are exposed when the _AIO_OS390 feature flag is #defined.
BPX1AIO calls may be mixed with aio_xxxx calls and any of the regular socket
functions. For a more detailed description of asynchronous I/O services, see z/OS
UNIX System Services Programming: Assembler Callable Services Reference.

The aio_lio_opcode field is set to LIO_WRITE by the function aio_write().
_POSIX_PRIORITIZED_IO is not supported. The aio_reqprio field may be set but it will be ignored.

_POSIX_SYNCHRONIZED_IO is not supported.

Returned Value

If the I/O operation is successfully queued, aio_write() returns 0 to the calling process.

If the I/O operation is not queued, aio_write() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The requested asynchronous I/O operation was not queued due to system resource limitations.</td>
</tr>
<tr>
<td>ENOSYS</td>
<td>The file associated with aio_fildes does not support the aio_write() function.</td>
</tr>
</tbody>
</table>

Each of the following conditions may be detected synchronously at the time of the call to aio_write(), or asynchronously. If any of the conditions below are detected synchronously, aio_write() returns −1 and sets the errno to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to −1, and the error status of the asynchronous operation will be set to the corresponding value.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The aio_fildes argument is not a valid file descriptor open for writing.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The aio_nbytes is not a valid value or aio_sigevent contains a value that is not valid.</td>
</tr>
<tr>
<td>EWOULDBLOCK</td>
<td>The file associated with aio_fildes is in nonblocking state and there is no data available.</td>
</tr>
</tbody>
</table>

In the case where aio_write() successfully queues the I/O operation but the operation is subsequently canceled or encounters an error, the return status of the asynchronous operation is set to −1, and the error status of the asynchronous operation is set to the error status normally set by the write() function call, or to the following value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECANCELED</td>
<td>The requested I/O was canceled before the I/O completed due to an explicit call to aio_cancel().</td>
</tr>
</tbody>
</table>

<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

unsigned int alarm(unsigned int seconds);
```

General Description

Generates a SIGALRM signal after the number of seconds specified by the `seconds` parameter has elapsed. The SIGALRM signal delivery is directed at the calling thread.

`seconds` is the number of real seconds to wait before the SIGALRM signal is generated. Because of processor delays, the SIGALRM signal may be generated slightly later than this specified time. If `seconds` is zero, any previously set alarm request is canceled.

Only one such alarm can be active at a time. If you set a new alarm time, any previous alarm is canceled.

This function is supported only in a POSIX program. See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information.

Special Behavior for XPG4

The fork() function clears pending alarms in the child thread. However, a new thread image created by one of the exec functions inherits the time left to an alarm in the old thread’s image.

Special Behavior for XPG4.2

alarm() will interact with the setitimer() function when the setitimer() function is used to set the 'real' interval timer (ITIMER_REAL).

alarm() does not interact with the usleep() function.

Returned Value

If a prior alarm request has not yet completed, alarm() returns the number of seconds remaining until that request would have generated a SIGALRM signal.
If there are no prior alarm requests with time remaining, `alarm()` returns 0. Because `alarm()` is always successful, there is no failure return. If any failures are encountered that prevent `alarm()` from completing successfully, an abend is generated.

**Example**

**CELEBA05**

```c
/* CELEBA05

The following example generates a SIGALRM signal.

*/

#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <time.h>
#include <unistd.h>

volatile int footprint=0;

void catcher(int signum) {
    puts("inside signal catcher!");
    footprint = 1;
}

main() {
    struct sigaction sact;
    volatile double count;
    time_t t;

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGALRM, &sact, NULL);

    alarm(5); /* timer will pop in five seconds */

    time(&t);
    printf("before loop, time is %%s", ctime(&t));
    for (count=0; (count<1e10) && (footprint == 0); count++);
    time(&t);
    printf("after loop, time is %%s", ctime(&t));

    printf("the sum so far is %.0f\n", count);

    if (footprint == 0)
        puts("the signal catcher never gained control");
    else
        puts("the signal catcher gained control");
}
```

**Output**

before loop, time is Fri Jun 16 08:37:03 2001
inside signal catcher!
after loop, time is Fri Jun 16 08:37:08 2001
the sum so far is 17417558

alloca() — Allocate Storage from the Stack

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>both</td>
<td></td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

void *alloca(unsigned int size);
```

General Description

The built-in alloca() function obtains memory from the stack. This eliminates the need for an explicit free() as the memory is freed when the stack is collapsed.

If the alloca() function is unable to obtain the requested storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

To avoid infringing on the user's name space, this nonstandard function is exposed only when you use the compiler option, LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

**Note:** Storage from an alloca() is done after a setjmp() (or any variation thereof) is freed on a longjmp() (or any variation thereof) to an XPLINK-compiled function, and not freed on a longjmp() to a NOXPLINK-compiled function. See the longjmp() family of functions for more details.

Returned Value

If successful, alloca() returns the address of the requested storage.

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <time.h>

char *asctime(const struct tm *timeptr);
```

General Description

Converts time stored as a structure, pointed to by *timeptr*, to a character string. The *timeptr* value can be obtained from a call to gmtime() or localtime(). Both functions return a pointer to a tm structure defined in "time.h" on page 93.

The string result that asctime() produces contains exactly 26 characters and has the format:

"%.3s %.3s%3d %.2d:%.2d:%.2d %d"

The following is an example of the string returned:

Fri Jun 16 02:03:55 2001

Notes:

- The calendar time returned by a call to the time() function begins at epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.
- The asctime() function uses a 24-hour clock format.
- The days are abbreviated to: Sun, Mon, Tue, Wed, Thu, Fri, and Sat.
- The months are abbreviated to: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.
- All fields have a constant width.
- Dates with only one digit are preceded either with a zero or a blank space.
- The newline character (\n) and the NULL character (\0) occupy the last two positions of the string.
- The asctime(), ctime(), and other time functions can use a common, statically allocated buffer for holding the return string. Each call to one of these functions may possibly destroy the result of the previous call.

Returned Value

If successful, asctime() returns a pointer to the resulting character string.

If the function is unsuccessful, it returns NULL.
Example

CELEBA06
/* CELEBA06

This example polls the system clock and prints a message giving the current time.

*/
#include <time.h>
#include <stdio.h>

int main(void)
{
    struct tm *newtime;
    time_t ltime;
    /* Get the time in seconds */
    time(&ltime);
    /* Break it down & store it in the structure tm */
    newtime = localtime(&ltime);
    /* Print the local time as a string */
    printf("The current date and time are \%s", asctime(newtime));
}

Output
The current date and time are Fri Jun 16 13:29:51 2001

<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _XOPEN_SOURCE 500
#include <time.h>

char *asctime_r(const struct tm *__restrict__ tm, char *__restrict__ buf);
```

General Description

The `asctime_r()` function converts the broken-down time in the structure pointed to by `tm` into a character string that is placed in the user-supplied buffer pointed to by `buf` (which contains at least 26 bytes) and then returns `buf`.

Returned Value

If successful, `asctime_r()` returns a pointer to a character string containing the date and time. This string is pointed to by the argument `buf`.

If unsuccessful, `asctime_r()` returns NULL.

There are no documented `errno` values.

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <math.h>

double asin(double x);
float asin(float x); /* C++ only */
long double asin(long double x); /* C++ only */
float asinf(float x);
long double asinl(long double x);
```

General Description

Calculates the arcsine of x, in the range -π/2 to π/2 radians.

The value of x must be between -1 and 1.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE Binary Floating-Point” on page 108](#) for more information about IEEE Binary Floating-Point.

Returned Value

If x is less than -1 or greater than 1, the function sets errno to EDOM, and returns 0. Otherwise, it returns a nonzero value.

If the correct value would cause an underflow, 0 is returned and the value ERANGE is stored in errno.

**Special Behavior for IEEE**

If successful, the function returns the arcsine of its argument x.

If x is less than -1 or greater than 1, the function sets errno to EDOM and returns NaNQ. No other errors will occur.

Example

```c
CELEBA07
/* CELEBA07

This example prompts for a value for x.
It prints an error message if x is greater than 1 or less than -1; otherwise, it assigns the arcsine of x to y.
```

double asinh(double x);

C99
#define _ISOC99_SOURCE
#include <math.h>

float asinhf(float x);
long double asinhl(long double x);
```

General Description

The asinh() functions return the hyperbolic arcsine of its argument x.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>

assert()

— Verify Condition

Standards

Standards / Extensions | C or C++ | Dependencies
------------------------|----------|----------------
ISO C                   | both     | Dependencies
POSIX.1                 |          |                
XPG4                    |          |                
XPG4.2                  |          |                
C99                     |          |                
Single UNIX Specification, Version 3 |          |                

Format

```c
#include <assert.h>

void assert(int expression);
```

General Description

The assert() macro inserts diagnostics into a program. If the expression (which will have a scalar type) is false (that is, compares equal to 0), a diagnostic message of the form shown below is printed to stderr, and abort() is called to abnormally end the program. The assert() macro takes no action if the expression is true (nonzero).

Without a compiler that is designed to support C99, or when compiling C++ code, the diagnostic message has the following format:

```
Assertion failed: expression, file filename, line line-number.
```

With a compiler that is designed to support C99, or when compiling C++ code, the diagnostic message has the following format:

```
Assertion failed: expression, file filename, line line-number, function function-name.
```

If you define NDEBUG to any value with a #define directive or with the DEFINE compiler option, the C/C++ preprocessor expands all assert() invocations to void expressions.

**Note:** The assert() function is a macro. Using the #undef directive with the assert() macro results in undefined behavior. The assert() macro uses __FILE__, __LINE__ and, with a compiler that is designed to support C99, __func__...

Returned Value

assert() returns no values.

Example

**CELEBA08**

```c
/* CELEBA08

   In this example, the assert() macro tests the string argument for a null string and an empty string, and verifies that the length argument is positive before proceeding.

   */  
#include <stdio.h>  
#include <assert.h>
```

190  z/OS V1R9.0 XL C/C++ Run-Time Library Reference
void analyze(char *, int);
int main(void)
{
    char *string1 = "ABC";
    char *string2 = ""
    int length = 3;

    analyze(string1, length);
    printf("string1 %s is not null or empty, "
        "and has length %d \n", string1, length);
    analyze(string2, length);
    printf("string2 %s is not null or empty," 
        "and has length %d\n", string2, length);
}

void analyze(char *string, int length)
{
    assert(string != NULL); /* cannot be NULL */
    assert(*string != '0'); /* cannot be empty */
    assert(length > 0); /* must be positive */
}

Output without a compiler that is designed to support C99
String1 ABC is not NULL or empty, and has length 3
Assertion failed: *string != '0', file: CELEBA08 C    A1, line: 26

Output with a compiler that is designed to support C99
String1 ABC is not NULL or empty, and has length 3
Assertion failed: *string != '0', file: CELEBA08 C    A1, line: 26 in function analyze

</tbody>
</table>

Format

```
#include <math.h>

double atan(double x);
float atan(float x); /* C++ only */
long double atan(long double x); /* C++ only */
float atanf(float x);
long double atanl(long double x);

double atan2(double y, double x);
float atan2(float y, float x); /* C++ only */
long double atan2(long double y, long double x); /* C++ only */
float atan2f(float y, float x);
long double atan2l(long double y, long double x);
```  

General Description

The atan() and atan2() functions calculate the arctangent of x and y/x, respectively.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

Returns a value in the range -pi/2 to pi/2 radians.

The atan2() functions return a value in the range -pi to pi radians. If both arguments of atan2() are zero, the function sets errno to EDOM, and returns 0. If the correct value would cause underflow, zero is returned and the value ERANGE is stored in errno.

Special Behavior for IEEE

If successful, atan2() returns the arctangent of y/x.

If both arguments of atan2() are zero, the function sets errno to EDOM and returns 0. No other errors will occur.

Example

```
CELEBA09
/* CELEBA09 */
#include <math.h>
#include <stdio.h>
```
int main(void)
{
    double a, b, c, d;
    c = 0.45;
    d = 0.23;
    a = atan(c);
    b = atan2(c, d);
    printf("atan( %f ) = %f\n", c, a);
    printf("atan2( %f, %f ) = %f\n", c, d, b);
}

Output
atan( 0.450000 ) = 0.422854
atan2( 0.450000, 0.230000 ) = 1.098299

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double atanh(double x);

C99
#define _ISOC99_SOURCE
#include <math.h>

float atanhf(float x);
long double atanhl(long double x);
```

General Description

The atanh() function returns the hyperbolic arctangent of its argument x.

Note: The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>atanh</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>atanhf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>atanhl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

If successful, atanh() returns the hyperbolic arctangent of its argument x.

atanh() fails, returns 0.0 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EDOM</td>
<td>The x argument has a value greater than 1.0.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The x argument has a value equal to 1.0.</td>
</tr>
</tbody>
</table>

Special Behavior for IEEE

If successful, the function returns the hyperbolic arctangent of its argument x.

If the absolute value of x is greater than 1.0, atanh() sets errno to EDOM and returns NaNQ. If the value of x is equal to 1.0, the function sets errno to ERANGE and returns +HUGE_VAL.

atexit

atexit() — Register Program Termination Function

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

int atexit(void (*func)(void));
```

General Description

Records a function, pointed to by `func`, that the system calls at normal program termination. Termination is a result of `exit()` or returning from `main()`, regardless of the language of the `main()` routine. Process termination started by `_exit()` or by a terminating signal under Language Environment is not included.

The functions are executed in the reverse order that they were registered. The registered function must return to ensure that all registered functions are called. The functions registered with `atexit()` are started before streams and files are closed. You may specify a number of functions to the limit set by the `ATEXIT_MAX` constant, which is defined in `<limits.h>`.

Under z/OS UNIX services only, when a process ends, the address space is ended; otherwise, the address space persists.

Special Behavior for z/OS XL C

The C Library `atexit()` function has the following restrictions:

- Any function registered by a fetched module that has been released is removed from the list at the time of `release()`. See `fetch()`, `fetchep()`, and `release()` for details about fetching and releasing modules.
- Any function registered in an explicitly loaded DLL (using `dllload()`) that has been freed (using `dllfree()`) is removed from the list. But, if the DLL in question has also been implicitly loaded, then the function is NOT removed from the atexit list.
- All C Library library functions can be used in a registered routine except `exit()`.
- When a program is running under CICS control, if an `EXEC CICS RETURN` command or an `EXEC CICS XCTL` command is issued, the `atexit()` list that has been previously registered is not run.
- Use of the `system()` library function within `atexit()` may result in undefined behavior.
- Use of non-C subroutines or functions in the `atexit()` list will result in undefined behavior.
- The `atexit()` list will not be run when `abort()` is called.

Special Behavior for C++

- All of the behaviors listed under "Special Behavior for z/OS XL C".
Because C and C++ linkage conventions are incompatible, atexit() cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to atexit(), the compiler will flag it as an error. To use the C++ atexit() function, you must ensure that all functions registered for atexit() have C linkage by declaring them as extern "C".

You can use try, throw, and catch in a function registered for atexit(). However, by the time an atexit() function is driven, all stack frames will have collapsed. As a result, the only catch clauses available for throw will be the ones coded in the atexit() function. If those catch clauses cannot handle the thrown object, terminate() will be called.

Special Behavior for XPG4.2

The maximum number of functions that can be registered is specified by the symbol ATEXIT_MAX which is defined in the limits.h header.

Returned Value

If successful, atexit() returns 0.

If unsuccessful, atexit() returns nonzero.

Example

CELEBA10

/* CELEBA10 */

This example uses the atexit() function to call the function goodbye() at program termination.

*/
#include <stdlib.h>
#include <stdio.h>

#ifdef __cplusplus /* the __cplusplus macro is */
extern "C" void goodbye(void); /* automatically defined by the */
#else /* C++/MVS compiler */
void goodbye(void);
#endif

int main(void)
{
    int rc;

    rc = atexit(goodbye);
    if (rc != 0)
        printf("Error in atexit");
    exit(0);
}

void goodbye(void)
/* This function is called at normal program termination */
{
    printf("The function goodbye was called \n at program termination\n");
}

Output

The function goodbye was called at program termination

__atoe() — ISO8859-1 to EBCDIC String Conversion

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

int __atoe(char *string);
```

General Description

The __atoe() function converts an ISO8859-1 character string `string` to its EBCDIC equivalent. The conversion is performed using the codeset page associated with the current locale. The input character string up to, but not including, the NULL is changed from an ISO8859-1 representation to that of the current locale.

The argument `string` points to the ISO8859-1 character string to be converted to its EBCDIC equivalent.

Returned Value

If successful, __atoe() converts the input ISO8859-1 character string to its equivalent EBCDIC value, and returns the length of the converted string.

If unsuccessful, __atoe() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The current locale does not describe a single-byte character set.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>There is insufficient storage to complete the conversion process.</td>
</tr>
</tbody>
</table>

Note: This function may internally call iconv_open() and iconv(). The errnos returned by these functions are propagated without modification.

Related Information

- "unistd.h" on page 96

__atoe_l

__atoe_l() — ISO8859-1 to EBCDIC Conversion Operation

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

int __atoe_l(char *bufferptr, int leng);
```

General Description

The __atoe_l() function converts `leng` ISO8859-1 bytes in the buffer pointed to by `bufferptr` to their EBCDIC equivalent. The conversion is performed using the codeset page associated with the current locale.

The argument `bufferptr` points to a buffer containing the ISO8859-1 bytes to be converted to their EBCDIC equivalent. The input buffer is treated as sequence of bytes, and all bytes in the input buffer are converted, including any imbedded NULLs.

Returned Value

If successful, __atoe_l() converts the input IOS8859-1 bytes to their equivalent EBCDIC value, and returns the number of bytes that were converted.

If unsuccessful, __atoe_l() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The current locale does not describe a single-byte character set.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>There is insufficient storage to complete the conversion process.</td>
</tr>
</tbody>
</table>

Note: This function may internally call iconv_open() and iconv(). The errnos returned by these functions are propagated without modification.

atof() — Convert Character String to Double

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

double atof(const char *nptr);
```

General Description

The atof() function converts the initial portion of the string pointed to by `nptr` to a `double`. This is equivalent to

```c
strtof(nptr, (char**)NULL)
```

The double value is either hexadecimal floating point or binary floating point, depending on the floating point mode of the thread invoking the atof() function. This function uses `_isBF()` to determine the floating point mode of the invoking thread.

See the “fscanf Family of Formatted Input Functions” on page 686 for a description of special infinity and NaN sequences recognized by z/OS formatted input functions, including atof() and strtod() in IEEE Binary Floating-Point mode.

Returned Value

The atof() function returns the converted value if the value can be represented, otherwise the return value is undefined.

Related Information

</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

int atoi(const char *nptr);
```

General Description

The `atoi()` function converts the initial portion of the string pointed to by `nptr` to a 'int'. This is equivalent to

```
(int)strtol(nptr, NULL, 10)
```

Returned Value

There are no documented `errno` values.

atoll

---

atoll() — Convert Character String to Signed Long Long

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Format

```c
#define _ISOC99_SOURCE
#include <stdlib.h>
long long atoll(const char *nptr);
```

### Compile Requirement

Use of this function requires the long long data type. See z/OS XL C/C++ Language Reference for information on how to make long long available.

### General Description

atoll() converts the initial portion of the string pointed to by `nptr` to a 'long long int'. This is equivalent to `strtoll(nptr, (char **)NULL, 10)`.

### Returned Value

If successful, atoll() returns the converted signed `long long` value, represented in the string. If unsuccessful, it returns an undefined value.

### Related Information

__a2e_l() — Convert Characters from ASCII to EBCDIC

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

size_t __a2e_l(char *bufptr, size_t szLen)
```

General Description

The __a2e_l() function converts `szLen` characters in `bufptr` from ASCII to EBCDIC, returning the number of characters converted if successful or -1 if not. Conversion occurs in place in the buffer. __a2e_l() is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned Value

If successful, __a2e_l() returns the number of characters converted.

If unsuccessful, __a2e_l() returns -1 and sets errno to the following value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The pointer to <code>bufptr</code> is NULL or <code>szLen</code> is a negative value.</td>
</tr>
</tbody>
</table>

</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>
size_t __a2e_s(char *string)
```

General Description

The __a2e_s() function converts a string from ASCII to EBCDIC, returning the string length if successful or -1 if not. Conversion occurs in place in the string. __a2e_s() is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned Value

If successful, __a2e_s() returns the string length.

If unsuccessful, __a2e_s() returns -1 and sets errno to the following value:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The pointer to string is NULL.</td>
</tr>
</tbody>
</table>

a64l() — Convert Base 64 String Representation to Long Integer

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

long a64l(const char *string);
```

General Description

The `a64l()` function converts a string representation of a base 64 number into its corresponding long value. It scans the string from left to right with the least significant character on the left, decoding each character as a 6-bit base 64 number. If the string pointed to by `string` contains more than six characters, `a64l()` uses only the first six. If the first six characters of the string contain a NULL character, `a64l()` uses only the characters preceding the first NULL. The following characters are used to represent digits:

<table>
<thead>
<tr>
<th>Character</th>
<th>Digit Represented</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>0</td>
</tr>
<tr>
<td>/</td>
<td>1</td>
</tr>
<tr>
<td>0-9</td>
<td>2-11</td>
</tr>
<tr>
<td>A-Z</td>
<td>12-37</td>
</tr>
<tr>
<td>a-z</td>
<td>38-63</td>
</tr>
</tbody>
</table>

Returned Value

If successful, `a64l()` returns the long value resulting from conversion of the input string.

If the string pointed to by `string` is NULL, `a64l()` returns 0.

There are no errno values defined.

Related Information

basename

basename() — Return the Last Component of a Pathname

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <libgen.h>

char *basename(char *path);
```

General Description

The basename() function takes the pathname pointed to by `path` and returns a pointer to the final component of the pathname, deleting any trailing ‘/’ characters.

If the string consists entirely of the ‘/’ character, basename() returns a pointer to the string “/”.

If `path` is a NULL pointer or points to an empty string, basename() returns a pointer to the string “.”. The basename() function may modify the string pointed to by `path`.

Examples:

<table>
<thead>
<tr>
<th>Input String</th>
<th>Output String</th>
</tr>
</thead>
<tbody>
<tr>
<td>“/usr/lib”</td>
<td>“lib”</td>
</tr>
<tr>
<td>“/usr/”</td>
<td>“usr”</td>
</tr>
<tr>
<td>“/”</td>
<td>“/”</td>
</tr>
</tbody>
</table>

Returned Value

If successful, basename() returns a pointer to the final component of `path`.

There are no errno values defined.

**bcm**p() — Compare Bytes in Memory

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

int bcmp(const void *s1, const void *s2, size_t n);
```

**General Description**

The `bcmp()` function compares the first `n` bytes of the area pointed to by `s1` with the area pointed to by `s2`.

**Note:** The `bcmp()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `memcmp()` function is preferred for portability.

**Returned Value**

If `s1` and `s2` are identical, `bcmp()` returns 0. Otherwise, `bcmp()` returns nonzero. Both areas are assumed to be at least `n` bytes long.

If the value of `n` is zero, `bcmp()` returns 0.

There are no errno values defined.

**Related Information**

</tr>
</tbody>
</table>

Format

```c
#define __XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

void bcopy(const void *s1, void *s2, size_t n);
```

General Description

The bcopy() function copies $n$ bytes from the area pointed to by $s1$ to the area pointed to by $s2$ using the memcpy() function.

Note: The bcopy() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The memmove() function is preferred for portability.

Returned Value

bcopy() returns no values.

There are no errno values defined.

bind() — Bind a Name to a Socket

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open

#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int bind(int socket, const struct sockaddr *address, socklen_t address_len);

Berkeley Sockets

#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int bind(int socket, struct sockaddr *address, int address_len);

General Description

The bind() function binds a unique local name to the socket with descriptor socket. After calling socket(), a descriptor does not have a name associated with it. However, it does belong to a particular address family as specified when socket() is called. The exact format of a name depends on the address family.

Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>socket</td>
<td>The socket descriptor returned by a previous socket() call.</td>
</tr>
<tr>
<td>address</td>
<td>The pointer to a sockaddr structure containing the name that is to be bound to socket.</td>
</tr>
<tr>
<td>address_len</td>
<td>The size of address in bytes.</td>
</tr>
</tbody>
</table>

The socket parameter is a socket descriptor of any type created by calling socket().

The address parameter is a pointer to a buffer containing the name to be bound to socket. The address_len parameter is the size, in bytes, of the buffer pointed to by address. For AF_UNIX, this function creates a file that you later need to unlink besides closing the socket.

Socket Descriptor Created in the AF_INET Domain

If the socket descriptor socket was created in the AF_INET domain, the format of the name buffer is expected to be sockaddr_in, as defined in the include file netinet/in.h:

```c
struct in_addr {
    ip_addr_t s_addr;
};

struct sockaddr_in {
    unsigned char sin_len;
    unsigned char sin_family;
```
The `sin_family` field must be set to AF_INET.

The `sin_port` field is set to the port to which the application must bind. It must be specified in network byte order. If `sin_port` is set to 0, the caller leaves it to the system to assign an available port. The application can call getsockname() to discover the port number assigned.

The `sin_addr.s_addr` field is set to the Internet address and must be specified in network byte order. On hosts with more than one network interface (called multihomed hosts), a caller can select the interface to which it is to bind. Subsequently, only UDP packets and TCP connection requests from this interface (which match the bound name) are routed to the application. If this field is set to the constant INADDR_ANY, as defined in `netinet/in.h`, the caller is requesting that the socket be bound to all network interfaces on the host. Subsequently, UDP packets and TCP connections from all interfaces (which match the bound name) are routed to the application. This becomes important when a server offers a service to multiple networks. By leaving the address unspecified, the server can accept all UDP packets and TCP connection requests made for its port, regardless of the network interface on which the requests arrived.

The `sin_zero` field is not used and must be set to all zeros.

**Socket Descriptor Created in the AF_INET6 Domain** If the socket descriptor `socket` was created in the AF_INET6 domain, the format of the name buffer is expected to be `sockaddr_in6`, as defined in the include file `netinet/in.h`. The structure is defined as follows:

```c
struct sockaddr_in6 {
    uint8_t     sin6_len;
    sa_family_t sin6_family;
    in_port_t   sin6_port;
    uint32_t    sin6_flowinfo;
    struct in6_addr sin6_addr;
    uint32_t    sin6_scope_id;
};
```

The `sin6_len` field is set to the size of this structure. The SIN6_LEN macro is defined to indicate the version of the sockaddr_in6 structure being used.

The `sin6_family` field identifies this as a sockaddr_in6 structure. This field overlays the sa_family field when the buffer is cast to a sockaddr structure. The value of this field must be AF_INET6.

The `sin6_port` field contains the 16-bit UDP or TCP port number. This field is used in the same way as the `sin_port` field of the sockaddr_in structure. The port number is stored in network byte order.

The `sin6_flowinfo` field is a 32-bit field that contains the traffic class and the flow label.

The `sin6_addr` field is a single in6_addr structure. This field holds one 128-bit IPv6 address. The address is stored in network byte order.
The `sin6_scope_id` field is a 32-bit integer that identifies a set of interfaces as appropriate for the scope of the address carried in the `sin6_addr` field. For a link scope `sin6_addr`, `sin6_scope_id`, this would be an interface index. For a site scope `sin6_addr`, `sin6_scope_id`, this would be a site identifier.

### Socket Descriptor Created in the AF_UNIX Domain

If the socket descriptor `socket` is created in the AF_UNIX domain, the format of the name buffer is expected to be `sockaddr_un`, as defined in the include file `un.h`.

```c
struct sockaddr_un {
    unsigned char sun_len;
    unsigned char sun_family;
    char sun_path[108]; /* pathname */
};
```

The `sun_family` field is set to AF_UNIX.

The `sun_path` field contains the NULL-terminated pathname, and `sun_len` contains the length of the pathname.

**Notes:**

1. For AF_UNIX, when a bind is issued, a file is created with a mode of 660. In order to allow other users to access this file, a `chmod()` should be issued to modify this mode if desired.
2. For AF_UNIX, when closing sockets that were bound, you should also use `unlink()` to delete the file created at bind() time.
3. The pathname the client uses on the bind() must be unique.
4. The `sendto()` call must specify the pathname associated with the server.
5. For AF_INET or AF_INET6, the user must have appropriate privileges to bind to a port in the range from 1 to 1023.

### Special Behavior for C++

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

**Note:** The `bind()` function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII Support” on page 2495 for details.

### Returned Value

If successful, `bind()` returns 0.

If unsuccessful, `bind()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Permission denied.</td>
</tr>
<tr>
<td>EADDRINUSE</td>
<td>The address is already in use. See the SO_REUSEADDR option described under <code>getsockopt()</code> — Get the Options Associated with a Socket” on page 861 and the SO_REUSEADDR described under the “setsockopt() — Set Options Associated with a Socket” on page 1843 for more information.</td>
</tr>
<tr>
<td>EADDRNOTAVAIL</td>
<td>The address specified is not valid on this host. For example, the Internet address does not specify a valid network interface.</td>
</tr>
</tbody>
</table>
The address family is not supported (it is not AF_UNIX, AF_INET, or AF_INET6).

The socket parameter is not a valid socket descriptor.

The socket is already bound to an address—for example, trying to bind a name to a socket that is already connected. Or the socket was shut down.

There has been a network or transport failure.

bind() is unable to obtain a buffer due to insufficient storage.

The descriptor is for a file, not for a socket.

The socket type of the specified socket does not support binding to an address.

The user is not authorized to bind to the port specified.

A component of the path prefix denies search permission, or the requested name requires writing in a directory with a mode that denies write permission.

The address argument is a NULL pointer.

An I/O error occurred.

Too many symbolic links were encountered in translating the pathname in address.

A component of a pathname exceeded NAME_MAX characters, or an entire pathname exceeded PATH_MAX characters.

A component of the pathname does not name an existing file or the pathname is an empty string.

A component of the path prefix of the pathname in address is not a directory.

The name would reside on a read-only file system.

The following are examples of the bind() call. It is a good idea to zero the structure before using it to ensure that the name requested does not set any reserved fields.

**AF_INET Domain Example**

The following example illustrates the bind() call binding to interfaces in the AF_INET domain. The Internet address and port must be in network byte order. To put the port into network byte order, the htonl() utility routine is called to convert a short integer from host byte order to network byte order. The address field is set using another utility routine, inet_addr(), which takes a character string representing the dotted-decimal address of an interface and returns the binary Internet address representation in network byte order.
int rc;
int s;
struct sockaddr_in myname;
/* Bind to a specific interface in the Internet domain */
/* make sure the sin_zero field is cleared */
memset(&myname, 0, sizeof(myname));
myname.sin_family = AF_INET;
myname.sin_addr.s_addr = inet_addr("129.5.24.1"); /* specific interface */
myname.sin_port = htons(1024);

rc = bind(s, (struct sockaddr *) &myname, sizeof(myname));
/* Bind to all network interfaces in the Internet domain */
/* make sure the sin_zero field is cleared */
memset(&myname, 0, sizeof(myname));
myname.sin_family = AF_INET;
myname.sin_addr.s_addr = INADDR_ANY; /* specific interface */
myname.sin_port = htons(1024);

rc = bind(s, (struct sockaddr *) &myname, sizeof(myname));
/* Bind to a specific interface in the Internet domain. 
   Let the system choose a port */
/* make sure the sin_zero field is cleared */
memset(&myname, 0, sizeof(myname));
myname.sin_family = AF_INET;
myname.sin_addr.s_addr = inet_addr("129.5.24.1"); /* specific interface */
myname.sin_port = 0;

rc = bind(s, (struct sockaddr *) &myname, sizeof(myname));

AF_UNIX Domain Example

The following example illustrates the bind() call binding to interfaces in the AF_UNIX domain.
/* Bind to a name in the UNIX domain */
struct sockaddr_un myname;
char socket_name[]="/tmp/socket.for._";

memset(&myname, 0, sizeof(myname));
myname.sun_family = AF_UNIX;
strcpy(myname.sun_path, socket_name);
myname.sun_len = sizeof(myname.sun_path);

rc = bind(s, (struct sockaddr *) &myname, SUN_LEN(&myname));

## brk

### brk() — Change Space Allocation

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int brk(void *addr);
```

#### General Description

**Restriction:** This function is not supported in AMODE 64.

The `brk()` function is used to change the space allocated for the calling process. The change is made by setting the process's break value to `addr` and allocating the appropriate amount of space. The amount of allocated space increases as the break value increases. The newly-allocated space is set to 0. However, if the application first decrements and then increments the break value, the contents of the reallocated space are not zeroed.

The storage space from which the `brk()` and `sbrk()` functions allocate storage is separate from the storage space that is used by the other memory allocation functions (`malloc()`, `calloc()`, etc.). Because this storage space must be a contiguous segment of storage, it is allocated from the initial heap segment only and thus is limited to the initial heap size specified for the calling program or the largest contiguous segment of storage available in the initial heap at the time of the first `brk()` or `sbrk()` call. Since this is a separate segment of storage, the `brk()` and `sbrk()` functions can be used by an application that is using the other memory allocation functions. However, it is possible that the user's region may not be large enough to support extensive usage of both types of memory allocation.

Prior usage of the `brk()` function has been limited to specialized cases where no other memory allocation function performed the same function. Because the `brk()` function may be unable to sufficiently increase the space allocation of the process when the calling application is using other memory functions, the use of other memory allocation functions, such as `mmap()`, is now preferred because it can be used portably with all other memory allocation functions and with any function that uses other allocation functions. Applications that require the use of `brk()` and/or `sbrk()` should refrain from using the other memory allocation functions and should be run with an initial heap size that will satisfy the maximum storage requirements of the program. The `brk()` function is not supported from a multithreaded environment, it will return in error if it is invoked in this environment.

**Note:**

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `malloc()` instead of `brk()` or `sbrk()`.
If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

## Returned Value

If successful, brk() returns 0.

If unsuccessful, brk() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>

bsd_signal

bsd_signal() — BSD Version of signal()

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

void (*bsd_signal(int sig, void (*func)(int)))(int);
```

General Description

The bsd_signal() function provides a partially compatible interface for programs written to use the BSD form of the signal() function.

BSD signal() differs from ANSI signal() in that the SA_RESTART flag is set and the SA_RESETHAND is cleared when bsd_signal() is used. Whereas for signal() both of these flags are cleared and _SA_OLD_STYLE is set.

There are three functions available for establishing a signal's action, signal(), bsd_signal(), and sigaction(). The sigaction() function is the strategic way to establish a signal's action. The bsd_signal() and signal() functions are provided for compatibility with BSD and ANSI, respectively.

The argument `sig` is the signal type. See Table 47 on page 1881 for a list of the supported signal types or refer to the <signal.h> header. The argument `func` is the signal action. It may be set to `SIG_DFL`, `SIG_IGN`, or the address of a signal catching function that takes one input argument.

Special Behavior for C++

Because C and C++ linkage conventions are incompatible, bsd_signal() cannot receive a C++ function pointer as the start routine function pointer. If you attempt to pass a C++ function pointer to bsd_signal(), the compiler will flag it as an error. You can pass a C or C++ function to bsd_signal() by declaring it as extern "C".

Usage note

1. The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.
2. The bsd_signal() function has been marked obsolescent in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The sigaction() function is preferred for portability.

Returned Value

If successful, bsd_signal() returns the previous action established for this signal type.

If unsuccessful, bsd_signal() returns `SIG_ERR` and sets errno to one of the following values:
Error Code     Description
EINVAL         The value of the argument *sig* was not a valid signal type, or an
               attempt was made to catch a signal that cannot be caught, or
               ignore a signal that cannot be ignored.

bsearch

bsearch() — Search Arrays

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>
void *bsearch(const void *key, const void *base, size_t num, size_t size,
               int (*compare)(const void *element1, const void *element2));
```

General Description

Performs a binary search of an array of `num` elements, each of `size` bytes.

The pointer `base` points to the initial element of the array to be searched. `key` points to the object containing the value being sought. The array must be sorted in ascending key sequence, according to the comparison function. Otherwise, undefined behavior occurs.

The `compare` parameter is a pointer to a function you must supply. It compares two array elements and returns a value specifying their relationship. The `bsearch()` function calls this function one or more times during the search, passing the `key` and the pointer to one array element on each call. The function compares the elements and then returns one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td>Object pointed to by <code>key</code> is less than the array element.</td>
</tr>
<tr>
<td>= 0</td>
<td>Object pointed to by <code>key</code> is equal to the array element.</td>
</tr>
<tr>
<td>&gt; 0</td>
<td>Object pointed to by <code>key</code> is greater than the array element.</td>
</tr>
</tbody>
</table>

Special Behavior for C++

Because C++ and C linkage conventions are incompatible, `bsearch()` cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to `bsearch()`, the compiler will flag it as an error. To use the C++ `bsearch()` function, you must ensure that the `compare` function has C linkage by declaring it as `extern "C"`.

Returned Value

If successful, `bsearch()` returns a pointer to a matching element of the array. If two or more elements are equal, the element pointed to is not specified.

If unsuccessful finding the `key`, `bsearch()` returns `NULL`.

Example

`CELEBB01`
This example performs a binary search on the argv array of pointers to the program arguments and finds the position of the argument PATH. It first removes the program name from argv, and then sorts the array alphabetically before calling bsearch().

The functions compare1 and compare2 compare the values pointed to by arg1 and arg2, and they return the result to bsearch().

#include <stdlib.h>
#include <stdio.h>
#include <string.h>

#ifdef __cplusplus
/* the __cplusplus macro is */
extern "C" { /* automatically defined by the */
#endif /* C++/MVS compiler */
   int compare1(const void *arg1, const void *arg2);
   int compare2(const void *arg1, const void *arg2);
#ifdef __cplusplus
}
#endif

int main(int argc, char *argv[]) {
   char **result;
   char *key = "PATH";
   int i;
   argv++;
   argc--;

   /* sort to ensure that the input is ordered */
   qsort((char *)argv, argc, sizeof(char *), compare1);

   result = (char**)bsearch(key, (void *)argv, argc, sizeof(char *), compare2);
   if (result != NULL) {
      printf("The key <PATH> was found.\n", *result);
   } else printf("Match not found\n");
}

int compare1(const void *arg1, const void *arg2) {
   return (strcmp(*(char **)arg1, *(char **)arg2));
}

int compare2(const void *arg1, const void *arg2) {
   return (strcmp((char *)arg1, *(char **)arg2));
}

Input
progname Is there PATH in this sentence?

Output
The key <PATH> was found.

btowc

btowc() — Convert Single-Byte Character to Wide-Character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wint_t btowc(int c);
```

General Description

The btowc() function determines whether c constitutes a valid (one-byte) character in the initial shift state.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned Value

If successful, btowc() returns the wide-character representation of the character c.

If c has the value EOF or if (unsigned char)c does not constitute a valid (one-byte) character in the initial shift state, btowc() returns WEOF.

There are no documented errno values.

bzero() — Zero Out Bytes in Memory

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

void bzero(void *s, size_t n);
```

General Description

The bzero() function places \( n \) zero-valued bytes in the area pointed to by \( s \).

Note: The bzero() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The memset() function is preferred for portability.

Returned Value

bzero() returns no values.

There are no errno values defined for bzero().

Related Information

__cabend

__cabend() — Terminate the process with an abend

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>AMODE 64</td>
</tr>
</tbody>
</table>

Format

```c
#include <ctest.h>

void __cabend(int abendcode, int reasoncode, int clean_up);
```

General Description

Causes an abnormal process termination and returns an abend code.

Note: When TRAP(OFF) is specified, CEE3ABD behaves similarly as cleanup 0.

Parameter | Description
---|---
abendcode | Numeric value for the user abend code.
reasoncode | Numeric value of the reason code.
clean_up | Specifies whether normal process cleanup should be performed with the type of dump the user requires.

0 - Issue the abend without cleanup
1 - Issue the abend with cleanup honoring the TERMTHDACT run-time option that the user has specified
2 - Issue the abend with cleanup honoring the TERMTHDACT run-time option for system dump of the user address space but always suppressing the CEEDUMP
3 - Issue the abend with cleanup honoring the TERMTHDACT run-time option but always suppressing both the system dump and the CEEDUMP
4 - Issue the abend with cleanup honoring the TERMTHDACT run-time option for CEEDUMP but always suppressing the system dump
5 - Issue the abend with cleanup forcing a system dump of the user address space but not specifying the TERMTHDACT run-time option
cabs(), cabsf(), cabsl() — Calculate the Complex Absolute Value

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td>a compiler that is designed to support C99</td>
</tr>
</tbody>
</table>

Format

```c
#include <complex.h>

double cabs(double complex z);
float cabsf(float complex z);
long double cabsl(long double complex z);
```

General Description

The `cabs()` family of functions compute the complex absolute value (also called norm, modules, or magnitude) of `z`.

**Note:** The following table shows the viable formats for these functions. See [IEEE Binary Floating-Point](#) on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>cabs</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>cabsf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>cabsl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

The `cabs` functions return the complex absolute value.

Example

```c
/*
 * This example calculates the complex absolute
 * value of complex number 'z'
 */
#include <complex.h>
#include <stdio.h>

void main()
{
    double complex z=3.5 + I*2.21;
    double res;

    res = cabs(z);
    printf("cabs(%f + %f) = %f\n",creal(z), cimag(z), res);
}
/*
 * Output:
 * cabs(3.5 + I*2.21) = 4.139336
 */
```
cabs, cabsf, cabsl

<td>Single UNIX Specification, Version 3</td>
<td></td>
<td>a compiler that is designed to support C99</td>
</tr>
</tbody>
</table>

Format

```
#include <complex.h>

double complex cacos(double complex z);
float complex cacosf(float complex z);
long double complex cacosl(long double complex z);
```

General Description

The cacos() family of functions compute the complex arc cosine of \( z \), with branch cuts outside the interval \([-1, +1]\) along the real axis.

Note: The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>cacos</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>cacosf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>cacosl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

The cacos() family of functions return the complex arc cosine value, in the range of a strip, mathematically unbounded along the imaginary axis and in the interval \([0, \pi]\) along the real axis.

Example

```c
/*
 * This example calculates the complex arc-cosine of
 * complex number 'z'
 */
#include <complex.h>
#include <stdio.h>

void main()
{
    long double complex z1=3.5 + I*2.21;
    double complex zd=(double complex)z1;
    float complex zf=(float complex)z1;
    long double resl;
    double resd;
    float resf;
    char *func = "cacos";
    printf("Example of the %s complex function\n",func);
    printf("%16.8f + i%16.8f
", resl.re, resl.im);
    printf("%16.8f + i%16.8f
", resd.re, resd.im);
    printf("%16.8f + i%16.8f
", resf.re, resf.im);
}
```
cacos, cacosf, cacosl

```c
resd = cacos(zd);
resf = cacosf(zf);
resl = cacosl(zl);
printf("%s(%f + %f*I) = %f\n", func, creal(zd), cimag(zd), resd);
printf("%s%f(%f + %f*I) = %f\n", func, crealf(zf), cimagf(zf), resf);
printf("%sL(%Lf + %Lf*I) = %Lf\n", func, creall(zl), cimagl(zl), resl);
```

Output:

Example of the cacos complex function

```
cacos(3.500000 + 2.210000*I) = 0.576628
```
```
cacosf(3.500000 + 2.209999*I) = 0.576627
```
```
cacosl(3.500000 + 2.210000*I) = 0.576628
```

calloc

calloc() — Reserve and Initialize Storage

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

void *calloc(size_t num, size_t size);
```

General Description

Reserves storage space for an array of `num` elements, each of length `size` bytes. The `calloc()` function then gives all the bits of each element an initial value of 0.

calloc() returns a pointer to the reserved space. The storage space to which the returned value points is aligned for storage of any type of object.

This function is also available to C applications in free-standing System Programming C (SPC) Facilities applications.

Special Behavior for C++

The C++ keywords new and delete are not interoperable with calloc(), free(), malloc(), or realloc().

Returned Value

If successful, calloc() returns the pointer to the area of memory reserved.

If there is not enough space to satisfy the request or if `num` or `size` is 0, calloc() returns NULL. If calloc() returns NULL because there is not enough storage, it sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>Insufficient memory is available</td>
</tr>
</tbody>
</table>

Example

```c
CELEBC01

/* CELEBC01

This example prompts for the number of array entries required and then reserves enough space in storage for the entries.

If &calloc. is successful, the example prints out each entry; otherwise, it prints out an error message.

*/
#include <stdio.h>
```
#include <stdlib.h>

int main(void)
{
    long * array; /* start of the array */
    long * index; /* index variable */
    int i; /* index variable */
    int num; /* number of entries in the array */

    printf( "Enter the number of elements in the array\n" );
    scanf( "%i", &num );

    /* allocate num entries */
    if ( (index = array = (long *)calloc( num, sizeof( long ))) != NULL )
    {
        for ( i = 0; i < num; ++i ) /* put values in array */
            *index++ = i; /* using pointer notation */

        for ( i = 0; i < num; ++i ) /* print the array out */
            printf( "array[%i] = %i\n", i, array[i] );
    }
    else /* out of storage */
    {
        printf( "Out of storage\n" );
        abort();
    }
}

Output
Enter the size of the array
array[ 0 ] = 0
array[ 1 ] = 1
array[ 2 ] = 2

</table>

**Returned Value**

The casinh() family of functions return the complex arc hyperbolic sine value, in the range of a strip, mathematically unbounded along the real axis and in the interval [-i π/2, +i π/2] along the imaginary axis.

**Example**

For an example of a similar function see cacos(), cexp() or cpow().

catclose() — Close a Message Catalog Descriptor

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <nl_types.h>

int catclose(nl_catd catd);
```

General Description

The catclose() function closes the message catalog identified by catd. If a catalog is opened more than once in the same process, a use count is incremented. catclose() decrements this use count. When the use count reaches zero then the file descriptor for that catalog is closed.

Returned Value

If successful, catclose() returns 0.

If unsuccessful, catclose() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The catalog descriptor is not valid.</td>
</tr>
<tr>
<td>EINTR</td>
<td>catclose() was interrupted by a signal.</td>
</tr>
</tbody>
</table>

catgets

catgets() — Read a Program Message

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <nl_types.h>

char *catgets(nl_catd catd, int set_id, int msg_id, const char *s);
```

General Description

The catgets() function attempts to read message msg_id, in set set_id, from the message catalog identified by catd. The catd argument is a message catalog descriptor returned from an earlier call to catopen(). The s argument points to a default message string which will be returned by catgets() if it cannot retrieve the identified message.

When message source files are processed by the gencat command, the CODESET used to create them is saved in the resulting message catalog. The catgets() function interrogates this CODESET value to see if it differs from the CODESET value of the current locale. If it does differ then catgets() uses the iconv() function to convert the message text coming from the message catalog into the codeset of the current locale. The default message string (s) is not affected by this conversion. If iconv() does not support the conversion specified by the two CODESETs then the default message string is returned.

Returned Value

If the identified message is retrieved successfully, catgets() returns a pointer to an internal buffer area containing the NULL-terminated message string.

If unsuccessful, catgets() returns s and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The catd argument is not a valid message catalog descriptor open for reading.</td>
</tr>
<tr>
<td>EINTR</td>
<td>The read operation was terminated due to the receipt of a signal, and no data was transferred.</td>
</tr>
</tbody>
</table>

Special Behavior for z/OS UNIX Services

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>May be returned for several reasons:</td>
</tr>
<tr>
<td></td>
<td>• The message catalog identified by catd is not a valid message catalog, or has been corrupted. Ensure that the message catalog was created using the z/OS UNIX gencat command.</td>
</tr>
<tr>
<td></td>
<td>• iconv() does not support the conversion between the codeset of the message catalog and that of the current locale. To check the</td>
</tr>
</tbody>
</table>
codeset that the message catalog was created in, look for the
codeset name at offset 28 into the message catalog.

ENOMSG  The message identified by set_id and msg_id is not in the message
catalog.

catopen

catopen() — Open a Message Catalog

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <nl_types.h>

nl_catd catopen(const char *name, int oflag);
```

General Description

The catopen() function opens a message catalog and returns a message catalog descriptor. The name argument specifies the name of the message catalog to be opened. If name contains a "/", then name specifies a complete name for the message catalog. Otherwise, the environment variable NLSPATH is used with name substituted for %N (see the XBD specification, Chapter 6, Environment Variables). If NLSPATH does not exist in the environment, or if a message catalog cannot be found in any of the components specified by NLSPATH, then the default path of "/usr/lib/nls/msg/%L/%N" is used. The "%L" component of this default path is replaced by the setting of LC_MESSAGES if the value of oflag is NL_CAT_LOCALE, or the LANG environment variable if oflag is 0. A change in the setting of the LANG or LC_MESSAGES will have no effect on existing open catalogs.

A message catalog descriptor remains valid in a process until that process closes it, or a successful call to one of the exec functions. When a message catalog is opened the FD_CLOEXEC flag will be set. See “fcntl() — Control Open File Descriptors” on page 527. Portable applications must assume that message catalog descriptors are not valid after a call to one of the exec functions.

If a catalog is opened more than once in the same process, a use count is incremented. When the use count reaches zero, by using catclose() to close the catalog, then the file descriptor for that catalog is closed.

Returned Value

If successful, catopen() returns a message catalog descriptor for use on subsequent calls to catgets() and catclose().

If unsuccessful, catopen() returns (nl_catd)-1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for the component of the path prefix of the message catalog or read permission is denied for the message catalog.</td>
</tr>
<tr>
<td>EMFILE</td>
<td>OPEN_MAX file descriptors are currently open in the calling process.</td>
</tr>
</tbody>
</table>
ENAMETOOLONG
The length of the pathname of the message catalog exceeds PATH_MAX, or a pathname component is longer than NAME_MAX.

ENFILE
Too many files are currently open in the system.

ENOENT
The message catalog does not exist or the name argument points to an empty string.

ENOMEM
Insufficient storage space is available.

ENOTDIR
A component of the path prefix of the message catalog is not a directory.

<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double cbart(double x);

C99
#define _ISOC99_SOURCE
#include <math.h>
float cbartf(float x);
long double cbartl(long double x);
```

**General Description**

The `cbart()` function calculates the real cube root of its argument `x`.

**Note:** The following table shows which functions work in IEEE Binary Floating-Point format and which work in hexadecimal floating-point format. See [IEEE Binary Floating-Point](page 108) for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cbart</code></td>

cclass() — Return Characters in a Character Class

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <collate.h>

int cclass(char *class, collel_t **list);
```

General Description

Finds all the collating elements of the class, `class`. The list is updated to point to the array of collating elements found. The list is valid until the next call to `setlocale()`.

The function supports user-defined character classes. In C Library programs, the function also supports POSIX.2 character classes.

Returned Value

If successful, `cclass()` returns the number of elements in the list pointed to by `list`.

If the first argument specifies a class that does not exist in the LC_CTYPE category of the current locale, `cclass()` returns −1.

Example

```c
CELEBC02
/* CELEBC02 */
#include <stdio.h>
#include <collate.h>

int main(void)
{
    collel_t *list; /* ptr to the digit class collation weights */
    int weights; /* no. of class collation class weights found */
    int i;

    weights = cclass("digit", &list);

    printf("weights=%d\n", weights);
    for (i=0; i<weights; i++)
        printf("*(list + %d) = %d\n", i, *(list + i));
}
```

__CcsidType() — Return Coded Character Set ID Type (ASCII/EBCDIC)

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

```c
#include <_Ccsid.h>

__csType __CcsidType(__ccsid_t Ccsid);
```

General Description

__CcsidType() returns a __csType value which indicates whether the Ccsid character codeset ID is ASCII or EBCDIC.

Returned Value

If Ccsid is valid, __CcsidType() returns a __csType value of _CSTYPE_EBCDIC or _CSTYPE_ASCII, indicating whether the Ccsid refers to an EBCDIC or ASCII codeset.

If Ccsid is not valid, __CcsidType() returns _CSTYPE_INVALID.

Related Information

- "_Ccsid.h" on page 35
- "__CSNameType() — Return Codeset Name Type (ASCII/EBCDIC)" on page 377

cds

cds() — Compare Double and Swap

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

int cds(cds_t *oldptr, cds_t *curptr, cds_t newwords);
```

General Description

The cds() built-in function compares the 8-byte value pointed to by `oldptr` to the 8-byte value pointed to by `curptr`. If they are equal, the 8-byte value `newwords` is copied into the location pointed to by `curptr`. If they are unequal, the value pointed to by `curptr` is copied into the location pointed to by `oldptr`.

To avoid infringing on the user’s name space, this nonstandard function is exposed only when you use the compiler option, LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The function uses the COMPARE DOUBLE AND SWAP (CDS) instructions, which can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas. For a detailed description, see the appendixes in the *z/Architecture Principles of Operation* on number representation and instruction.

Returned Value

`cds()` returns 0 if the 8-byte value pointed to by `oldptr` is equal to the 8-byte value pointed to by `curptr`.

Otherwise `cds()` returns 1.

Related Information

- *z/Architecture Principles of Operation*
- "stdlib.h" on page 85

cdump() — Request a Main Storage Dump

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <ctest.h>

int cdump(char *dumptitle);
```

General Description

1. Creates a display of the activation stack, by calling trace in the same way as the ctrace() function does.
2. Displays the Language Environment-formatted dump.
3. If the source file was compiled with TEST(SYM), cdump() displays the contents of the user's variables. The output is identified with `dumptitle`. See the CEE3DMP Language Environment callable service in z/OS Language Environment Programming Guide, SA22-7561 to determine where the output is written to.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

When cdump() is invoked from a user routine, the C/C++ library issues an OS SNAP macro to obtain a dump of virtual storage. The first invocation of cdump() results in a SNAP identifier of 0. For each successive invocation, the ID is increased by one to a maximum of 256, after which the ID is reset to 0.

The output of the dump is directed to the CEESNAP data set. The DD definition for CEESNAP is as follows:

```bash
//CEESNAP DD SYSOUT= *
```

If the data set is not defined, or is not usable for any reason, cdump() returns a failure code of 1. This occurs even if the call to CEE3DMP is successful. For more information see “Debugging C/C++ Routines” in z/OS Language Environment Debugging Guide.

Returned Value

If successful, cdump() returns 0.

If unsuccessful, cdump() returns nonzero.

</tbody>
</table>

Format

```c
#include <math.h>

double ceil(double x);
float ceilf(float x); /* C++ only */
long double ceill(long double x); /* C++ only */
float ceil(long double x);
long double ceil(long double x);
```

General Description

Computes the smallest integer that is greater than or equal to \( x \).

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE Binary Floating-Point " on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

Returns the calculated value as a double, float, or long double value.

If there is an overflow, the function sets errno to ERANGE and returns HUGE_VAL.

Special Behavior for IEEE

The ceil() functions are always successful.

Example

**CELEBC04**

```c
/* CELEBC04 */

This example sets \( y \) to the smallest integer greater than 1.05, and then to the smallest integer greater than \(-1.05\).

The results are 2.0 and \(-1.0\), respectively.
```

```c
#include <math.h>
#include <stdio.h>
int main(void)
{
    double y, z;
```
# ceil, ceilf, ceill

```c
y = ceil(1.05); /* y = 2.0 */
z = ceil(-1.05); /* z = -1.0 */
printf("y = \%fn z = \%fn", y, z);
```

__Decimal64 ceild64(__Decimal64 x);
__Decimal128 ceild128(__Decimal128 x);
__Decimal32 ceil(__Decimal32 x); /* C++ only */
__Decimal64 ceil(__Decimal64 x); /* C++ only */
__Decimal128 ceil(__Decimal128 x); /* C++ only */
```

General Description

Computes the smallest integer that is greater than or equal to \( x \).

**Note:**
- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

These functions are always successful.

Example

```c
/* CELEBC50 */

This example illustrates the ceild32() function.

This example sets \( y \) to the smallest integer greater than 1.05, and then to the smallest integer greater than -1.05.

The results are 2.0 and -1.0, respectively.

*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    __Decimal32 y, z;
    y = ceild32(+1.05DF);  /* y = +2.0 */
    z = ceild32(-1.05DF);  /* z = -1.0 */
    printf("ceild32(+1.05) = \%Hf\n" "ceild32(-1.05) = \%Hf\n", y, z);
}
```

__certificate() — Register/Deregister/Authenticate a Digital Certificate

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R7</td>
</tr>
</tbody>
</table>

Format

#define _OPEN_SYS
#include <unistd.h>

int __certificate(int function_code,
                  int certificate_length,
                  char *certificate,...);

General Description

The __certificate() function allows the user to register or deregister a digital certificate with or from the userid that is associated with the current security environment, or to authenticate a security environment using a digital certificate in lieu of a userid/password combination.

The function takes at least the following arguments:

function_code  Specifies one of the following functions:

- __CERTIFICATE_REGISTER
  Register the passed certificate to the user. No new security environment is created, and no authentication of the user is done.

- __CERTIFICATE_DEREGISTER
  Deregister the passed certificate from the user. Certificate must have been previously registered to the user.

- __CERTIFICATE_AUTHENTICATE
  As of z/OS V1R4, authenticate the passed certificate for this caller. The certificate must have already been registered.

certificate_length  The length of the digital certificate. A zero length will cause −1 return value with errno set to EINVAL.

certificate  The certificate must be a single BER encoded X.509 certificate. PKCS7, PEM, or Base64 encoded certificates are allowed.

Note: Only a single BER encoded X.509 certificate is supported for the authenticate function.

As of z/OS V1R4, the __CERTIFICATE_AUTHENTICATE function code requires the following additional parameters to be specified on the function call:

buflen (size_t)

Specifies the size of the buffer pointed to by buf. Up to buflen bytes of userid (including the null terminator) will be copied into the buffer. Note that truncation may occur if the buffer is too small. The buffer
__certificate

size should be large enough for any userid on the system. A value less than 1 will cause -1 return value with errno set to EINVAL.

buf (char *) Pointer to character buffer where __certificate() will place the userid associated with the digital certificate. A value of NULL will cause -1 return value with errno set to EINVAL.

Usage Notes

1. The __certificate function is intended for servers that support the automatic registration of certificates for clients they are supporting (on the World Wide Web for example).

2. The __CERTIFICATE_REGISTER function code will associate the passed certificate with whatever user identity is present. If the task level identity is present the certificate is associated with the task. Task level security can be created by pthread_security_np(), __login() or by any other means of creating a task level ACEE. If no task level identity (ACEE) is present, the certificate will be associated with the address space identity.

3. The __certificate() function calls the z/OS z/OS UNIX System Services BPX1SEC service. For a more detailed description of the BPX1SEC service, see z/OS UNIX System Services Programming: Assembler Callable Services Reference.

Restrictions

A security manager supporting digital certificate registration and deregistration must be installed and operational.

Returned Value

If successful, __certificate() returns 0.

If unsuccessful, __certificate() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Permission is denied.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>A parameter is not valid.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>An MVS environmental error or internal error occurred.</td>
</tr>
<tr>
<td>EMVSSAF2ERR</td>
<td>An error occurred in the security product. Certificate is already defined for another process or certificate is not valid or certificate does not meet required format. Also, realized when an internal error has occurred.</td>
</tr>
<tr>
<td>ENOSYS</td>
<td>The function is not implemented or installed.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The operation was not permitted. Calling process may not be authorized in BPX.DAEMON facility class.</td>
</tr>
</tbody>
</table>

Use __errno2() to obtain a more detailed reason code (in most cases) when __certificate() fails.

cexp(), cexpf(), cexpl() — Calculate the Complex Exponential

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7, a compiler that is designed to support C99</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <complex.h>

double complex cexp(double complex z);
float complex cexpf(float complex z);
long double complex cexpl(long double complex z);
```

General Description

The cexp() family of functions compute the complex base-e exponential of `z`.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>

<td>X</td>
<td>X</td>
</tr>
<tr>
<td>cexpf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>cexpl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

The cexp() family of functions return the complex base-e exponential value.

Example

```c
/*
 * This example illustrates the complex exponential
 * function
 */
#include <complex.h>
#include <stdio.h>

void main()
{
    double complex z=6.0146 + I*(-2.41958),
    res;
    res = cexp(z);
    printf("cexp(%.1f + (%.1f)*I) = %.1f + (%.1f)*I\n",creal(z), cimag(z), creal(res), cimag(res));
}
```

Output:
```
cexp(6.014600 + (-2.419580)*I) = -307.216850 + (-270.545937)*I
```

cfgetispeed

cfgetispeed() — Determine the Input Baud Rate

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <termios.h>

speed_t cfgetispeed(const struct termios *termpt);"
```

General Description

Extracts the input baud rate from the `termios` structure indicated by `*termpt`. The `termios` structure contains information about a terminal. A program should first use `tcgetattr()` to get the `termios` structure, and then use `cfgetispeed()` to extract the speed from the structure. The program can then use `cfgetispeed()` to set a new baud rate in the structure and `tcsetattr()` to pass the changed value to the system.

Although in a z/OS UNIX application valid speeds can be set with `cfsetispeed()` and passed to the system with `tcsetattr()`, the speed has no effect on the operation of a pseudoterminal. However, the operation will have an effect if issued for an OCS remote terminal.

Returned Value

cfgetispeed() returns a code indicating the baud rate; see Table 22. These codes are defined in the `termios.h` header file and have an unsigned integer type.

There are no documented `errno` values.

Table 22. Baud Rate Codes

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <termios.h>

int cfsetispeed(struct termios *termptr, speed_t speed);
```

General Description

Specifies a new input baud rate for the termios control structure, `*termptr`. cfsetispeed() records this new baud rate in the control structure but does not actually change the terminal device file. The program must call tcsetattr() to modify the terminal device file to reflect the settings in the termios structure.

A program should first use tcgetattr() to get the termios structure. Then it should use cfsetispeed() to set the speed in termios and tcsetattr() to pass the modified termios structure to the system.

Although in a z/OS UNIX application valid speeds can be set with cfsetispeed() and passed to the system with tcsetattr(), the speed has no effect on the operation of a pseudoterminal. However, the operation will have an effect if issued for an OCS remote terminal.

The `speed` argument indicates the new baud rate with one of the following codes, defined in the termios.h header file. The codes have an unsigned integer type. Table 22 on page 258 shows the codes to set the baud rate.

Returned Value

If successful, cfsetispeed() sets the baud rate in the control structure and returns 0.

If unsuccessful, cfsetispeed() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>An unsupported value for speed</td>
</tr>
</tbody>
</table>

Example

CELEBC07

```c
/* CELEBC07

   This example specifies a new input baud rate.
*/
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>
```
main()
{
    struct termios term;
    if (tcgetattr(0, &term) != 0)
        perror("tcgetattr() error");
    else if (cfsetispeed(&term, B0) != 0)
        perror("cfsetispeed() error");
    else if (tcsetattr(0, TCSANOW, &term) != 0)
        perror("tcsetattr() error");
}

__chattr() — Change the Attributes of a File or Directory

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __chattr(char* pathname, attrib_t *attributes, int attributes_len);
```

General Description

The __chattr() function modifies the attributes that are associated with a file. It can be used to change the mode, owner, access time, modification time, change time, reference time, audit flags, general attribute flags, file tag, and file format and size. The file to be impacted is defined by the pathname argument.

The attributes argument is the address of an attrib_t structure which is used to identify the attributes to be modified and the new values desired. The attrib_t type is an f_attributes structure as defined in <sys/stat.h> for use with the __chattr() function. For proper behavior the user should ensure that this structure has been initialized to zeros before it is populated. Available elements of the f_attributes structure are defined in Table 23:

**Note:** If you set att_nodelfilesmask, att_sharelibmask, att_nodelfiles, att_sharelib, att_noshareasmask, att_apfauthmask, att_progctlmask, att_noshareas, att_apfauth or att_progctl, then att_setgen must also be set. The att_setgen flag is a required indicator when setting “general” attributes.

### Returned Value

If successful, __chattr() returns 0.

If unsuccessful, __chattr() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The calling process did not have appropriate permissions. Possible reasons include:</td>
</tr>
<tr>
<td></td>
<td>• The calling process was attempting to set access time or modification time to current time, and the effective UID of the calling process does not match the owner of the file; the process does not have write permission for the file; or the process does not have appropriate privileges.</td>
</tr>
<tr>
<td></td>
<td>• The calling process was attempting to truncate the file, and it does not have write permission for the file.</td>
</tr>
<tr>
<td>ECICS</td>
<td>An attempt was made to change file tag attributes under non-OTE CICS and file tagging is not supported in that environment.</td>
</tr>
</tbody>
</table>
EFBIG  The calling process was attempting to change the size of a file, but the specified length is greater than the maximum file size limit for the process.

EINVAL  The attributes structure containing the requested changes is not valid.

ELOOP    A loop exists in symbolic links that were encountered during resolution of the pathname argument. This error is issued if more than 24 symbolic links are detected in the resolution of pathname.

ENAMETOOLONG  
pathname is longer than 1023 characters, or a component of the pathname is longer than 255 characters. (Filename truncation is not supported.)

ENOENT    No file named pathname was found.

ENOTDIR   Some component of pathname is not a directory.

EPERM    The operation is not permitted for one of the following reasons:

- The calling process was attempting to change the mode or the file format but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the owner but it does not have appropriate privileges.
- The calling process was attempting to change the general attribute bits but it does not have write permission for the file.
- The calling process was attempting to set a time value (not current time) but the effective UID does not match the owner of the file, and it does not have appropriate privileges.
- The calling process was attempting to set the change time or reference time to current time but it does not have write permission for the file.
- The calling process was attempting to change auditing flags but the effective UID of the calling process does not match the owner of the file and the calling process does not have appropriate privileges.
- The calling process was attempting to change the Security Auditor’s auditing flags but the user does not have auditor authority.

EROF S   pathname specifies a file that is on a read-only file system.

Example

```c
#define _POSIX_SOURCE 1
#define _OPEN_SYS_FILE_EXT 1
#include <stdio.h>
#include <fcntl.h>
#include <sys/stat.h>

int main(int argc, char *argv[]) {
    int fd;
    attrib_t myAtt;
    struct stat attr;
    char filename[] = "chattr.testfile";
```
Create an empty file

```c
if ( (fd = creat(filename, S_IROWXU | S_IRGRP | S_IROTH)) < 0) {
    perror("Failed to create testfile");
    exit(1);
}
close(fd);
```

Clear myAtt structure

```c
memset(&myAtt, 0, sizeof(myAtt));
```

Update myAtt to request file tag change and set file tag values

```c
myAtt.att_filetag.ft_ccsid = 12345;
myAtt.att_filetag.ft_txtflag = 1;
```

Change Attributes

```c
if ( __chattr(filename, &myAtt, sizeof(myAtt)) != 0 ) {
    perror("Failed to change attributes for testfile");
    exit(2);
}
```

Verify Change

```c
if ( stat(filename, &attr) != 0 ) {
    perror("Failed to acquire statistics for testfile");
    exit(3);
}
```

```c
if ((attr.st_tag.ft_ccsid == 12345) && (attr.st_tag.ft_txtflag == 1)) {
    printf("File attributes changed successfully\n");
}
```

Output

chaudit() — Change Audit Flags for a File by Path

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _OPEN_SYS 1
#include <sys/stat.h>

int chaudit(const char *pathname, unsigned int flags,
             unsigned int option);
```  

General Description

Changes the audit flags for a file to indicate the type of requests the security product should audit. chaudit() can change user audit flags or security auditor audit flags, depending on the `option` specified.

`pathname` is the name of the file for which the audit flags are to be changed.

`flags` is the setting for the audit flags:

- `AUDTREADFAIL` Audit the failing read requests.
- `AUDTREADSUCC` Audit the successful read requests.
- `AUDTWRITEFAIL` Audit the failing write requests.
- `AUDTWRITESUCC` Audit the successful write requests.
- `AUDTEXECFAIL` Audit the failing execute or search requests.
- `AUDTEXECSUCC` Audit the successful execute or search requests. The bitwise inclusive-OR of any or all of these can be used to set more than one type of auditing.

`option` indicates whether the user audit flags or the security-auditor audit flags are to be changed:

- `AUDT_USER (0)` Change user flags. The user must be the file owner or have appropriate authority to change the user audit flags for a file.
- `AUDT_AUDITOR (1)` Change security auditor audit flags. The user must have security-auditor authority to modify the security auditor audit flags for a file.

Returned Value

If successful, chaudit() returns 0.

If unsuccessful, chaudit() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The calling process does not have permission to search some component of <code>pathname</code>.</td>
</tr>
<tr>
<td>EINVAL</td>
<td><code>option</code> is not AUDT_USER or AUDT_AUDITOR.</td>
</tr>
</tbody>
</table>
chaudit

ELOOP  A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of pathname is greater than POSIX_SYMLOOP (a value defined in the limits.h header file).

ENAMETOOLONG  

pathname is longer than PATH_MAX characters or a component of pathname is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values are determined using pathconf().

ENOENT  There is no file named pathname, or pathname is an empty string.

ENOTDIR  A component of the path prefix is not a directory.

EPERM  The effective user ID (UID) of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS  pathname specifies a file that is on a read-only file system.

Example

CELEBC09

/* CELEBC09

   This example changes the audit flags.

*/

#define _OPEN_SYS
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _OPEN_SYS
#include <stdio.h>

main() {
    int fd;
    char fn[]="chaudit.file";

    if ((fd = creat(fn, S_IRUSR|S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        if (chaudit(fn, AUDTREADFAIL, AUDT_USER) != 0)
            perror("chaudit() error");
        unlink(fn);
    }
}

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

int chdir(const char *pathname);
```

General Description

Makes `pathname` your new working directory.

Returned Value

If successful, chdir() changes the working directory and returns 0.

If unsuccessful, chdir() does not change the working directory, returns −1, and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The process does not have search permission on one of the components of <code>pathname</code>.</td>

__check_resource_auth_np

__check_resource_auth_np() — Determine Access to MVS Resources

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

int __check_resource_auth_np( char *principal_uuid,
                             char *cell_uuid,
                             char *userid,
                             char *security_class,
                             char *entity_name,
                             int access_type);
```

General Description

The __check_resource_auth_np() function is used to check the access a user has to an MVS resource.

For authorization to use this function, the caller must have read permission to the BPX.SERVER Facility class, or if BPX.SERVER is not defined, the caller must be a superuser (UID=0).

The user identity can be specified in several forms. The identities are scanned in the order below, and the access check will be made with the first identity that is found:

- `userid`
- `principal UUID` and if known, a `cell UUID`
- caller's thread-level (task) security context, if one exists
- caller's process-level (address space) security context

Note:

- When no identity is specified by the caller and the caller's task has an ACEE created with pthread_security_np() for a SURROGATE (non-password) client, both the task and address space level ACEEs are used in determining the type of access permitted to a resource.
- The __check_resource_auth_np() function supports the general resources only. In particular, the `security_class` parameter cannot specify DATASET.

For systems using RACF, the class name specified must be in the RACF class descriptor table.

The parameters supported are:

- `principal_uuid` Specifies a 36-byte principal UUID. A value of NULL indicates that no principal UUID is specified.
- `cell_uuid` Specifies a 36-byte cell UUID. A value of NULL indicates that no cell UUID is specified.
- `userid` Specifies a user ID. A value of NULL indicates that no user ID is specified. The `userid` must be 1-8 characters in length.
__check_resource_auth_np

security_class Specifies the name of a class of resources. The access check will be made on a resource in this security class. The security_class must be 1-8 characters in length.

entity_name Specifies the name of a resource profile name. The access check will be made on the resource specified by the resource profile name. The entity_name must be 1-246 characters in length.

access Specifies a numeric value that identifies the type of access to check for. Possible access values are:

- __READ_RESOURCE
  check if the specified user has read access to the resource.

- __UPDATE_RESOURCE
  check if the specified user has update access to the resource.

- __CONTROL_RESOURCE
  check if the specified user has control access to the resource.

- __ALTER_RESOURCE
  check if the specified user has alter access to the resource.

Returned Value

If successful, __check_resource_auth_np() returns 0.

If unsuccessful, __check_resource_auth_np() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>

CheckSchEnv

CheckSchEnv() — Check WLM Scheduling Environment

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX System Services</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <sys/__wlm.h>

int CheckSchEnv(const char * sched_env,
                 const char * system_name);

General Description

The CheckSchEnv() function provides the ability for an application to connect to check the WLM scheduling environment.

*sched_env Points to a 16 byte character string that represents the WLM scheduling environment to be queried. If the environment name is less than 16 characters, the name should be right padded with blanks.

*sys_name Points to a 8 bytes character string that represents the system name to be queried. If the system name is less than 8 characters, the name should be right padded with blanks.

Returned Value

If successful, CheckSchEnv() returns 0.

If unsuccessful, CheckSchEnv() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>
</tr>
<tr>
<td>EINVAL</td>

chmod

chmod() — Change the Mode of a File or Directory

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _POSIX_SOURCE
#include <sys/stat.h>

int chmod(const char *pathname, mode_t mode);
```

General Description

Changes the mode of the file or directory specified in `pathname`.

The `mode` argument is created with one of the following symbols defined in the `sys/stat.h` header file.

Any mode flags that are not defined will be turned off, and the function will be allowed to proceed.

- `S_IRGRP` Read permission for the file’s group.
- `S_IROTH` Read permission for users other than the file owner.
- `S_IRUSR` Read permission for the file owner.
- `S_IRWXG` Read, write, and search or execute permission for the file’s group. `S_IRWXG` is the bitwise inclusive-OR of `S_IRGRP`, `S_IWGRP`, and `S_IXGRP`.
- `S_IRWXO` Read, write, and search or execute permission for users other than the file owner. `S_IRWXO` is the bitwise inclusive-OR of `S_IROTH`, `S_IWOTH`, and `S_IXOTH`.
- `S_ISGID` Privilege to set group ID (GID) for execution. When this file is run through an exec function, the effective group ID of the process is set to the group ID of the file. The process then has the same authority as the file owner, rather than the authority of the actual invoker.
- `S_ISUID` Privilege to set the user ID (UID) for execution. When this file is run through an exec function, the effective user ID of the process is set to the owner of the file. The process then has the same authority as the file owner, rather than the authority of the actual invoker.
- `S_ISVTX` The sticky bit indicating shared text. Keep loaded as an executable file in storage.
- `S_IWGRP` Write permission for the file’s group.
- `S_IWOTH` Write permission for users other than the file owner.
S_IWUSR Write permission for the file owner.
S_IXGRP Search permission (for a directory) or execute permission (for a file) for the file’s group.
S_IXOTH Search permission for a directory, or execute permission for a file, for users other than the file owner.
S_IXUSR Search permission (for a directory) or execute permission (for a file) for the file owner.

Special Behavior for XPG4.2

If a directory is writable and the mode bit S_ISVTX is set on the directory, a process may remove or rename files within that directory only if one or more of the following is true:

- The effective user ID of the process is the same as that of the owner ID of the file.
- The effective user ID of the process is the same as that of the owner ID of the directory.
- The process has appropriate privileges.

A process can set mode bits only if the effective user ID of the process is the same as the file’s owner or if the process has appropriate privileges (superuser authority). chmod() automatically clears the S_ISGID bit in the file’s mode bits if all these conditions are true:

- The calling process does not have appropriate privileges, that is, superuser authority (UID=0).
- The group ID of the file does not match the group ID or supplementary group IDs of the calling process.
- One or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set to 1.

Returned Value

If successful, chmod() marks for update the st_ctime field of the file and returns 0.

If unsuccessful, chmod() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The process does not have search permission on some component of the pathname prefix.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of pathname is greater than POSIX_SYMLOOP (a value defined in the limits.h header file).</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>pathnamename is longer than PATH_MAX characters, or some component of pathnamename is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathnamename string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values are determined using pathconf().</td>
</tr>
<tr>
<td>ENOENT</td>
<td>There is no file named pathnamename, or the pathnamename argument is an empty string.</td>
</tr>
</tbody>
</table>
**Example**

```c
CELEBC11

/* CELEBC11 */

This example changes the permission from the file owner to the file's group.

*/
#define _POSIX_SOURCE
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  char fn[]="/./temp.file";
  FILE *stream;
  struct stat info;

  if ((stream = fopen(fn, "w")) == NULL)
    perror("fopen() error");
  else {
    fclose(stream);
    stat(fn, &info);
    printf("original permissions were: %08x
", info.st_mode);
    if (chmod(fn, S_IRWXU|S_IRWXG) != 0)
      perror("chmod() error");
    else {
      stat(fn, &info);
      printf("after chmod(), permissions are: %08x
", info.st_mode);
    }
    unlink(fn);
  }
}

Output

original permissions were: 030001b6
after chmod(), permissions are: 030001f8
```

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

int chown(const char *pathname, uid_t owner, gid_t group);
```

General Description

Changes the owner or group (or both) of a file. `pathname` is the name of the file whose owner or group you want to change. `owner` is the user ID (UID) of the new owner of the file. `group` is the group ID (GID) of the new group for the file.

If `_POSIX_CHOWN_RESTRICTED` is defined in the `<unistd.h>` header file, a process can change the group of a file only if one of these is true:
1. The process has appropriate privileges.
2. Or all of the following are true:
   a. The effective user ID of the process is equal to the user ID of the file owner.
   b. The `owner` argument is equal to the user ID of the file owner or `(uid_t)-1`,
   c. The `group` argument is either the effective group ID or a supplementary group ID of the calling process.

If `pathname` is a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, `chown()` clears the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file mode and returns successfully.

If `pathname` is not a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, `chown()` clears the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file.

When `chown()` completes successfully, it marks the `st_ctime` field of the file to be updated.

Special Behavior for XPG4.2

If `owner` or `group` is specified as `(uid_t)-1` or `(gid_t)-1` respectively, the corresponding ID of the file is unchanged.

Returned Value

If successful, `chown()` updates the owner, group, and change time for the file and returns 0.

If unsuccessful, `chown()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>
chown

EACCES The process does not have search permission on some component of the pathname prefix.

EINTR Added for XPG4.2: The chown() function was interrupted by a signal which was caught.

EINVAL owner or group is not a valid user ID (UID) or group ID (GID).

EIO Added for XPG4.2: An I/O error occurred while reading or writing to the file system.

ELOOP A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of pathname is greater than POSIX_SYMLOOP (a value defined in the limits.h header file).

ENAMETOOLONG pathname is longer than PATH_MAX characters, or some component of pathname is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined using pathconf().

ENOENT There is no file named pathname, or the pathname argument is an empty string.

ENOTDIR Some component of the pathname prefix is not a directory.

EPERM The effective user ID of the calling process does not match the owner of the file, or the calling process does not have appropriate privileges, that is, superuser authority (UID=0).

EROFS pathname is on a read-only file system.

Example

CELEBC12

/* CELEBC12

This example changes the owner and group of a file.
*/

#define _POSIX_SOURCE
#include <unistd.h>
#include <sys/stat.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char fn[]="/temp.file";
    FILE *stream;
    struct stat info;
    if ((stream = fopen(fn, "w")) == NULL)
        perror("fopen() error");
    else {
        close(stream);
        stat(fn, &info);
        printf("original owner was %d and group was %d\n", info.st_uid, info.st_gid);
        if (chown(fn, 25, 0) != 0)
            perror("chown() error");
        else {
            stat(fn, &info);
printf("after chown(), owner is \%d and group is \%d\n",
       info.st_uid, info.st_gid);
}
unlink(fn);
}

Output
original owner was 0 and group was 0
after chown(), owner is 25 and group is 0

chpriority

chpriority() — Change the Scheduling Priority of a Process

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SOURCE 2
#include <sys/resource.h>

int chpriority(int which, id_t who, int prioritytype, int priority);
```

General Description

The chpriority() function changes the scheduling priority of a process, process group or user.

Processes are specified by the values of the `which` and `who` arguments. The `which` argument may be one of the following values: PRIO_PROCESS, PRIO_PGRP, or PRIO_USER, indicating that the `who` argument is to be interpreted as a process ID, a process group ID, or a user ID, respectively. A 0 (zero) value for the `who` argument specifies the current process, process group or user ID.

If more than one process is specified, the chpriority() function changes the priorities of all of the specified processes.

The default priority is 0; negative priorities cause more favorable scheduling. The range of legal priority values is -20 to 19. If the CPRIO_ABSOLUTE value is specified for the `prioritytype` argument and the priority value specified to chpriority() is less than the system’s lowest supported priority value, the system’s lowest supported value is used; if it is greater than the system’s highest supported value, the system’s highest supported value is used. If the CPRIO_RELATIVE value is specified on the `prioritytype` argument, request for values above or below the legal limits result in the priority value being set to the corresponding limit.

The changing of a process’s scheduling priority value has the equivalent effect of a process’s nice value, since they both represent the process’s relative CPU priority. For example, changing one’s scheduling priority value using the chpriority() function to its maximum value (19) has the equivalent effect of increasing one’s nice value to its maximum value $2^\{NZERO\}-1$, and will be reflected on the nice(), getpriority(), chpriority(), and setpriority() functions.

Only a process with appropriate privilege can lower its priority. In addition to lowering the priority value, a process with appropriate privilege has the ability to change the priority of any process regardless of the process’s saved set-user-ID value.

Returned Value

If successful, chpriority() returns 0.

If unsuccessful, chpriority() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
EACCES  The priority is being changed to a lower value and the current process does not have the appropriate privilege.

EINVAL  The value of the which argument was not recognized, or the value of the who argument is not a valid process ID, process group ID or user ID, or the value of the prioritytype argument was not recognized.

ENOSYS  The system does not support this function.

EPERM  A process was located, but the save set-user-ID of the executing process does not match the saved set-user-ID of the process whose priority is to be changed.

ESRCH  No process could be located using the which and who argument values specified.

chroot

chroot() — Change Root Directory

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <unistd.h>

int chroot(const char *path);
```

General Description

The `path` argument points to a pathname naming a directory. The `chroot()` function causes the named directory to become the root directory, that is the starting point for path searches for pathnames beginning with `/`. The process’s working directory is unaffected by `chroot()`. Only a superuser can request `chroot()`.

The dot-dot entry in the root directory is interpreted to mean the root directory. Thus, dot-dot cannot be used to access files outside the subtree rooted at the root directory.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned Value

If successful, `chroot()` changes the root directory, and returns 0.

If unsuccessful, `chroot()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for a component of <code>path</code></td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of pathname is greater than <code>POSIX_SYMLOOP</code> (a value defined in the <code>limits.h</code> header file).</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>Pathname is longer that <code>PATH_MAX</code> characters, or some component of pathname is longer that <code>NAME_MAX</code> characters while <code>_POSIX_NO_TRUNC</code> is in effect. For symbolic links, the</td>
</tr>
</tbody>
</table>
length of the pathname string substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values are determined using `pathconf()`.

- **ENOENT** A component of `path` does not name an existing directory or `path` is an empty string.
- **ENOTDIR** A component of the `path` name is not a directory.
- **EPERM** The effective user ID does not have appropriate privileges.

**clearenv() — Clear Environment Variables**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1a</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

**POSIX - C only**

```c
#define _POSIX1_SOURCE
#include <env.h>

int clearenv(void);
```

**Non-POSIX**

```c
#include <stdlib.h>

int clearenv(void);
```

**General Description**

Clears all environment variables from the environment table and frees the associated storage.

clearenv() also resets all behavior modified by z/OS XL C/C++ specific environment variables back to their defaults. For example, if a binary file was opened, then it would support seeking by byte offsets, regardless of record format. If the file is a Variable Record format MVS DASD file, then clearing the environment variable causes seeking by encoded values the next time it is opened.

To avoid infringing on the user's name space, the non-POSIX version of this function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

For details about environment variables, see “Using Environment Variables” in [z/OS XL C/C++ Programming Guide](#).  

**Special Behavior for POSIX C**

clearenv() can change the value of the pointer environ. Therefore, a copy of that pointer made before a call to clearenv() may no longer be valid after the call to clearenv(). See “z/OS XL C/C++ applications with z/OS UNIX System Services C functions” on page 13 for more information about using POSIX support.

**Returned Value**

If successful, clearenv() returns 0.
If unsuccessful, clearenv() returns nonzero and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>The process requires more space than is available.</td>
</tr>
</tbody>
</table>

**Example**

**CELEBC13**

/* CELEBC13 */

This C/MVS example needs to be run with POSIX(ON).

It clears the process environment variable list.

#define _POSIX_SOURCE 1
#include <env.h>
#include <stdio.h>

extern char **environ;

int count_env() {
    int num;
    for (num=0; environ[num] != NULL; num);
    return num;
}

main() {
    printf("before clearenv(), there are %d environment variables\n", count_env());
    if (clearenv() != 0)
        perror("clearenv() error");
    else {
        printf("after clearenv(), there are %d environment variables\n", count_env());
        setenv("var1", "value1", 1);
        setenv("var−two", "Value Two", 1);
        printf("after setenv()’s, there are %d environment variables\n", count_env());
        if (clearenv() != 0)
            perror("clearenv() error");
        else
            printf("after clearenv(), there are %d environment variables\n", count_env());
    }
}

**Output**

before clearenv(), there are 9 environment variables
after clearenv(), there are 0 environment variables
after setenv()’s, there are 2 environment variables
after clearenv(), there are 0 environment variables

**CELEBC14**

/* CELEBC14 */

This example is for a non-POSIX environment, and thus will work under C++/MVS.

*/
int main(void)
{
    char *x;

    /* set 3 environment variables to "Y" */
    setenv("_EDC_ANSI_OPEN_DEFAULT","Y",1);
    setenv("_EDC_BYTE_SEEK","Y",1);
    setenv("_EDC_COMPAT","3",1);

    /* query the setting of _EDC_BYTE_SEEK */
    x = getenv("_EDC_BYTE_SEEK");
    if (x != NULL)
        printf("_EDC_BYTE_SEEK = %s\n",x);
    else
        printf("_EDC_BYTE_SEEK is undefined\n");

    /* clear the environment variable table */
    clearenv();

    /* query the setting of _EDC_BYTE_SEEK */
    x = getenv("_EDC_BYTE_SEEK");
    if (x != NULL)
        printf("_EDC_BYTE_SEEK = %s\n",x);
    else
        printf("_EDC_BYTE_SEEK is undefined\n");
}

Output
_EDC_BYTE_SEEK = Y
_EDC_BYTE_SEEK is undefined

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <stdio.h>

void clearerr(FILE *stream);
```

General Description

Resets the error indicator and EOF indicator for the stream that stream points to. Generally, the indicators for a stream remain set until your program calls clearerr() or rewind().

Returned Value

clearerr() returns no values.

Example

```
CELEBC15

/* CELEBC15 */

    This example reads a data stream and then checks that a read
    error has not occurred.

    */

#include <stdio.h>

int main(void)
{
    char string[100];
    FILE *stream;
    int eofvalue;

    stream = fopen("myfile.dat", "r");

    /* scan an input stream until an end-of-file character is read */
    while (!feof(stream))
        fscanf(stream,"%s",&string[0]);

    /* print EOF value: will be nonzero */
    eofvalue=feof(stream);
    printf("feof value=%d",eofvalue);

    /* print EOF value-after clearerr, will be equal to zero */
    clearerr(stream);
    eofvalue=feof(stream);
    printf("feof value=%d",eofvalue);
}
```

clock

clock() — Determine Processor Time

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <time.h>

clock_t clock(void);
```

General Description

Approximates the processor time used by the program, since the beginning of an implementation-defined time period that is related to the program invocation. To measure the time spent in a program, call the clock() function at the start of the program, and subtract its returned value from the value returned by subsequent calls to clock(). Then, to obtain the time in seconds, divide the value returned by clock() by CLOCKS_PER_SEC.

If you use the system() function in your program, do not rely on clock() for program timing, because calls to system() may reset the clock.

In a multithread POSIX C application, if you are creating threads with a function that is based on a POSIX.4a draft standard, the clock() function is thread-scoped.

Returned Value

If the time is available and can be represented, clock() returns the calculated time.

If unsuccessful, clock() returns (clock_t)−1. clock() may return −1 when running with STIMER REAL TQE present on MVS/ESA Version 3 Release 1 Modification 2 (or earlier) system.

Special Behavior for XPG4

If _XOPEN_SOURCE or _XOPEN_SOURCE_EXTENDED are defined when your application is compiled, CLOCKS_PER_SEC is defined as 1000000. Also, in this case, the following C/370 pragma in the <time.h> header is used to compile your application:

```
#pragma map (clock(), "@@OCLCK")
```

Because of this pragma, when your application executes, it will attempt to access an XPG4 version of clock() which returns a clock_t value in units of 1000000 CLOCKS_PER_SEC. The XPG4 version of clock() is only available if POSIX(ON) is specified for execution of your application.
If _XOPEN_SOURCE or _XOPEN_SOURCE_EXTENDED are defined when you compile your program AND your application is run with POSIX(OFF), clock() will return (clock_t)-1.

If neither _XOPEN_SOURCE or _XOPEN_SOURCE_EXTENDED are defined when you compile your application, the historical C/370 value of CLOCKS_PER_SEC will be used and clock() calls in your application will be mapped to the historical C/370 version of clock() which returns a clock_t value in historical C/370 CLOCKS_PER_SEC units whether your application executes with POSIX(ON) or POSIX(OFF).

Example

```c
/* This example prints the time elapsed since the program was invoked. */
#include <time.h>
#include <stdio.h>

double time1, timedif; /* use doubles to show small values */

int main(void)
{
    time1 = (double) clock(); /* get initial time */
    timedif = ((double) clock()) / CLOCKS_PER_SEC - time1;
    printf("The elapsed time is %f seconds\n", timedif);
}
```

</tr>
</tbody>
</table>

Format

```
#include <complex.h>

double complex clog(double complex z);
float complex clogf(float complex z);
long double complex clogl(long double complex z);
```

General Description

The clog() family of functions compute the complex natural (base-e) logarithm of $z$, with a branch cut along the negative real axis.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>clog</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>clogf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>clogl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

The clog() family of functions return the complex natural logarithm value, in the range of a strip, mathematically unbounded along the real axis and in the interval $[-i \pi, +i \pi]$ along the imaginary axis.

Example

For an example of a similar function see cacos(), cexp() or cpow().

</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>
int close(int fildes);
```

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>
int close(int socket);
```

```c
#define _OE_SOCKETS
#include <unistd.h>
int close(int socket);
```

General Description

Closes a file descriptor, `fildes`. This frees the file descriptor to be returned by future `open()` calls and other calls that create file descriptors. The `fildes` argument must represent a hierarchical file system (HFS) file.

When the last open file descriptor for a file is closed, the file itself is closed. If the file's link count is 0 at that time, its space is freed and the file becomes inaccessible.

When the last open file descriptor for a pipe or FIFO file is closed, any data remaining in the pipe or FIFO file is discarded. See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information about using POSIX support.

close() unlocks (removes) all outstanding record locks that a process has on the associated file.

Behavior for Sockets

close() call shuts down the socket associated with the socket descriptor `socket`, and frees resources allocated to the socket. If `socket` refers to an open TCP connection, the connection is closed. If a stream socket is closed when there is input data queued, the TCP connection is reset rather than being cleanly closed.

<table>

<tr>
<td>socket</td>
<td>The descriptor of the socket to be closed.</td>
</tr>
</tbody>
</table>
**Note:** All sockets should be closed before the end of your process. You should issue a shutdown() call before you issue a close() call for a socket.

For AF_INET and AF_INET6 stream sockets (SOCK_STREAM) using SO_LINGER socket option, the socket does not immediately end if data is still present when a close is issued. The following structure is used to set or unset this option, and it can be found in `sys/socket.h`.

```c
struct linger {
    int l_onoff; /* zero=off, nonzero=on */
    int l_linger; /* time is seconds to linger */
};
```

If the l_onoff switch is nonzero, the system attempts to deliver any unsent messages. If a linger time is specified, the system waits for \( n \) seconds before flushing the data and terminating the socket.

For AF_UNIX, when closing sockets that were bound, you should also use unlink() to delete the file created at bind() time.

**Special Behavior for XPG4.2**

If a STREAMS-based *fildes* is closed and the calling process was previously registered to receive a SIGPOLL signal for events associated with that STREAM, the calling process will be unregistered for events associated with the STREAM. The last close() for a STREAM causes the STREAM associated with *fildes* to be dismantled. If O_NONBLOCK is not set and there have been no signals posted for the STREAM, and if there is data on the module's write queue, close() waits for an unspecified time (for each module and driver) for any output to drain before dismantling the STREAM. The time delay can be changed using an I_SETCLTIME ioctl() request. If the O_NONBLOCK flag is set, or if there are any pending signals, close() does not wait for output to drain, and dismantles the STREAM immediately.

**Note:** z/OS UNIX services do not supply any STREAMS devices or pseudodevices. See "open() — Open a File" on page 1313 for more information.

If *fildes* refers to the master side of a pseudoterminal, a SIGHUP signal is sent to the process group, if any, for which the slave side of the pseudoterminal is the controlling terminal.

If *fildes* refers to the slave side of a pseudoterminal, a zero-length message will be sent to the master.

If *fildes* refers to a socket, close() causes the socket to be destroyed. If the socket is connection-oriented and the SO_LINGER option is set for the socket and the socket has untransmitted data, then close() will block for up to the current linger interval until all data is transmitted.

**Returned Value**

If successful, close() returns 0.

If unsuccessful, close() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The call did not complete because the specified socket descriptor is currently being used by another thread in the same process.</td>
</tr>
</tbody>
</table>
For example, in a multithreaded environment, close() fails and returns EAGAIN when the following sequence of events occurs (1) thread is blocked in a read() or select() call on a given file or socket descriptor and (2) another thread issues a simultaneous close() call for the same descriptor.

EBADF $fildes$ is not a valid open file descriptor, or the $socket$ parameter is not a valid socket descriptor.

EBUSY The file cannot be closed because it is blocked.

EINTR close() was interrupted by a signal. The file may or may not be closed.

EIO Added for XPG4.2: An I/O error occurred while reading from or writing to the file system.

ENXIO $fildes$ does not exist. The minor number for the file is incorrect.

Example

```c
#define _POSIX_SOURCE
#include <fcntl.h>
#include <unistd.h>
#include <stdio.h>
#include <string.h>

main() {
  int fd;
  char out[20]="Test string";
  if ((fd = creat("./myfile", S_IRUSR | S_IWUSR)) < 0)
    perror("creat error");
  else {
    if (write(fd, out, strlen(out)+1) == -1)
      perror("write() error");
    if (fd = 0) perror("write() error");
    close(fd);
  }
}
```

closedir

closedir() — Close a Directory

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <dirent.h>

int closedir(DIR *dir);
```

General Description

Closes the directory indicated by `dir`. It frees the buffer that `readdir()` uses when reading the directory stream.

Returned Value

If successful, `closedir()` returns 0.

If unsuccessful, `closedir()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>dir</code> does not refer to an open directory stream.</td>
</tr>
<tr>
<td>EINTR</td>
<td><code>closedir()</code> was interrupted by a signal. The directory may or may not be closed.</td>
</tr>
</tbody>
</table>

Example

```
CELEBC18
/* CELEBC18 */

This example closes a directory.

*/
#define _POSIX_SOURCE
#include <dirent.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  DIR *dir;
  struct dirent *entry;
  int count;
  
  if ((dir = opendir("/")) == NULL) {
    perror("opendir() error");
  } else {
    count = 0;
    while ((entry = readdir(dir)) != NULL) {
      printf("directory entry %03d: %s\n", ++count, entry->d_name);
    }

    closedir(dir);
  }
```
closedir

closedir(dir);

Output

directory entry 001: .
directory entry 002: ..
directory entry 003: bin
directory entry 004: dev
directory entry 005: etc
directory entry 006: lib
directory entry 007: tmp
directory entry 008: u
directory entry 009: usr

closelog()

— Close the Control Log

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <syslog.h>

void closelog(void);
```

General Description

The closelog() function closes the log file.

Returned Value

closelog() neither accepts an input nor returns a result. The system control log is closed for this process.

No errors are defined.

Related Information

clrmemf() — Clear Memory Files

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int clrmemf(int level);
```

General Description

Removes memory files created by the current program and any program that was called using a non-POSIX system() call. clrmemf() can remove memory files regardless of whether they are open or not.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The argument `level` indicates which memory files are to be removed. The level can be one of the following:

- `__LOWER` Removes memory files that were created in other programs and called from this program using system().
- `__CURRENT` Removes only the memory files created at the current level.
- `__CURRENT_LOWER` Removes all the memory files created by the current program and by all the programs called at the current level.

Special Behavior for Multiple Shared PICI C Environments

Only files created by the C environment from which the clrmemf() function is called will be cleared.

Returned Value

If successful, clrmemf() returns 0.

If unsuccessful, clrmemf() returns nonzero.

Example

```c
/*
   In this example, when Program2 calls clrmemf(__CURRENT) only
   A3.FILE and A4.FILE will be removed.
*/
```
clrmemf

/***** Program1 *****/
...
fp1 = fopen("A1.FILE","w,type=memory(hiperspace)");
fp2 = fopen("A2.FILE","w,type=memory(hiperspace)");
  system("Program2");
...
/***** Program2 *****/
...
fp3 = fopen("A3.FILE","w,type=memory");
fp4 = fopen("A4.FILE","w,type=memory");
  system("Program3");
...
  clrmemf(__CURRENT);
...
/***** Program3 *****/
...
fp5 = fopen("A5.FILE","w,type=memory");
fp6 = fopen("A6.FILE","w,type=memory");
...

__cnvblk() — Convert Block

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <unistd.h>

void __cnvblk(char bits[8], char bytes[64], int flag);
```

General Description

The __cnvblk() function maps an 8 character array, `bits`, of bits to or from a 64 character array, `bytes`, of bytes depending on the value of `flag`.

If the value of `flag` is 0, __cnvblk() sets all bytes in the `bytes` array to 0x00 for which the corresponding bits in the `bits` array have value 0, and it sets all bytes in the `bytes` array to 0x01 for which the corresponding bits in the `bits` array have value 1.

If the value of `flag` is not 0, __cnvblk() sets all bits in the `bits` array to 0 for which corresponding bytes in the `bytes` array have value 0x00, and it sets all bits in the `bits` array to 1 for which the corresponding bytes in the `bytes` array have value 0x01.

This function may be used to prepare input to setkey() or encrypt() functions and to map results back to 8 bit characters.

Returned Value

If the value of `flag` is zero, __cnvblk() functions without error checking.

If the value of `flag` is nonzero, __cnvblk() checks for errors, and if found, sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of a byte in the array <code>bytes</code> is not 0x00 or 0x01.</td>
</tr>
</tbody>
</table>

Note: Because __cnvblk() returns no values, applications wishing to check for errors should set errno to 0, call __cnvblk(), then test errno and, if it is nonzero, assume an error has occurred.

collequiv() — Return a List of Equivalent Collating Elements

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <collate.h>

int collequiv(collel_t c, collel_t **list);
```

General Description

Finds all the collating elements whose primary weight is the same as the primary weight of `c`. It then updates the list to point to the first element of the array in which all the found elements are stored. The list of elements is valid until the next call to `setlocale()`, with categories `LC_ALL`, `LC_COLLATE`, or `LC_CTYPE`.

Another call to `collequiv()` may override the current list.

For information about the effect of `setlocale()` and `locale.h`, see “Internationalization: Locales and Character Sets” in z/OS XL C/C++ Programming Guide.

Returned Value

If successful, `collequiv()` returns the number of collating elements found.

If the value of `c` is not in the valid range of collating elements in the current locale, `collequiv()` returns −1.

Notes:

- If the collating element passed is specified with the weight of `IGNORE` in the `LC_COLLATE` category, the list returned will contain all the characters specified as `IGNORE`.
- The list will only contain characters defined in the charmap file in the current locale.

Example

```c
CELEBC22

/* CELEBC22

This example prints the collating elements that have an equivalent weight as the collating element passed in argv[1].

*/
#include "stdio.h"
#include "locale.h"
#include "collate.h"
#include "stdlib.h"
#include "wctype.h"
#include "wchar.h"

main(int argc, char *argv[]) {
    collel_t e, *rp;
```
int i;

setlocale(LC_ALL, "");
if ((e = strtocoll(argv[1])) == (collel_t)-1) {
    printf("\"%s\" collating element not defined\n", argv[1]);
    exit(1);
}
if ((i = collequiv(e, &rp)) == -1) {
    printf("Invalid collating element \"%s\"\n", argv[1]);
    exit(1);
}
for (; i--; rp++) {
    if (ismccollel(*rp))
        printf("\"%s\", colltostr(*rp));
    else if (iswprint(*rp))
        printf("\"%lc\", *rp);
    else
        printf("\"%x\", *rp);
}

collorder

collorder() — Return List of Collating Elements

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <collate.h>

int collorder(collel_t **list);
```

General Description

Finds the number of collating elements in the collate order list and sets a pointer to the list. The list returned is valid until another call to setlocale().

Notes:
- Collating elements specified with the weight of IGNORE in the LC_COLLATE category are defined as having the lowest weight.
- The list will only contain characters defined in the charmap file in the current locale.

Example

CELEBC23

```c
/* CELEBC23

This example creates a list of all the collating elements using the &collo. function.

*/
#include <stdio.h>
#include <locale.h>
#include <collate.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
    collel_t e, *rp;
    int i;

    setlocale(LC_ALL, "TEXAN.IBM-1024");
    i = collorder(&rp);
    for (; i-- > 0; rp++) {
        if (ismcallel(*rp))
            printf("%s ", colltostr(*rp));
        else if (iswprint(*rp))
            printf("%lc ", *rp);
        else
            printf("%x ", *rp);
    }
}
```

collrange

**collrange() — Calculate the Range List of Collating Elements**

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

### Format

```
#include <collate.h>

int collrange(collel_t start, collel_t end, collel_t **list);
```

### General Description

Finds a list of collating elements whose primary weights are between the `start` and `end` points, inclusive. The number returned is the number of elements in the list, whose pointer is returned.

This value will be zero if the end point collates earlier than the `start` point. The list returned is valid until the next call to `setlocale()`.

### Returned Value

If successful, `collrange()` returns the number of elements in the list, whose pointer is returned.

If either `start` or `end` are out of range, `collrange()` returns -1.

### Notes:

- Collating elements specified with the weight of `IGNORE` in the LC_COLLATE category are defined having the lowest weight. Therefore, such elements can only be specified as the starting collating element.
- The list will only contain characters defined in the charmap file in the current locale.

### Example

**CELEBC24**

```c
/* CELEBC24

This example prints the collating elements in the range between the start and end points passed in argv[1] and argv[2], using the &collrap. function.

*/
#include <stdio.h>
#include <locale.h>
#include <collate.h>
#include <stdlib.h>
#include <wctype.h>
#include <wchar.h>

main(int argc, char *argv[]) {
    collel_t s, e, *rp;
    int i;

    setlocale(LC_ALL, "TEXAN.IBM-1024");
```
if ((s = strtocoll(argv[1])) == (collel_t)-1) {
    printf("'%s' collating element not defined\n", argv[1]);
    exit(1);
}
if ((e = strtocoll(argv[2])) == (collel_t)-1) {
    printf("'%s' collating element not defined\n", argv[2]);
    exit(1);
}
if (((i = collrange(s, e, &rp)) == -1) {
    printf("Invalid range for '%s' to '%s'\n", argv[1], argv[2]);
    exit(1);
}
for (; i--; rp++) {
    if (ismccolel(*rp))
        printf("'%s' ", colltostr(*rp));
    else if (iswprint(*rp))
        printf("'%lc' ", *rp);
    else
        printf("'%x' ", *rp);
}

Related Information

colltostr

colltostr() — Return a String for a Collating Element

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <collate.h>
char *colltostr(collel_t c);
```

General Description

Converts c to the string of the collating element. The colltostr() function is the
inverse of strtocoll().

An application program can use the returned array from colrange() or collequiv(),
calling ismccollel() on each element, only calling colltostr() if ismccollel() is true for
the element. The string returned is valid until another call to setlocale().

Returned Value

If a value is passed representing a single character or a value that is not in range,
colltostr() returns NULL.

Example

```c
CELEBC25
/* CELEBC25

This example prints all the collating elements in the
collating sequence, using the &colltop function to get the
string for the multi-character collating elements.
*/

#include <collate.h>
#include <locale.h>
#include <stdio.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
  collel_t e, *rp;
  int i;

  setlocale(LC_ALL, "");
  i = collorder(&rp);
  for (; i--; rp++) {
    if (ismccollel(*rp))
      printf("%s ", colltostr(*rp));
    else if (iswprint(*rp))
      printf("%lc ", *rp);
    else
      printf("%x ", *rp);
  }
} 
```

compile

compile() — Compile Regular Expression

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define INIT declarations
#define GETC() getc_code
#define PEEK() peek_code
#define UNGETC() ungetc_code
#define RETURN(ptr) return_code
#define ERROR(val) error_code

#define _XOPEN_SOURCE
#include <regexp.h>

char *compile(char *instring, char *expbuf, const char *endbuf, int eof);
```

General Description

**Restriction:** This function is not supported in AMODE 64.

The compile() function takes as input a simple regular expression and produces a compiled expression that can be used with the step() and advance() functions.

The first parameter `instring` is never used explicitly by compile(). It is a pointer to a character string defining a source regular expression. It is useful for programs that pass down different pointers to input characters. Programs which invoke functions to input characters or have characters in an external array can pass down `(char *)0` for this parameter.

`expbuf` is a pointer to the place where the compiled regular expression will be placed.

`endbuf` points to one more than the highest address where the compiled regular expression may be placed. If the compiled expression cannot fit in `(endbuf-expbuf)` bytes, a call to ERROR(50) is made. (See “ Returned Value” below.)

`eof` is the character which marks the end of the regular expression.

The z/OS UNIX services implementation of the compile() function does **not** accept internationalized simple expressions as input. Internationalized simple expressions (for example, `[=c=]` (an equivalence class)) may yield unpredictable results.

Programs must have the following five macros declared before the `#include <regexp.h>` statement. The macros GETC(), PEEKC() and UNGETC() operate on the regular expression given as input to compile().

**GETC()**

This macro returns the value of the next character (byte) in the regular expression pattern. Successive calls to GETC() should return successive characters of the regular expression.

**PEEK()**

This macro returns the next character (byte) in the regular
expression pattern. Immediate successive calls to PEEK() should return the same byte, which should also be the next character returned by GETC().

UNGETC(c)  This macro causes the argument c to be returned by the next call to GETC(). No more than one character is ever needed and this character is guaranteed to be the last character read by GETC(). The value of the macro UNGETC() is always ignored.

RETURN(ptr)  This macro is used on normal exit of the compile() function. The value of the argument ptr is a pointer to the character after the last character of the compiled regular expression.

ERROR(val)  This macro is the abnormal return from compile(). The argument val is an error number. (See “Returned Value” below for meanings.) This call should never return.

Notes:
1. z/OS UNIX services do not provide any default macros if the above user macros are not provided.
2. Each program that includes the <regexp.h> must have a #define statement for INIT. It is used for dependent declarations and initializations. For example, it can be used to set a variable to point to the beginning of the regular expression so that this variable can be used in the declarations for GETC(), PEEK(), and UNGETC().
3. The external variables cirf, sed, and nbra are reserved.
4. The application must provide the proper serialization for the compile(), step(), and advance() functions if they are run under a multithreaded environment.

Simple Regular Expressions

A Simple Regular Expression (SRE) specifies a set of character strings. The simplest form of regular expression is a string of characters with no special meaning. A small set of special characters, known as metacharacters, do have special meaning when encountered in patterns.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>The character c where c is not a special character.</td>
</tr>
<tr>
<td>\c</td>
<td>The character c where c is any special character. For example, a\e is equivalent to a.e.</td>
</tr>
<tr>
<td>^</td>
<td>The beginning of the string being compared</td>
</tr>
<tr>
<td>$</td>
<td>The dollar symbol matches the end of the string.</td>
</tr>
<tr>
<td>.</td>
<td>The period symbol matches any one character.</td>
</tr>
</tbody>
</table>
| [string]   | A string within square brackets specifies any of the characters in string. Thus, [abc], if compared to other strings, would match any which contained a, b, or c. The ] (right bracket) can be used alone within a pair of brackets, but only if it immediately follows either the opening left bracket or if it immediately follows [^.

Ranges may be specified as c–c. The hyphen symbol, within square brackets, means “through”. It fills in the intervening characters according to the collating sequence. For example, [a–z] is equivalent to [abc...xyz]. If the end character in the range is lower in collating sequence to the start character, then only the range
The caret symbol, when inside square brackets, negates the characters within the square brackets. Thus, \[^{abc}\] would fail to match any which contains even one a, b, or c.

Note: Characters ., *, [, and \ (period, asterisk, left square bracket, and backslash, respectively) have special meaning, except when they appear within square brackets ([]), or are preceded by \.

* The asterisk symbol indicates 0 or more of any preceding characters. For example, \(a*\) will match any of the following: e, ae, aee, aaaa, .... The longest leftmost match is chosen.

\(r\) The occurrence of regular expression \(r\) followed by the occurrence of regular expression \(x\).

\(m\) Integer values enclosed in \(\{\}\) indicate the number of times to apply the preceding regular expression. \(m\) is the minimum number and \(u\) is the maximum number. \(u\) must be less than 256. If you specify only \(m\), it indicates the exact number of times to apply the regular expression.

\(m\) is equivalent to \(\{m,255\}\). They both match \(m\) or more occurrences of the expression. The * (asterisk) operation is equivalent to \(\{0,\}\).

The maximum number of occurrences is matched.

^ The character ^ at the beginning of an expression permits a successful match only immediately after a newline or at the beginning of each of the string to which a match is to be applied. The character $ at the end of an expression requires a trailing newline.

Note: The compile() function is physically embedded in the regexp.h header. This header will be protected from multiple invocations just like other c headers.

Note: The compile(), step(), and advance() functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX
Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions fnmatch(), glob(), regcomp() and regexec(), which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.

Returned Value

If successful, compile() exits using the user-provided macro RETURN(ptr). The value of the argument ptr is a pointer to the character after the last character of the compiled regular expression.

If unsuccessful, compile() exits using the user-provided macro ERROR(val). The argument val is an error number identifying the error. The following error numbers are defined:

<table>
<thead>
<tr>
<th>Errcode</th>
<th>Description String</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Range endpoint too large</td>
</tr>
<tr>
<td>16</td>
<td>Bad number</td>
</tr>
<tr>
<td>25</td>
<td>digit out of range</td>
</tr>
<tr>
<td>36</td>
<td>Illegal or missing delimiter</td>
</tr>
<tr>
<td>41</td>
<td>No remembered search string</td>
</tr>
<tr>

confstr

confstr() — Get Configurable Variables

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

#define _XOPEN_SOURCE
#include <unistd.h>

size_t confstr(int name, char *buf, size_t len);

General Description

The confstr() function provides a method for applications to get configuration-defined string values. Its use and purpose are similar to the sysconf() function, but it is used where string values rather than numeric values are returned.

The name argument represents the system variable to be queried. It may be any one of the following symbolic constants, defined in <unistd.h>:

_CS_PATH Request the value of the PATH environment variable that will find all standard utilities.

_CS_POSIX_V6_ILP32_OFF32_CFLAGS Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with 32-bit types.

_CS_POSIX_V6_ILP32_OFF32_LDFLAGS Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with 32-bit types.

_CS_POSIX_V6_ILP32_OFF32_LIBS Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with 32-bit int, long, pointer, and off_t types.

_CS_POSIX_V6_ILP32_OFFBIG_CFLAGS Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with 32-bit int, long, and pointer types, and an off_t type using at least 64 bits.

_CS_POSIX_V6_ILP32_OFFBIG_LDFLAGS Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with 32-bit int, long, and pointer types, and an off_t type using at least 64 bits.

CS_POSIX_V6_ILP32_OFFBIG_LIBS Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with 32-bit int, long, and pointer types, and an off_t type using at least 64 bits.

_CS_POSIX_V6_LP64_OFF64_CFLAGS Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with 64-bit int, long, and pointer types, and a long double type using at least 64 bits.
utility to build an application using a programming model with 32-bit int and 64-bit long, pointer, and off_t types.

_CS_POSIX_V6_LP64_OFF64_LDFLAGS
Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with 32-bit int and 64-bit long, pointer, and off_t types.

_CS_POSIX_V6_LP64_OFF64_LIBS
Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with 32-bit int and 64-bit long, pointer, and off_t types.

_CS_POSIX_V6_LPBIG_OFFBIG_CFLAGS
Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with an int type using at least 32 bits and long, pointer, and off_t types using at least 64 bits.

_CS_POSIX_V6_LPBIG_OFFBIG_LDFLAGS
Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with an int type using at least 32 bits and long, pointer, and off_t types using at least 64 bits.

_CS_POSIX_V6_LPBIG_OFFBIG_LIBS
Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with an int type using at least 32 bits and long, pointer, and off_t types using at least 64 bits.

_CS_POSIX_V6_WIDTH_RESTRICTED_ENVS
Request the list of names of programming environments supported by the implementation in which the widths of the blksize_t, cc_t, mode_t, nfds_t, pid_t, prtdiff_t, size_t, speed_t, ssize_t, suseconds_t, tcflag_t, useconds_t, wchar_t, and wint_t types are no greater than the width of type long.

z/OS UNIX services use the following constant:

-CS_SHELL Request the fully qualified name of the default shell.

If the len argument is not zero, and if the name argument has a configuration-defined value, confstr() copies that value into the buffer pointed to by the buf argument. If the value to be returned is longer than len bytes, including the terminating NULL, then confstr() truncates the string to len-1 bytes and NULL-terminates the results. The application can detect that the string was truncated by comparing the value returned by confstr() with len.

If the len argument is zero, and the buf argument is a NULL pointer, then confstr() still returns the integer value defined below, but does not return a string. If the len argument is zero, but the buf argument is not a NULL pointer the results are unspecified.

Returned Value

If name has a configuration-defined value, confstr() returns the size of the buffer that would be needed to hold the entire configuration-defined string value. If this return value is greater than len, the string returned in buf is truncated.
confstr

If *name* does not have a configuration-defined value, confstr() returns 0 and leaves errno unchanged.

If *name* is not valid, confstr() returns 0 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of the <em>name</em> argument is not valid.</td>
</tr>
</tbody>
</table>

conj(), conjf(), conjl() — Calculate the Complex Conjugate

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7 a compiler that is designed to support C99</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <complex.h>

double complex conj(double complex z);
float complex conjf(float complex z);
long double complex conjl(long double complex z);
```

General Description

The conj() family of functions compute the complex conjugate of z by reversing the sign of its imaginary part.

Note: The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

```
<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>conj</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>conjf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>conjl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>
```

Returned Value

If successful, they return the complex conjugate value.

Example

```
/*
 * This example illustrates the complex conjugate function
 */
#include <complex.h>
#include <stdio.h>

void main()
{
    long double complex z = -2.99 - I*3.99, zres;
    zres = conjl(z);
    printf("The complex conjugate of %Lf + %Lf*I is %Lf + %Lf*I\n", creall(z), cimagl(z), zres);
}
```

Output

The complex conjugate of -2.990000 + -3.990000*I is -2.990000 + 3.990000*I

Format

**X/Open**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int connect(int socket, const struct sockaddr *address, socklen_t address_len);
```

**Berkeley Sockets**

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int connect(int socket, struct sockaddr *address, int address_len);
```

General Description

For stream sockets, the connect() call attempts to establish a connection between two sockets. For datagram sockets, the connect() call specifies the peer for a socket. The `socket` parameter is the socket used to originate the connection request. The connect() call performs two tasks when called for a stream socket. First, it completes the binding necessary for a stream socket (in case it has not been previously bound using the bind() call). Second, it attempts to make a connection to another socket.

**Note:** For the X/Open socket function, the `socket` description applies to `socket`, `address` to `address`, and `address_len` to `address_len`. `const` is added to `struct sockaddr`.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>socket</code></td>
<td>The socket descriptor.</td>
</tr>
<tr>
<td><code>address</code></td>
<td>The pointer to a socket address structure containing the address of the socket to which a connection will be attempted.</td>
</tr>
<tr>
<td><code>address_len</code></td>
<td>The size of the socket address pointed to by <code>address</code> in bytes.</td>
</tr>
</tbody>
</table>

The connect() call on a stream socket is used by the client application to establish a connection to a server. The server must have a passive open pending. A server that is using sockets must successfully call bind() and listen() before a connection can be accepted by the server with accept(). Otherwise, connect() returns −1 and the error code is set to ECONNREFUSED.

If `socket` is in blocking mode, the connect() call blocks the caller until the connection is set up, or until an error is received. The caller can test the completion of the connection setup by calling select() and testing for the ability to write to the socket.

When called for a datagram socket, connect() specifies the peer with which this socket is associated. This gives the application the ability to use data transfer calls...
reserved for sockets that are in the connected state. In this case, read(), write(),
readv(), writev(), send(), and recv() calls are then available in addition to sendto(),
recvfrom(), sendmsg(), and recvmsg() calls. Stream sockets can call connect() only
once, but datagram sockets can call connect() multiple times to change their
association. Datagram sockets can dissolve their association by connecting to an
incorrect address, such as the NULL address (all fields zeroed).

The address parameter is a pointer to a buffer containing the name of the peer to
which the application needs to connect. The address_len parameter is the size, in
bytes, of the buffer pointed to by address.

Servers in the AF_INET Domain

If the server is in the AF_INET domain, the format of the name buffer is expected to
be sockaddr_in, as defined in the include file netinet.in.h.

```c
struct in_addr {
    ip_addr_t s_addr;
};

struct sockaddr_in {
    unsigned char sin_len;
    unsigned char sin_family;
    unsigned short sin_port;
    struct in_addr sin_addr;
    unsigned char sin_zero[8];
};
```

The sin_family field must be set to AF_INET. The sin_port field is set to the port to
which the server is bound. It must be specified in network byte order. The sin_zero
field is not used and must be set to all zeros.

Servers in the AF_INET6 Domain

If the server is in the AF_INET6 domain, the format of the name buffer is expected to
be sockaddr_in6, as defined in the netinet.in.h:

```c
struct sockaddr_in6 {
    uint8_t char sin6_len;
    sa_family_t sin6_family;
    in_port_t sin6_port;
    uint32_t sin6_flowinfo;
    struct in6_addr sin6_addr;
    uint32_t sin6_scope_id;
};
```

The sin6_family must be set to AF_INET6.

Servers in the AF_UNIX Domain

If the server is in the AF_UNIX domain, the format of the name buffer is expected to
be sockaddr_un, as defined in the include file un.h.

```c
struct sockaddr_un {
    unsigned char sun_len;
    unsigned char sun_family;
    char sun_path[108]; /* pathname */
};
```
The `sun_family` field is set to AF_UNIX. The `sun_path` field contains the NULL-terminated pathname, and `sun_len` contains the length of the pathname.

**Special Behavior for C++**

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` feature test macro.

**Note:** The `connect()` function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII Support" on page 2495 for details.

**Returned Value**

If successful, `connect()` returns 0.

If unsuccessful, `connect()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EADDRNOTAVAIL</td>
<td>The specified address is not available from the local machine.</td>
</tr>
<tr>
<td>EAFNOSUPPORT</td>
<td>The address family is not supported.</td>
</tr>
<tr>
<td>EALREADY</td>
<td>The socket descriptor <code>socket</code> is marked nonblocking, and a previous connection attempt has not completed.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The <code>socket</code> parameter is not a valid socket descriptor.</td>
</tr>
<tr>
<td>ECONNREFUSED</td>
<td>The connection request was rejected by the destination host.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using <code>address</code> and <code>address_len</code> would result in an attempt to copy the address into a portion of the caller’s address space to which data cannot be written.</td>
</tr>
<tr>

<td><code>connect()</code> caller was attempting to extract a user’s identity and the caller’s process was not verified to be a server. To be server-verified, the caller’s process must have permission to the BPX.SERVER profile (or superuser and BPX.SERVER is undefined) and have called either the <code>__passwd()</code> or <code>pthread_security_np()</code> services before calling <code>connect()</code> to propagate identity.</td>
</tr>
<tr>
<td>EPROTOTYPE</td>
<td>The protocol is the wrong type for this socket.</td>
</tr>
</tbody>
</table>
ETIMEDOUT  The connection establishment timed out before a connection was made.

The following are for AF_UNIX only:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for a component of the path prefix, or write access to the named socket is denied.</td>
</tr>
<tr>
<td>EIO</td>
<td>An I/O error occurred while reading from or writing to the file system.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>Too many symbolic links were encountered in translating the pathname in address.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>A component of a pathname exceeded NAME_MAX characters, or an entire pathname exceeded PATH_MAX characters.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>A component of the pathname does not name an existing file or the pathname is an empty string.</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>A component of the path prefix of the pathname in address is not a directory.</td>
</tr>
</tbody>
</table>

Example

The following are examples of the connect() call. The Internet address and port must be in network byte order. To put the port into network byte order, the htons() utility routine is called to convert a short integer from host byte order to network byte order. The address field is set using another utility routine, inet_addr(), which takes a character string representing the dotted-decimal address of an interface and returns the binary Internet address representation in network byte order. Finally, it is a good idea to zero the structure before using it to ensure that the name requested does not set any reserved fields. These examples could be used to connect to the servers shown in the examples listed with the call bind() — Bind a Name to a Socket on page 211.

```c
int s;
struct sockaddr_in inet_server;
struct sockaddr_un unix_server;
int rc;
int connect(int s, struct sockaddr *name, int namelen);

/* Connect to server bound to a specific interface in the Internet domain */
/* make sure the sin_zero field is cleared */
memset(&inet_server, 0, sizeof(inet_server));
inet_server.sin_family = AF_INET;
inet_server.sin_addr = inet_addr("129.5.24.1"); /* specific interface */
inet_server.sin_port = htons(1024);
rc = connect(s, (struct sockaddr *) &inet_server, sizeof(inet_server));

/* Connect to a server bound to a name in the UNIX domain */
/* make sure the sun_addr, sun_port, sun_nodeid fields are cleared */
memset(&unix_server, 0, sizeof(unix_server));
unix_server.sun_family = AF_UNIX;
strncpy(unix_server.sun_path, "mysocket");
unix_server.sun_len = sizeof(unix_server.sun_len);
strncpy(mvsservername.sunix_name, "APPL ", 8);
rc = connect(s, (struct sockaddr *) &unix_server, sizeof(unix_server));
```

ConnectExportImport

ConnectExportImport() — WLM Connect for Export or Import Use

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX System Services</td>
<td>both</td>
<td>OS/390 V2R9</td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__wlm.h>

unsigned long ConnextExportImport(const char *subsystype,
                                   const char *subsysname);
```

**AMODE 64**

```c
#include <sys/__wlm.h>

unsigned int ConnextExportImport(const char *subsystype,
                                 const char *subsysname);
```

General Description

Provides the ability for an application to connect to WLM to use the ExportWorkUnit(), UndoExportWorkUnit(), ImportWorkUnit(), and UndoImportWorkUnit() functions.

Note that if you need to use the CreateWorkUnit() function, you should use ConnectWorkMgr() instead.

The ConnextExportImport() function uses the following parameters:

* `subsystype` Points to a NULL-terminated character string containing the subsystem type by which to identify the connector. The export and import functions do not use the string. A meaningful string should be used since it can appear in WLMDATA IPCS reports. The character string can be up to 4 bytes in length.

* `subsysname` Points to a NULL-terminated character string containing the subsystem name by which to identify the connector. The export and import functions do not use the string. A meaningful string should be used since it can appear in WLMDATA IPCS reports. The character string can be up to 8 bytes in length.

Returned Value

If successful, ConnextExportImport() returns 0.

If unsuccessful, ConnextExportImport() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>An argument of this function contained a value that is not correct.</td>
</tr>
</tbody>
</table>
EMVSWLMERROR
A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.

unsigned int ConnectServer(const char *subsystype,
                            const char *subsysname,
                            const char *applenv,
                            int *paralleleu);
```

General Description

The ConnectServer function provides the ability for an application to connect to WLM as a WLM server manager to perform WLM server manager functions.

*subsystype* Points to a NULL-terminated character string containing the generic subsystem type (CICS, IMS, WEB, etc.). This is the primary category under which WLM classification rules are grouped. The character string can be up to 4 bytes in length.

*subsysname* Points to a NULL-terminated character string containing the subsystem name used for classifying work requests. The character string can be up to 8 bytes in length.

*applenv* Points to a NULL-terminated character string that contains the name of the application environment under which work requests are processed. The character string can be up to 32 bytes in length.

*paralleleu* Points to an integer which contains the maximum number of tasks within the address space which will be created to process concurrent work requests.

Returned Value

If successful, ConnectServer() returns a nonzero value representing a WLM connect token.

If unsuccessful, ConnectServer() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>An argument of this function contained an incorrect value.</td>
</tr>
</tbody>
</table>
EMVSAF2ERR
An error occurred in the security product.

EMVSWLMERROR
The WLM connect failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM
The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

__console

__console() — Console Communication Services

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__messag.h>

int __console(struct __cons_msg *cons, char *modstr, int *concmd);
```

General Description

The __console() function is used to communicate with the operator’s console. The __console() function allows users to send messages to the operator’s console and to wait on a modify/stop request from the console.

The parameters supported are:

- **cons**: If the argument is not NULL, it points to a structure specifying the message that is to be sent to the operator’s console. If the argument is NULL then no message is sent.

- **modstr**: Specifies the string where __console() returns the data entered at the operator’s console. If modstr is not NULL the invoker will wait until an operator MODIFY’s the invoking job and specifies ‘APPL=’ parameter. See [z/OS MVS System Commands](z/OS MVS System Commands) for more information on the MODIFY console command. If the argument is NULL then the __console() function will not wait on operator console commands.

- **concmd**: If a console command was issued against the invoking job, the __console() function will set the command type. Valid types are, _CC_modify (function received a modify request) and _CC_stop (function received a stop request).

The cons structure is defined in the `<sys/__messag.h>` header and has the following format.

```c
struct __cons_msg {
    short __reserved0;
    char __reserved1[2];
    union {
        struct {
            int __msg_length;
            char __msg[7];
            char __reserved2[8];
        } __f1;
        __format;
    } __format;
};
```

- **__reserved0**: Reserved for future use.
- **__reserved1[2]**: Reserved for future use.
- **__format.__f1.__msg_length**: Length of message, not including the NULL terminator.
__console

__format._f1.__msg    A character string containing the message to be
sent to the operator console.

__format._f1.__reserved2[8]  Reserved for future use.

**Note:** The length of the message must be between 1 and 17850 characters for
invokers with appropriate privileges, and between 1 and 17780 for invokers
without appropriate privileges. The number of lines written to the console is
limited to 255. In the case of an unprivileged user, one of those lines is used
for the message ID and the invoker’s login name. If the message length is
exceeded, no lines are written and the service returns anEINVAL. If the
number of lines is exceeded, the service returns anEINVAL, but the first 255
lines are written to the console.

**Returned Value**

If successful, __console() returns 0.

If unsuccessful, __console() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>One of the following errors was detected:</td>
</tr>
<tr>
<td></td>
<td>• All or part of the cons structure is not addressable by the caller.</td>
</tr>
<tr>
<td></td>
<td>• All or part of the modstr string is not addressable by the caller.</td>
</tr>
<tr>
<td>EINTR</td>
<td>__console() was interrupted by a signal.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The cons structure contains errors.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>z/OS environmental or internal error has occurred.</td>
</tr>
</tbody>
</table>

**Example**

**CELEBC41**

/* CELEBC41 */

This example prints a simple message to the console using the
__console() function.

```c
#include <sys/__message.h>
#include <errno.h>
#include <string.h>
#include <stdio.h>

int main(int argc, char** argv) {
    struct __cons_msg cmsg;
    char buf[256] = "A message on the console";
    int rc;
    int cmsg_cmd = 0;

    /* fill in the __cons_msg structure */
    cmsg.__format._f1.__msg = buf;
    cmsg.__format._f1.__msg_length = strlen(buf);

    rc = __console(&cmsg,NULL,&cmsg_cmd);
    if(rc == -1) {
        printf("__console() failed\n");
        printf("%s",strerror(errno));
    }
    else {
        printf("__console() successful. Check console for message.\n");
    }
} /* CELEBC41 */
```
```c
__console
```

} }

  return 0;

)

</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R10</td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__messag.h>

int __console2(struct __cons_msg2 *cons, char *modstr, int *concmd);
```

General Description

Used to communicate with the operator's console. The __console2() function allows users to send messages to the operator's console with the ability to specify routing codes and message descriptor codes, wait on a modify/stop request from the console, and to delete messages from operator console using either message IDs or tokens.

The parameters to the __console2() function are as follows:

- **cons**: Specifies the address of the structure containing the console communication information. The mapping of the structure is provided below. If this parameter is NULL, then no message is sent to the operator's console and/or no messages are deleted from the console.

- **modstr**: The address of a 128-byte buffer that is to be used to receive a string of EBCDIC data from the console MODIFY command. All characters that appear to the right of the 'APPL=' are placed into this buffer, left justified. The data returned is folded to uppercase. If this parameter is NULL, the __console2() function does not wait on operator console commands.

- **concmd**: Address of a 32-bit integer where __console2() returns the type of command that was issued on the console. The types are:
  - _CC_modify: function received a modify request
  - _CC_stop: function received a stop request

  **Note**: If this parameter is set to NULL, the __console2() function will fail with EFAULT.

The console communication information is specified in structure pointed to by the cons parameter. The structure contains the following elements:

- **__cm2_format**: Must be set to one of the following:
  - __CONSOLE_FORMAT_2: Used to indicate format 2.

- **__cm2_msglength**: The length of the message to be written to the console. A value of zero indicates that no message is to be sent to the operator's console.
Note: The length of the message must be between 1 and 17850 characters for invokers with appropriate privileges, and between 1 and 17780 for invokers without appropriate privileges. The number of lines written to the console is limited to 255. In the case of an unprivileged user, one of those lines is used for the message ID and the invoker’s login name. If the message length is exceeded, no lines are written and the service returns an EINVAL. If the number of lines is exceeded, the service returns an EINVAL, but the first 255 lines are written to the console.

__cm2_msg Pointer to a NULL terminated string containing the message to be written to the console. A value of NULL indicates no message is to be sent to the operator’s console.

__cm2_routcde
Pointer to an unsigned int array containing the routing code or codes to be assigned to the message. The array is terminated by a zero value. Allowable routing codes are 1-28 for unauthorized users, and 1-128 for authorized users. See z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO for more information on routing codes.

Note: An authorized user is one with appropriate privileges, as described in z/OS UNIX System Services Programming: Assembler Callable Services Reference, SA22-7803 in the chapter on Authorization.

__cm2_descr Pointer to an unsigned int array containing the message descriptor code or codes to be assigned to the message. The array is terminated by a zero value. Allowable descriptor codes are 1-13. Descriptor codes 1 through 6, 11, and 12 are mutually exclusive. Codes 7 through 10, and 13 can be assigned in combination with any other code. See z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO for more information on descriptor codes.

__cm2_mcsflag
Specifies one or more of the following flags:

__CONSOLE_HRDCPY Queue the message for hard copy only. The message will not be displayed on the console.

__cm2_token
Specifies a 4-byte token to be associated with this message. This field is used to identify a group of messages which can be deleted using the DOM feature of the __console2() function. The token must be unique within an address space and can be any value. A token value of zero indicates no token is specified and the message issued will not be associated with any token.

__cm2_msgid
An unsigned int (32-bit) field where the __console2() function will place the message ID associated with the message last sent to the console. This message ID can be used to delete a message when it is no longer needed by specifying it using the DOM feature of the __console2() function. A value of NULL indicates that the message ID is not to be returned.
__console2

**Note:** The value returned in __cm2msgid is an internal message identifier associated with the message written to the console. The value is not text and it should not be confused with any textual part of a message that might otherwise be considered a message ID.

**__cm2_dom_token**

Specifies a 4-byte token which represents a message or group of messages to be deleted from the console. All messages previously issued with this token will be deleted from the console. This field is mutually exclusive with __cm2_dommsgid. A value of zero indicates that no token is specified.

**__cm2_dommsgid**

Pointer to an unsigned int array containing message IDs to be deleted from the console. A maximum of 60 message IDs may be in the array. The array is terminated by a zero value. The array terminator is not part of the 60 message IDs. This field is mutually exclusive with __cm2_dom_token. A value of NULL indicates that no message IDs are specified.

**Note:** All operations can be done in a single request. The order of operation is to issue messages, delete messages, and then wait for a modify/stop command.

**Returned Value**

If successful, __console2() returns 0.

If unsuccessful, __console2() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>The __console2() function was unable to address all or part of the cons structure, all of part of the routing codes array, all or part of the descriptor codes array, all or part of the array of DOM message IDs, all or part of the modstr, or the concmd parameter was NULL. Another possible cause is that __cm2msgid points to storage which is not accessible.</td>
</tr>
<tr>
<td>EINTR</td>
<td>The __console2() function was interrupted by a signal.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The structure pointed to by cons contains errors. For example, mutually exclusive parameters were specified, a non-valid routing code was specified, a non-valid descriptor code or mutually exclusive descriptor codes were specified, or there were more than 60 entries in the array of DOM message IDs.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>z/OS environmental or internal error has occurred. Use __errno2() to obtain more diagnostic information that will help to determine the cause of the problem.</td>
</tr>
<tr>
<td>EPERM</td>
<td>An unauthorized caller specified a routing code in the range 29-128. Only authorized (superuser) callers (UID=0) can specify routing codes in that range.</td>
</tr>
</tbody>
</table>

**Example**

__convert_id_np() — Convert Between DCE UUID and Userid

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

int __convert_id_np(int function_code,
                     char *principal_uuid,
                     char *cell_uuid,
                     char *userid);
```

General Description

The __convert_id_np() function is used to retrieve the DCE UUID associated with a userid or the userid associated with a DCE UUID.

This function is intended for DCE servers which process requests from multiple clients. For example, DCE RPC requests from clients are identified by a DCE UUID only. This function enables servers to extract the userid of the requester.

The parameters supported are:

- `function_code`: Identifies whether extracting a userid or UUID. Possible function codes are:
  - __GET_USERID: Return the userid associated with the specified UUIDs.
  - __GET_UUID: Return the UUIDs associated with the specified userid.

- `principal_uuid`: When __GET_USERID is specified, `principal_uuid` contains the UUID of the user for the specified userid. When __GET_UUID is specified, `principal_uuid` returns the extracted UUID for the userid specified. The caller must provide a 36-byte field for the returned `principal_uuid`.

- `cell_uuid`: When __GET_USERID is specified, `cell_uuid` should contain the cell UUID if known. If not known, `cell_uuid` must be NULL. When __GET_UUID is specified, `cell_uuid` will return the extracted cell UUID, if it is defined for the specified userid. The caller must provide a 36-byte field for the returned `cell_uuid`.

- `userid`: When __GET_USERID is specified, `userid` will return the extracted userid for the specified UUID. The caller must provide a 9 byte field for the returned userid. When __GET_UUID is specified, `userid` contains the userid for whom the UUID should be extracted. The userid must be 1 to 8 characters in length.

Returned Value

If successful, __convert_id_np() returns 0.
If unsuccessful, __convert_id_np() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>

#include <math.h>

_Decimal32 copysignd32(_Decimal32 x, _Decimal32 y);
_Decimal64 copysignd64(_Decimal64 x, _Decimal64 y);
_Decimal128 copysignd128(_Decimal128 x, _Decimal128 y);
_Decimal32 copysign(_Decimal32 x, _Decimal32 y); /*C++ only */
_Decimal64 copysign(_Decimal64 x, _Decimal64 y); /*C++ only */
_Decimal128 copysign(_Decimal128 x, _Decimal128 y); /*C++ only */
```

**General Description**

The `copysign` functions produce a value with the magnitude of `x` and the sign of `y`.

**Note:**
- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

**Returned Value**

The `copysign` functions return a value with the magnitude of `x` and the sign of `y`.

**Example**

```c
/* CELEBC47
   This example illustrates the copysignd64() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 x = 1.20D, y = -1.00D , z;
    z = copysignd64(x, y);
    printf("The result of copysignd64(%Df,%Df) is %Df\n",x,y,z);
}
```

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <math.h>

double cos(double x);
float cosf(float x); /* C++ only */
long double cosl(long double x); /* C++ only */
float cosf(float x);
long double cosl(long double x);
```

**General Description**

Calculates the cosine of `x`. The value `x` is expressed in radians.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See the [IEEE Binary Floating-Point](https://www.ibm.com/support/knowledgecenter/en/SSLTBK_21.1.0/com.ibm.zos.v2r11.tskc/... on page 108 for more information about IEEE Binary Floating-Point.

**Returned Value**

Returns the calculated value.

If `x` is outside prescribed limits, the value is not calculated. Instead, the function returns 0 and sets the `errno` to `ERANGE`. If the correct value would cause an underflow, zero is returned and the value `ERANGE` is stored in `errno`.

**Special Behavior for XPG4.2**

The following error is added:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EDOM</td>
<td>The argument exceeded an internal limit for the function (approximately $2^{60}$).</td>
</tr>
</tbody>
</table>

**Example**

`CELEBC26`

```c
/* CELEBC26

This example calculates \( y \) to be the cosine of \( x \).

*/
#include <math.h>
#include <stdio.h>
```
int main(void)
{
    double x, y;
    x = 7.2;
    y = cos(x);
    printf("cos( \%lf ) = \%lf\n", x, y);
}

Output
cos( 7.200000 ) = 0.608351

#### Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 cosd32(_Decimal32 x);
_Decimal64 cosd64(_Decimal64 x);
_Decimal128 cosd128(_Decimal128 x);
_Decimal32 cos(_Decimal32 x); /* C++ only */
_Decimal64 cos(_Decimal64 x); /* C++ only */
_Decimal128 cos(_Decimal128 x); /* C++ only */
```

#### General Description

Calculates the cosine of x. The value x is expressed in radians.

**Note:**
- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See “IEEE Decimal Floating-Point” for more information.

#### Returned Value

Returns the calculated value.

If x is outside prescribed limits, the value is not calculated. Instead, the function returns 0 and sets errno to EDOM.

#### Example

```c
/* CELEBC48

This example illustrates the cosd128() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x, y;
    x = 7.2DL;
    y = cosd128(x);
    printf("cosd128(%.0f) = %.0f\n", x, y);
}
```

</tbody>
</table>

Format

```
#include <math.h>

double cosh(double x);
floating cosh(float x); /* C++ only */
long double cosh(long double x); /* C++ only */
float coshf(float x);
long double coshl(long double x);
```

General Description

Calculates the hyperbolic cosine of \( x \). The value \( x \) is expressed in radians.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [IEEE Binary Floating-Point](#) on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

If the result overflows, the function returns HUGE_VAL and sets errno to ERANGE.

Example

**CELEBC27**

```
/* CELEBC27 */

This example calculates \( y \) to be the hyperbolic cosine of \( x \).

```

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x,y;
    x = 7.2;
    y = cosh(x);
    printf("cosh( %lf ) = %lf\n", x, y);
}
```

**Output**

cosh( 7.200000 ) = 669.715755

__cospid32(), __cospid64(), __cospid128() — Calculate Cosine of pi *x

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```cpp
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 __cospid32(_Decimal32 x);
_Decimal64 __cospid64(_Decimal64 x);
_Decimal128 __cospid128(_Decimal128 x);
```

General Description

Calculates the cosine of pi * x. The value x is expressed in radians.

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See “IEEE Decimal Floating-Point” for more information.

Returned Value

Returns the calculated value.

If x is outside the prescribed limits, the value is not calculated. Instead, the function either returns 1, or returns 0 and sets errno to ERANGE.

Example

```cpp
/* CELEBC49

This example illustrates the __cospid32() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void) {
    _Decimal32 x, y;
    x = 1.0DF;
    y = __cospid32(x);
    printf("__cospid32(%.6f) = %.6f\n", x, y);
}
```

__cpl() — CPL Interface Service

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>OS/390 V2R9</td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__cpl.h>

int __cpl(int functioncode, int bufferlen, char *buffer);
```

General Description

__cpl() is currently called by the CFSizer (Coupling Facility structure sizer) tool. An IBM customer answers a minimum set of questions from an IBM web page, about one or more IBM products and then clicks the submit button. The **submit** invokes a C **cgi** program that parses the data, calls __cpl() to Query the Coupling Facility or size one or more Coupling Facility structures and then display the results back to the web client browser.

- **functioncode**: A value that specifies what function BPX1CPL will perform. The following function codes are defined.
  - CPL_QUERY (equates to value of 1)
  - CPL_CFSIZER (equates to a value of 2)
  - CPL_CFSIZER_W_LVL (equates to a value of 3)
  
  CF level 8 or higher is required to use the computesize function. To provide a consistent result, the code must loop through all online CFs and find the one at the highest CF level. Issuing computesize against CFs at different levels gives different sizes back to the user resulting in inconsistent results when multiple requests are issued.

- **bufferlen**: The length of the input/output storage area (**buffer**) for BPX1CPL

- **buffer**: Storage area for input/output for BPX1CPL

__cpl() is an interface to the BPX1CPL Assembler Callable Service. For more information on parameters and behavior of BPX1CPL, please refer to `z/OS UNIX System Services Programming: Assembler Callable Services Reference`, SA22-7803

Returned Value

If successful, __cpl() returns 0.

If unsuccessful, __cpl() returns -1 and sets errno to one of the following values:

- **EFAULT**: One of the parameters contained an address that was not accessible to the caller.
- **EINVAL**: The **functioncode** parameter contains a value that is not correct.
- **EMVSCLERROR**: A __cpl() service failed.
__cpl

ENOSYS  The __cpl() service failed because the system is not at the correct level.

EPERM  The calling thread’s address space is not permitted.

Usage Note
Access to __cpl() is controlled using a new RACF class profile BPX.CF. For any of these cases to run, a BPX.CF class profile must be created and access level provided.

__cpl() is only valid on a Parallel Sysplex enabled system with a CFlevel 8 or higher Coupling Facility. Most installations run with two or more Coupling Facilities for availability and recoverability reasons. As such, the code was designed to provide the flexibility of allowing the caller to specify a CF or if not specified, MVS will select the first CF at CFlevel 8 it finds.

<td></td>
<td>a compiler that is designed to support C99</td>
</tr>
</tbody>
</table>

Format

```c
#include <complex.h>

double complex cpow(double complex x, double complex y);
float complex cpowf(float complex x, float complex y);
long double complex cpowl(long double complex x, long double complex y);
```

General Description

The cpow() family of functions computes the complex value of \( x \) to the power of \( y \), with a branch cut for the first parameter along the negative real axis.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpow</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>cpowf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>cpowl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

The cpow() family of functions return the complex power value.

Example

```c
/*
 * This example illustrates the complex power of complex number 'z'
 */
#include <complex.h>
#include <stdio.h>

void main()
{
  long double complex zl=-0.5 + I*0.5, zpowl=(long double complex)3.0;
  double complex zd=(double complex)zl, zpowl=(double complex)zpowl;
  float complex zf=(float complex)zd, zpof=(float complex)zpowl;

  long double resl;
  double resd;
  float resf;

  printf("Illustrates the cpow function. Expected result is 0.25 in all cases\n");
  resd = cpow(zd,zpowl);
  resf = cpowf(zf,zpof);
  resl = cpowl(zl,zpowl);
  printf("\tcpow(%f + I*%f,%f + I*%f) = %f\n",creal(zd), cimag(zd), creal(zpowl), cimag(zpowl), resd);
```

Chapter 3. Part 3. Library Functions 361
printf("cpowf(%f + I*%f, %f + I*%f) = %f\n", crealf(zd), cimagf(zd), crealf(zpowf), cimagf(zpowf), resf);
printf("cpowl(%Lf + I*%Lf, %Lf + I*%Lf) = %Lf\n", creall(zl), cimagl(zl), creall(zpowl), cimagl(zpowl), resl);
}
Output

Illustrates the cpow function. Expected result is 0.25

- cpow(-0.500000 + I*0.500000, 3.000000 + I*0.000000) = 0.250000
- cpowf(-0.500000 + I*0.500000, 3.000000 + I*0.000000) = 0.250000
- cpowl(-0.500000 + I*0.500000, 3.000000 + I*0.000000) = 0.250000

Related Information

- "complex.h" on page 36
- "cabs(), cabsf(), cabsl() — Calculate the Complex Absolute Value" on page 225
cproj(), cprojf(), cprojl() — Calculate the Projection

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td>a compiler that is designed to support C99</td>
</tr>
</tbody>
</table>

Format

```c
#include <complex.h>

double complex cproj(double complex z);
float complex cprojf(float complex z);
long double complex cprojl(long double complex z);
```

General Description

The cproj() family of functions compute a projection of \( z \) onto the Riemann sphere: \( z \) projects to \( z \) except that all complex infinities (even those with one infinite part and one NaN part) project to positive infinity on the real axis. If \( z \) has an infinite part, then cproj(\( z \)) is equivalent to:

\[
\text{INFINITY} + \text{I} \times \text{copysign}(0.0, \text{cimag}(\text{z}))
\]

**Note:** The following table shows the viable formats for these functions. See [IEEE Binary Floating-Point](#) on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>cproj</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>cprojf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>cprojl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

The cproj() family of functions return the value of the projection onto the Riemann sphere.

For a variable \( z \) of complex type, \( z == \text{creal}(z) + \text{cimag}(z) \times \text{I} \).

Special behavior for hex

On hexadecimal floating point mode, cproj(\( z \)) family of functions always returns \( z \).

Example

```c
#include <complex.h>
#include <stdio.h>

/*
 * Illustrates complex function cproj().
 * 
 * NOTE: When compiled in HEX(FLOAT), cproj(z) should always return z
 */
```
cproj, cprojf, cprojl

/*
#define INFINITEL 1.0L/0.0L /* An infinite number */

void InitReal ( long double complex *z, long double RealPart)
{
    union LongDoubleComplexMap {
        long double complex w;
        long double ldarray[2];
    } z1;
    z1.w = *z;
    z1.ldarray[0] = RealPart;
    *z = z1.w;
}

main() {
    long double complex z,w;
    z = 2.5 + I*(-3.999);
    printf("Ilustrates function cproj() ");
    #ifdef _BFP
        printf ("(IEEE mode)");
    #else
        printf ("(HFP mode)" );
    #endif
    printf("\n\n z = %Lf + I*%Lf\n\n",creall(z),cimagl(z));
    w = cprojl(z);
    printf(" cproj(z) = %Lf + I*%Lf\n",creall(w),cimagl(w));

    printf(" Initializing z(real) with infinity ...\n");
    InitReal(z,INFINITEL);
    printf(" z = %Lf + %Lf*%I\n",creall(z),cimagl(z));
    w = cprojl(z);
    printf(" cproj(z) = %Lf + %Lf*%I\n",creall(w),cimagl(w));
}

Output
Ilustrates function cproj() (IEEE mode)

z = 2.500000 + I*-3.999000

cproj(z) = 2.500000 + I*-3.999000

Initializing z(real) with infinity ...

z = INF + -3.999000*I

cproj(z) = INF + -0.000000*I

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <fcntl.h>

int creat(const char *pathname, mode_t mode);
```

General Description

The function call: `creat(pathname, mode)` is equivalent to the call:
```
open(pathname, O_CREAT|O_WRONLY|O_TRUNC, mode);
```

Thus the file named by `pathname` is created, unless it already exists. The file is then opened for writing only, and is truncated to zero length. See "open() — Open a File" on page 1313 for further information.

The `mode` argument specifies the file permission bits to be used in creating the file. Here is a list of symbols that can be used for a mode:

- S_IRGRP: Read permission for the file's group.
- S_IROTH: Read permission for users other than the file owner.
- S_IRUSR: Read permission for the file owner.
- S_IWGRP: Write permission for the file's group.
- S_IWOTH: Write permission for users other than the file owner.
- S_IXGRP: Execute permission for the file's group.
- S_IXOTH: Execute permission for users other than the file owner.
- S_I RouWXG: Read, write, and search, or execute permission for the file's group.
- S_IXWXO: Read, write, and search, or execute permission for users other than the file owner.
- S_IRWXU: Read, write, and search, or execute, for the file owner.
- S_ISGID: Privilege to set group ID (GID) for execution. When this file is run through an exec function, the effective group ID of the process is set to the group ID of the file, so that the process has the same authority as the file owner rather than the authority of the actual invoker.
- S_ISUID: Privilege to set the user ID (UID) for execution. When this file is run through an exec function, the effective user ID of the process is set to the owner of the file, so that the process has the same authority as the file owner rather than the authority of the actual invoker.
- S_ISVTX: Indicates shared text. Keep loaded as an executable file in storage.
- S_IWGRP: Write permission for the file's group.
S_IWOTH  Write permission for users other than the file owner.
S_IWUSR  Write permission for the file owner.
S_IXGRP  Search permission (for a directory) or execute permission (for a file) for the file's group.
S_IXOTH  Search permission for a directory, or execute permission for a file, for users other than the file owner.
S_IXUSR  Search permission (for a directory) or execute permission (for a file) for the file owner.

Large Files for HFS

Note: Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option LANGLEVEL(LONGLONG) and also define the Feature Test Macro (FTM) _LARGE_FILES before any headers are included will enable this function to operate on HFS files that are larger than 2 gig-1 in size. File size and offset fields will be enlarged to 63 bits in width so any other function operating on this file will have to be enabled with the same FTM. The function call: creat(pathname,mode) is equivalent to the call: open(pathname, O_CREAT|O_WRONLY|O_TRUNC|O_LARGEFILE, mode);

Returned Value

If successful, creat() returns a file descriptor for the open file.

If unsuccessful, creat() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>
| EACCES     | One of the following error conditions exists:  
  • The process did not have search permission on a component in pathname.
  • The file exists but the process did not have appropriate permissions to open the file in the way specified by the flags.
  • The file does not exist, and the process does not have write permission on the directory where the file is to be created.
  • O_TRUNC was specified, but the process does not have write permission on the file. |
| EINTR      | open() was interrupted by a signal. |
| EISDIR     | pathname is a directory, and options specifies write or read/write access. |
| ELOOP      | A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of pathname is greater than POSIX_SYMLOOP. |
| EMFILE     | The process has reached the maximum number of file descriptors it can have open. |
| ENAMETOOLONG | pathname is longer than PATH_MAX characters or some component of pathname is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, this error occurs if the length of a pathname string substituted for a symbolic  

Chapter 3. Part 3. Library Functions  367
creat

link in the pathname argument exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined with pathconf().

ENFILE The system has reached the maximum number of file descriptors it can have open.

ENOENT O_CREAT is specified, and either the path prefix does not exist or the pathname argument is an empty string.

ENOSPC The directory or file system intended to hold a new file has insufficient space.

ENOTDIR A component of pathname is not a directory.

EOVERFLOW The named file is a regular file and the size of the file cannot be represented correctly in an object of type off_t

EROFS pathname is on a read-only file system.

Example

CELEBC28

/* CELEBC28 */

This example creates a file.

*/

#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main()
{
    char fn[]="creat.file", text[]="This is a test";
    int fd;

    if ((fd = creat(fn, S_IRUSR | S_IWUSR)) < 0)
        perror("creat() error");
    else {
        write(fd, text, strlen(text));
        close(fd);
        unlink(fn);
    }
    return(fd);
}

CreateWorkUnit() — Create WLM Work Unit

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX System Services</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__wlm.h>

int CreateWorkUnit(wlmetok_t *enclavetoken,
                   server_classify_t classify,
                   char *arrival_time,
                   char *func_name);
```

General Description

The CreateWorkUnit function provides the ability for an application to create a WLM work unit.

*enclavetoken Points to a data field of type wlmetok_t where the CreateWorkUnit() function is to return the WLM work unit enclave token.

*classify Points to a server_classify_t structure that contains the classification information for the work request macro.

*arrival_time Points to a NULL-terminated character string that represents the arrival time in STICK format of the associated work request.

*func_name Points to a NULL-terminated character string that represents the descriptive function name of the associated work request.

Returned Value

If successful, CreateWorkUnit() returns a pointer to work unit enclave token of type wlmetok_t.

If unsuccessful, CreateWorkUnit() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>An argument of this function contained an incorrect value.</td>
</tr>
<tr>
<td>EMVSSAF2ERR</td>
<td>An error occurred in the security product.</td>
</tr>
<tr>
<td>EMVSWLMERROR</td>
<td>The WLM create failed. Use __errno2() to obtain the WLM service reason code for the failure.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The calling thread’s address space is not permitted to the BPX.WLMSERVER Facility class. The caller’s address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).</td>
</tr>
</tbody>
</table>

crypt() — String Encoding Function

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <unistd.h>

char *crypt(const char *key, const char *salt);
```

General Description

The crypt() function encodes the string pointed to by the `key` argument. It perturbs the Data Encryption Standard (DES) encryption algorithm with the first two characters in the string pointed to by the `salt` argument to perform this encoding. The first two `salt` characters must be chosen from the set:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . /
```

This function can be called from any thread.

Returned Value

If successful, crypt() returns a pointer to a thread specific encoded string. The first two characters of the returned value are those of the `salt` argument.

Notes:

1. The return value of crypt() points to a thread-specific buffer which is overwritten each time crypt() is called from the same thread.
2. The values returned by crypt() are not portable to other X/Open-conforming systems.

If unsuccessful, crypt() returns a NULL pointer and sets `errno` to indicate the error.

Special Behavior for z/OS UNIX Services

The crypt() function will fail if:

```
<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>First two characters of <code>salt</code> argument are not from the <code>salt</code> set.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Storage for crypt() output buffer is not available for thread from which crypt() has been invoked.</td>
</tr>
</tbody>
</table>
```

**cs() — Compare and Swap**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <stdlib.h>

int cs(cs_t *oldptr, cs_t *curptr, cs_t newword);
```

**General Description**

The cs() built-in function compares the 4-byte value pointed to by `oldptr` to the 4-byte value pointed to by `curptr`. If they are equal, the 4-byte value, `newword`, is copied into the location pointed to by `curptr`. If they are unequal, the value pointed to by `curptr` is copied into the location pointed to by `oldptr`.

If this function is used in a multi-threading environment, then it is the user's responsibility to protect the `oldptr` variable. The user can create a local variable per thread to contain this value or provide locking code to protect the global variable used. The `oldptr` variable may not reflect the `curptr` variable if the `curptr` variable changes via another thread before the user has a chance to examine `oldptr`.

To avoid infringing on the user's name space, this nonstandard function is exposed only when you use the compiler option `LANGLVL(EXTENDED)`. When you use `LANGLVL(EXTENDED)` any relevant information in the header is also exposed.

The function uses the COMPARE SWAP (CS) instructions, which can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas. For a detailed description, refer to the appendixes in the *z/Architecture Principles of Operation* on number representation and instruction.

**Returned Value**

`cs()` returns 0 if the 4-byte value pointed to by `oldptr` is equal to the 4-byte value pointed to by `curptr`.

If the value is not equal, `cs()` returns 1.

**Related Information**

- *z/Architecture Principles of Operation*

csid() — Character Set ID for Multibyte Character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <stdlib.h>

int csid(const char *c)
```

External Entry Point

@@CSID, __csid;

General Description

determines the character set identifier for the specified multibyte character pointed to by c, that begins in the initial shift state.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLEVEL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLEVEL(EXTENDED). When you use LANGLEVEL(EXTENDED) any relevant information in the header is also exposed.

Returned Value

If successful, csid() returns the character-set identifier for the multibyte character.

If the character is not valid, csid() returns −1.

Note: The multibyte character passed must begin in the initial shift state.

Example

CELEBC29

```c
/* CELEBC29

This example checks character set ID for a character.

*/
#include "locale.h"
#include "stdio.h"
#include "stdlib.h"

main() {
    char *string = "A";
    int rc;

    rc = csid(string);
    printf("character '%s' is in character set id %i\n", string, rc);
}
```
Output
character 'A' is in character set id 0

__CSNameType() — Return Codeset Name Type (ASCII/EBCDIC)

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

#include <_Ccsid.h>

__csType __CSNameType(char *codesetName);

General Description

The __CSNameType() function returns a __csType value which indicates whether the codesetName codeset name is ASCII or EBCDIC.

Returned Value

If codesetName is valid, __CSNameType() returns a __csType value of __CSTYPE_EBCDIC or __CSTYPE_ASCII, indicating whether the codeset name refers to an EBCDIC or ASCII codeset.

If codesetName is not valid, __CSNameType() returns __CSTYPE_INVALID.

csnap

**csnap() — Request a Condensed Dump**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <ctest.h>

int csnap(char *dumptitle);
```

**General Description**

Creates a display of the activation stack, including the Dynamic Storage Area (DSA), for each presently active function. Other environmental control blocks that may be required by IBM Service are also displayed. Under Language Environment, these consist of the Common Anchor Area (CAA) and the z/OS XL C/C++ CAA information. The output is identified with `dumptitle`. See the `CEE3DMP` Language Environment callable service in the `z/OS Language Environment Programming Guide`, SA22-7561, to determine where the output is written to.

To avoid infringing on the user’s name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use `LANGLVL(EXTENDED)`. To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with `LANGLVL(EXTENDED)`. When you use `LANGLVL(EXTENDED)` any relevant information in the header is also exposed.

**Returned Value**

If successful, `csnap()` returns 0.

If unsuccessful, `csnap()` returns nonzero.

**Example**

```c
#include <ctest.h>

int main(void) {
    int rc;
    rc = csnap("Sample csnap output");
}
```

**Related Information**

__csplist — Retrieve CSP Parameters

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <csp.h>
__csplist;
```

General Description

**Restriction:** This function is not supported in AMODE 64.

__csplist is a macro intended to be used to access the parameter list passed from Cross System Product (CSP) to your C Library program. The macro evaluates to the address of the first element of the parameter list. You can use array indexing to extract the subsequent parameters, casting each parameter to the expected type, as shown in the example below. If no parameters are passed, __csplist[0] equals NULL.

You must include the #pragma runopts(plist(ims)) directive if CSP is used to invoke a z/OS XL C program.

argc will always be 1. See z/OS XL C/C++ User’s Guide for information about the PLIST compiler option.

If you are expecting an integer and then a structure of type s_type, you should have the statements:

```c
int_var = (int *)__csplist[0];
s_var   = (s_type *)__csplist[1];
```

Related Information

ctdli() — Call to DL/I

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

**C only:**

```c
#include <ims.h>    /* or #include <cics.h> */

#define _CTDLI_PARMCOUNT    /* First arg is an explicit parameter count */
int ctdli(int parmcount, const char *function, ...);
```

or

```c
#define _CTDLI_NOPARMCOUNT  /* Parameter count is implicit in varargs */
int ctdli(const char *function,...);
```

**C++:**

```c
#include <ims.h>    /* or #include <cics.h> */

int ctdli(int parmcount, const char *function, ...);
```

General Description

**Restriction:** This function is not supported in AMODE 64.

Invokes DL/I facilities. The first argument `parmcount` is optional for C, but is mandatory for C++ applications. The `parmcount` value specifies the number of arguments in the variable argument list for the `ctdli()` call to `function`.

In C, when specifying a `parmcount`, use the `_CTDLI_PARMCOUNT` feature test macro. Otherwise, define `_CTDLI_NOPARMCOUNT` and make `function` the first argument. If the compile unit contains both types of call (sometimes passing `parmcount` and sometimes not), then define `_CTDLI_NOPARMCOUNT` and always cast the first argument to `(const char *)` if you want to avoid messages when compiling with the checkout option.

The `function` argument specifies the DL/I function you want to perform. Because the format of the `ctdli()` call depends on the function selected, all of the variations are not given here. For complete details on the available functions, refer to the COBOL publications.

To avoid infringing on the user’s name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use `LANGLVL(EXTENDED)`.

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with `LANGLVL(EXTENDED)`. When you use `LANGLVL(EXTENDED)` any relevant information in the header is also exposed.
To invoke ctdli() from an IMS transaction, you need either the #pragma runopts(env(ims),plist(os)), or you need to specify the compiler options TARGET(IMS) and PLIST(OS).

**Returned Value**

The Program Control Block (PCB) status field (2 bytes) is stored as an unsigned int and used as the returned value for ctdli().

If the PCB status field contains blanks (hex '4040'), ctdli() returns 0.

**Example**

```c
/* The following program demonstrates the use of the ctdli() function.
   It is a skeleton of a message processing program that calls ctdli()
to retrieve messages and data.

   Do use the TARGET(IMS) and PLIST(IMS) compile options for C++ applications.
*/
#ifndef __cplusplus
#pragma runopts(env(ims),plist(os))
#endif
#include <stdlib.h>
#include <ims.h>
#define n 20 /* I/O area size - Application dependent */
typedef struct {PCB_STRUCT(10)} PCB_10_TYPE;

int main(void)
{
    /* Function codes for ctdli */
    static const char func_GU[4] = "GU ";
    static const char func_ISRT[4] = "ISRT";

    char ssa_name[] = "ORDER (ORDERKEY = 666666)"
;
    int rc;

    char msg_seg_io_area[n];
    char db_seg_io_area[n];
    char alt_msg_seg_out[n];

    PCB_STRUCT_8_TYPE *alt_pcb;
    PCB_10_TYPE *db_pcb;
    IO_PCB_TYPE *io_pcb;

    io_pcb = (IO_PCB_TYPE *)__pcblist[0];
    alt_pcb = __pcblist[1];
    db_pcb = (PCB_10_TYPE *)__pcblist[2];

    /* Get first message segment from message region */
    rc = ctdli(func_GU, io_pcb, msg_seg_io_area);

    /* Get the data from the database having the specified key value */
    rc = ctdli(func_GU, db_pcb, db_seg_io_area, ssa_name);

    /* Build output message in program's I/O area */
    rc = ctdli(func_ISRT, alt_pcb, alt_msg_seg_out);
}
```

z/OS V1R9.0 XL C/C++ Run-Time Library Reference
ctermid() — Generate Pathname for Controlling Terminal

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

char *ctermid(char *string);
```

General Description

`string` points to a memory location where the ctermid() function stores the name of the current controlling terminal. The memory location must be able to hold at least \_l_ctermid characters, where \_l_ctermid is a symbol defined in the stdio.h header file.

ctermid() returns a string that can be used as a pathname to refer to the controlling terminal for the current process. If `string` is not NULL, ctermid() stores the pathname in the specified location and returns the value of `string`. Otherwise, ctermid() uses a location of its own and returns a pointer to that location.

The pathname returned can be used to access the controlling terminal, if the process has a controlling terminal.

Returned Value

ctermid() is always successful; it returns a string that can be used as a pathname to refer to the controlling terminal for the current process.

There are no documented errno values.

Example

```c
CELEBC32

/* CELEBC32 */

    This example refers to the controlling terminal for the current process.

    */
#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>

main()
    {
    char termid[1025];

    if (ctermid(termid) == NULL)
ctermid

```c
perror("ctermid() error");
else
    printf("The control terminal is %s\n", termid);
}
```

**Output**
The control terminal is /dev/tty

**Related Information**

ctest() — Start Debug Tool

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <ctest.h>

int ctest(char *command);
```

General Description

Invokes the Debug Tool from your application program. The parameter `command` is a character pointer to a list of valid Debug Tool commands, that `ctest()` uses to invoke Debug Tool.

If you choose not to compile your program with hooks, you can use well-placed `ctest()` function calls instead. (A hook is a conditional exit that transfers control to the debugger, when the code is run under the debugger.) You would create a hook when you compile with the TEST option, causing the exit to be in your generated code waiting to run. A hook has minimal effect on a program that is running without the debugger.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

For more information on the Debug Tool, refer to .

Returned Value

If successful, `ctest()` returns 0.

If unsuccessful, `ctest()` returns nonzero.

Examples

To let the debug tool gain control of your program, issue the command:

```c
test(NULL);
```

To display the call chain from within a program and then let the program continue execution, issue the function call: `ctest("list calls; go;")`. To set a breakpoint from within a `ctest()` call, try:

```c
char *cmd = "at line 17 list my_struct; go;";
ctest(cmd);
```

ctime() — Convert Time to Character String

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <time.h>

char *ctime(const time_t *timer);
```

General Description

Converts the calendar time pointed to by `timer` to local time in the form of a character string. A value for `timer` is usually obtained by a call to the `time()` function.

The `ctime()` function is equivalent to the function call: `asctime(localtime(timer))`

Returned Value

If successful, `ctime()` returns a pointer to a date and time string. The string returned by `ctime()` contains exactly 26 characters and has the format:

```
"%3s %3s%3d %2d:%2d:%2d %d\n"
```

For example: `Mon Jul 16 02:03:55 1987\n`

If an error occurs, `ctime()` returns no value.

Notes:

- Under AMODE 64, if `timeval` value causes actual time to go beyond 23:59:59 Dec. 31st, 9999, 00:00:00 Jan. 1st, 0 is used to indicate `timeval` value too big. For detailed description, read the notes under "localtime() — Convert Time and Correct for Local Time" on page 1119.
- This function is sensitive to time zone information which is provided by:
  - The TZ environmental variable when POSIX(ON) and TZ is correctly defined, or by the _TZ environmental variable when POSIX(OFF) and _TZ is correctly defined.
  - The LC_TOD category of the current locale if POSIX(OFF) or TZ is not defined.

The time zone external variables `tzname`, `timezone`, and `daylight` declarations remain feature test protected in `time.h`.

- The calendar time returned by a call to the `time()` function begins at epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.
- The `ctime()` function uses a 24-hour clock format.
- The days are abbreviated to: Sun, Mon, Tue, Wed, Thu, Fri, and Sat.
- The months are abbreviated to: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.
ctime

- All fields have a constant width.
- Dates with only one digit are preceded either with a 0 or a blank space.
- The newline character (\n) and the NULL character (\0) occupy the last two positions of the string.
- The asctime(), ctime(), and other time functions may use a common, statically allocated buffer for holding the return string. Each call to one of these functions may destroy the result of the previous call.

Special Behavior for POSIX C
- Under C Library POSIX applications only, this function is sensitive to time zone information, which is provided by:
  - The TZ environment variable if time() is called from a POSIX program and TZ is defined. The names of the time zones are parsed out of TZ and placed in the tzone array.
  - The LC_TOD locale category, either time() is called from a non-POSIX program, or if TZ is not defined.

See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information about using POSIX support.

Example

CELEBC33
/

* CELEBC33

This example polls the system clock by using the library function &lt;time.h&gt;.
It then prints a message giving the current date and time.

*/
#include &lt;time.h&gt;
#include &lt;stdio.h&gt;

int main(void)
{
    time_t ltime;
    time(&ltime);
    printf("the time is %s", ctime(&ltime));
}

Output
the time is Fri Jun 16 16:03:38 2001

ctime_r

cftime_r() — Convert Time Value to Date and Time Character String

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <time.h>

char *ctime_r(const time_t *clock, char *buf);
```

General Description

The cftime_r() function converts the calendar time pointed to by `clock` to local time in exactly the same form as ctime() and puts the string into the array pointed to by `buf`, which contains at least 26 bytes and returns `buf`.

Unlike ctime(), the thread-safe version cftime_r() is not required to set `tzname`.

Returned Value

If successful, cftime_r() returns a pointer to the string pointed to by `buf`.

If unsuccessful, cftime_r() returns a NULL pointer.

There are no documented errno values.

ctrace() — Request a Traceback

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <ctest.h>

int ctrace(char *dumptitle);
```

General Description

Requests a traceback. The output is identified with `dumptitle`. `ctrace()` invokes the CEE3DMP Language Environment callable service with the following options: TRACEBACK, NOFILE, NOBLOCK, NOVARIABLE, NOSTORAGE, STACKFRAME(ALL), NOCOND, NOENTRY. See the CEE3DMP Language Environment callable service in z/OS Language Environment Programming Guide, SA22-7561 to determine where the output is written to.

If you compile the code using the GONUMBER option, this function will display, along with the traceback, the statement numbers and the offset information.

To avoid infringing on the user’s name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

**Note:** The offsets displayed by `ctrace()` are from the beginning of the functions, whereas by default, compiler listings show offsets from the beginning of the source file. You can override the displayed offsets with the OFFSET compile-time option.

Returned Value

If successful, `ctrace()` returns 0.

If unsuccessful, `ctrace()` returns nonzero.

Example

```c
CELEBC34
/* CELEBC34

    This example shows how ctrace() is used and the output produced.

*/
#include <ctest.h>
int main(void) {
```
```c
int rc;
rc = ctrace("Sample ctrace output");
}
```

cuserid() — Return Character Login of the User

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdio.h>

char *cuserid(char *s);
```

General Description

The cuserid() function generates a character representation of the name associated with the real or effective user ID of the process.

If `s` is a NULL pointer, this representation is generated in an area that may be overwritten by subsequent calls to cuserid(). A pointer to the area is returned. If `s` is not a NULL pointer, `s` is assumed to point to an array of at least `{L_cuserid}` bytes; the representation is deposited in this array. The symbolic constant `{L_cuserid}` is defined in `<stdio.h>` and has a value greater than 0.

Note:

- This function and constant `{L_cuserid}` are kept for historical reasons. They were part of the Legacy Feature in Single UNIX Specification, Version 2, but have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use getpwuid() instead of cuserid().
- If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned Value

If `s` is not a NULL pointer, cuserid() returns `s`.

If `s` is not a NULL pointer and the login name cannot be found, the NULL byte `\0` will be placed at `*s`.

If `s` is a NULL pointer and the login name cannot be found, cuserid() returns a NULL pointer.

If `s` is a NULL pointer and the login name can be found, cuserid() returns the address of a buffer local to the calling thread containing the login name.

### dbm_clearerr() — Clear Database Error Indicator

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_clearerr(DBM *db);
```

#### General Description

The `dbm_clearerr()` function clears the error condition of the database. The argument `db` is a handle to a database previously obtained by `dbm_open()`. Note that this does not correct any problems with the database due to previous failures. It simply allows `dbm_` operations to proceed. The database may be in an inconsistent or damaged state.

**Special Behavior for z/OS UNIX Services**

In a multithreaded environment, the database error indicator is global to all threads using the database handle. Thus, clearing the error indicator affects all threads using the database handle.

#### Returned Value

The return value is unspecified by X/Open.

If successful, `dbm_clearerr()` returns 0.

If unsuccessful, `dbm_clearerr()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Non-valid database descriptor specified.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

void dbm_close(DBM *db);
```

General Description

The `dbm_close()` function closes a database. The `db` argument is the database handle returned by a previous call to `dbm_open()`.

Special Behavior for z/OS UNIX Services

A `dbm_close()` function call removes access to the specified database handle to all threads within the process.

Returned Value

`dbm_close()` returns no values.

<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_delete(DBM *db, datum key);
```

General Description

The dbm_delete() function deletes a record and its key from the database. The `db` argument specifies the database handle returned by a previous call to dbm_open(). The `key` argument identifies the record the program is deleting. The `key` datum must contain a `dptr` pointer to the key, and the key length in `dsize`.

After calling dbm_delete(), during a pass through the keys by dbm_firstkey() and dbm_nextkey(), the application positioning must be reset by calling dbm_firstkey(). If not, unpredictable results may occur including retrieval of the same key multiple times, or not at all.

File space is not physically reclaimed by a dbm_delete() operation. That is, the file size is not reduced. However, the space is available for reuse, subject to hashing.

Special Behavior for z/OS UNIX Services

In a multithreaded environment, changes made to the database by a dbm_delete() operation affect all threads using the database handle. Thus, all other threads must also reset their positioning by using the dbm_firstkey() function before using dbm_nextkey(). A previously executed dbm_fetch() operation by another thread for the same key still has correct buffer pointers to the previous data. The dbm_delete() operation does not affect this. All other operations on other threads, such as dbm_fetch() to this (now) deleted key will fail.

Returned Value

If successful, dbm_delete() returns 0.

If unsuccessful, dbm_delete() returns −1 and sets the error value in errno. Also, the database error indicator may be set.

</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_error(DBM *db);
```

General Description

The `dbm_error()` function returns the error condition of the database. The argument `db` is a handle to a database previously obtained by `dbm_open()`.

Special Behavior for z/OS UNIX Services

In a multithreaded environment, the database error indicator is global to all threads using the database handle. Thus, the database error indicator may be set as a result of a database operation by another thread.

Returned Value

`dbm_error()` returns 0 if the error condition is not set.

`dbm_error()` returns nonzero if the error condition is set.

- "dbm_open() — Open a Database" on page 407
- "dbm_store() — Store Database Record" on page 409
The `dbm_fetch()` function reads a record from the database. The argument `db` is a handle to a database previously obtained by `dbm_open()`. The argument `key` is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching. A `datum` is a structure that consists of two members, `dptr` and `dsize`. The member `dptr` is a char pointer to an array of data that is `dsize` bytes in length. (Note: The data is arbitrary binary data and is not NULL-terminated.)

The `dptr` is valid only until the next `dbm_` operation by this thread.

Special Behavior for z/OS UNIX Services

In a multithreaded environment, the `dbm_fetch()` function returns a `dptr` in the `datum` structure to a data area that is thread-specific. This data area is not affected by other threads operations on the database, with the exception of a `dbm_close()` operation, which invalidates the `datum`.

Returned Value

If successful, `dbm_fetch()` returns the `datum` containing a pointer to the data content `dptr`, and the data length `dsize`.

If unsuccessful, `dbm_fetch()` returns a NULL pointer in `dptr` and returns the error value in `errno`. Also, the database error indicator may be set.

<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

datum dbm_firstkey(DBM *db);
```

**General Description**

The `dbm_firstkey()` function returns the first key in the database. The argument `db` is a handle to a database previously obtained by `dbm_open()`. Since the keys are arbitrary binary data, the order of key return by `dbm_firstkey()` and `dbm_nextkey()` does not reflect any lexical ordering. In addition, the return order does not reflect record insertion ordering. All keys can be retrieved from the database by executing a loop such as:

```c
for (key = dbm_firstkey(db); key.dptr !NULL; key = dbm_nextkey(db))
```

That is, establish positioning to the beginning by use of the `dbm_firstkey()` function, then loop doing `dbm_nextkey()` function calls until a NULL `dptr` is returned in the `datum`.

The returned `dptr` is valid only until the next `dbm_` operation by this thread.

**Special Behavior for z/OS UNIX Services**

In a multithreaded environment, the `dbm_firstkey()` function returns a pointer to data that is thread-specific. In addition, each thread maintains its own positioning information for `dbm_nextkey()` operations. However, other threads making modifications to the database, for example using `dbm_store()` or `dbm_delete()` can cause unpredictable results for threads executing `dbm_nextkey()`, including keys retrieved multiple times or not at all. The application must reset positioning to the beginning using `dbm_firstkey()` if another thread has done a modification to the database.

**Returned Value**

If successful, `dbm_firstkey()` returns the `datum` containing a pointer to the key `dptr`, and the key length `dsize`.

If unsuccessful, `dbm_firstkey()` returns a NULL pointer in `dptr` and returns the error value in `errno`. Also, the database error indicator may be set.

<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

datum dbm_nextkey(DBM *db);
```

**General Description**

The `dbm_nextkey()` function returns the next key in the database. The argument `db` is a handle to a database previously obtained by `dbm_open()`. Since the keys are arbitrary binary data, the order of key return by `dbm_firstkey()` and `dbm_nextkey()` does not reflect any lexical ordering. In addition, the return order does not reflect record insertion ordering. All keys can be retrieved from the database by executing a loop such as:

```c
for (key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

That is, establish positioning to the beginning by use of the `dbm_firstkey()` function, then loop doing `dbm_nextkey()` function calls until a NULL `dptr` is returned in `datum`.

The returned `dptr` is valid only until the next `dbm_` operation by this thread.

**Special Behavior for z/OS UNIX Services**

In a multithreaded environment, the `dbm_nextkey()` function returns a pointer to data that is thread-specific. In addition, each thread maintains its own positioning information for `dbm_nextkey()` operations. However, other threads making modifications to the database, for example using `dbm_store()` or `dbm_delete()` can cause unpredictable results for threads executing `dbm_nextkey()`, including keys retrieved multiple times or not at all. The application must reset positioning to the beginning using `dbm_firstkey()` if another thread has done a modification to the database.

**Returned Value**

If successful, `dbm_nextkey()` returns the `datum` containing a pointer to the key `dptr`, and the key length `dsize`.

If unsuccessful, `dbm_nextkey()` returns a NULL pointer in `dptr` and returns the error value in `errno`. Also, the database error indicator may be set.

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

DBM *dbm_open(const char *file, int open_flags, mode_t file_mode);
```

**General Description**

The `dbm_open()` function opens a database. The `file` argument is the pathname of the database, not including the filename suffix (the part after the .). The database is stored in two files. One file is a directory containing a bit map of blocks in use and has .dir as its suffix. The second file contains all the data and has .pag as its suffix. The `open_flags` argument has the same meaning as the `flags` argument of `open()` except that a database opened for write-only access opens the files for read and write access. The `file_mode` argument has the same meaning as the third argument of `open()`.

The number of records that can be stored in the database is limited by the file space available for the .dir and .pag files, and by the underlying key hashing. If multiple keys hash to the same 32 bit hash value, the number of keys for that hash value is limited to the amount of data (key sizes plus content sizes plus overhead) that can be stored in a single logical block of 1024 bytes.

**Special Behavior for z/OS UNIX Services**

In a multithreaded environment, the `dbm_` functions have both POSIX process wide and thread-specific characteristics. z/OS UNIX services provide the following multithreaded behavior:

1. A database handle returned by the `dbm_open()` function is a process wide resource. This means that multiple threads within the process can access the database using the same database handle.

2. Each thread using a given database handle has its own positioning information for `dbm_firstkey()` and `dbm_nextkey()` operations. This means that multiple threads can each be executing a `dbm_nextkey()` loop.

3. Each thread using a given database handle has its own buffering for `dbm_fetch()` operations. This means that a pointer to a keys content (as returned by `dbm_fetch()`)) remains valid, even if other threads modify the database.

4. Database modifications are automatically reflected to all of the threads using the same database handle. For example, if a thread adds a key/data pair using `dbm_store()`, a `dbm_fetch()` of that key by another thread will be successful.

5. Operations which modify the database, such as `dbm_store()` and `dbm_delete()`, can cause unpredictable results to threads executing `dbm_nextkey()`. If a database modification is done, all threads should reset positioning using a `dbm_firstkey()` call before executing `dbm_nextkey()`.
dbm_open

6. A dbm_close() operation removes access to the database for all threads that use the database handle.

7. Multiple dbm_open() operations, whether by a single thread, multiple threads within a process, or by multiple processes are permitted, but for read access only. No protection is provided for database modification, and modification can result in unpredictable results, including database destruction.

Returned Value

If successful, dbm_open() returns a pointer to the database descriptor.

If unsuccessful, dbm_open() returns a NULL pointer and stores the error value in errno.

dbm_store() — Store Database Record

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_store(DBM *db, datum key, datum content, int store_mode);
```

General Description

The `dbm_store()` function writes a record to a database. The `db` argument specifies the database handle returned by a previous call to `dbm_open()`. The `key` argument identifies the record the program is deleting. The `key` datum must contain a `dptr` pointer to the key, and the key length in `dsize`. The argument `content` is a datum that describes the data record being stored. The `content` datum contains a `dptr` pointer to the data, and the data length in `dsize`.

The argument `store_mode` controls whether `dbm_store()` replaces a already existing record that has the same key. The `store_mode` argument may be any one of the following set of symbols defined in the `<ndbm.h>` include file:

- **DBM_INSERT**: Do not add the `key` and `content` pair if the `key` already exists in the database. If the `key` doesn't already exist, add the new `key` and `content` pair.
- **DBM_REPLACE**: Replace the `key` and `content` pair in the database with the new pair if the `key` already exists. If the `key` doesn't already exist, add the new `key` and `content` pair.

After calling `dbm_store()`, during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application positioning must be reset by calling `dbm_firstkey()`. If not, unpredictable results may occur including retrieval of the same key multiple times, or not at all.

The number of records that can be stored in the database is limited by the file space available for the `.dir` and `.pag` files, and by the underlying key hashing. If multiple keys hash to the same 32 bit hash value, the number of keys for that hash value is limited to the amount of data (key sizes plus content sizes plus overhead) that can be stored in a single logical block of 1024 bytes.

Special Behavior for z/OS UNIX Services

In a multithreaded environment, changes made to the database by a `dbm_store()` operation affect all threads using the database handle. Thus, all other threads must also reset their positioning by using the `dbm_firstkey()` function before using `dbm_nextkey()`. A previously executed `dbm_fetch()` operation by another thread for the same `key` still has correct buffer pointers to the previous data. The `dbm_store()` operation does not affect this. All other operations, such as `dbm_fetch()` or `dbm_delete()`, will automatically have access to the new `key` and `content` pair.
dbm_store

Returned Value

If successful, dbm_store() returns 0. If DBM_INSERT is specified, and the key already exists, dbm_store() returns 1.

If unsuccessful, dbm_store() returns −1 and sets errno to one of the following values. Also, the database error indicator may be set.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFBIG</td>
<td>Seek/Write operation failed attempting to write new block. This error is not part of the errno set described by X/Open for this function. You may be able to store other key and content pairs when the key hashes to a different value.</td>
</tr>
<tr>
<td>ENOSPC</td>
<td>key plus content plus block overhead does not fit into a block. This error is not part of the errno set described by X/Open for this function. The key plus content underlying data lengths need be less or equal to 1012 bytes in length.</td>
</tr>
</tbody>
</table>

decabs() — Decimal Absolute Value

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <decimal.h>

decimal(n,p) decabs(decimal(n,p) pdec);
```

General Description

The built-in function decabs() accepts a decimal type expression as an argument and returns the absolute value of the decimal argument, in the same decimal type as the argument. The function does not change the content of the argument.

The parameter \( n \) can be any integral value between 1 and DEC_DIG. The parameter \( p \) can be any integral value between 0 and DEC_PRECISION, although it must be less than or equal to \( n \). DEC_DIG and DEC_PRECISION are defined inside decimal.h.

If the content of the given argument is not in native packed decimal format, behavior is undefined.

Example

```
CELEBD01
/* CELEBD01 */
#include <decimal.h>

decimal(10,2) p1, p2;
int main(void) {
   p2 = -1234.56d;
   p1 = decabs(p2);
   printf("p1 = %D(10,2), p2 = %D(10,2)\n", p1, p2);
   return(0);
}
```

Output

\( p1 = 1234.56, p2 = -1234.56 \)

Related Information

- "decimal.h" on page 39
- "dechk() — Check for Valid Decimal Types" on page 412
- "decfix() — Fix Up a Nonpreferred Sign Variable" on page 414
decchk

decchk() — Check for Valid Decimal Types

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <decimal.h>

int decchk(decimal(n,p) pdec);
```

General Description

The built-in function decchk() accepts a decimal type expression as an argument and returns a status value of type `int`.

The status can be interpreted as follows:

- **DEC_VALUE_OK**: A valid decimal representation value (including the less-preferred but valid sign, A-F).
- **DEC_BAD_NIBBLE**: The leftmost half-byte is not 0 in a decimal type number that has an even number of digits. For example, 123 is stored in decimal(2,0). If such a number is packed, then it is used.
- **DEC_BAD_DIGIT**: Digits not allowed (not 0-9). If such a number is packed, then it is used.
- **DEC_BAD_SIGN**: Sign not allowed (not A-F). If such a number is packed, then it is used.

The function return status can be masked to return multiple status.

The parameter `n` can be any integral value between 1 and `DEC_DIG`. The parameter `p` can be any integral value between 0 and `DEC_PRECISION`, although it must be less than or equal to `n`. `DEC_DIG` and `DEC_PRECISION` are defined inside `decimal.h`.

If the content of the given argument is not in native packed decimal format, the behavior is undefined.

Example

```c
#include <decimal.h>

decimal(10,2) p1;
char mem2[3] = { 0x12, 0x34, 0x5c }; /* bad half-byte */
char mem3[3] = { 0x02, 0xa4, 0x5c }; /* bad digit */
char mem4[3] = { 0x02, 0x34, 0x56 }; /* bad sign */
char mem5[3] = { 0x12, 0xa4, 0x56 }; /* bad half-byte, digit and sign */
decimal(4,0) *pp2;
decimal(4,0) *pp3;
decimal(4,0) *pp4;
decimal(4,0) *pp5;
int main(void) {
  p1 = 123456.78d;
  pp2 = (decimal(4,0) *) mem2;
  /* ... */
}
pp3 = (decimal(4,0) *) mem3;
pp4 = (decimal(4,0) *) mem4;
pp5 = (decimal(4,0) *) mem5;

if (decchk(p1) == DEC_VALUE_OK) {
    printf("p1 is a valid decimal representation value.\n");
}
if (decchk(*pp2) == DEC_BAD_NIBBLE) {
    printf("pp2 points to a bad half-byte value!\n");
}
if (decchk(*pp3) == DEC_BAD_DIGIT) {
    printf("pp3 points to an illegal digit!\n");
}
if (decchk(*pp4) == DEC_BAD_SIGN) {
    printf("pp4 points to an illegal sign!\n");
}
/* The wrong way ----- */
if (decchk(*pp5) == DEC_BAD_SIGN) {
    printf("YOU SHOULD NOT GET THIS!!!!!\n");
}  /* The right way ----- */
if ((decchk(*pp5) & DEC_BAD_SIGN) == DEC_BAD_SIGN) {
    printf("pp5 points to an illegal sign!\n");
}
return(0);

Output
p1 is a valid decimal representation value.
pp2 points to a bad half-byte value!
pp3 points to an illegal digit!
pp4 points to an illegal sign!
pp5 points to an illegal sign!

decfix() — Fix Up a Nonpreferred Sign Variable

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <decimal.h>

decimal(n,p) decfix(decimal(n,p) pdec);
```

General Description

The built-in function decfix() accepts a decimal type expression as an argument and returns a decimal value that has the same type and same value as the argument with the correct preferred sign. The function does not change the content of the argument.

The parameter \( n \) can be any integral value between 1 and DEC_DIG. The parameter \( p \) can be any integral value between 0 and DEC_PRECISION, though it must be less than or equal to \( n \). DEC_DIG and DEC_PRECISION are defined inside decimal.h.

If the content of the given argument is not in native packed decimal format, behavior is undefined.

Example

```
#include <decimal.h>

char *ptr;
char mem[3] = { 0x01, 0x23, 0x4A };
decimal(4,0) *pp;
decimal(4,0) p;
int main(void)
{
    pp = (decimal(4,0) *) mem;
p = decfix(pp);
    ptr = (char *) p;
    printf("Before decfix : \%X\%X\%X\n", mem[0], mem[1], mem[2]);
    printf("After decfix : \%X\%X\%X\n", ptr[0], ptr[1], ptr[2]);
    return(0);
}
```

Output

Before decfix : 1234A
After decfix : 1234C

Format

```c
#include <sys/__wlm.h>

int DeleteWorkUnit(wlmetok_t *enclavetoken);
```

General Description

The DeleteWorkUnit() function provides the ability for an application to delete a WLM work unit.

*enclavetoken* Points to a work unit enclave token that was returned from a call to CreateWorkUnit() or ContinueWorkUnit().

Returned Value

If successful, DeleteWorkUnit() returns 0.

If unsuccessful, DeleteWorkUnit() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>

difftime() — Compute Time Difference

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <time.h>

double difftime(time_t time2, time_t time1);
```

General Description

Computes the difference in seconds between `time2` and `time1`, which are calendar times returned by `time()`.

The `difftime()` function returns the difference between two calendar times as a double. The return value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking `difftime()`. The `difftime()` function uses `__isBFP()` to determine which floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) to return on the invoking thread.

Returned Value

Returns the elapsed time in seconds from `time1` to `time2` as a double.

Example

```c
CELEBD04
/* CELEBD04 */

/* This example shows a timing application using &diff. */
/* The example calculates how long, on average, it takes a */
/* user to input some data to the program. */

#include <time.h>
#include <stdio.h>

int main(void)
{
    time_t start, finish;
    int i, n, num;
    int answer;

    printf("11 x 55 = ? Enter your answer below\n");
    time(&start);
    scanf("%d", &answer);
    time(&finish);
    printf("You answered %s in %.0f seconds.\n", answer == 605 ? "correctly" : "incorrectly",
             difftime(finish, start));
}
```
Output

11 x 55 = ? Enter your answer below

605

You answered correctly in 20 seconds

dirname() — Report the Parent Directory of a Pathname

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <libgen.h>

char *dirname(char *path);
```

General Description

The `dirname()` function takes a pointer to a character string that contains a pathname, and returns a pointer to a string that is a pathname of the parent directory of that file. Trailing ‘/’ characters in the path are not counted as part of the path.

If `path` does not contain a ‘/’ then `dirname()` returns a pointer to the string “.”. If `path` is a NULL pointer or points to an empty string, `dirname()` returns a pointer to the string “.”.

The `dirname()` function may modify the string pointed to by `path`.

Examples:

<table>
<thead>
<tr>
<th>Input String</th>
<th>Output String</th>
</tr>
</thead>
<tbody>
<tr>
<td>“/usr/lib”</td>
<td>“/usr”</td>
</tr>
<tr>
<td>“/usr/”</td>
<td>“/”</td>
</tr>
<tr>
<td>“usr”</td>
<td>“.”</td>
</tr>
<tr>
<td>“/”</td>
<td>“/”</td>
</tr>
<tr>
<td>“.”</td>
<td>“.”</td>
</tr>
<tr>
<td>“..”</td>
<td>“.”</td>
</tr>
</tbody>
</table>

Returned Value

If successful, `dirname()` returns a pointer to a string that is the parent directory of `path`.

If `path` is a NULL pointer or points to an empty string, `dirname()` returns a pointer to a string “.”.

There are no `errno` values defined.

__discarddata

__discarddata() — Release Pages Backing Virtual Storage

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>OS/390 V2R10</td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

int __discarddata(void *addr, size_t size);
```

General Description

The __discarddata() function is used to release segments of real storage backing virtual storage. Segments backing virtual storage are released beginning at location `addr` for a length of `size`. For AMODE 31, the `addr` must begin on a page (4K) boundary and size must be a multiple of 4K. For AMODE 64, the `addr` must begin on a segment (1 MB) boundary and size must be a multiple of 1 MB.

Returned Value

If successful, __discarddata() returns 0.

If unsuccessful, because `addr` does not begin on a page (4K) boundary or `size` is not a multiple of 4K, __discarddata() returns -1.

There are no errno values defined.

Related Information

- "stdlib.h" on page 85
DisconnectServer() — Disconnect from WLM Server

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX System Services</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__wlm.h>

int DisconnectServer(unsigned long *conn_tkn);
```

AMODE 64

```c
#include <sys/__wlm.h>

int DisconnectServer(unsigned int *conn_tkn);
```

General Description

The DisconnectServer function provides the ability for an application to disconnect from WLM.

*conn_tkn* Specifies the connect token that represents the WLM connection that is to be disconnected.

Returned Value

If successful, DisconnectServer() returns 0.

If unsuccessful, DisconnectServer() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>
</tr>
<tr>

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

div_t div(int numerator, int denominator);
div_t div(long numerator, long denominator); /* C++ only */
```

General Description

Calculates the quotient and remainder of the division of `numerator` by `denominator`.

Special Behavior for C++:

For C++ applications, div() is also overloaded for the type long.

Returned Value

Returns a structure of type `div_t`, containing both the quotient `int quot` and the remainder `int rem`. This structure is defined in stdlib.h. If the returned value cannot be represented, the behavior of div() is undefined. If `denominator` is 0, the same exception will be raised as if you divided by 0. That is, you get the error CEE3209S (Fixed-point divide exception).

dlclose

dlclose() — Close a dlopen() object

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R6</td>
</tr>
</tbody>
</table>

Format

#define _UNIX03_SOURCE
#include <dlfcn.h>

void dlclose(void *handle);

General Description

Informs the system that the Dynamic Link Library (DLL) referenced by a handle returned from a previous dlopen() invocation is no longer needed by the application. Once a DLL has been closed, an application should assume that its symbols and the symbols of any dependent DLLs are no longer available to dlsym().

Returned Value

NULL is returned if the referenced DLL was successfully closed. If the DLL could not be closed, or if handle does not refer to an open DLL, a non-zero value will be returned.

Application Usage

1. A conforming application should use a handle returned from a dlopen() invocation only within a given scope, bracketed by the dlopen() and dlclose() operations. The value of a handle must be treated as an opaque object by the application, used only in calls to dlsym() and dlclose().
2. DLLs that are loaded explicitly, that is with dlopen(), and are not freed with a corresponding call to dlclose(), are freed automatically at enclave termination in LIFO sequence.
3. Non-local C++ static destructors defined in a DLL are executed only once, when the DLL program object is deleted from memory.
4. More detailed diagnostic information is available through dlerror(), the_EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.
5. This function is not available under SPC, MTF and CSP environments.

Example

The following example illustrates use of dlopen() and dlclose():

```c
/* Open a dynamic library and then close it ... */
#include <dlfcn.h>
void *mylib;
int eret;
mylib = dlopen("mylib.so", RTLD_LOCAL | RTLD_LAZY);
... eret = dlclose(mylib);
...```
Related Information

- "dlerror() — Get diagnostic information" on page 426
- "dlopen() — Gain access to a Dynamic Link Library (DLL)" on page 427
- "dlsym() — Obtain the address of a symbol from a dlopen() object" on page 430
- "dlfcn.h" on page 40
dlerror

**dlerror() — Get diagnostic information**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R6</td>
</tr>
</tbody>
</table>

**Format**

```c
#define _UNIX03_SOURCE
#include <dlfcn.h>

void dlerror(void);
```

**General Description**

Returns a null-terminated character string (with no trailing <newline>) that describes the last error that occurred while processing a DLL by dlopen(), dlsym(), or dlclose(). NULL is returned if no errors have occurred since the last invocation of dlerror().

**Note:** dlerror() is thread safe, so the information returned describes the last error that occurred on that thread.

**Returned Value**

A null-terminated character string is returned if successful, otherwise NULL is returned.

**Application Usage**

1. Messages returned by dlerror() reside in a static buffer that is overwritten on each new call to dlerror() on that thread.
2. Application code should not write to this buffer.
3. Programs wishing to preserve an error message should make their own copies of that message.
4. This function is not available under SPC, MTF and CSP environments.

**Example**

The following example prints out the last dynamic linking error:

```c
... 
#include <dlfcn.h>

char *errstr;

errstr = dlerror();
if (errstr != NULL)
    printf("A dynamic linking error occurred: %%s\n", errstr);
...
```

dlopen() — Gain access to a Dynamic Link Library (DLL)

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R6</td>
</tr>
</tbody>
</table>

Format

```c
#define _UNIX03_SOURCE
#include <dlfcn.h>

void *dlopen(const char *file, int mode);
```

General Description

Makes the Dynamic Link Library (DLL) specified by `file` available to the calling program.

If the `file` argument contains a single slash ("/"), it is used as the UNIX file system pathname for the DLL. If the environment variable `LIBPATH` is set, each directory listed will be searched for the DLL. Otherwise, the current directory will be searched.

**Note:** Searching for a DLL in the UNIX file system is case-sensitive.

If the `file` argument begins with two slashes ("//"), then an attempt is made to load the DLL from the caller’s MVS load library search order (in order: STEPLIB/JOBLIB, LPA, Link List). The DLL name must be eight characters or less, and is converted to uppercase.

If the `file` argument doesn’t begin with one or two slashes ("/" or "/"), and doesn’t contain a single slash ("/") anywhere in the name, then it is ambiguous as to where the DLL resides.

- If the POSIX(ON) run-time option is specified, then the UNIX file system is searched first for the DLL, and if not found, the MVS load library is searched.
- If the POSIX(OFF) run-time option is specified, then the MVS load library is searched first for the DLL, and if not found, the UNIX file system is searched.

Under the CICS environment, the search sequence for DLL load modules is the same as that used for dynamically loaded CICS modules. Loading DLLs from the UNIX file system is not supported under CICS.

More details on how DLLs are located can be found in section "Loading DLLs" of the z/OS Language Environment Programming Guide.

A successful call returns a handle which the caller may use on subsequent calls to `dlsym()` and `dlclose()`. The value of this handle should not be interpreted in any way by the caller.

Only a single copy of a DLL is brought into the address space, even if invoked multiple times for the same DLL, and even if different values of the `file` parameter are used to reference the same DLL.
The `mode` parameter describes how `dlopen()` operates on a file with respect to the processing of dependent DLLs and the scope of visibility of the symbols provided within `file`. If a `file` is specified in multiple invocations, `mode` is interpreted at each invocation. The `mode` is a bitwise-OR of the values specified.

### Mode Values

When a DLL is loaded, it may contain implicit references to symbols in another “dependent” DLL, whose addresses are not known until that DLL is loaded. These implicit references must be relocated before the symbols can be accessed, which means loading the DLL containing the references. The `mode` parameter governs when these relocations (and loads) take place and may have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>RTLD_LAZY</code></td>
<td>When possible, the loading of dependent DLLs, and resolution of symbols contained therein, may be deferred until the first reference to one of those symbols. This is the default behavior.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Once <code>RTLD_NOW</code> has been specified, all relocations will have been completed causing additional <code>RTLD_NOW</code> operations to be redundant and any further <code>RTLD_LAZY</code> operations irrelevant.</td>
</tr>
<tr>
<td><code>RTLD_NOW</code></td>
<td>Load all dependent DLLs for the DLL being loaded and resolve all symbols before returning. This may include zero or more levels of nested dependent DLLs, all of which are loaded at this time.</td>
</tr>
<tr>
<td><code>RTLD_GLOBAL</code></td>
<td>Allows symbols in the DLL being loaded to be visible when resolving symbols through the global symbol object that was opened with <code>dlopen(NULL,0)</code>. All dependent DLLs are always implicitly loaded as if <code>RTLD_GLOBAL</code> had been specified. This is the default behavior.</td>
</tr>
<tr>
<td><code>RTLD_LOCAL</code></td>
<td>Prevents symbols in the DLL being loaded to be visible when resolving symbols through the global symbol object that was opened with <code>dlopen(NULL,0)</code>. All dependent DLLs of this DLL continue to be implicitly loaded as if <code>RTLD_GLOBAL</code> had been specified.</td>
</tr>
</tbody>
</table>

If a subsequent call is made for this same DLL with a `mode` of `RTLD_GLOBAL`, then the DLL will maintain the `RTLD_GLOBAL` status regardless of any previous or future specification of `RTLD_LOCAL`, as long as the DLL remains loaded (see `dlclose()`).

If the value of `file` is NULL, `dlopen()` returns a “global symbol object” handle. This object will provide access (via `dlsym()`) to the symbols exported from:

- The main application, and dependent DLLs for the main application that were loaded at program start-up, and
- The set of DLLs loaded using `dlopen()` with the `RTLD_GLOBAL` flag. This set of DLLs can change dynamically as other DLLs are opened and closed.

Symbols introduced by the call to `dlopen()` for a DLL, and available through `dlsym()`, are those which are exported by the DLL. Typically such symbols will be those identified by a `#pragma export` in C, or with the `EXPORTALL` compile option. For
details on how to specify exported data and functions, for C/C++ as well as other
languages, refer to section "Building a Simple DLL" in the z/OS Language
Environment Programming Guide.

Returned Value
NULL is returned if:
• file cannot be found or opened for reading
• file is not in correct DLL executable format
• an error occurred during the process of loading file, or relocating its symbolic
  references

Application Usage
1. For details on how to create and use DLLs, refer to Chapter 4 of the z/OS
   Language Environment Programming Guide.
2. The AMODE of the application must be the same as the AMODE of the DLL.
3. Non-local C++ static constructors defined in a DLL are executed only once,
   when the DLL program object is physically loaded into memory.
4. More detailed diagnostic information is available through dlerror(), the
   _EDC_DLL_DIAG environment variable, and the Language Environment DLL
   Failure control block (CEEDLLF) chain.
5. This function is not available under SPC, MTF and CSP environments.

Example
The following example illustrates use of dlopen() and dlclose():
...
/* Open a dynamic library and then close it ... */
#include <dlfcn.h>

void *mylib;
int eret;

mylib = dlopen("mylib.so", RTLD_LOCAL | RTLD_LAZY);
...
ere = dlclose(mylib);
...

Related Information
• "dlclose() — Close a dlopen() object" on page 424

• "dlsym() — Obtain the address of a symbol from a dlopen() object" on page 430
• "dlfcn.h" on page 40
**dlsym**

**dlsym() — Obtain the address of a symbol from a dlopen() object**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R6</td>
</tr>
</tbody>
</table>

**Format**

```c
#define __UNIX03_SOURCE
#include <dlfcn.h>

void *dlsym(void *__restrict__ handle, const char *__restrict__ name);
```

**General Description**

Obtains the address of a symbol defined within a Dynamic Link Library (DLL) made accessible through a dlopen() call. The `handle` argument is the value returned from a call to dlopen() (which has not been released by a call to dlclose()), and `name` is the symbol’s name as a character string.

The DLL that was loaded by dlopen() will be searched for the named symbol. If the symbol is not found in that DLL, then the dependent DLLs of that DLL will be searched, followed by any dependents of those, and continuing in a breadth-first manner until the named symbol is found or all dependent DLLs have been searched. This search order determines how duplicate symbols in different DLLs will be found, although the order in which dependent DLLs at the same level are searched is indeterminate.

Also note that a search of dependent DLLs by dlsym() will not result in unloaded dependent DLLs being loaded. Only the dependent DLLs loaded as part of the call to dlopen() will be searched. If the full set of dependent DLLs need to be available to subsequent calls to dlsym(), make sure the DLL is opened with the `RTLD_NOW` load flag. It is indeterminate which dependent DLLs are loaded when `RTLD_LAZY` is specified.

The only exception to this is the global symbol object obtained via a dlopen(NULL,0) call, in which case all DLLs (excluding those opened with `RTLD_LOCAL`) are searched in the order in which they were loaded.

**Notes:**

- The named symbol can be either an exported data item or function.
- DLLs are enclave level resources. See [z/OS XL C/C++ Programming Guide](https://www.ibm.com/support/docview/groups?rs=510&url=/en/ibm/zos/bm<IEnumerable%20name%20for%20the%20product%20or%20service%20on%20the%20Z/OS%20Print%20Library%20Web%20page> for more information about the use of DLLs in a multi-threaded environment.

**Returned Value**

NULL is returned:

- If `handle` does not refer to a valid DLL opened by dlopen(),
- or the named symbol (`name`) cannot be found within any of the DLLs associated with `handle`. 
Application Usage

1. C++ symbol names should be passed to dlsym() in mangled form; dlsym() does not perform any name mangling on behalf of the calling application.

2. More detailed diagnostic information is available through dlerror(), the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.

3. This function is not available under SPC, MTF and CSP environments.

Example

The following example shows how dlopen() and dlsym() can be used to access either function or data objects. For simplicity, error checking has been omitted.

```c
void *handle;
int *iptr, (*fptr)(int);

/* open the needed object */
handle = dlopen("/usr/home/me/libfoo.so", RTLD_LOCAL | RTLD_LAZY);

/* find the address of function and data objects */
fptr = (int (*)(int))dlsym(handle, "my_function");
iptr = (int *)dlsym(handle, "my_object");

/* invoke function, passing value of integer as a parameter */
(*fptr)(*iptr);
```

Related Information

dllfree

dllfree() — Free the Supplied DLL

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <dll.h>

int dllfree(dllhandle *dllHandle);
```

General Description

Frees the supplied DLL. It also deletes the DLL from memory if the handle was the last handle accessing the DLL.

Notes:

- This function is deprecated; use dlclose() instead.
- This function is not available under SPC, MTF and CSP environments.
- If a DLL is loaded implicitly, it cannot be deleted with dllfree(). For more information on the implicit use of DLLs, see z/OS XL C/C++ Programming Guide.
- DLLs that are loaded explicitly, that is with dllload(), and are not freed with a corresponding call to dllfree(), are freed automatically at enclave termination in LIFO sequence.
- C++ destructors are executed only once, when the DLL load module is physically deleted.

Returned Value

dllfree() returns one of the following values and set errno if the return code is not 0:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful</td>
</tr>
<tr>
<td>1</td>
<td>The dllHandle supplied is NULL or dllhandle is inactive.</td>
</tr>
<tr>
<td>2</td>
<td>There are no DLLs to be deleted.</td>
</tr>
<tr>
<td>3</td>
<td>DLL is not physically deleted because there is another dllHandle for this DLL or there is an implicit reference to the DLL.</td>
</tr>
<tr>
<td>4</td>
<td>Delete of DLL failed.</td>
</tr>
<tr>
<td>5</td>
<td>No match is found for input dllHandle.</td>
</tr>
<tr>
<td>6</td>
<td>Not supported under this environment.</td>
</tr>
<tr>
<td>7</td>
<td>C++ destructors are currently running for this DLL. A dllfree() is already in progress.</td>
</tr>
<tr>
<td>8</td>
<td>The handle passed to dllfree() was obtained from dlopen().</td>
</tr>
</tbody>
</table>
Application Usage

1. More detailed diagnostic information is available through the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain. The default action is to issue an error message to the Language Environment message file.

Example

CELEBDL4
/* CELEBDL4

The following example shows how to use dllfree() to free the dllhandle for the DLL stream.
*/

#include <stdio.h>
#include <dl1.h>
#include <stdlib.h>

int main()
{
    dllhandle *handle;
    char *name="stream";
    int (*fptr1)(int);
    int (*fptr)(int);
    int *ptr_var1;
    int *ptr_var;
    int rc=0;

    handle = dllload(name); /* call to stream DLL */
    if (handle == NULL) {
        perror("failed on call to stream DLL");
        exit(-1);
    }

    fptr1 = (int (*)(int)) dllqueryfn(handle,"f1");
    /* retrieving f1 function */
    if (fptr == NULL) {
        perror("failed on retrieving f1 function");
        exit(-2);
    }

    ptr_var1 = dllqueryvar(handle,"var1");
    /* retrieving var1 variable */
    if (ptr_var1 == NULL) {
        perror("failed on retrieving var1 variable");
        exit(-3);
    }

    rc = fptr(*ptr_var1); /* execute DLL function f1 */
    *ptr_var1++;
    /* increment value of var1 */

    rc = dllfree(handle); /* freeing handle to stream DLL */
    if (rc != 0) {
        perror("failed on dllfree call");
    }
    return (0);
}

dllload() — Load the DLL and Connect it to the Application

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <dll.h>

dllhandle *dllload(const char *dllName);
```

General Description

**Note:** This function is deprecated; use dlopen() instead.

Loads the Dynamic Link Library (DLL) into memory (if it has not been previously loaded) and connects it to the application. The function that called the DLL receives a handle that uniquely identifies the requested DLL for subsequent explicit requests for that DLL.

A different handle is returned for each successful call to dllload(). A DLL is physically loaded only once, even though there may be many calls to dllload(). C++ constructors are run only once.

The `dllName` identifies the DLL load module to be loaded. It must be a character string terminated with the NULL character. The DLL module must be a member of a PDS or an alias to it.

**Note:** The `AMODE` of the application must be the same as the `AMODE` of the DLL load module.

This function is not available under SPC, MTF and CSP environments.

The `dllName` identifies the DLL load to be loaded. It must be a character string, terminated with the NULL character. The DLL module must be a member of a PDS or an alias to it.

If the file argument contains a single slash (`/`), it is used as the UNIX file system pathname for the DLL. If the environment variable LIBPATH is set, each directory listed will be searched for the DLL. Otherwise, the current directory will be searched.

**Note:** Searching for a DLL in the UNIX file system is case-sensitive.

If the file argument begins with two slashes (`//`), then an attempt is made to load the DLL from the caller’s MVS load library search order (in order: STEPLIB/JOBLIB, LPA, Link List). The DLL name must be eight characters or less, and is converted to uppercase. Note that qualified DLL names are not supported and the MVS load library search order is used (for example, update or use STEPLIB to specify any number of qualifiers to be included in the search).
dlload

If the file argument doesn’t begin with one or two slashes (’/’ or ‘//’), and doesn’t contain a single slash (’/’) anywhere in the name, then it is ambiguous as to where the DLL resides.

- If the POSIX(ON) run-time option is specified, then the UNIX file system is searched first for the DLL, and if not found, the MVS load library is searched.
- If the POSIX(OFF) run-time option is specified, then the MVS load library is searched first for the DLL, and if not found, the UNIX file system is searched.

Under CICS environment, the search sequence for DLL load modules is the same as that used for dynamically loaded CICS modules. Loading DLLs from the UNIX file system is not supported under CICS.

For a description of how a DLL is loaded and the search sequence used, refer to the section on Loading DLLs in z/OS Language Environment Programming Guide.

Returned Value

If successful, dlload() returns a unique handle that identifies the DLL.

If unsuccessful, dlload() returns NULL and may set errno to one of the following values:

Error Code      Description

ELEFENCE        The DLL contains a member language not supported on this version of the operating system.

ENOEXEC         The new process image file has the appropriate access permission but is not in the proper format.

Note: Reason codes further qualify the errno. For most of the reason codes, see z/OS UNIX System Services Messages and Codes.

For ENOEXEC, the reason codes are:

<table>
<thead>
<tr>
<th>Reason Code</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>X’xxxx0C27’</td>
<td>The target UNIX file system file is not in the correct format to be an executable file.</td>
</tr>
<tr>
<td>X’xxxx0C31’</td>
<td>The target UNIX file system file is built at a level that is higher than that supported by the running system.</td>
</tr>
</tbody>
</table>

Application Usage

1. More detailed diagnostic information is available through the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.

Example

CELEBDL1

/* CELEBDL1

The following example shows how to invoke dlload() functions from a simple C application.

*/

#include <stdio.h>
#include <dll.h>

main() {
    dllhandle *handle;
    char *name="stream";

    handle = dllload(name);
    if (handle == NULL) {
        perror("failed on dllload of stream DLL");
        exit(-1);
    }
}

dllqueryfn

daqueryfn() — Obtain a Pointer to a DLL Function

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <dll.h>

void (*dllqueryfn(dllhandle *dllHandle, const char *funcName))();
```

General Description

**Note:** This function is deprecated; use dlsym() instead.

Obtains a pointer to a DLL function (funcName). It uses the dllHandle returned from a previous successful call to dllload() for input. funcName represents the name of an exported function from the DLL. It must be a character string terminated with the NULL character.

This function is not available under the SPC, MTF, and CSP environments.

Returned Value

If successful, dllqueryfn() returns a pointer to a function, funcName, that can be used to invoke the desired function in a DLL.

If unsuccessful, dllqueryfn() returns NULL and sets errno.

Application Usage

1. More detailed diagnostic information is available through the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDDLLF) chain.

Example

```c
CELEBDL2

/* CELEBDL2

The following example shows how to use dllqueryfn() to obtain a pointer to a function, f1 that is in DLL load module stream.

*/
#include <stdio.h>
#include <dll.h>

main()
{
dllhandle *handle;
char *name="stream";
int (*fptr1)();

handle = dllload(name);
if (handle == NULL) {
    perror("failed on dllload of stream DLL");
    exit(-1);
}
```
fptr1 = (int (*)(())) dllqueryfn(handle,"f1");
if (fptr1 == NULL) {
    perror("failed on retrieving f1 function");
    exit (-2);
}

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <dll.h>

void* dllqueryvar(dllhandle *dllHandle, const char *varName);
```

General Description

Obtains a pointer to a DLL variable (varName). It uses the dllHandle returned from a previous successful call to dllload() for input. varName represents the name of an exported variable from the DLL. It must be a character string terminated with the NULL character.

This function is not available under SPC, MTF and CSP environments.

Returned Value

If successful, dllqueryvar() returns a pointer to a variable in the storage of the DLL.

If unsuccessful, dllqueryvar() returns NULL and sets errno.

Application Usage

1. More detailed diagnostic information is available through the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.

Example

```
CELEBDL3
/* CELEBDL3

The following example shows how to use dllqueryvar() to obtain a pointer to a variable, var1, that is in DLL load module stream.

*/
#include <stdio.h>
#include <dll.h>

int main() {
    dllhandle *handle;
    char *name="stream";
    int (*fpotr1)(int);
    int *ptr_var1;
    int rc=0;

    handle = dllload(name);
    if (handle == NULL) {
        perror("failed on dllload of stream DLL");
        exit(-1);
    }

    fpotr1 = (int (*)(int)) dllqueryfn(handle,"f1");
```
/* retrieving f1 function */
if (fptr1 == NULL) {
    perror("failed on retrieving f1 function");
    exit(-2);
}

ptr_var1 = dllqueryvar(handle,"var1");
if (ptr_var1 == NULL) {
    perror("failed on retrieving var1 variable");
    exit(-3);
}

**dn_comp**

**dn_comp() — Resolver Domain Name Compression**

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSD 4.3</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
</tbody>
</table>

### Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_comp(const char *exp_dn, u_char *comp_dn, int length,
            u_char **dnptrs, u_char **lastdnptr);
```

### General Description

The `dn_comp()` function compresses the domain name `exp_dn` and stores it in `comp_dn`. The size of the compressed name is returned or -1 if there were errors. The size of the array pointed to by `comp_dn` is given by `length`. The compression uses an array of pointers `dnptrs` to previously-compressed names in the current message. The first pointer points to the beginning of the message and the list ends with NULL. The limit to the array is specified by `lastdnptr`.

A side effect of `dn_comp()` is to update the list of pointers for labels inserted into the message as the name is compressed. If `dnptr` is NULL, names are not compressed. If `lastdnptr` is NULL, the list of labels is not updated.

**Note:** The `dn_comp()` function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII Support” on page 2495 for details.

### Returned Value

If successful, `dn_comp()` returns the size of the compressed name.

If unsuccessful, `dn_comp()` returns -1 to report the error, when the name to be compressed was not found before the end of the buffer was reached.

There are no documented errno values.

dn_expand

dn_expand() — Resolver Domain Name Expansion

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSD 4.3</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_expand(const u_char *msg, const u_char *eomorig,
              const u_char *comp_dn, char *exp_dn, int length);
```

General Description

The `dn_expand()` function expands the compressed domain name `comp_dn` to a full domain name. The compressed name is contained in a query or reply message; `msg` is a pointer to the beginning of the message. The expanded name is placed in the buffer indicated by `exp_dn` which is of size `length`. The size of the expanded name is returned or -1 if there was an error.

**Note:** The `dn_expand()` function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII Support” on page 2495 for details.

Returned Value

If successful, `dn_expand()` returns the size of the expanded name.

If unsuccessful, `dn_expand()` returns -1 to report the error, when the name to be expanded was not found before the end of the buffer was reached.

There are no documented errno values.

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_find(u_char *exp_dn, u_char *msg, u_char **dnptrs, u_char **lastdnptr);
```

General Description

The dn_find() function will search for the expanded name `exp_dn` in the list of previously compressed names `dnptrs`.

`dnptrs` is the pointer to the first name in the list, not the pointer to the start of the message. The limit to the array is specified by `lastdnptr`.

**Note:** The dn_find() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII Support " on page 2495 for details.

Returned Value

If successful, dn_find() returns the offset of the expanded name `exp_dn` found in the message.

If unsuccessful, dn_find() returns -1 to report the error, when the name was not found before the end of the list was reached.

There are no documented errno values.

</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_skipname(const u_char *comp_dn, u_char *eom);
```

General Description

The `dn_skipname()` function skips the compressed domain name `comp_dn` and returns the position in the answer buffer that follows the `comp_dn` compressed domain name. If the information supplied in `comp_dn` is not a compressed domain name, -1 is returned to report the error.

Note: The `dn_skipname()` function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII Support " on page 2495 for details.

Returned Value

If successful, `dn_skipname()` returns the position in the answer buffer that follows the `comp_dn` compressed domain name.

If unsuccessful, `dn_skipname()` returns -1 to report the error, when the name to be skipped was not found before the end of the buffer was reached.

There are no documented errno values.

drand48() — Pseudo-Random Number Generator

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdlib.h>

double drand48(void);
```

General Description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval \([0.0,1.0)\). These functions have been extended so that the returned value will be in the proper floating-point format (hexadecimal or IEEE) based on the floating-point mode of the invoking thread.

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval \([0,2^{31})\).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval \([-2^{31},2^{31})\).

The drand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, \(X(i)\), according to the linear congruential formula:

\[
X(n+1) = (ax(n) + c) \mod (2^{48}) \quad n \geq 0
\]

The initial values of \(X\), \(a\), and \(c\) are:

\[
X(0) = 1
\]

\[
a = 5deece66d \quad (\text{base } 16)
\]

\[
c = b \quad (\text{base } 16)
\]

C/370 provides storage to save the most recent 48-bit integer value of the sequence, \(X(i)\). This storage is shared by the drand48(), lrand48() and mrand48() functions. The value, \(X(n)\), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function. Likewise, the values of \(a\) and \(c\), may be changed by calling the lcong48() function. Thereafter, whenever the seed48() or srand48() function is called to change \(X(n)\), the initial values of \(a\) and \(c\) are also reestablished.

Special Behavior for z/OS UNIX Services

You can make the drand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.
drand48

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, and the drand48() function is called from thread t, the drand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread t. The sequence of values for a thread is generated according to the linear congruential formula:

\[ X(t,n+1) = (a(t)X(t,n) + c(t)) \mod (2^{48}) \quad n \geq 0 \]

The initial values of X(t), a(t) and c(t) for the thread t are:

\[ X(t,0) = 1 \]
\[ a(t) = 5deece66d \text{ (base 16)} \]
\[ c(t) = b \text{ (base 16)} \]

C/370 provides storage which is specific to the thread t to save the most recent 48-bit integer value of the sequence, X(t,i), generated by the drand48(), lrand48() or mrand48() function. The value, X(t,n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function from the thread t. Likewise, the values of a(t) and c(t) for thread t may be changed by calling the lcong48() function from the thread. Thereafter, whenever the seed48() or srand48() function is called from the thread t to change X(t,n), the initial values of a(t) and c(t) are also reestablished.

Returned Value

drand48() transforms the generated 48-bit value, X(n+1), to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

Special Behavior for z/OS UNIX Services

If thread-specific behavior is requested for the drand48 family and rand48() is called on thread t, drand48() transforms the generated 48-bit value, X(t,n+1), to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

int dup(int fildes);
```

General Description

Returns a new file descriptor that is the lowest numbered available descriptor. The new file descriptor refers to the same open file as `fildes` and shares any locks that may be associated with `fildes`.

The following operations are equivalent:
```
fds = dup(fildes);
fds = fcntl(fildes, F_DUPFD, 0);
```

For further information, see "fcntl() — Control Open File Descriptors" on page 527.

Note: When `fildes` is an XTI endpoint, the lowest numbered available file descriptor must not exceed 65535.

Returned Value

If successful, dup() returns a new file descriptor.

If unsuccessful, dup() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EMFILE</td>
<td>The process has already reached its maximum number of open file descriptors.</td>
</tr>
</tbody>
</table>

Example

```c
CELEBD05
/* CELEBD05

This example duplicates an open file descriptor, using dup().

*/
#define _POSIX_SOURCE
#include <errno.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
```
void print_inode(int fd) {
    struct stat info;
    if (fstat(fd, &info) != 0)
        fprintf(stderr, "fstat() error for fd %d: %s\n", fd, strerror(errno));
    else
        printf("The inode of fd %d is %d\n", fd, (int) info.st_ino);
}

main() {
    int fd;
    if ((fd = dup(0)) < 0)
        perror("&dupf error");
    else {
        print_inode(0);
        print_inode(fd);
        puts("The file descriptors are different but");
        puts("they point to the same file.");
        close(fd);
    }
}

Output
The inode of fd 0 is 30
The inode of fd 3 is 30
The file descriptors are different but they point to the same file.

**dup2() — Duplicate an Open File Descriptor to Another**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _POSIX_SOURCE
#include <unistd.h>

int dup2(int fd1, int fd2);
```

**General Description**

Returns a file descriptor with the value `fd2`. `fd2` now refers to the same file as `fd1`, and the file that was previously referred to by `fd2` is closed. The following conditions apply:

- If `fd2` is less than 0 or greater than `OPEN_MAX`, `dup2()` returns −1 and sets `errno` to `EBADF`.
- If `fd1` is a valid file descriptor and is equal to `fd2`, `dup2()` returns `fd2` without closing it.
- If `fd1` is not a valid file descriptor, `dup2()` fails and does not close `fd2`.
- If a file descriptor does not already exist, `dup2()` can be used to create one, a duplicate of `fd1`.

**Note:** If `fd1` is an XTI endpoint, `fd2` must not exceed 65535.

**Returned Value**

If successful, `dup2()` returns `fd2`.

If unsuccessful, `dup2()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fd1</code> is not a valid file descriptor, or <code>fd2</code> is less than 0 or greater than <code>OPEN_MAX</code>.</td>
</tr>
<tr>
<td>EINTR</td>
<td><code>dup2()</code> was interrupted by a signal.</td>
</tr>
</tbody>
</table>

**Example**

```c
CELEBD06

/* CELEBD06

   This example duplicates an open file descriptor, using `dup2()`.

*/

#define _POSIX_SOURCE
#include <errno.h>
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
```
#include <stdio.h>

void print_inode(int fd)
{
    struct stat info;
    if (fstat(fd, &info) != 0)
        fprintf(stderr, "fstat() error for fd %d: %s\n", fd, strerror(errno));
    else
        printf("The inode of fd %d is %d\n", fd, (int) info.st_ino);
}

main()
{
    int fd;
    char fn[]="dup2.file";

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else
    {
        print_inode(fd);
        if ((fd = dup2(0, fd)) < 0)
            perror("dup2() error");
        else
        {
            puts("After dup2()...");
            print_inode(0);
            print_inode(fd);
            puts("The file descriptors are different but they");
            puts("point to the same file which is different than");
            puts("the file that the second fd originally pointed to.");
            close(fd);
        }
        unlink(fn);
    }
}

Output
The inode of fd 3 is 3031
After dup2()...
The inode of fd 0 is 30
The inode of fd 3 is 30
The file descriptors are different but they
point to the same file which is different than
the file that the second fd originally pointed to.

dy alloc ( ) — Allocate a Data Set

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <dynit.h>

int dynalloc (__dyn_t *dyn_parms);
```

General Description

Dynamically allocates a data set using the SVC 99 service on MVS, by building an SVC 99 parameter list based on parameters specified in `dyn_parms`. `dynalloc()` corresponds to verb code 1 for SVC 99.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED), any relevant information in the header is also exposed.

For a description of the `__dyn_t` structure, see Table 24 on page 454. For more information on SVC 99, the SVC 99 extension block, and the text unit keys and values, refer to z/OS MVS Programming: Authorized Assembler Services Guide, SA22-7608.

The Request Block Extension and the Error Message Parameter list can be used to process the messages returned by SVC99 when an error occurs. To use this feature you must allocate and initialize these structures using the processes described in the MVS manuals. You must also inform the `dynalloc()` function that they are present by assigning their addresses to `__rbx` or `__emsgparmlist`.

Because additional fields have been added to the `__dyn_t` structure, you should recompile existing source code with the latest dynit.h header file to access the new fields.

Some values, such as `ddname` and `dsname`, will be converted to uppercase internally when they are used by the `dynalloc()` function.

To dynamically allocate a data set on MVS, you should:

- Invoke `dyninit()` with a variable of type `__dyn_t`.
- Assign values to the appropriate fields in the variable that will satisfy the `svc99()` request.
- Invoke `dynalloc()` with this variable.

</tr>
</tbody>
</table>

\(^1\) If an element exceeds its maximum allowable length, it is truncated to that length.
Special Behavior for POSIX C

For POSIX C programs, allocations established by dynalloc() persist neither after an exec nor in the child process after fork(). See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information about using POSIX support.

Special Behavior for Enhanced ASCII

When compiled ASCII, there is one input element in the __dyn_t structure that must contain EBCDIC text strings and there is a consideration to note with respect to retrieval of error messages related to a dynamic allocation failure. On input, any character data provided in __miscitems must be specified in the EBCDIC codeset. The __dynalloc() function does not decode the text units and convert the character data. The text units are passed directly to the system. When __emsgparmlist is specified, indicating intent to retrieve error messages using the IEFDB476 service, it should be noted that all error messages returned by the service will be in the EBCDIC codeset.

Note: The dynalloc() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII Support " on page 2495 for details.

Special behavior for AMODE 64

The __dyn_t structure's definition is changed to require three of its pointer elements to be 32 bits wide. This is because the system services that work with these control structures require 31-bit addressable storage. The __miscitems are additional text units that are not already supported by elements of the __dyn_t structure. These are propagated by dynalloc() directly to into an SVC 99 call. The __rbx is propagated by dynalloc() directly into an SVC 99 call. The __emsgparmlist address is designed to be passed as a parameter to the IEFDB476 service, which is an AMODE 31 service, to retrieve messages associated with a dynamic allocation failure. The __dyn_t structure itself can be in 64-bit addressable storage. The __dyn_t structure must be initialized using dyninit() macro defined in <dyninit.h> to ensure the proper "hidden" version indicator is used. Improper initialization of the __dyn_t structure will result in undefined behavior.

Returned Value

If successful under MVS, dynalloc() returns 0.

If SVC 99 is not supported on your system, or if a text string passed to SVC 99 cannot be built from a field in the dyn_parms structure, a negative value is returned.

The value −1 is returned if there is not sufficient storage to process all the text units. Otherwise, the return code is the value returned from SVC 99, and the error and information codes are found in those fields of the dyn_parms structure.

For example, if you pass NULL to dynalloc(), the return code is nonzero.

For more information on return codes, refer to z/OS MVS Programming: Authorized Assembler Services Guide, SA22-7608.

Example

CELEBD07
This example dynamically allocates a data set.

```c
#include <dynit.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#define ZERO 0

int main () {
  __dyn_t ip;
  dyninit(&ip);

  ip.__ddname = "mydd"; /* MYDD DD */
  ip.__dsname = "PLIXXX.MY.DATASET"; /* DSN='PLIXXX.MY.DATASET' */
  ip.__status = __DISP_NEW; /* DISP=(NEW,CATLG) */
  ip.__normdisp = __DISP_CATLG;
  ip.__alcunit = __CYL; /* SPACE=(CYL,(2,1)), */
  ip.__primary = 2;
  ip.__secondary = 1;
  ip.__dirblk = 1;
  ip.__misc_flags = __RELEASE & __CONTIG; /* RLSE,CONTIG */
  ip.__dsorg = __DSORG_PO; /* DCB=(DSORG=PO, */
  ip.__recfm = F + B + A; /* RECFM=FBA, */
  ip.__lrecl = 121; /* LRECL=121, */
  ip.__blksize = 12100; /* BLKSIZE=12100 */

  if (dynalloc(&ip) != ZERO)
    printf("Dynalloc failed with error code %d, info code %d\n",
           ip.__errcode, ip.__infocode);
}
```

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <dynit.h>

int dynfree(__dyn_t *dyn_parms);
```

General Description

Dynamically deallocates an z/OS data set in accordance with the attributes defined in `dyn_parms`.

To avoid infringing on the user’s name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The only fields in `__dyn_t` that are used by dynfree() are:

- char *__ddname
- char *__dsname
- char *__member
- char *__pathname
- char *__normdisp
- char *__pathndisp
- char **__miscitems

If any other fields are specified, they will be ignored. For more information on the `__dyn_t` structure, see Table 24 on page 454.

To dynamically deallocate a data set on z/OS, you should:
- Invoke dyninit() with a variable of type `__dyn_t`
- Assign values to the appropriate fields that will satisfy the svc99() request
- Invoke dynfree() with this variable.

Note: The dynfree() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII Support” on page 2495 for details.

Returned Value

If successful under z/OS, dynfree() returns 0.

If unsuccessful, dynfree() returns nonzero. dynfree() returns −1 if there is not sufficient storage to process all the text units.
Example

/*
 * This example dynamically deallocates a data set.
 */
#include <dynit.h>
int main(void) {
   __dyn_t ip;
   dyninit(ip);
   ip.__ddname = "mydd";
   dynfree(&ip);
}

Related Information

dyninit() — Initialize __dyn_t Structure

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <dynit.h>

int dyninit(__dyn_t *dynParms);
```

General Description

Initializes the __dyn_t structure that is used to build the parameter lists that are passed to the dynalloc() function and the dynfree() function. If you do not initialize the __dyn_t structure using dyninit(), undefined behavior may result.

The __dyn_t structure is defined in the dynit.h header file. A description of the elements is found in "dynalloc() — Allocate a Data Set" on page 453.

Returned Value

If successful under MVS, dyninit() returns 0.

If unsuccessful, dyninit() returns nonzero.

Example

```c
CELEBD09

/* CELEBD09
   This example initializes a __dyn_t structure, called ip.
*/

#include <stdio.h>
#include <string.h>
#include <dynit.h>

main()
{
    char dsn[]="USER.TESTDATASET";
    __dyn_t ip;
    int ret;

    dyninit(&ip);
    ip.__ddname = "TEST";
    ip.__dsname = dsn;
    ip.__status = __DISP_NEW;
    ip.__normdisp = __DISP_DELETE;
    ip.__alcunit = __TRK;
    ip.__primary = 1;
    ip.__unit = "SYSDA ";

    if ((ret = dynalloc(&ip)) != 0)
        printf("dynalloc() ret=%d, error code %04x, info code %04x\n",
               ret, ip.__errcode, ip.__infocode);
    else {
        dyninit(&ip);
    }
}
```

462  z/OS V1R9.0 XL C/C++ Run-Time Library Reference
ip.__ddname = "TEST";
if ((ret = dynfree(&ip)) != 0)
    printf("dynfree() ret=%d, error code %04x, info code %04x\n", ret, ip.__errcode, ip.__infocode);
else puts("success!");
}

ecvt

ecvt() — Convert Double to String

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *ecvt(double x, int ndigit, int *__restrict__ decpt, int *__restrict__ sign);
```

General Description

The ecvt() function converts double floating-point argument values to floating-point output strings. The ecvt() function has been extended to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of double argument values by using __isBFP().

z/OS XL C/C++ formatted output functions, including the ecvt() function, convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences. See “fprintf Family of Formatted Output Functions” on page 655 for a description of the special infinity and NaN output sequences.

The ecvt() function converts `x` to a NULL-terminated string of `ndigit` digits (where `ndigit` is reduced to an unspecified limit determined by the precision of a double) and returns a pointer to the string. The high-order digit is nonzero, unless the value is 0. The low-order digit is rounded. The position of the radix character relative to the beginning of the string is stored in the integer pointed to by `decpt` (negative means left of the returned digits). The radix character is not included in the returned string. If the sign of the result is negative, the integer pointed to by `sign` is nonzero, otherwise it is 0.

The function returns a pointer to a buffer used only by the calling thread which may be overwritten by subsequent calls to ecvt(), “fcvt() — Convert Double to String” on page 538 and “gcvt() — Convert Double to String” on page 737.

If the converted value is out of range or is not representable, the function returns NULL.

**Note:** This function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `sprintf()` function is preferred for portability.

Returned Value

If successful, ecvt() returns the character equivalent of `x` as specified above.

If unable to allocate the return buffer, or the conversion fails, ecvt() returns NULL.

**encrypt**

**encrypt() — Encoding Function**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE
#include <unistd.h>

void encrypt(char block[64], int edflag);
```

**General Description**

The encrypt() function uses an array of 16 48-bit keys produced by the setkey() function to encode bytes specified by the `block` argument according to the Data Encryption Standard (DES) encryption algorithm or to decode argument bytes according to the DES decryption algorithm.

The `block` argument of encrypt() is an array of length 64 bytes containing only the bytes with numerical value of 0 and 1. The array is modified in place using keys produced by setkey(). If `edflag` is 0, the argument is encoded using the DES encryption algorithm. If `edflag` is 1 the argument is decoded using the DES decryption algorithm.

**Special Behavior for z/OS UNIX Services**

The encrypt() function is thread-specific. Thus, for each thread from which the encrypt() function is called by a threaded application, the setkey() function must first be called from the thread to establish a DES key array for the thread.

**Returned Value**

encrypt() returns no values.

**Special Behavior for z/OS UNIX Services**

encrypt() will set errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>64 byte input array contains bytes with values other than 0x00 or 0x01.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>If setkey() has not been called or failed to produce a DES key array for the thread from which encrypt() is called.</td>
</tr>
<tr>
<td>ENOSYS</td>
<td>If DES key array exists for thread from which encrypt() is called to decode data.</td>
</tr>
</tbody>
</table>

**Note:** Because encrypt() returns no values, applications wishing to check for errors should set errno to 0, call encrypt(), then test errno and, if it is nonzero, assume an error has occurred.

endgrent

endgrent() — Group Database Entry Functions

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <grp.h>

void endgrent(void);
struct group *getgrent (void);
void setgrent(void);
```

General Description

The `getgrent()` function returns a pointer to the broken-out fields of a line in the group database, mapped by the `group` structure defined in the `<grp.h>` header file. Repeated calls to `getgrent()` return a pointer to the next `group` structure in the database, until End Of File (EOF), at which point a NULL pointer is returned. `setgrent()` interrupts this sequential search and rewinds the user database to the beginning, such that the next `getgrent()` returns a pointer to the first `group` structure. Use of `setgrent()` is optional after an End Of File (EOF), as the next `getgrent()` after end of file again returns a pointer to the first `group` structure. `endgrent()` is optionally used to close the user database when searching is complete.

The `setgrent()` function effectively rewinds the group database to allow repeated searches.

The `endgrent()` function may be called to close the group database when processing is complete.

Returned Value

When first called, `getgrent()` returns a pointer to the next group structure in the group database. Upon subsequent calls it returns a pointer to a group structure, or it returns a NULL pointer on either End Of File (EOF) or an error. The return value may point to static data that is overwritten by each call.

There are no documented `errno` values.

#include <netdb.h>

void endhostent(void);
```

**Berkeley Sockets**

```c
#define _OE_SOCKETS
#include <netdb.h>

void endhostent();
```

General Description

The endhostent() function closes the local host tables, which contains information about known hosts.

You can use the `X_SITE` environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization. For more information on these local host tables or the environment variables, see [z/OS Communications Server: IP Configuration Guide](https://www.ibm.com/support/docview.wss?uid=swg21537993).

Special Behavior for C++

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

endutxent() — Close the utmpx Database

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

void endutxent(void);
```

General Description

The endutxent() function closes the utmpx database for the current thread. The database may be opened by getutxent(), getutxid(), getutxline(), or pututxline().

Because the endutxent() function processes thread-specific data the endutxent() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

Programs must not reference the data passed back by getutxline(), getutxid(), getutxent(), or pututxline() after endutxent() has been called (the storage has been freed.)

After getutxline(), getutxent(), getutxid(), or pututxline(), the utmpx database is open. No other process can do pututxline() to this utmpx database until this process issues endutxent() or __utmpxname() to close the utmpx database, or this process ends. You can cause all z/OS UNIX user logins/logouts to hang if you fail to exit() or issue endutxent() or __utmpxname(), and you have the main /etc/utmpx database open in your process. endutxent() resets the name of the next utmpx file to open back to the default. If you want to do additional utmpx operations using a nonstandard utmpx file name, you must reissue __utmpxname() after closing the utmpx database with endutxent().

Returned Value

endutxent() returns no values.

erand48

erand48() — Pseudo-Random Number Generator

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdlib.h>

double erand48(unsigned short int x16v[3]);
```

General Description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval \([0.0,1.0)\). These functions have been extended so that the returned value will be in the proper floating-point format (hexadecimal or IEEE) based on the floating-point mode of the invoking thread.

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval \([0,2^{31})\).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval \([-2^{31},2^{31})\).

The erand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, \(X(i)\), according to the linear congruential formula:

\[
X(n+1) = (aX(n) + c) \mod (2^{48}) \quad n \geq 0
\]

The erand48() function uses storage provided by the argument array, \(x16v[3]\), to save the most recent 48-bit integer value in the sequence, \(X(i)\). The erand48() function uses \(x16v[0]\) for the low-order (rightmost) 16 bits, \(x16v[1]\) for the middle-order 16 bits, and \(x16v[2]\) for the high-order 16 bits of this value.

The initial values of \(a\) and \(c\) are:

\[
a = 5deece66d \quad \text{(base 16)}
\]

\[
c = b \quad \text{(base 16)}
\]

The values \(a\) and \(c\), may be changed by calling the lcong48() function. The initial values of \(a\) and \(c\) are restored if either the seed48() or srand48() function is called.

Special Behavior for z/OS UNIX Services

You can make the erand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.
If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested and the erand48() function is called from thread t, the erand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread according to the linear congruential formula:

\[ X(t,n+1) = (a(t)X(t,n) + c(t)) \mod(2^{48}) \quad n \geq 0 \]

The erand48() function uses storage provided by the argument array, x16v[3], to save the most recent 48-bit integer value in the sequence, X(t,i). The erand48() function uses x16v[0] for the low-order (rightmost) 16 bits, x16v[1] for the middle-order 16 bits, and x16v[2] for the high-order 16 bits of this value.

The initial values of a(t) and c(t) on the thread t are:

\[ a(t) = 5deece66d \quad \text{base 16} \]
\[ c(t) = b \quad \text{base 16} \]

The values a(t) and c(t) may be changed by calling the lcong48() function from the thread t. The initial values of a(t) and c(t) are restored if either the seed48() or srand48() function is called from the thread.

**Returned Value**

erand48() saves the generated 48-bit value, X(n+1), in storage provided by the argument array, x16v[3]. erand48() transforms the generated 48-bit value to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

**Special Behavior for z/OS UNIX Services**

If thread-specific behavior is requested for the drand48 family and erand48() is called on thread t, erand48() saves the generated 48-bit value, X(t,n+1), in storage provided by the argument array, x16v[3]. erand48() transforms the generated 48-bit value to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

**Compiler Option** LANGLVL(EXTENDED), LANGLVL(SAA), or LANGLVL(SAA2)

```c
#include <math.h>

double erf(double x);
double erfc(double x);
```

XPG4

```c
#define _XOPEN_SOURCE
#include <math.h>

double erf(double x);
double erfc(double x);
```

C99

```c
#define _ISOC99_SOURCE
#include <math.h>

float erff(float x);
long double erf(long double x);
float erfcf(float x);
long double erfcl(long double x)
```

General Description

Calculates the error and complementary error functions:

\[
2\pi^{-1/2} \int_{0}^{x} e^{-t^2} dt
\]

Because the erfc() function calculates the value of 1.0 - erf(x), it is used in place of erf() for large values of x.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.
### Returned Value

Both `erf()` and `erfc()` return the calculated value.

If the correct value would cause underflow, 0 is returned and the value of the macro `ERANGE` is stored in `errno`. A range error is returned if `x` is too large.

### Special Behavior for IEEE

`erf()` and `erfc()` are always successful.

### Requirements

This function is exposed by specifying on the compile step either the specific option `LANGLEVEL(LONGLONG)` or the general option `LANGLEVEL(EXTENDED)`.

### Example

**CELEBE01**

/* CELEBE01 */

This example uses `&erf` and `&erfc` to compute the error function of two numbers.

```c
#include <stdio.h>
#include <math.h>

double smallx, largex, value;

int main(void)
{
    smallx = 0.1;
    largex = 10.0;

    value = erf(smallx); /* value = 0.112463 */
    printf("Error value for 0.1: \%f\n", value);

    value = erfc(largex); /* value = 2.088488e-45 */
    printf("Error value for 10.0: \%e\n", value);
}
```

**Output**

Error value for 0.1: 0.112463
Error value for 10.0: 2.088488e-45

__err2ad() — Return Address of Reason Code of Last Failure

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
int *__err2ad(void);
```

General Description

The __err2ad() function returns the address of the errno2. The errno2 may be set by the z/OS XL C/C++ run-time library, z/OS UNIX callable services or other callable services.

__err2ad() provides assistance in diagnosing problems by allowing an application to reset the errno2 value prior to calling a function.

For more information about ___errno2(), see [z/OS XL C/C++ Run-Time Library Reference](#).

Returned Value

__err2ad() is always successful.

Related Information

- "__errno2() — Return Reason Code Information" on page 482
__errno2

__errno2() — Return Reason Code Information

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

int __errno2(void);

General Description

The __errno2() function can be used when diagnosing application problems. This function enables z/OS XL C/C++ application programs to access additional diagnostic information, errno2 (errnojr), associated with errno. The errno2 may be set by the z/OS XL C/C++ run-time library, z/OS UNIX callable services or other callable services. The errno2 is intended for diagnostic display purposes only and it is not a programming interface. The __errno2() function is not portable.

Note: Not all functions set errno2 when errno is set. In the cases where errno2 is not set, the __errno2() function may return a residual value. You may use the __err2ad() function to clear errno2 to reduce the possibility of a residual value being returned.

Returned Value

The __errno2() function is always successful. The returned value is intended for diagnostic display purposes only.

The returned value may input to the BPXMTEXT utility to produce detailed information about the reported error if available.

For more information about the return value, see the z/OS UNIX System Services Command Reference, z/OS UNIX System Services Programming: Assembler Callable Services Reference, SA22-7803 and z/OS Language Environment Debugging Guide.

Example

CELEBE02

/* CELEBE02 */

The following example's output only occurs if the buffer is flushed.

*/
#include <errno.h>
#include <stdio.h>
FILE *myfopen(const char *fn, const char *mode) {
   FILE *f;
f = fopen(fn,mode);
if (f==NULL) {
   perror("fopen() failed");
   printf("__errno2 = %08x\n", __errno2());
}
return(f);
}
Sample output of routine using __errno2(), CELEBE02:

fopen() failed: EDC5129I No such file or directory. __errno2 = 05620062

CELEBE08

#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>
#include <stdlib.h>

int main(void){
  FILE *fp;
  /* add errno2 to perror message */
  setenv("_EDC_ADD_ERRNO2", "1", 1);
  fp = fopen("testfile.dat", "r");
  if (fp == NULL)
    perror("fopen() failed");
  return 0;
}

Sample output of routine using _EDC_ADD_ERRNO2, CELEBE08:

fopen() failed: EDC5129I No such file or directory. (errno2=0x05620062)

CELEBE09

#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>

int main(void){
  FILE *f;
  f = fopen("testfile.dat", "r");
  if (f == NULL){
    perror("fopen() failed");
    printf("__errno2 = %08x\n", __errno2());
  }
  /* reset errno2 to zero */
  *__err2ad() = 0x0;
  printf("__errno2 = %08x\n", __errno2());
  f = fopen("testfile.dat", "r");
  if (f == NULL){
    perror("fopen() failed");
    printf("__errno2 = %08x\n", __errno2());
  }
  return 0;
}

For more information about _EDC_ADD_ERRNO2 , see z/OS XL C/C++ Programming Guide. For more information about __err2ad() , see z/OS XL C/C++ Run-Time Library Reference.

__etoa

__etoa() — EBCDIC to ISO8859-1 String Conversion

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <unistd.h>

int __etoa(char *string);

General Description

The __etoa() function converts an EBCDIC character string string to its ISO8859-1 equivalent. The conversion is performed using the codeset page associated with the current locale. The input character string up to, but not including, the NULL character is changed from the current locale to an ISO8859-1 representation.

The argument string points to the EBCDIC character string to be converted to its ISO8859-1 equivalent.

Returned Value

If successful, __etoa() converts the input EBCDIC string to its equivalent ISO8859-1 value, and returns the length of the converted string.

If unsuccessful, __etoa() returns −1 and sets errno to one of the following values. (This function internally may call iconv_open() and iconv(). The errnos returned by these functions are propagated without modification.)

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The current locale does not describe a single-byte character set.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>There is insufficient storage to complete the conversion process.</td>
</tr>
</tbody>
</table>

Related Information

__etoa_l() — EBCDIC to ISO8859-1 Conversion Operation

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

int __etoa_l(char *bufferptr, int leng);
```

General Description

The __etoa_l() function converts `leng` EBCDIC bytes in the buffer pointed to by `bufferptr` to their ISO8859-1 equivalent. The conversion is performed using the codeset page associated with the current locale.

The argument `bufferptr` points to a buffer containing the EBCDIC bytes to be converted to their ISO8859-1 equivalent. The input buffer is treated as a sequence of bytes, and all bytes in the input buffer are converted, including any imbedded NULLs.

Returned Value

If successful, __etoa_l() converts the input EBCDIC bytes to their equivalent ISO8859-1 value, and returns the number of bytes converted.

If unsuccessful, __etoa_l() returns −1 and sets `errno` to one of the following values. (This function may internally call `iconv_open()` and `iconv()`. The `errno`s returned by these functions are propagated without modification.)

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The current locale does not describe a single-byte character set.</td>
</tr>
<tr>
<td>ENOMEM</td>

</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>
extern char **environ;

int execl(const char *path, const char *arg, ..., NULL);
int execlp(const char *path, const char *arg, ..., NULL, char *const envp[]);
int execv(const char *path, char *const argv[]);
int execvp(const char *file, char *const argv[]);
int execlp(const char *file, const char *arg, ..., NULL, char *const envp[]);
int execvp(const char *file, char *const argv[]);
```

Note: Although POSIX.1 does not require that the unistd.h include file be included, it is recommended that you include it for portability.

General Description

All exec functions run a new program by replacing the current process image with a new process image obtained from a file in the HFS (hierarchical file system).

For information on specifying names for MVS data sets and HFS files, see z/OS XL C/C++ Programming Guide.

A successful exec function never returns control because the calling process is overwritten with the new process.

The argument path is a string giving the absolute or relative pathname of a file. This file contains the image of the process to be run.

file is a string that is used in determining the pathname of the file containing the image of the process to be run. If file contains a slash character (/), it is assumed to be the absolute or relative pathname of the file. If file does not contain a slash, the system searches for the given file name under the list of directories given by the PATH environment variable. The system checks under directories in the order they appear in the PATH variable, and executes the first file whose name matches the file string. The file must reside in the HFS.

The exec functions use the following environment variables:

STEPLIB Supports the creation and propagation of a STEPLIB environment to the new process image. The following are the accepted values for the STEPLIB environment variable and the actions taken for each value:

- STEPLIB=NONE. No Steplib DD is to be created for the new process image.
• STEPLIB=CURRENT. The TASKLIB, STEPLIB or JOBLIB DD data set allocations that are active for the calling task at the time of the call to exec() are propagated to the new process image, if they are found to be cataloged. Uncataloged data sets are not propagated to the new process image.

• STEPLIB=Dsn1:Dsn2:,...DsnN. The specified data sets, Dsn1:Dsn2:,...DsnN, are built into a STEPLIB DD in the new process image.

Note: The actual name of the DD is not STEPLIB, but is a system-generated name that has the same effect as a STEPLIB DD. The data sets are concatenated in the order specified. The specified data sets must follow standard MVS data set naming conventions. Data sets found to be in violation of this standard are ignored. If the data sets do follow the standard, but:

– The caller does not have the proper security access to a data set
– A data set is uncataloged or is not in load library format

then the data set is ignored. Because the data sets in error are ignored, the executable file may run without the proper STEPLIB environment. If a data set is in error due to improper security access, a X'913' abend is generated. The dump for this abend can be suppressed by your installation.

If the STEPLIB environment variable is not specified, the exec() default behavior is the same as if STEPLIB=CURRENT were specified.

If the program to be invoked is a set-user-ID or set-group-ID file and the user-ID or group-ID of the file is different from that of the current process image, the data sets to be built into the STEPLIB environment for the new process image must be found in the system sanction list for set-user-id and set-group-id programs. Only those data sets that are found in the sanction list are built into the STEPLIB environment for the new process image. For detailed information regarding the sanction list, and for information on STEPLIB performance considerations, see z/OS UNIX System Services Planning, GA22-7800.

’B’PX_JOBNAME
Used to change the jobname of the new process image. The jobname change is allowed only if the invoker has appropriate privileges and is running in an address space created by fork. If these conditions are not met, the environment variable is ignored. Accepted values are strings of 1–8 alphanumeric characters. Incorrect specifications are ignored.

’B’PX_ACCT_DATA
Used to change the account data of the new process image. Rules for specifying account data:
• Up to 142 actual account data characters are allowed, including any commas
• Sub-parameters must be separated by commas.
• There is no restriction on the character set.
• If the account data is greater than 142 characters, the data is ignored.

_BPXK_JOBLOG

The _BPXK_JOBLOG environment variable can be used to specify that WTO messages are to be written to an open HFS job log file. The following are the allowable values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nn</td>
<td>Job log messages are to be written to open file descriptor nn.</td>
</tr>
<tr>
<td>STDERR</td>
<td>Job log messages are to be written to the standard error file descriptor, 2.</td>
</tr>
<tr>
<td>None</td>
<td>Job log messages are not to be written. This is the default.</td>
</tr>
</tbody>
</table>

The file that is used to capture messages can be changed at any time by calling the oe_env_np service (BPX1ENV) and specifying _BPXK_JOBLOG with a different file descriptor.

Message capturing is turned off if the specified file descriptor is marked for close on a fork or exec.

Message capturing is process-related. All threads under a given process share the same job log file. Message capturing may be initiated by any thread under that process.

Multiple processes in a single address space can each have different files active as the JOBLOG file; some or all of them can share the same file; and some processes can have message capturing active while others do not.

Only files that can be represented by file descriptors may be used as job log files; MVS data sets are not supported.

Message capturing will be propagated on a fork() or spawn(). In the case where a file descriptor was specified, the physical file must be the same for message capturing to continue in the forked or spawned process. If STDERR was specified, the file descriptor may be re-mapped to a different physical file.

Message capturing may be overridden on exec() or spawn() by specifying the _BPXK_JOBLOG environment variable as a parameter to the exec() or spawn() function.

Message capturing will only work in forked (BPXAS) address spaces.

Note: This is not true joblog support, messages that would normally go to the JESYSMSG data set are captured, but messages that go to JESMSGLG are not captured.

Special Behavior for XPG4

If this file is not a valid executable object, the execlp() and execvp() functions invoke /bin/sh with the invoker’s pathname and the rest of the input arguments. It is similar to invoking:

```
exec1("/bin/sh",
    "sh",
    ",--",
```
exec

        fully_expanded.pathname,
        arg1, arg2, ..., argn,
        NULL
    );

where arg1, arg2, ..., argn are the caller's arguments to execlp() or execvp(), and
fully_expanded.pathname is the pathname of the shell script found by searching
the directories in the current PATH.

arg, ..., NULL is a series of pointers to NULL-terminated character strings specifying
arguments for the process being invoked. If the new process is a main(), these
strings are stored in an array, and a pointer to the array is passed in the argv
parameter. The first argument is required, and it should point to a string containing
the name of the file that is associated with the process that exec is starting. A NULL
pointer must follow the last argument string pointer.

argv[] is a pointer to an array of pointers to NULL-terminated character strings.
There must be a NULL pointer after the last character string to mark the end of the
array. These strings are used as arguments for the process being invoked. argv[0]
should point to a string containing the name of a file associated with the process
being started by exec. envp[] is a pointer to an array of pointers to NULL-terminated
character strings. There must be a NULL pointer after the last character string to
mark the end of the array. The strings of envp provide the environment variables for
the new process.

All the forms of exec functions provide a way to locate the file containing the new
process you want to run and a collection of arguments that should be passed to the
new process. Each form of exec has its own method for specifying this information.

Some exec calls explicitly pass an environment using an envp argument. In
versions where an environment is not passed explicitly—execl(), execlp(), execv(),
and execvp()—the system uses the entire environment of the caller. The caller's
environment is assumed to be the environment variables that the external variable
**environ points to.

The variable ARG_MAX, obtained from z/OS UNIX services by an invocation of
sysconf(_SC_ARG_MAX), specifies the maximum number of bytes that can be used
for arguments and environment variables passed to the process being invoked. The
number of bytes includes the NULL terminator on each string.

A process started by an exec function has all of the open file descriptors that were
present in the caller, except for those files opened with the close-on-exec flag
FD_CLOEXEC. See "fcntl() — Control Open File Descriptors" on page 527 for more
information about this flag. In file descriptors that remain open, all attributes remain
unchanged (including file locks).

Directory streams that are open in the calling process image are closed in the new
process image.

The state of conversion descriptors and message catalog descriptors is undefined.

Signals set to be ignored in the caller, SIG_IGN, are set to be ignored in the new
process image. Be careful to take care of signals that are being ignored. Although
sigaction() specifying a handler is not passed by, SIG_IGN is. Blocking of signals is
also passed by. All other signals are set to the default action, SIG_DFL, in the new
process image, no matter how the caller handled such signals.
The real user ID (UID), real group ID (GID), and supplementary group IDs of the new process are the same as those of the caller. If the set-user-ID mode bit of the program file is on, the effective user ID of the new process is set to the file’s owner. Similarly, if the set-group-ID mode bit of the program file is on, the effective group ID of the new process is set to the file’s group. The effective user ID of the new process image is saved as the saved set-user-ID, and the effective group ID of the new process image is saved as the saved set-group-ID.

Any shared memory segments attached to the calling process image will not be attached to the new process image, see “shmat() — Shared Memory Attach Operation” on page 1864. Any shared memory segments attached to the calling process image will be detached (that is, the value of shm_nattch decremented by one). If this is the last thread attached to the shared memory segment and a shmctl() RMID has been issued, the segment will be removed from the system.

Special Behavior for XPG4.2

Interval timers are preserved across an exec.

The new process also inherits the following from the caller:

- Controlling terminal (XPG4.2)
- Nice value (see “nice() — Change Priority of a Process” on page 1304 (XPG4)
- semadj values (see “semop() — Semaphore Operations” on page 1734 (XPG4)
- Process ID
- Parent process ID
- Process group ID
- Resource limits (see “setrlimit() — Control Maximum Resource Consumption” on page 1837 and “ulimit() — Get/Set Process File Size Limits” on page 2287 (XPG4)
- Session membership
- Time left until an alarm clock signal
- Working directory
- Root directory
- File mode creation mask
- File size limit (see “ulimit() — Get/Set Process File Size Limits” on page 2287 (XPG4)
- Process signal mask
- Pending signals
  - tms_utime, tms_stime, tms_cutime, and tms_cstime. See “times() — Get Process and Child Process Times” on page 2206 for more about these qualities.

A successful exec function automatically opens the specified program file, and updates the access time st_atime for that file. The program file is closed automatically after the program has been read from the file. The precise time of this close operation is undefined.

Special Behavior for z/OS UNIX Services

Notes:

1. A prior loaded copy of an HFS program in the same address space is reused under the same circumstances that apply to the reuse of a prior loaded MVS unauthorized program from an unauthorized library by the MVS XCTL service with the following exceptions:
   - If the calling process is in Ptrace debug mode, a prior loaded copy is not reused.
• If the calling process is not in Ptrace debug mode, but the only prior loaded usable copy found of the HFS program is in storage modifiable by the caller, the prior copy is not reused.

2. If the specified file name represents an external link or a sticky bit file, the program is loaded from the caller’s MVS load library search order. For an external link, the external name is only used if the name is eight characters or less, otherwise the caller receives an error from the loadhfs service. For a sticky bit program, the file name is used if it is eight characters or less. Otherwise, the program is loaded from the HFS.

3. If the calling task is in a WLM enclave, the resulting task in the new process image is joined to the same WLM enclave. This allows WLM to manage the old and new process images as one 'business unit of work' entity for system accounting and management purposes.

Note: If you are expecting this function to take advantage of the z/OS UNIX magic number support, the Language Environment run-time option to POSIX(ON) must have been set when the process was initialized. Attempting to use magic number support with a process initialized with POSIX(OF) may produce undesirable effects. See z/OS UNIX System Services Planning, GA22-7800 and z/OS UNIX System Services User’s Guide, SA22-7801 for details and uses of the z/OS UNIX magic number.

Returned Value

If successful, an exec function never returns control because the calling process is overwritten with the new process.

If unsuccessful, an exec function returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2BIG</td>
<td>The combined argument list and environment list of the new process has more bytes than the system-defined length. See “sysconf() — Determine System Configuration Options” on page 2111 for information about the system-defined length.</td>
</tr>
<tr>
<td>EACCES</td>
<td>The process did not have appropriate permissions to run the specified file, for one of these reasons:</td>
</tr>
<tr>
<td></td>
<td>• The process did not have permission to search a directory named in your path.</td>
</tr>
<tr>
<td></td>
<td>• The process did not have execute permission for the file to be run.</td>
</tr>
<tr>
<td></td>
<td>• The system cannot run files of this type.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>A bad address was received as an argument of the call, or the user exit program checked.</td>
</tr>
<tr>
<td></td>
<td>Consult Reason Code to determine the exact reason the error occurred. The following reason code can accompany the return code: JRExecParmErr and JRExitRtnError.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The new process image file has the appropriate permission and has a recognized format, but the system does not support execution of a file with this format.</td>
</tr>
</tbody>
</table>
| ELOOP      | A loop exists in symbolic links. This error is issued if the number of
symbolic links detected in the resolution of the path or file argument is greater than POSIX_SYMLOOP (a value defined in the limits.h header file)

EMVSSAF2ERR The executable file is a set-user-ID or set-group-ID file, and the file owner's UID or GID is not defined to RACF.

ENAMETOOLONG All or part of the file name is too long. This can happen if:
  • A path or file argument exceeds the value of PATH_MAX, or an element of your path exceeds PATH_MAX.
  • Any pathname component is greater than NAME_MAX, and _POSIX_NO_TRUNC is in effect.
  • The length of a pathname string substituted for a symbolic link in the path argument exceeds PATH_MAX.

The PATH_MAX and NAME_MAX values are determined with pathconf().

ENOENT One or more pathname components in path or file does not exist. This error is also issued if path or file is a NULL string.

ENOEXEC The new process image file has the appropriate access permission but has an unrecognized format. This errno can be returned from any one of the exec family of functions, except for execlp() and execvp().

Note: Reason codes further qualify the errno. For most of the reason codes, see z/OS UNIX System Services Messages and Codes

For ENOEXEC, the reason codes are:

<table>
<thead>
<tr>
<th>Reason Code</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'xxxx0C27'</td>
<td>The target HFS file is not in the correct format to be an executable file.</td>
</tr>
<tr>
<td>X'xxxx0C31'</td>
<td>The target HFS file is built at a level that is higher than that supported by the running system.</td>
</tr>
</tbody>
</table>

ENOMEM The new process requires more memory than is permitted by the operating system.

ENOTDIR A directory component of path or file is not really a directory.

Example

CELEBE03

/* CELEBE03 */

This example runs a program, using the exec1() function.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/wait.h> /*FIX: used be <wait.h>*/
#include <sys/types.h>
#include <unistd.h>

main() {

pid_t pid;
int status;

if ((pid = fork()) == 0) {
    exec("/bin/false", NULL);
    perror("The exec() call must have failed");
    exit(255);
} else {
    wait(&status);
    if (WIFEXITED(status))
        printf("child exited with status of \d\n", WEXITSTATUS(status));
    else
        puts("child did not exit successfully\n");
}

Output
child exited with status of 1

<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

void exit(int status);
```

General Description

The `exit()` function:

1. Calls all functions registered with the `atexit()` function, and destroys C++ objects with static storage duration, all in last-in-first-out (LIFO) order. C++ objects with static storage duration are destroyed in the reverse order of the completion of their constructor. (Automatic objects are not destroyed as a result of calling `exit()`.)
   Functions registered with `atexit()` are called in the reverse order of their registration. A function registered with `atexit()`, before an object `obj1` of static storage duration is initialized, will not be called until `obj1`'s destruction has completed. A function registered with `atexit()`, after an object `obj2` of static storage duration is initialized, will be called before `obj2`'s destruction starts.

2. Flushes all buffers, and closes all open files.
3. All files opened with `tmpfile()` are deleted.
4. Returns control to the host environment from the program.

Process termination in `_exit()` is equivalent to program termination in `exit()`.

The argument `status` can have a value from 0 to 255 inclusive or be one of the macros `EXIT_SUCCESS` or `EXIT_FAILURE`. The value of `EXIT_SUCCESS` is defined in `stdlib.h` as 0; the value of `EXIT_FAILURE` is 8.

This function is also available to C applications in a stand-alone Systems Programming C (SPC) Environment.

In a POSIX C program, `exit()` returns control to the kernel with the value of `status`. The kernel then performs normal process termination. See “z/OS XL C/C++ applications with z/OS UNIX System Services C functions” on page 13 for more information about using POSIX support.

POSIX-level thread cleanup routines are not executed. These includes cleanup routines created with `pthread_cleanup_push()` and destructor routines created with `pthread_key_create()`.

Special Behavior for C++
If exit() is called in a z/OS XL C++ program, the program terminates without leaving the current block, and therefore destructors are not called for local (automatic) variables. Destructors for initialized static objects will be called in the reverse order of the completion of their constructors.

Functions registered with atexit() are called in the reverse order of their registration. A function registered with atexit(), before an object obj1 of static storage duration is initialized, will not be called until obj1’s destruction has completed. A function registered with atexit(), after an object obj2 of static storage duration is initialized, will be called before obj2’s destruction starts.

Returned Value

exit() returns no values.

exit() returns control to its host environment, with the returned value status.

For example, if program A invokes program B using a call to the system() function, and program B calls the exit() function, then program B returns to its host environment, which is program A.

Example

/* This example flushes all buffers, closes any open files, and ends the program if it cannot open the file myfile. */
#include <stdio.h>
#include <stdlib.h>
FILE *stream;
int main(void)
{
  ...
  if ((stream = fopen("myfile.dat", "r")) == NULL)
  {
    printf("Could not open data file\n");
    exit(EXIT_FAILURE);
  }
}

</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

void _exit(int status);
```

General Description

Ends the current process and makes an exit status value for the process available to the system.

The argument `status` specifies a return status for the process that is ending. Ending the process has the following results:

- `_exit()` closes all open file descriptors and directory streams in the caller.
- If the caller’s parent is currently suspended because of `wait()` or `waitpid()`, the low-order 8 bits of `status` become available to the parent. For a discussion on accessing those 8 bits, refer to "waitpid() — Wait for a Specific Child Process to End" on page 2354.
- If the caller’s parent is not currently suspended because of `wait()` or `waitpid()`, `_exit()` saves the `status` value so that it can be returned to the parent if the parent calls `wait()` or `waitpid()`.
- A `SIGCHILD` signal is sent to the parent process.
- If the process calling `_exit()` is a controlling process, the `SIGHUP` signal is sent to each process in the foreground process group of the controlling terminal belonging to the caller.
- If the process calling `_exit()` is a controlling process, `_exit()` disassociates the associated controlling terminal from the session. A new controlling process can then acquire the terminal.
- Exiting from a process does not end its child processes directly. The `SIGHUP` signal may end children in some cases. Children that survive when a process ends are assigned a new parent process ID. The new parent process ID is always 1, indicating the root ancestor of all processes.
- If a process ends and orphans a process group and if a member of that group is stopped, each member of the group is sent a `SIGHUP` signal, followed by a `SIGCONT` signal.
- All threads are ended, and their resources cleaned up. (Threads are MVS tasks that call a z/OS UNIX callable service.) POSIX-level thread cleanup routines are not executed. These include cleanup routines created with `pthread_cleanup_push()` and destructor routines created with `pthread_key_create()`.
These results occur whenever a process ends. _exit() does not cause C run-time library cleanup to be performed; therefore, stream buffers are not necessarily flushed.

**Note:** If _exit() is issued from a TSO/E address space, it ends the calling task and all its subtasks.

**Special Behavior for C++**

If _exit() is called in a C++ program, the program terminates without leaving the current block, and destructors are not called for local (automatic) variables. In addition, unlike exit(), destructors for global (static) variables are not called.

**Returned Value**

_exit() is always successful and returns no values.

No value is stored in errno for this function.

**Example**

**CELEBE05**

```c
/* CELEBE05

This example ends a process.
*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>

main() {
    puts("Remember that stream buffers are not automatically");
    puts("flushed before _exit()!");
    fflush(NULL);
    _exit(0);
}
```

**Output**

Remember that stream buffers are not automatically flushed before _exit()!

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <stdlib.h>

void _Exit(int status);
```

General Description

When running POSIX(OFF), the _Exit() function is equivalent to exit() with the exception that it does not run atexit() registered routines or signal handlers registered using signal().

When running POSIX(ON), the _Exit() function is equivalent to _exit().

Returned Value

The _Exit() function does not return to its caller.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <math.h>

double exp(double x);
float exp(float x);     /* C++ only */
long double exp(long double x); /* C++ only */
float expf(float x);
long double expl(long double x);
```
General Description

Calculates the exponent of x, defined as $e^{**x}$, where $e$ equals 2.17128128....

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

If successful, the function returns the calculated value.

If an overflow occurs, the function returns HUGE_VAL. If an underflow occurs, it returns 0. Both overflow and underflow set errno to ERANGE.

Example

CELEBE06

/* CELEBE06

This example calculates y as the exponential function of x.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y;
    x = 5.0;
    y = exp(x);
    printf("exp( %f ) = %f
\n", x, y);
}

Output

exp( 5.000000 ) = 148.413159

expd32, expd64, expd128

expd32(), expd64(), expd128() — Calculate Exponential Function

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 expd32(_Decimal32 x);
_Decimal64 expd64(_Decimal64 x);
_Decimal128 expd128(_Decimal128 x);

_Decimal32 exp(_Decimal32 x); /* C++ only */
_Decimal64 exp(_Decimal64 x); /* C++ only */
_Decimal128 exp(_Decimal128 x); /* C++ only */
```

General Description

Calculates the exponent of x, defined as e**x, where e equals 2.17128128....

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Binary Floating-Point " on page 108 for more information.

Returned Value

If successful, the function returns the calculated value.

If an overflow occurs, the function returns HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128. If an underflow occurs, it returns 0. Both overflow and underflow set errno to ERANGE.

Example

```c
/* CELEBE11

This example illustrates the expd64() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 x, y;
    x = 5.000;
    y = expd64(x);
    printf("expd64(%.0f) = %.0f\n", x, y);
}
```

expm1

expm1(), expm1f(), expm1l() — Exponential Minus One

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>C99</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double expm1(double x);

C99
#define _ISOC99_SOURCE
#include <math.h>

float expm1f(float x);
long double expm1l(long double x);
```

General Description

The `expm1()` functions calculate the function:

\[ e^x - 1.0 \]

Note: The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>expm1</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>expm1f</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>expm1l</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

If successful, `expm1()` returns the above function calculated on `x`.

If unsuccessful, `expm1()` may fail as follows:

- If `x` is negative and exceeds an internally defined large value, `expm1()` functions will return `-1.0`.
- If the value of the function overflows, `expm1()` functions will return `HUGE_VAL` or `HUGE_VALF` or `HUGE_VALL` as appropriate, and set `errno` to `ERANGE`.

ExportWorkUnit() — WLM Export Service

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX System Services</td>
<td>both</td>
<td>OS/390 V2R9</td>
</tr>
</tbody>
</table>

Format

```
#include <sys/__wlm.h>

int ExportWorkUnit(wlmetok_t *enclavetoken,
                   wlmxtok_t *exporttoken,
                   unsigned long *conntoken);
```

General Description

Exports an enclave to all systems in a parallel sysplex, enabling dispatchable units on other systems to join the enclave.

The ExportWorkUnit() function uses the following parameters:

- `*enclavetoken` Points to a work unit enclave token that was returned from a call to CreateWorkUnit() or ContinueWorkUnit().
- `*exporttoken` Points to a data field of type wlmxtok_t where the ExportWorkUnit() function is to return the WLM work unit export token.
- `*conntoken` Specifies the connect token that represents the connection to WLM.

Returned Value

If successful, ExportWorkUnit() returns 0.

If unsuccessful, ExportWorkUnit() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>An argument of this function contained a value that is not correct.</td>
</tr>
<tr>
<td>EMVSSAF2ERR</td>
<td>An error occurred in the security product.</td>
</tr>
<tr>
<td>EMVSWLMERROR</td>
<td>A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.</td>
</tr>
</tbody>
</table>
|EPERM         | The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class, if the
BPX.WLMSERVER class is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

extlink_np

extlink_np() — Create an External Symbolic Link

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

int extlink_np(const char *ename, const char *elink);
```

General Description

Creates the external symbolic link file named by `elink` with the object specified by `ename`. The `ename` is not resolved, and refers to an object outside the HFS (hierarchical file system). The variable `elink` is the name of the external symbolic link file created, and `ename` is the name of the object contained within that file.

Returned Value

If successful, `extlink_np()` returns 0.

If unsuccessful, `extlink_np()` returns −1, does not affect any file it names, and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>A component of the <code>elink</code> path prefix denies search permission.</td>
</tr>
<tr>
<td>EEXIST</td>
<td>The file named by <code>elink</code> already exists.</td>
</tr>
<tr>
<td>EINVAL</td>
<td><code>elink</code> has a slash as its last component, which indicates that the preceding component will be a directory. An external link cannot be a directory.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error is issued if the number of symbolic links encountered during resolution of the <code>elink</code> argument is greater than POSIX_SYMLOOP.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td><code>pathname</code> is longer than <code>PATH_MAX</code> characters, or some component of <code>pathname</code> is longer than <code>NAME_MAX</code> characters while <code>_POSIX_NO_TRUNC</code> is in effect. For symbolic links, the length of the <code>pathname</code> string substituted for a symbolic link exceeds <code>PATH_MAX</code>. The <code>PATH_MAX</code> and <code>NAME_MAX</code> values can be determined with <code>pathconf()</code>.</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>A component of the path prefix of <code>elink</code> is not a directory.</td>
</tr>
<tr>

ExtractWorkUnit

ExtractWorkUnit() — Extract Enclave Service

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX System Services</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__wlm.h>

int ExtractWorkUnit(wlmetok_t *enclavetoken);
```

General Description

The ExtractWorkUnit() function will allow the task to retrieve the enclaves token for the purpose of performance management.

The ExtractWorkUnit() function uses the following parameter:

* `enclavetoken` Points to a data field of type wlmetok_t where the ExtractWorkUnit() function is to return the WLM work unit token to which the current process is joined.

Returned Value

If successful, ExtractWorkUnit() returns 0.

If unsuccessful, ExtractWorkUnit() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this service contained an address that was not accessible to the caller.</td>
</tr>
<tr>

__e2a_l() — Convert Characters from EBCDIC to ASCII

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

size_t __e2a_l(char *bufptr, size_t szLen)
```

General Description

The __e2a_l() function converts `szLen` characters in `bufptr` between IBM-1047 and ISO8859-1, returning the number of characters converted if successful or -1 if not. Conversion occurs in place in the buffer. __e2a_l() is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned Value

If successful, __e2a_l() returns the number of characters converted.

If unsuccessful, __e2a_l() returns -1 and sets errno to the following value:

<table>
<thead>
<tr>
<th>Error Code</th>

__e2a_s()

__e2a_s() — Convert String from EBCDIC to ASCII

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

```
#include <unistd.h>

size_t __e2a_s(char *string)
```

General Description

The __e2a_s() function converts a string between IBM-1047 and ISO8859-1, returning the string length if successful or -1 if not. Conversion occurs in place in the string. __e2a_s() is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned Value

If successful, __e2a_s() returns the string length.

If unsuccessful, __e2a_s() returns -1 and sets errno to the following value:

<table>

</tbody>
</table>

Format

```c
#include <math.h>

double fabs(double x);
float fabs(float x);  /* C++ only */
long double fabs(long double x); /* C++ only */
float fabsf(float x);
long double fabsl(long double x);
```

General Description

The fabs() functions calculate the absolute value of a floating-point argument.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “IEEE Binary Floating-Point” on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

Returns the absolute value of the float input.

Example

```c
/* This example calculates y as the absolute value of x. */
#include <math.h>

int main(void)
{
    double x, y;
    x = -5.6798;
    y = fabs(x);
    printf("fabs( %f ) = %f\n", x, y);
}
```

Output

```
fabs( -5.679800 ) = 5.679800
```

fabsd32(), fabsd64(), fabsd128() — Calculate Floating-Point Absolute Value

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 fabsd32(_Decimal32 x);
_Decimal64 fabsd64(_Decimal64 x);
_Decimal128 fabsd128(_Decimal128 x);
_Decimal32 fabs(_Decimal32 x); /* C++ only */
_Decimal64 fabs(_Decimal64 x); /* C++ only */
_Decimal128 fabs(_Decimal128 x); /* C++ only */
```

General Description

The fabs() functions calculate the absolute value of a decimal floating-point argument.

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Binary Floating-Point" on page 108 for more information

Returned Value

Returns the absolute value of the decimal floating-point input.

Example

```c
/* CELEBF75

   This example illustrates the fabsd128() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x, y;
    x = -5.6798DL;
    y = fabsd128(x);
    printf("fabsd128(%DDf) = %DDf\n", x, y);
}
```

fattach

fattach() — Attach a STREAMS-based File Descriptor to a File in the File System Name Space

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int fattach(int fildes, const char *path);
```

General Description

The fattach() function attaches a STREAMS-based file descriptor to a file, effectively associating a pathname with `fildes`. The `fildes` argument must be a valid open file descriptor associated with a STREAMS file. The `path` argument points to a pathname of an existing file. The process must have appropriate privileges, or must be the owner of the file named by `path` and have write permission. A successful call to fattach() causes all pathnames that name the file named by `path` to name the STREAMS file associated with `fildes`, until the STREAMS file is detached from the file. A STREAMS file can be attached to more than one file and can have several pathnames associated with it.

The attributes of the named STREAMS file are initialized as follows: the permissions, user ID, group ID, and times are set to those of the file named by `path`, the number of links is set to 1, and the size and device identifier are set to those of the STREAMS file associated with `fildes`. If any attributes of the named STREAMS file are subsequently changed (for example, by chmod()), neither the attributes of the underlying file nor the attributes of the STREAMS file to which `fildes` refers are affected.

File descriptors referring to the underlying file, opened before an fattach() call, continue to refer to the underlying file.

Returned Value

If successful, fattach() returns 0.

If unsuccessful, fattach() returns -1 and sets errno to one of the following values.

**Note:** z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for fattach() to attach a STREAMS-based file descriptor to a file. It will always return -1 with errno set to indicate the failure. See "open() — Open a File" on page 1313 for more information.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for a component of the path prefix, or the process is the owner of <code>path</code> but does not have write permissions on the file named by <code>path</code>.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The <code>fildes</code> argument is not a valid open file descriptor.</td>
</tr>
</tbody>
</table>
EBUSY The file named by path is currently a mount point or has a
STREAMS file attached to it.
EINVAL The fildes argument does not refer to a STREAMS file.
ELOOP Too many symbolic links were encountered in resolving path.
ENAMETOOLONG
The size of path exceeds PATH_MAX, or a component of path is
longer than NAME_MAX, or pathname resolution of a symbolic link
produced an intermediate result whose length exceeds PATH_MAX.
ENOENT A component of path does not name an existing file or path is an
empty string.
ENOTDIR A component of the path prefix is not a directory.
EPERM The effective user ID of the process is not the owner of the file
named by path and the process does not have appropriate
privilege.

__fchattr

__fchattr() — Change the Attributes of a File or Directory by File Descriptor

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

```c
#define __OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __fchattr(int filedes, attrib_t *attributes, int attributes_len);
```

General Description

The __fchattr() function modifies the attributes that are associated with a file. It can be used to change the mode, owner, access time, modification time, change time, reference time, audit flags, general attribute flags, file tag, and file format and size. The file to be impacted is defined by its file descriptor with the filedes argument.

The attributes argument is the address of an attrib_t structure which is used to identify the attributes to be modified and the new values desired. The attrib_t type is an f_attributes structure as defined in <sys/stat.h> for use with the __fchattr() function. For proper behavior, the user should ensure that this structure has been initialized to zeros before it is populated. The f_attributes structure is defined as indicated in Table 23 on page 267.

The f_attributes structure is defined in <sys/stat.h> for use with the __fchattr() function.

Returned Value

If successful, __fchattr() returns 0.

If unsuccessful, __fchattr() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>
| EACCES     | The calling process did not have appropriate permissions. Possible reasons include:  
• The calling process was attempting to set access time or modification time to current time, and the effective UID of the calling process does not match the owner of the file; the process does not have write permission for the file; or the process does not have appropriate privileges.  
• The calling process was attempting to truncate the file, and it does not have write permission for the file. |
| EBADF      | The filedes parameter is not a valid file descriptor. |
| ECICS      | An attempt was made to change file tag attributes under non-OTE CICS and file tagging is not supported in that environment. |
| EFBIG      | The calling process was attempting to change the size of a file but the specified length is greater than the maximum file size limit for the process. |
EINVAL  The attributes structure containing the requested changes is not valid.

EPERM  The operation is not permitted for one of the following reasons:
  • The calling process was attempting to change the mode or the file format but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
  • The calling process was attempting to change the owner but it does not have appropriate privileges.
  • The calling process was attempting to change the general attribute bits but it does not have write permission for the file.
  • The calling process was attempting to set a time value (not current time) but the effective UID does not match the owner of the file, and it does not have appropriate privileges.
  • The calling process was attempting to set the change time or reference time to current time but it does not have write permission for the file.
  • The calling process was attempting to change auditing flags but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
  • The calling process was attempting to change the Security Auditor’s auditing flags but the user does not have auditor authority.

EROF S  **pathname** specifies a file that is on a read-only file system.

**Related Information**

* “sys/stat.h” on page 89

fchaudit

fchaudit() — Change Audit Flags for a File by Descriptor

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/stat.h>

int fchaudit(int fildes, unsigned int flags, unsigned int option);
```

General Description

Changes the audit flags of a file. The parameter `fildes` is the file descriptor for the open file whose audit flags are to be changed. `flags` specifies what the audit flags should be changed to:

- `AUDTREADFAIL` Audit failing read requests.
- `AUDTREADSUCC` Audit successful read requests.
- `AUDTWRITEFAIL` Audit failing write requests.
- `AUDTWRITESUCC` Audit successful write requests.
- `AUDTEXECFAIL` Audit failing execute or search requests.
- `AUDTEXECSUCC` Audit successful execute or search requests. The bitwise inclusive-OR of any or all of these can be used to set more than one type of auditing.

The parameter `option` specifies whether the user audit flags or the security auditor audit flags should be changed:

- `AUDT_USER (0)` User audit flags are changed. The user must be the file owner or have appropriate authority to change the user audit flags for a file.
- `AUDT_AUDITOR (1)` Security-auditor audit flags are changed. The user must have security auditor authority to change the security auditor audit flags for a file.

Returned Value

If successful, `fchaudit()` returns 0.

If unsuccessful, `fchaudit()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td><code>option</code> does not contain a 0 or 1.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The effective user ID (UID) of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.</td>
</tr>
<tr>
<td>EROFS</td>
<td><code>fildes</code> is associated with a file that is on a read-only file system.</td>
</tr>
</tbody>
</table>
Example

CELEBF02

/* CELEBF02

The following program changes the audit flags of a file.

*/
#define _OPEN_SYS
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#include <stdio.h>

main() {
  int fd;
  char fn[]="fchaudit.file";
  if ((fd = creat(fn, S_IRUSR|S_IWUSR)) < 0)
    perror("creat() error");
  else {
    if (fchaudit(fd, AUDTREADSUCC, AUDT_USER) != 0)
      perror("fchaudit() error");
    close(fd);
    unlink(fn);
  }
}

fchdir

fchdir() — Change Working Directory

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int fchdir(int fildes);
```

General Description

The fchdir() function has the same effect as chdir() except that the directory that is to be new current working directory is specified by the file descriptor `fildes`.

Returned Value

If successful, fchdir() changes the working directory and returns 0.

If unsuccessful, fchdir() does not change the working directory, returns -1, and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for the directory referenced by <code>fildes</code>.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The <code>fildes</code> arguments is not an open file descriptor.</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>The open file descriptor <code>fildes</code> does not refer to a directory.</td>
</tr>
</tbody>
</table>

fchmod() — Change the Mode of a File or Directory by Descriptor

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1a</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX1_SOURCE 2
#include <sys/stat.h>

int fchmod(int fildes, mode_t mode);
```

General Description

Sets the S_ISUID, S_ISGID, and file permission bits of the open file identified by `fildes`, its file descriptor.

The `mode` argument is created with one of the symbols defined in the `sys/stat.h` header file. For more information on these symbols, refer to `chmod() — Change the Mode of a File or Directory` on page 280.

Returned Value

If successful, `fchmod()` marks for update the `st_ctime` field of the file and returns 0.

If unsuccessful, `fchmod()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The effective user ID (UID) does not match the owner of the file, and the calling process does not have appropriate privileges.</td>
</tr>
<tr>
<td>EROFS</td>
<td>The file resides on a read-only file system.</td>
</tr>
</tbody>
</table>

Example

```c
CELEBF03

/* CELEBF03

   This example changes a file permission.

*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char fn[]="temp.file";
    int fd;
    struct stat info;
```
fchmod

if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
else {
    stat(fn, &info);
    printf("original permissions were: %08x\n", info.st_mode);
    if (fchmod(fd, S_IRWXU|S_IRWXG) != 0)
        perror("fchmod() error");
    else {
        stat(fn, &info);
        printf("after fchmod(), permissions are: %08x\n", info.st_mode);
    }
    close(fd);
    unlink(fn);
}

Output
original permissions were: 03000080
after fchmod(), permissions are: 030001f8

fchown() — Change the Owner or Group by File Descriptor

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1a</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX1_SOURCE 2
#include <unistd.h>

int fchown(int fildes, uid_t owner, gid_t group);
```

General Description

Changes the owner or group (or both) of a file. `fildes` is the file descriptor for the file. `owner` is the user ID (UID) of the new owner of the file. `group` is the group ID of the new group for the file.

If `_POSIX_CHOWN_RESTRICTED` is defined in the `unistd.h` header file, a process can change the group of a file only if one of the following conditions is true:

1. The process has appropriate privileges.
   Or
2. All of the following are true:
   a. The effective user ID of the process is equal to the user ID of the file owner.
   b. The `owner` argument is equal to the user ID of the file owner or `(uid_t)-1`,
   c. The `group` argument is either the effective group ID or a supplementary group ID of the calling process.

If `fildes` points to a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set when `fchown()` returns successfully, it clears the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file mode.

If the file referred to by `fildes` is not a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file are cleared.

When `fchown()` completes successfully, it marks the `st_ctime` field of the file to be updated.

Returned Value

If successful, `fchown()` updates the change time for the file and returns 0.

If unsuccessful, `fchown()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EPERM</td>
<td>Either the effective user ID does not match the owner of the file, or</td>
</tr>
</tbody>
</table>
fchown

the calling process does not have appropriate privileges, and
POSIX_CHOWN_RESTRICTED indicates that such privilege is
required.

EROFs The file resides on a read-only system.

Example

CELEBF04
/* CELEBF04
     This example changes the owner ID and group ID.
*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <unistd.h>
#include <sys/stat.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char fn[]="temp.file"
    FILE *stream;
    int fd;
    struct stat info;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        stat(fn, &info);
        printf("original owner was %d and group was %d\n", info.st_uid,
                info.st_gid);
        if (fchown(fd, 25, 0) != 0)
            perror("fchown() error");
        else {
            stat(fn, &info);
            printf("after fchown(), owner is %d and group is %d\n", info.st_uid, info.st_gid);
        }
    close(fd);
    unlink(fn);
}

Output
original owner was 0 and group was 500
after fchown(), owner is 25 and group is 0

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int fclose(FILE *stream);
```

General Description

Flushes a stream, and then closes the file associated with that stream. Afterwards, the function releases any buffers associated with the stream. To flush means that unwritten buffered data is written to the file, and unread buffered data is discarded.

A pointer to a closed file cannot be used as an input value to the freopen() function.

Note:

- The storage pointed to by the FILE pointer is freed by the fclose() function. An attempt to use the FILE pointer to a closed file is not valid. This restriction is true even when fclose() fails.
- If an application has locked a (FILE *) object (with flockfile() or ftrylockfile()), it is responsible for relinquishing the locked (FILE *) object (with funlockfile()) before calling fclose(). Failure to relinquish a locked (FILE *) object may cause deadlock (or looping).

Returned Value

If successful closing the stream, fclose() returns 0.

If a failure occurs in flushing buffers or in outputting data, fclose() returns EOF. An attempt will still be made to close the file.

Special Behavior for XPG4

fclose() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The O_NONBLOCK flag is set and output cannot be written immediately.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The underlying file descriptor is not valid.</td>
</tr>
<tr>
<td>EFBIG</td>
<td>Writing to the output file would exceed the maximum file size or the process’s file size supported by the implementation.</td>
</tr>
<tr>
<td>EINTR</td>
<td>The fclose() function was interrupted by a signal before it had written any output.</td>
</tr>
</tbody>
</table>
**fclose**

**EIO**  The process is in a background process group and is attempting to write to its controlling terminal, but TOSTOP (defined in the termio.h include file) is set, the process is neither ignoring nor blocking SIGTTOU signals, and the process group of the process is orphaned.

**ENOSPC**  There is no free space left on the output device.

**ENXIO**  A request was made of a nonexistent device, or the request was outside the device.

**EPIPE**  fclose() is trying to write to a pipe or FIFO that is not open for reading by any process. This error also generates a SIGPIPE signal.

**Example**

```c
/* This example opens a file myfile.dat for reading as a stream and then closes the file.
 */
#include <stdio.h>

int main(void) {
    FILE *stream;
    stream = fopen("myfile.dat", "r");
    ...
    if (fclose(stream)) /* Close the stream. */
        printf("fclose error\n");
}
```

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <unistd.h>
#include <fcntl.h>

int fcntl(int socket, int cmd, ...);
```

General Description

Performs various actions on open file descriptors.

The argument `fildes` is a file descriptor for the file you want to manipulate. `action` is a symbol indicating the action you want to perform on `fildes`. These symbols are defined in the `<fcntl.h>` header file. If needed, “...” indicates a third argument. The type of the third argument depends on `action`, and some actions do not need an additional argument.

Behavior for Sockets

The operating characteristics of sockets can be controlled with the `fcntl()` call. The operations to be controlled are determined by `cmd`. The `arg` parameter is a variable with a meaning that depends on the value of the `cmd` parameter.

<table>
<thead>
<tr>
<th>Parameter</th>

</tr>
</tbody>
</table>

The `action` argument can be one of the following symbols:

- `F_CLOSFD` Closes a range of file descriptors. A third `int` argument must be
specified to indicate the upper limit for the range of the file descriptors to be closed, while *fildes* specifies the lower limit. If −1 is specified for the third argument, all file descriptors greater than or equal to the lower limit are closed.

F_DUPFD Duplicates the file descriptor. A third *int* argument must be specified. `fcntl()` returns the lowest file descriptor greater than or equal to this third argument that is not already associated with an open file. This file descriptor refers to the same file as *fildes* and shares any locks. The flags FD_CLOEXEC and FD_CLOFORK are turned off in the new file descriptor, so that the file is kept open if an exec function is called.

**Note:** If *fildes* is an XTI endpoint, there must be at least one available file descriptor greater than or equal to the third argument and less than 65536.

F_DUPFD2 Duplicates the file descriptor. A third *int* argument must be specified to indicate which file descriptor to use as the duplicate. This file descriptor is closed if already open and then used as the new file descriptor. The new file descriptor refers to the same file as *fildes* and shares any locks. The flags FD_CLOEXEC and FD_CLOFORK are turned off in the new file descriptor, so that the file is kept open if an exec function is called.

**Note:** If *fildes* is an XTI endpoint, the third argument must not exceed the limit of 65535.

F_GETFD Obtains the file descriptor flags for *fildes*. `fcntl()` returns these flags as its result. For a list of supported file descriptor flags, see "File Flags" on page 531.

F_SETFD Sets the file descriptor flags for *fildes*. You must specify a third *int* argument, giving the new file descriptor flag settings. `fcntl()` returns 0 if it successfully sets the flags.

F_GETFL Obtains the file status flags and file access mode flags for *fildes*. `fcntl()` returns these flags as its result. For a list of supported file status and file access mode flags, see "File Flags" on page 531.

**Behavior for Sockets:** This command gets the status flags of socket descriptor `socket`. With the `_OPEN_SYS` feature test macro you can query the FNDELAY flag. With the `_XOPEN_SOURCE_EXTENDED` feature test macro you can query the O_NDELAY flag. The FNDELAY and O_NDELAY flags mark `socket` as being in nonblocking mode. If data is not present on calls that can block, such as `read()`, `readv()`, and `recv()`, the call returns with −1, and the error code is set to EWOULDBLOCK.

F_SETFL Sets the file status flags for *fildes*. You must specify a third *int* argument, giving the new file descriptor flag settings. `fcntl()` does not change the file access mode, and file access bits in the third argument are ignored. `fcntl()` returns 0 if it successfully sets the flags.

**Behavior for Sockets:** This command sets the status flags of socket descriptor `socket`. With the `_OPEN_SYS` feature test macro you can set the FNDELAY flag. With the `_XOPEN_SOURCE_EXTENDED` feature test macro you can set the O_NDELAY flag.
F_GETLK Obtains locking information for a file. See “File Locking” on page 532.

F_SETLK Sets or clears a file segment lock. See “File Locking” on page 532.

F_SETLKW Sets or clears a file segment lock; but if a shared or exclusive lock is blocked by other locks, fcntl() waits until the request can be satisfied. See “File Locking” on page 532.

F_GETOWN Behavior for Sockets: Obtains the PID for the filedes and returns this value. The value returned will be either the process ID or the process group ID that is associated with the socket. If it is a positive integer, it specifies a process ID. If it is a negative integer (other than -1), it specifies a process group ID.

F_SETOWN Behavior for Sockets: Sets either the process ID or the process group ID that is to receive either the SIGIO or SIGURG signals for the socket associated with filedes. The SIGURG signal is generated as a result of receiving out-of-band data. Refer to send(), sendto(), sendmsg(), and recv(), recvfrom() and recvmsg() for more information on sending and receiving out-of-band data.

You must specify a third int argument, giving the PID requested. This value can be either a positive integer, specifying a process ID, or a negative integer (other than -1), specifying a process group ID. The difference between specifying a process ID or a process group ID is that in the first case only a single process will receive the signal, while in the second case all processes in the process group will receive the signal.

F_SETTAG Sets the file tag for the file referred to by file descriptor filedes.

The third argument flag is the address of a populated file_tag structure.

If the flag argument supplied to fcntl(F_SETTAG) does not have the ft_deferred bit set ON, fcntl() will immediately set the file's File Tag with the provided flag's ft_ccsid and ft_txtflag values.

If the flag argument supplied to fcntl(F_SETTAG) has the ft_deferred bit set ON, fcntl() will not set the file's File Tag until first write to the file. The CCSID used to tag the file will be the current Program CCSID at the time of first write, regardless of the flag ft_ccsid value, however the ft_txtflag value will be used.

If the ft_ccsid of the specified file_tag differs from the Program CCSID, automatic file conversion will occur, provided:

- The ft_txtflag is set to ON.
- The BPXPRMxx member AUTOCVT() is ON or environment variable _BPXK_AUTOCVT is ON.

If AUTOCVT(OFF) and _BPXK_AUTOCVT=OFF, the file will be tagged with the specified file_tag's ft_ccsid and ft_txtflag values, but automatic conversion will not occur.

If the flag argument supplied to fcntl(F_SETTAG) has the ft_deferred bit set ON, pipes and FIFOs are tagged from the write end with the Program CCSID of the first writer.

F_CONTROL_CVT Controls or queries the conversion status of the open file referred to.
by file descriptor `fildes`. Conversion control is generally used to provide CCSID information for untagged files or untagged programs.

Character set conversion between a program and a file, pipe or other I/O stream can be enabled or changed with `FCONTROL_CVT`. A pair of CCSID's is specified or defaulted, one for the program and one for the data. As the program reads and writes data, the system will convert from one CCSID to the other.

The third `f_cnvrt` argument is the required address of an `f_cnvrt` structure. This structure is defined in `<fcntl.h>` and includes the following members:

*Table 25. Struct f_cnvrt Element Descriptions*

<table>
<thead>
<tr>
<th>Element</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pccsid</code></td>
<td>short</td>
<td>The Program CCSID - This is output from query and input to setting conversion ON. A value of 0 on input indicates to use the previously set value or the current Program CCSID.</td>
</tr>
<tr>
<td><code>fccsid</code></td>
<td>short</td>
<td>The File CCSID - This is output from query and input to setting conversion ON. A value of 0 on input indicates to use the CCSID from the File Tag as stored in the file, specified on mount, or set by a prior call.</td>
</tr>
</tbody>
</table>
Table 25. Struct f_cnvrt Element Descriptions (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cvtcmd</td>
<td>int</td>
<td>Conversion Control Command. The following conversion controls are available:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Query Conversion - Returns whether or not conversion is in effect and the Program and File CCSIDs being used. On input, cvtcmd is set to QUERYCVT, and on output, it is changed to either SETCVTON or SETCVTOFF to indicate that conversion is currently ON or OFF respectively. The current CCSIDs are also returned in their respective positions in the f_cnvrt structure.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Set Conversion OFF - Turns OFF any conversion that may be in effect. On input, cvtcmd is set to SETCVTOFF and the rest of the f_cnvrt is ignored. There is no output. A program can use this to override an automatic conversion that might be established by the environment within which it is invoked. If conversion is currently in effect, the CCSIDs being used will be remembered while conversion is turned OFF, so that the prior conversion may be resumed without the program having to remember what the prior CCSIDs were.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Set Conversion ON - Turns ON conversion and optionally specifies the CCSIDs to use in place of the Program or File CCSIDs that are currently in effect. A value of 0 for the Program CCSID indicates that the current Program CCSID be used. A value of 0 for the file CCSID indicates that no change should be made to the File CCSID. This does not affect the stored File Tag or the current Program CCSID. It only changes the values being used to control conversion on this data stream.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• On input, cvtcmd is set to either SETCVTON to unconditionally turn on conversion or to SETAUTOCVTON to turn ON conversion only if AUTOCVT=YES was specified in BPXPRMxx or _BPXK_AUTOCVT=ON.</td>
</tr>
</tbody>
</table>

The call fails if a conversion table is not installed for the resulting CCSID pair.

**Warning:** Flipping the autoconversion mode off and on, or changing the CCSID values during the execution of a program in which file conversion and/or tagging takes place, or setting the CCSIDs to values that are not compatible with the program or file, can be quite unpredictable.

**File Flags**

There are several types of flags associated with each open file. Flags for a file are represented by symbols defined in the <fcntl.h> header file.

The following *file descriptor* flags can be associated with a file:
If this flag is 1, the file descriptor is closed if the process executes one of the exec function calls. If it is 0, the file remains open.

If this flag is 1 when a fork occurs, the file descriptor will be closed for the child process. If it is 0, the file remains open for the child.

The following file status flags can be associated with a file:

- **O_APPEND** Append mode. If this flag is 1, every write operation on the file begins at the end of the file.
- **O_ASYNCSIG** If this flag is 1, then asynchronous I/O will be used for the file.
- **O_NONBLOCK** No blocking. If this flag is 1, read and write operations on the file return with an error status if they cannot perform their I/O immediately. If this flag is 0, read and write operations on the file wait (or “block”) until the file is ready for I/O. For more details, see "read() — Read From a File or Socket" on page 1602 and "write() — Write Data on a File or Socket" on page 2464.
- **O_SYNC** Force synchronous update. If the flag is 1, every write() operation on the file is written to permanent storage. That is, the file system buffers are forced to permanent storage. (See "fsync() — Write Changes to Direct-Access Storage" on page 709.) If this flag is 0, update operations on the file will not be completed until the data has been written to permanent storage. On return from a function that performs a synchronous update, the program is assured that all data for the file has been written to permanent storage.

The following file access mode flags can be associated with a file:

- **O_RDONLY** The file is opened for reading only.
- **O_RDWR** The file is opened for reading and writing.
- **O_WRONLY** The file is opened for writing only.

Two masks can be used to extract flags:

- **O_ACCMODE** Extracts file access mode flags.
- **O_GETFL** Extracts file status flags and file access mode flags.

File Locking

A process can use fcntl() to lock out other processes from a part of a file, so that the process can read or write to that part of the file without interference from others. File locking can ensure data integrity when several processes have a file accessed concurrently. File locking can only be performed on file descriptors that refer to regular files. Locking is not permitted on file descriptors that refer to directories, FIFOs, pipes, character special files, or any other type of files.

A structure that has the type struct flock (defined in the <fcntl.h> header file) controls locking operations. This structure has the following members:

- **short l_type** Indicates the type of lock, using one of the following symbols (defined in the <fcntl.h> header file):
  - F_RDLCK Indicates a read lock, also called a shared lock. The process can read the locked part of the file,
and other processes cannot obtain write locks for that part of the file in the meantime. More than one process can have a read lock on the same part of a file simultaneously.

To establish a read lock, a process must have the file accessed for reading.

**F_WRLCK** Indicates a write lock, also called an exclusive lock. The process can write on the locked part of the file, and no other process can establish a read lock or write lock on that same part or on an overlapping part of the file. A process cannot put a write lock on part of a file if there is already a read lock on an overlapping part of the file. To establish a write lock, a process must have accessed the file for writing.

**F_UNLCK** Unlocks a lock that was set previously. An unlock (F_UNLCK) request in which l_len is non-zero and the offset of the last byte of the requested segment is the maximum value for an object of type off_t, when the process has an existing lock in which l_len is 0 and which includes the last byte of the requested segment, is treated as a request to unlock from the start of the requested segment with an l_len equal to 0. Otherwise, an unlock (F_UNLCK) request attempts to unlock only the requested segment.

**short l_whence** One of three symbols used to determine the part of the file that is affected by this lock. These symbols are defined in the <unistd.h> header file and are the same as symbols used by lseek():

- SEEK_CUR The current file offset in the file
- SEEK_END The end of the file
- SEEK_SET The start of the file.

**off_t l_start** Gives the byte offset used to identify the part of the file that is affected by this lock. The part of the file affected by the lock begins at this offset from the location given by l_whence. For example, if l_whence is SEEK_SET and l_start is 10, the locked part of the file begins at an offset of 10 bytes from the beginning of the file.

**off_t l_len** Gives the size of the locked part of the file in bytes. If l_len is 0, the locked part of the file begins at the position specified by l_whence and l_start, and extends to the end of the file. If l_len is positive, the area affected starts at l_start and end at l_start + l_len-1. If l_len is negative, the area affected starts at l_start + l_len and end at l_start-1. Locks may start and extend beyond the current end of a file, but cannot extend before the beginning of the file. A lock can be set to extend to the largest possible value of the file offset for that file by setting l_len to 0. If such a lock also has l_start set to 0 and l_whence is set to SEEK_SET, the whole file is locked.

**pid_t l_pid** Specifies the process ID of the process that holds the lock. This is an output field used only with F_GETLK actions.
You can set locks by specifying F_SETLK as the action argument for fcntl(). Such a function call requires a third argument pointing to a struct flock structure, as in this example:

```c
struct flock lock_it;
lock_it.l_type = F_RDLCK;
lock_it.l_whence = SEEK_SET;
lock_it.l_start = 0;
lock_it.l_len = 100;
fcntl(fildes,F_SETLK,&lock_it);
```

This example sets up an flock structure describing a read lock on the first 100 bytes of a file, and then calls fcntl() to establish the lock. You can unlock this lock by setting _l_type_ to F_UNLCK and making the same call. If an F_SETLK operation cannot set a lock, it returns immediately with an error saying that the lock cannot be set.

The F_SETLKW operation is similar to F_SETLK, except that it waits until the lock can be set. For example, if you want to establish an exclusive lock and some other process already has a lock established on an overlapping part of the file, fcntl() waits until the other process has removed its lock. If fcntl() is waiting in an F_SETLKW operation when a signal is received, fcntl() is interrupted. After handling the signal, fcntl() returns −1 and sets errno to EINTR.

F_SETLKW operations can encounter deadlocks when process A is waiting for process B to unlock a region, and B is waiting for A to unlock a different region. If the system detects that an F_SETLKW might cause a deadlock, fcntl() fails with errno set to EDEADLK.

A process can determine locking information about a file by using F_GETLK as the action argument for fcntl(). In this case, the call to fcntl() should specify a third argument pointing to a flock structure. The structure should describe the lock operation you want. When fcntl() returns, the structure indicated by the flock pointer is changed to show the first lock that would prevent the proposed lock operation from taking place. The returned structure shows the type of lock that is set, the part of the file that is locked, and the process ID of the process that holds the lock. In the returned structure:

- _l_whence_ is always SEEK_SET.
- _l_start_ gives the offset of the locked portion from the beginning of the file.
- _l_len_ is the length of the locked portion.

If there are no locks that prevent the proposed lock operation, the returned structure has F_UNLCK in _l_type_, and is otherwise unchanged.

A process can have several locks on a file simultaneously but only one type of lock set on a given byte. Therefore, if a process puts a new lock on part of a file that it had locked previously, the process has only one lock on that part of the file: the type of the lock is the one specified in the most recent locking operation.

All of a process’s locks on a file are removed when the process closes any file descriptor that refers to the locked file. Locks are not inherited by child processes created with fork().

All locks are advisory only. Processes can use locks to inform each other that they want to protect parts of a file, but locks do not prevent I/O on the locked parts. If a process has appropriate permissions on a file, it can perform whatever I/O it chooses, regardless of what locks are set. Therefore, file locking is only a convention, and it works only when all processes respect the convention.
Large Files for HFS

**Note:** Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option LANG_LVL(LONGLONG) and also define the Feature Test Macro (FTM) _LARGE_FILES before any headers are included will enable this function to operate on HFS files that are larger than 2 gig-1 in size. File size and offset fields will be enlarged to 63 bits in width so any other function operating on this file will have to be enabled with the same FTM.

Usage of the F_GETFL command will return the setting of O_LARGEFILE status flag when fcntl() has been enabled to operate on large files.

**Returned Value**

If successful, the value fcntl() returns will depend on the *action* that was specified.

If unsuccessful, fcntl() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The process tried to set a lock with F_SETLK, but the lock is in conflict with a lock already set by some other process on an overlapping part of the file.</td>
</tr>
<tr>
<td>EBADF</td>
<td><em>fildes</em> is not a valid open file descriptor; or the process tried to set a read lock on a file descriptor open for writing only; or the process tried to set a write lock on a file descriptor open for reading only; or the socket parameter is not a valid socket descriptor.</td>
</tr>
<tr>
<td>EDEADLK</td>
<td>The system detected the potential for deadlock in a F_SETLKW operation.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>fcntl() was interrupted by a signal during a F_SETLKW operation.</td>
</tr>
<tr>
<td>EINTR</td>
<td>In a locking operation, <em>fildes</em> refers to a file with a type that does not support locking, or the struct flock pointed to by the third argument has an incorrect form.</td>
</tr>
<tr>
<td>EMFILE</td>
<td>In an F_DUPFD operation, the process has already reached its maximum number of file descriptors, or there are no available file descriptors greater than the specified third argument.</td>
</tr>
<tr>
<td>ENOLCK</td>
<td>In an F_SETLK or F_SETLKW operation, the specified file has already reached the maximum number of locked regions allowed by the system.</td>
</tr>
<tr>
<td>EOVERFLOW</td>
<td>One of the values to be returned cannot be represented correctly.</td>
</tr>
</tbody>
</table>
The cmd argument is F_GETLK, F_SETLK or F_SETLKW and the smallest or, if l_len is nonzero, the largest offset of any byte in the requested segment cannot be represented correctly in an object of type off_t.

**EPERM** The operation was F_CLOSF D, but all the requested file descriptors were not closed.

### Examples

**CELEBF06**

/* CELEBF06

This example illustrates one use of fcntl().
The example will compile only with C/MVS.

*/

#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <signal.h>
#include <stdio.h>

void catcher(int signum) {
    puts("inside catcher...");
}

main() {
    int p[2], flags;
    struct sigaction sact;
    char c;

    if (pipe(p) != 0)
        perror("pipe() error");
    else {
        sigemptyset(&sact.sa_mask);
        sact.sa_flags = 0;
        sact.sa_handler = catcher;
        sigaction(SIGALRM, &sact, NULL);

        alarm(10);

        if (read(p[0], &c, 1) == -1)
            perror("first read() failed");

        if ((flags = fcntl(p[0], F_GETFL)) == -1)
            perror("first fcntl() failed");
        else if (fcntl(p[0], F_SETFL, flags | O_NONBLOCK) == -1)
            perror("second fcntl() failed");
        else {
            alarm(10);

            if (read(p[0], &c, 1) == -1)
                perror("second read() failed");

            alarm(0);
        }
    }
    close(p[0]);
    close(p[1]);
}

### Output
inside catcher...
first read() failed: Interrupted function call
second read() failed: Resource temporarily unavailable

Sockets example:
#define _OPEN_SYS
int s;
int rc;
int flags;
;
/* Place the socket into nonblocking mode */
rc = fcntl(s, F_SETFL, FNDELAY);

/* See if asynchronous notification is set */
flags = fcntl(s, F_GETFL, 0);
if (flags & FNDELAY)
  /* it is set */
else
  /* it is not */

fcvt

fcvt() — Convert Double to String

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *fcvt(double x, int ndigit, int *__restrict__ decpt, int *__restrict__ sign);
```

General Description

The fcvt() function converts double floating-point argument values to floating-point output strings. The fcvt() function has been extended to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of double argument values by using __isBFP().

z/OS XL C/C++ formatted output functions, including the fcvt() function, convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences. See “fprintf Family of Formatted Output Functions” on page 655 for a description of the special infinity and NaN output sequences.

The fcvt() function converts x to a NULL-terminated string which has ndigit digits to the right of the radix point (where the total number of digits in the output string is restricted by the precision of a double) and returns a pointer to the string. The function behaves identically to “ecvt() — Convert Double to String” on page 464 in all respects other than the number of digits in the return value.

Note: This function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The sprintf() function is preferred for portability.

Returned Value

If successful, fcvt() returns the character equivalent of x as specified above.

If unable to allocate the return buffer, or the conversion fails, fcvt() returns NULL.

fdelrec() — Delete a VSAM Record

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int fdelrec(FILE *stream);
```

General Description

Removes the record previously read by fread() from the VSAM file associated with `stream`. The fdelrec() function can only be used after an fread() call has been performed and before any other operation on that file pointer. For example, if you need to acquire the file position using ftell() or fgetpos(), you can do it either before the fread() or after the fdelrec(). An fread() after an fdelrec() will retrieve the next record.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The fdelrec() function can be used with key sequenced data sets (KSDS), KSDS PATHs, and relative record data set (RRDS) opened in an update mode (that is, rb+/r+b, wb+/w+b, or ab+/a+b), with type=record.

VSAM does not support deletions from ESDSs.

Returned Value

If successful, fdelrec() returns 0.

If unsuccessful, fdelrec() returns nonzero.

Example

```c
/* This example shows how a VSAM record is deleted using the fdelrec() function. */
#include <stdio.h>
FILE *stream;
char buf[80];
int num_read;
int rc;
stream = fopen("DD:MYCLUS", "rb+,type=record");
num_read = fread(buf, 1, sizeof(buf), stream);
```
fdelecrec

rc = fdelecrec(stream);
;

fdetach() — Detach a Name from a STREAMS-based File Descriptor

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int fdetach(const char *path);
```

General Description

The fdetach() function detaches a STREAMS-based file from the file to which it was attached by a previous call to fattach(). The `path` argument points to the pathname of the attached STREAMS file. The process must have appropriate privileges or be the owner of the file. A successful call to fdetach() causes all pathnames that named the attached STREAMS file to again name the file to which the STREAMS file was attached. All subsequent operations on `path` will operate on the underlying file and not on the STREAMS file.

All open file descriptions established while the STREAMS file was attached to the file referenced by `path`, will still refer to the STREAMS file after the fdetach() has taken effect.

If there are no open file descriptors or other references to the STREAMS file, then a successful call to fdetach() has the same effect as performing the last close() on the attached file.

Returned Value

If successful, fdetach() returns 0.

If unsuccessful, fdetach() returns −1 and sets errno to one of the following values.

**Note:** 

z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for fdetach() to detach a file from a STREAMS-based file descriptor. See "open() — Open a File" on page 1313 for more information.

<table>

fdopen() — Associate a Stream with an Open File Descriptor

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE  
#include <stdio.h>      

FILE *fdopen(int fildes, const char *options);
```

General Description

Associates a stream with an open file descriptor. A _stream_ is a pointer to a _FILE_ structure that contains information about a file. A stream permits user-controllable buffering and formatted input and output. For a discussion of the z/OS UNIX services implementation of buffering, see z/OS XL C/C++ Programming Guide.

The specified _options_ must be permitted by the current mode of the file descriptor. For example, if the file descriptor is open-read-only (O_RDONLY), the corresponding stream cannot be opened write-only (w).

These options are the same as for an fopen() operation:

### Special Behavior for XPG4.2

The values for options are changed to include binary streams.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>r or rb</td>
<td>Open for reading.</td>
</tr>
<tr>
<td>w or wb</td>
<td>Open for writing.</td>
</tr>
<tr>
<td>a or ab</td>
<td>Open for appending.</td>
</tr>
<tr>
<td>r+ or rb+ or r+b</td>
<td>Open for update (reading and writing).</td>
</tr>
<tr>
<td>w+ or wb+ or w+b</td>
<td>Open for update (reading and writing).</td>
</tr>
<tr>
<td>a+ or ab+ or a+b</td>
<td>Open for update at End Of File (EOF) (reading and writing).</td>
</tr>
</tbody>
</table>

All these options have the same behavior as the corresponding fopen() options, except that w, wb, w+, wb+ and w+b do not truncate the file.

The file position indicator of the new stream is the file offset associated with the file descriptor. The error indicator and End Of File (EOF) indicator for the stream are cleared.

Returned Value

If successful, fdopen() returns a FILE pointer to the control block for the new stream.
If unsuccessful, fdopen() returns NULL and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>filedes is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The specified mode is incorrect or does not match the mode of the open file descriptor.</td>
</tr>
</tbody>
</table>

Example

CELEBF08

/* CELEBF08 */

This example associates stream with the file descriptor fd which is open for the file fdopen.file. The association is made in write mode.

```c
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <unistd.h>

main() {
    char fn[]="fdopen.file";
    FILE *stream;
    int fd;

    if ((fd = creat(fn, S_IWUSR)) < 0) 
        perror("creat() error");
    else {
        if ((stream = fdopen(fd, "w")) == NULL) {
            perror("fdopen() error");
            close(fd);
        }
        else {
            fputs("This is a test", stream);
            fclose(stream);
        }
    }
}
```

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int feclearexcept (int excepts);
```

General Description

feclearexcept() clears the supported floating-point exceptions represented by `excepts`.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>feclearexcept</td>
<td></td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

If successful, feclearexcept() returns 0 if the argument passed is 0 or if all the exceptions are successfully cleared.

Related Information

fe_dec_getround

fe_dec_getround() — Get the Current Rounding Mode

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

#define __STDC_WANT_DEC_FP__
#include <fenv.h>

int fe_dec_getround(void);

General Description

The fe_dec_getround function gets the current rounding mode for decimal floating-point operations.

The following rounding modes are defined for decimal floating-point, and are located in fenv.h:

- **FE_DEC_DOWNWARD**
  rounds towards minus infinity

- **FE_DEC_TONEAREST**
  rounds to nearest

- **FE_DEC_TOWARDZERO**
  rounds toward zero

- **FE_DEC_UPWARD**
  rounds toward plus infinity

- **FE_DEC_TONEARESTFROMZERO**
  rounds to nearest, ties away from zero

- **_FE_DEC_AWAYFROMZERO**
  rounds away from zero

- **_FE_DEC_TONEARESTTOWARDZERO**
  rounds to nearest, ties toward zero

- **_FE_DEC_PREPAREFORSHORTER**
  rounds to prepare for shorter precision

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

If successful, returns the value of the current rounding mode for decimal floating-point operations.

If there is no such rounding mode or the current rounding mode can't be determined returns -1.
Example

/* CELEBF77

sample program that issues fe_dec_getround()/setround()

This program calls fe_dec_getround() to get the DFP rounding mode.
Then it will compare the returned value with FE_DEC_TONEAREST
rounding mode. If not the same, it will call fe_dec_setround() to
set the rounding mode to the desired value FE_DEC_TONEAREST.
*/

#define __STDC_WANT_DEC_FP_
#include <fenv.h>
#include <stdlib.h>
#include <stdio.h>

int main(int argc, char *argv[]){
    int r;
    if ((r = fe_dec_getround()) == -1){
        perror("fe_dec_getround");
        exit (-1);
    }
    printf("The Decimal floating point rounding mode is %d\n", r);
    if (r != FE_DEC_TONEAREST){
        printf("The DFP rounding mode is not FE_DEC_TONEAREST.\n");
        if (fe_dec_setround(FE_DEC_TONEAREST) == -1){
            perror("fe_dec_setround");
            exit (-1);
        }
    }
    printf("The DFP rounding mode has been set to FE_DEC_TONEAREST.\n");
    return 0;
}

Related Information

fe_dec_setround

- fe_dec_setround() — Set the Current Rounding Mode

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <fenv.h>

int fe_dec_setround(int round);
```

General Description

The `fe_dec_setround` function establishes the rounding mode for decimal floating-point operations represented by its argument `round`. If the argument is not equal to the value of a valid rounding mode, the rounding mode is not changed.

The following rounding modes are defined for decimal floating-point, and are located in `fenv.h`:

- **FE_DEC_DOWNWARD**
  - rounds towards minus infinity
- **FE_DEC_TONEAREST**
  - rounds to nearest
- **FE_DEC_TOWARDZERO**
  - rounds toward zero
- **FE_DEC_UPWARD**
  - rounds toward plus infinity
- **FE_DEC_TONEARESTFROMZERO**
  - rounds to nearest, ties away from zero
- **_FE_DEC_AWAYFROMZERO**
  - rounds away from zero
- **_FE_DEC_TONEARESTTOWARDZERO**
  - rounds to nearest, ties toward zero
- **_FE_DEC_PREPAREFORSHORTER**
  - rounds to prepare for shorter precision

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

If successful, returns a zero value.

If the argument is not equal to a valid rounding mode, returns -1. The following error nos are defined:
**Error Code** | **Definition**
--- | ---
EINVAL | The rounding mode specified is not a valid Decimal Floating Point rounding mode.
EMVSERR | The function was unable to set the specified rounding mode due to an internal error.

**Example**

```c
/* CELEBF77

sample program that issues fe_dec_getround()/setround()

This program calls fe_dec_getround() to get the DFP rounding mode. Then it will compare the returned value with FE_DEC_TONEAREST rounding mode. If not the same, it will call fe_dec_setround() to set the rounding mode to the desired value FE_DEC_TONEAREST.
*/

#define __STDC_WANT_DEC_FP__
#include <fenv.h>
#include <stdlib.h>
#include <stdio.h>

int main(int argc, char *argv[]){
    int r;
    if ((r = fe_dec_getround()) == -1){
        perror("fe_dec_getround");
        exit (-1);
    }
    printf("The Decimal floating point rounding mode is %d\n", r);
    if (r != FE_DEC_TONEAREST){
        printf("The DFP rounding mode is not FE_DEC_TONEAREST.\n");
        if (fe_dec_setround(FE_DEC_TONEAREST) == -1){
            perror("fe_dec_setround");
            exit (-1);
        }
    }
    printf("The DFP rounding mode has been set to FE_DEC_TONEAREST.\n");
    return 0;
}
```

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <stdio.h>

int feof(FILE *stream);
```

General Description

Indicates whether the EOF flag is set for the given stream pointed to by `stream`.

The EOF flag is set when the user attempts to read past the EOF. Thus, a read of the last character in the file does not turn the flag on. A subsequent read attempt reaches the EOF.

For HFS files, a simultaneous reader cannot see the extensions automatically. Use `clearerr()` is required to reset the EOF flag.

If the file has a simultaneous writer that extends the file, the flag can be turned on by the reader before the file is extended. After the extension becomes visible to the reader, a subsequent read will get the new data and set the flag appropriately (see `fflush()`). For example, if the read does not read past the EOF, the flag is turned off. If a file does not have a simultaneous writer that is extending the file, it is not possible to read past EOF.

A successful repositioning in a file (with `fsetpos()`, `rewind()`, `fseek()`) or a call to `clearerr()` resets the EOF flag. For a terminal file, when the EOF flag is set, subsequent reads will continue to deliver no data until the EOF flag is cleared. This can be accomplished by calling `clearerr()` or `rewind()`.

The terminal can only read past the EOF after the `rewind()` function or the `clearerr()` function is called. The EOF flag is cleared by calling `rewind()`, `fsetpos()`, `fseek()`, or `clearerr()` for this stream.

Returned Value

If and only if the EOF flag is set for `stream`, `feof()` returns nonzero.

Otherwise, `feof()` returns 0.

Example

```
CELEBF09
/* CELEBF09
   This example scans the input stream until it reads an EOF character.
```
/*
#include <stdio.h>
#include <stdlib.h>

main() {
    FILE *stream;
    int rc;
    stream = fopen("myfile.dat","r");

    /* myfile.dat contains 3 characters "abc" */
    while (1) {
        rc = fgetc(stream);
        if (rc == EOF) {
            if (feof(stream)) {
                printf("at EOF\n");
                break;
            } else {
                printf("error\n");
                break;
            }
        } else
            printf("read %c\n",rc);
    }
}

Output
read a
read b
read c
at EOF

feraiseexcept

feraiseexcept() — Raise the Supported Floating-Point Exceptions

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <fenv.h>

int feraiseexcept(int excepts);
```

General Description

feraiseexcept() raises the supported floating-point exceptions represented by `excepts`. The order in which these floating-point exceptions are raised is unspecified.

**Note:** The following table shows the viable formats for these functions. See “IEEE Binary Floating-Point” on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>feraiseexcept</td>
<td></td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

If successful, feraiseexcept() returns 0 if the argument passed is 0 or if all the exceptions are successfully raised.

Related Information

.
ferror() — Test for Read/Write Errors

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int ferror(FILE *stream);
```

General Description

Tests for an error in reading from or writing to the specified `stream`. If an error occurs, the error indicator for the `stream` remains set until you close the `stream`, call `rewind()`, or call `clearerr()`.

If a non-valid parameter is given to an I/O function, z/OS XL C/C++ does not turn the error flag on. This case differs from one where parameters are not valid in context with one another.

Returned Value

If successful, `ferror()` returns a nonzero value to indicate an error for the stream pointed to by `stream`.

If unsuccessful, `ferror()` returns 0.

Example

```c
CELEBF10

/* CELEBF10 */

This example puts data out to a stream and then checks that a write error has not occurred.

*/
#include <stdio.h>

int main(void)
{
    FILE *stream;
    char *string = "Important information";
    stream = fopen("myfile.dat","w");

    fprintf(stream, "%s\n", string);
    if (ferror(stream))
    {
        printf("write error\n");
        clearerr(stream);
    }
```
ferror

}  
if (fclose(stream))  
printf("fclose error\n");  
}

fesetenv() — Set the Floating-Point Environment

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R9</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C/C++ DFP</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <fenv.h>

int fesetenv(const fenv_t *envp);
```

General Description

fesetenv() establishes the floating-point environment represented by the object pointed to by `envp`. The argument `envp` points to an object set by a call to `fegetenv()` or `feholdexcept()`, or equal to a floating-point environment macro. `fesetenv()` merely installs the state of the floating-point status flags represented through `envp` and does not raise these floating-point exceptions.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point " on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>fesetenv</td>
<td></td>
<td>X</td>
</tr>
</tbody>
</table>

**Note:**
- If the hardware has the decimal floating-point facility installed, this function can be used to set the decimal floating-point rounding mode.
- This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

If successful, `fesetenv()` returns 0 if the settings are restored.

If unsuccessful, `fesetenv()` returns -1 and sets one of the following `errno` values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The rounding mode specified is not a valid Decimal Floating Point rounding mode.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>The function was unable to set the specified rounding mode due to an internal error.</td>
</tr>
</tbody>
</table>

fesetexceptflag() — Set the Floating-Point Status Flags

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <fenv.h>

int fesetexceptflag(const fexcept_t *flagp, int excepts);
```

General Description

fesetexceptflag() sets the floating-point status flags indicated by `excepts` to the states stored in the object pointed to by `flagp`. The value of `flagp` should be set by `fegetexceptflag()`, whose second argument represents the floating-point exceptions indicated by the argument `excepts`. This function does not raise floating-point exceptions, but only sets the state of the flags.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>fesetexceptflag</td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

Returned Value

If successful, fesetexceptflag() returns 0 if `excepts` is 0 or if all selected exceptions are successfully set.

Related Information
fesetround

fesetround() — Set the Current Rounding Mode

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99 Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <fenv.h>

int fesetround(int round);
```

General Description

fesetround() establishes the rounding mode represented by `round`. If the argument is not equal to the value of a rounding mode macro, the rounding mode is not changed.

**Note:** The following table shows the viable formats for these functions. See [“IEEE Binary Floating-Point” on page 108](#) for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>fesetround</td>
<td></td>
<td>X</td>
</tr>
</tbody>
</table>

**Note:** This function will not return or update decimal floating-point rounding mode bits. The `fe_dec_getround()` and `fe_dec_setround()` functions can be used to get and set the current rounding mode for decimal floating-point operations.

Returned Value

If successful, fesetround() returns 0 when `round` is set to a rounding mode.

Related Information

- “`fe_dec_getround()` — Get the Current Rounding Mode” on page 548
- “`fe_dec_setround()` — Set the Current Rounding Mode” on page 550
fetch() — Get a Load Module

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>C</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

void (*fetch(const char *name))();
```

General Description

Dynamically loads the load module specified by name into memory. The load module can then be invoked from a z/OS XL C program. The name or the alias by which the fetchable load module is identified in the load module library must appear in a fetch() library function call.

To avoid infringing on the user's name space, this nonstandard function has two names. One name, the external entry point name, is prefixed with two underscore characters, and the other name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters __fetch()) or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED), any relevant information in the header is also exposed.

You cannot fetch a module that contains a main(). If you do, fetch() will not return a usable pointer. Use of the pointer will result in undefined behavior. To call these types of modules, use the system() library function. Alternatively, when creating the module, you can reset the entry point so that the linkage is provided by z/OS XL C.

When non-reentrant modules have been fetched multiple times, you should release them in the reverse order; otherwise the load modules may not be deleted immediately.

You can fetch modules written in C and C++. For C modules, the source of the fetched module must, in general, contain #pragma linkage(..., fetchable) (the exception is described below). To fetch a C++ module, the routine must be declared extern "C", and must be declared in a #pragma linkage(..., fetchable) directive.

See also “fetchep() — Share Writable Static” on page 578 for more information about the need for #pragma Linkage.

Note: For C or C++ modules that are compiled with the XPLINK option and are to be fetched, #pragma linkage(..., fetchable) is required. They cannot use the technique of resetting the entry point. If an application tries to fetch() an XPLINK routine that did not specify FETCHABLE, then an error will be returned.

XPLINK programs can fetch non-XPLINK programs, and vice versa. The function descriptor returned by fetch() will contain glue code to support a
stack swap and parameter list conversion if necessary. Calls to a fetched routine that do not cross an XPLINK linkage boundary will not incur any glue code overhead.

If the fetched module is compiled as a DLL it can import variables and functions from other DLL modules, but it cannot export variables or functions.

Nested fetching is supported. That is, a fetched module can also invoke the fetch() library function to dynamically load a separate fetchable module.

Multiple fetching is also supported. Fetching a module more than once will result in separate fetch pointers. If the module is marked “reentrant”, multiple fetches will not reload the module into storage. Under MVS, you can place the reentrant module into the Extended Link Pack Area or the Link Pack Area (ELPA/LPA) to save time on the load. Although multiple copies of the reentrant module are not brought into storage, each fetch returns a separate pointer. If a module is not reentrant, multiple fetches cause multiple loads into storage. Be aware that if you fetch() a non-reentrant module multiple times, the module may not get deleted by release() until all fetch instances have been released. Also, you should keep in mind that multiple loads of a non-reentrant module can be costly in terms of storage.

Writable statics are, in general, process-scoped. The exception is that, when a thread calls a fetched module, the writable statics are changed for that thread only, that is, thread-scoped.

Under MVS, fetchable (or dynamically loaded) modules must be link-edited and accessible using the standard system search. MVS supports fetching of non-reentrant, serially reusable, and reentrant modules.

Under POSIX, however, the fetchable, dynamically loaded modules cannot be in the HFS (Hierarchical File System). Note also, that the POSIX and XPG4 external variables are propagated. Refer to z/OS XL C/C++ Programming Guide for more information on external variables. See z/OS XL C/C++ applications with z/OS UNIX System Services C functions for more information about using POSIX support.

Unless your program is naturally reentrant, each reentrant module has a different copy of writable static. Follow these steps to allow the fetching of your reentrant module that has writable static:
1. Compile the module to be fetched with the RENT compile-time option.
2. Using the object module created in step 1, generate a fetchable member. You must specify the entry point as the function you are fetching unless you have included a #pragma linkage(...) directive.

See Figure 3 on page 567 for the program flow of a fetchable module. (FECB refers to a Fetch Control Block, which is a z/OS XL C internal control block used by fetch().)
To dynamically fetch a set of functions with shared writable static, you can use the library function fetchep(). See "fetchep() — Share Writable Static" on page 578 for more details.

Both the module being fetched and the module invoking the fetch() library function can be reentrant.

You can fetch modules without specifying the directive, #pragma linkage(..., FETCHABLE), in the fetched module. If you do, then using the fetch pointer will result in calling the entry point for that module. When you link the module, you must reset the entry point. In addition, you cannot have any writable static.

It follows that fetching a reentrant C module containing writable statics requires that you use the #pragma linkage(... FETCHABLE) preprocessor directive in the fetched module.

If the entry point linkage is not a C linkage, you must use a pragma linkage with a function pointer defined by a typedef. The following sample excerpt would set up a COBOL linkage for a COBOL routine.

define int COBOL_FUNC ();
define #pragma linkage (COBOL_FUNC, COBOL)

COBOL_FUNC * fetch_ptr;
fetch_ptr = (COBOL_FUNC *) fetch(module); /* loads fetched module */
fetch_ptr(args);    /* sets up the proper linkage for the call */

Once the module is fetched, calling the fetched function is similar to making an interlanguage call.

fetch() also supports AMODE switching: when the function call is made, AMODE will be switched; upon return, the AMODE will be restored. Beware of calling fetched modules with AMODE=24 that try to access variables or the library above the line.

Notes:
You cannot call functions through a function pointer that crosses load module boundaries, except through fetchep(). (See "fetchep() — Share Writable Static" on page 578 for more information.) For example, you cannot pass the address of a function to a fetched routine and invoke it from the fetched routine because the z/OS C writable static will not be swapped.

If you need to access code that has to run in a restricted addressing mode (such as a AMODE 24), you can package the code into a module to be fetched. The module can then be linked using the restricted addressing mode, but fetched from a program with an unrestricted addressing mode.

A program that invokes fetch() many times without releasing all of the load modules may run out of memory.

**Link Considerations**

When linking the function to be fetched, you must link in the necessary libraries and specify the entry point as the function you are fetching unless you have included this directive: `#pragma linkage(..., FETCHABLE).

When linking the main() z/OS C function, you must specify the necessary libraries to use the functions you are fetching. For example, if you are fetching a COBOL function, specify the COBOL library. This requirement does not apply to Language Environment.

When running main(), specify the run-time libraries you will need for main(), as well as the functions you will fetch. This requirement does not apply to Language Environment.

**Special Behavior for C++**

A z/OS XL C++ program cannot call fetch(). If you attempt to call fetch() from a z/OS XL C++ program, the compiler will issue an error message. There are three alternatives to fetch() under z/OS XL C++:

- You can replace fetch() with DLL (Dynamic Link Library) calls.
- You can provide a C DLL module to fetch modules, as shown at 571.
- A z/OS XL C++ program may statically call a z/OS XL C function that, in turn, fetches another module.

Refer to "Examples of Alternatives to fetch() Under C++" on page 571 for illustration of these points.

**Returned Value**

If successful, fetch() returns a pointer to a stub that will call the entry point to the fetched load module.

If the load fails, fetch() returns NULL and may set errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELEFENCE</td>
<td>The DLL contains a member language not supported on this version of the operating system.</td>
</tr>
</tbody>
</table>
Examples of Using fetch() with C

The following example demonstrates how to compile, link, and run a program that fetches a function in another object module that contains the directive: 
#pragma linkage(......, FETCHABLE).

Begin with the main program.
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)(); /* pointer to a function returning an int */

int main(void)
{
    int result;
    funcPtr add;

    printf("fetch module\n");
    add = (funcPtr) fetch("f1a"); /* load module F1A */
    if (add == NULL) {
        printf("ERROR: fetch failed\n");
    } else {
        printf("execute fetched module\n");
        result = (*add)(1,2); /* execute module F1A */
        printf("1 + 2 == %d\n", result);
    }
}

Then the fetched function:
#pragma linkage(func1, fetchable)

int func1(int a, int b)
{
    printf("in fetched module\n");
    return(a+b);
}

Next, JCL to compile, link, and run under MVS:

//F1A EXEC EDCC,INFILE='userid.TEST.SOURCE(F1A)' // OUTFILE='userid.TEST.OBJ(F1A),DISP=SHR', // CPARM='NOSEQ,NOMARGIN,REN'T //F1B EXEC EDCPL,INFILE='userid.TEST.OBJ(F1A)' // OUTFILE='userid.TEST.LOAD(F1A),DISP=SHR' //F1 EXEC EDCCLG,INFILE='userid.TEST.SOURCE(F1)' //GO.STEPLIB DD // DD DSN=userid.TEST.LOAD,DISP=SHR

This example demonstrates the use of fetch() with COBOL and how to compile, link, and run the program.

/* cbl */
#include <stdlib.h>
#include <stdio.h>

typedef void funcV(); /* function returning void */
#pragma linkage(funcV, COBOL) /* establish Cobol linkage */

int main(void)
Here is the fetched COBOL subroutine COB1A.

IDENTIFICATION DIVISION.
PROGRAM-ID. COB1A.

****************************************************************
* This subroutine receives 2 integer parameters.               *
* The first is added to the second and the result is stored   *
* back into the first.                                        *

//SYSSUT1 DD UNIT=SYSDA,SPACE=(CYL,(1,1))
Examples of Alternatives to fetch() Under C++

This example shows how to use DLL as an alternative to fetch(). Here, myfunc() is the function to be dynamically loaded using DLL, and main() invokes DLL.

CELEBF52

// CELEBF52−part 1 of 2−other file is CELEBF53.

// This example shows how to use DLL as an alternative to fetch().

// C++ program that invokes myfunc using DLL

#include <stdlib.h>
#include <stdio.h>
#include <dll.h>

extern "C" { // needed to indicate C linkage
    typedef int (*funcPtr)(); // pointer to a function returning an int
}

int main (void)
{
    dllhandle *dllh;
    funcPtr  fptr;

    if ((dllh = dllload( "celebf53" )) == NULL) {
        perror( "failed to load celebf53" );
    }
exit(-1);
}
if ((fptr = (funcPtr) dllqueryfn(dllh, "myfunc")) == NULL) {
    perror("failed to retrieve myfunc");
    exit(-2);
}
if (fptr() != 0) {
    perror("failed to execute myfunc");
    exit(-3);
}
if (dllfree(dllh) != 0) {
    perror("failed to free celebf53");
    exit(-4);
}
return(0);
}

#include <stdio.h>
#include <stdlib.h>
#include <dll.h>
#include <iostream.h>

extern "C" {
    typedef int (*funcPtr)(); // pointer to a function returning an int
}

int main(void) {
    dllhandle *dllh;
    funcPtr   fptr;
    if ((dllh = dllload("mydll")) == NULL) {
        perror("failed to load mydll");
        exit(-1);
    }

    CELEBF53
    /* CELEBF53-part 2 of 2-other file is CELEBF52.
       This example shows how to use DLL as an alternative to fetch().
    */
    
    /*
     * C function dynamically loaded using DLL
     */
    #include <stdio.h>

    int myfunc (void)
    {
        printf("Hello world\n");
        return(0);
    }

    The following example shows how a C++ program can dynamically call a
    function in a C DLL module, to fetch other C modules.

    CELEBF54
    // CELEBF54-part 1 of 3-other files are CELEBF55, CELEBF56.
    // This example shows how a C++ program can dynamically call a
    // function in a C DLL module, to fetch other C modules
    // C++ program that dynamically calls a function in a C DLL module
    //
    #include <stdio.h>
    #include <stdlib.h>
    #include <dll.h>
    #include <iostream.h>

    extern "C" {
        // needed to indicate C linkage
        typedef int (*funcPtr)(); // pointer to a function returning an int
    }

    int main (void) {
        dllhandle *dllh;
        funcPtr   fptr;
        if ((dllh = dllload("mydll")) == NULL) {
            perror("failed to load mydll");
            exit(-1);
        }
```c
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)(); /* pointer to a function returning an int */

int fwrap (void)
{
    funcPtr fptr;

    if ((fptr = (funcPtr) dllqueryfn( dllh, "fwrap" )) == NULL) {
        perror("failed to retrieve fwrap");
        exit(-2);
    }
    if ( fptr() != 0 ) {
        perror("failed to execute fwrap");
        exit(-3);
    }
    if ( dllfree( dllh ) != 0 ) {
        perror("failed to free mydll");
        exit(-4);
    }
    return( 0 );
}

/* CELEBF56-part 3 of 3-other files are CELEBF54, CELEBF56.
   This example shows how a C++ program can dynamically call a function
   in a C DLL module, to fetch other C modules
   fwrap function used in a DLL module-it fetches mymod, which contains myfunc */
#include <stdio.h>
#pragma linkage(myfunc, fetchable)

int myfunc (void)
{
    printf("in fetched module\n");
    return( 0 );
}
```

The following example shows how to statically call a C function that in turn fetches other functions. Here, myfunc() is the function to be fetched, fetcher() is a C function that fetches myfunc(), and main() is a function that statically calls fetcher().

**CELEBF57**
// This example shows how to statically call a C function that
// fetches other functions.

// C++ statically calling a C program that uses fetch()
#include <iostream.h>
extern "C" { // needed to indicate C linkage
  int fetcher (void);
}
int main (void)
{
  cout << "The fetcher says: ";
  fetcher();
  cout << "and returns";
  return (0);
}

CELEBF58
/* This example shows how to statically call a C function that fetches
other functions. */

/* C function that fetches mymod which contains myfunc */
#include <stdio.h>
#include <stdlib.h>
typedef int (*funcPtr)(); // pointer to a function returning an int *

int fetcher (void)
{
  funcPtr fptr;
  if ((fptr = (funcPtr) fetch( "mymod" )) == NULL) {
    perror( "failed to fetch mymod" );
    return ( -1 );
  } else {
    fptr(); // * invoke fetched function */
    return (0);
  }
}

CELEBF59
/* This example shows how to statically call a C function that fetches
other functions. */

/* C function to be fetched */
#include <stdio.h>
#pragma linkage(myfunc, fetchable)

int myfunc (void)
{
  printf( "Hello world ");
  return (0);
}
Although fetching and using DLL are functionally comparable, there is one subtle difference. Fresh copies of static and global variables are allocated each time a module is fetched, but not each time a DLL load of the same module is done.

The following example shows that, when a module is fetched multiple times, fresh copies of static and global variables are allocated.

**CELEBF60**

```c
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)(int); /*pointer to a function returning an int*/

int main (void)
{
    funcPtr fptr1, fptr2;

    if ((fptr1 = (funcPtr) fetch( "mymod" )) == NULL) {
        perror( "failed to fetch mymod" );
        return( -1 );
    }
    if ( fptr1(100) != 0 ) {
        perror( "failed to execute myfunc" );
        exit( -2 );
    }
    if ((fptr2 = (funcPtr) fetch( "mymod" )) == NULL) {
        perror( "failed to fetch mymod" );
        return( -3 );
    }
    if ( fptr2(100) != 0 ) {
        perror( "failed to execute myfunc" );
        exit( -4 );
    }
    return( 0 );
}
```

**CELEBF61**

```c
#include <stdio.h>
#pragma linkage(myfunc, fetchable)

int globvar = 5;

int myfunc (int x)
{
    globvar += x;
    printf( "%d\n", globvar );
    return( 0 );
}
```

Running this example would produce the following results:
The following example shows that fresh copies of static and global variables are not allocated for multiple DLL loads of the same module.

**CELEBF62**

// CELEBF62-part 1 of 2-other file is CELEBF63.
// This example shows how copies of variables are allocated when multiple DLL loads are done.

// C++ program doing multiple DLL loads of the same module

```c
#include <stdlib.h>
#include <stdio.h>
#include <dll.h>

extern "C" { //needed to indicate C linkage
typedef int (*funcPtr)(int); //pointer to a function returning an int
}

int main (void)
{
    dllhandle *dllh1, *dllh2;
    funcPtr fptr;
    if ((dllh1 = dllload( "mydll" )) == NULL) {
        perror( "failed to load mydll" );
        exit( -1 );
    }
    if ((fptr = (funcPtr) dllqueryfn( dllh1, "myfunc" )) == NULL) {
        perror( "failed to retrieve myfunc" );
        exit( -2 );
    }
    if (fptr(100) != 0 ) {
        perror( "failed to execute myfunc" );
        exit( -3 );
    }
    if ((dllh2 = dllload( "mydll" )) == NULL) {
        perror( "failed to load mydll" );
        exit( -4 );
    }
    if ((fptr = (funcPtr) dllqueryfn( dllh2, "myfunc" )) == NULL) {
        perror( "failed to retrieve myfunc" );
        exit( -5 );
    }
    if (fptr(100) != 0 ) {
        perror( "failed to execute myfunc" );
        exit( -6 );
    }
    if (dllfree( dllh1 ) != 0 ) {
        perror( "failed to free mydll" );
        exit( -7 );
    }
    return( 0 );
}
```

**CELEBF63**

/* CELEBF63-part 2 of 2-other file is CELEBF62.
   This example shows how copies of variables are allocated when multiple DLL loads are done. */

/* C function invoked using DLL */
#include <stdio.h>
#include <stdlib.h>

int globvar = 5;
int myfunc (int);

int myfunc (int x)
{
    globvar += x;
    printf("%d\n", globvar);
    return( 0);
}

Running this example would produce the following results:

fetchep()

— Share Writable Static

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <stdlib.h>

void (*fetchep( void (*entry_point)()))();

General Description

Dynamically fetches a set of functions with shared writable static variables. fetchep() is used to register an entry point. It returns a pointer that may be passed across the fetch boundary and used as if it were the original entry point. Therefore, you can create more than one entry point from a fetched module. A call to the new entry point will use the same writable static as the original fetch pointer uses on each invocation.

fetchep() is called within a fetched module but not from the same level as the fetch() call. If fetchep() is called in the root program that is not a fetched module, fetchep() returns a fetch pointer that will use the root program’s writable static (if any exists).

If the entry_point given as input to fetchep() is a function address external to the current module or is an non-valid function address, use of the resulting pointer returned from the call will result in undefined behavior.

If writable static is required, then this directive must be used:

#pragma linkage(entry_point, FETCHABLE)

In addition, the steps for fetching a reentrant module must be followed as described in “fetch() — Get a Load Module” on page 565. If writable static is not required, the C module using fetchep() need not contain the directive:

#pragma linkage(..., FETCHABLE).

You can release the new fetch pointer without any effect on the original or any other fetch pointer created from the original fetch pointer. If the original fetched function is released, however, all the fetch pointers created using the fetchep() function will also be released. Trying to use a fetch pointer once it has been released or its origin has been released will result in undefined behavior.

To avoid infringing on the user’s name space, this nonstandard function has two names. One name, the external entry point name, is prefixed with two underscore characters, and the other name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

Note: The external entry point name for fetchep() is __fetchep(), NOT __ftchep().

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters...
Examples

These examples and diagram demonstrate the program flow of a call to fetch() and subsequent calls to fetchep().

```c
/* The module that calls fetch() */
#include <stdlib.h>
typedef int (*FUNC_T)();

int main(void) {
    FUNC_T (*myfunc)();
    FUNC_T myfunc1;
    FUNC_T myfunc2;
    FUNC_T myfunc3;

    myfunc = (FUNC_T (*)(())) fetch("MYMOD");
    myfunc1 = myfunc(0);
    myfunc2 = myfunc(1);
    myfunc3 = myfunc(2);
}
```

/* The following code is the fetched module. Please see fetch() for information on how to compile and link the above. */

```c
/* inside MYMOD */
#include <stdlib.h>
typedef int (*FUNC_T)();
int k; /* global variable to share within MYMOD */
#pragma linkage(x, fetchable)
FUNC_T x(int a)
{
    switch(a)
    {
    case 0:
        return (FUNC_T) fetchep((void (*)(()))func1);
    case 1:
        return (FUNC_T) fetchep((void (*)(()))func2);
    case 2:
        return (FUNC_T) fetchep((void (*)(()))func3);
    }

    int func1(int a, int b)
    {
        k = 6;
    ...
    }

    int func2(int a, int b)
    {
        k = 4;
    ...
    }

    int func3(int a, int b)
    {
        k = 5;
    ...
    }
```

fetestexcept() — Test the Floating-Point Status Flags

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <fenv.h>

int fetestexcept(int excepts);
```

General Description

fetestexcept() determines which of a specified subset of floating-point exception flags are currently set. `excepts` specifies the floating-point status flags to be queried.

Note: The following table shows the viable formats for these functions. See “IEEE Binary Floating-Point” on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>fetestexcept</td>
<td></td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

If successful, fetestexcept() returns the value of the bitwise OR for the floating-point exception macros corresponding to the currently set floating-point exceptions included in `excepts`.

Related Information

.
feupdateenv

feupdateenv() — Save the Currently Raised Floating-Point Exceptions

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R9</td>
</tr>

<td></td>
<td></td>
</tr>
<tr>
<td>C/C++ DFP</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <fenv.h>

int feupdateenv(const fenv_t *envp);
```

General Description

feupdateenv() saves the currently raised floating-point exceptions in its automatic storage, installs the floating-point environment represented by the object pointed to by `envp`, and then raises the saved floating-point exceptions. `envp` should point to an object set by feholdexcept() or fegetenv(), or equal a floating-point environment macro.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point " on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>feupdateenv</td>
<td></td>
<td>X</td>
</tr>
</tbody>
</table>

**Note:**

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- If the hardware has the decimal floating-point facility installed, this function can update the decimal floating-point rounding mode.
- This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

If successful, feupdateenv() returns 0 if the settings have been restored.

If unsuccessful, feupdateenv() returns -1 and sets one of the following errno values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The rounding mode specified is not a valid Decimal Floating Point rounding mode.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>The function was unable to set the specified rounding mode due to an internal error.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int fflush(FILE *stream);
```

General Description

Flushes the stream pointed to by `stream`. If `stream` is NULL, it flushes all open streams.

The `fflush()` function is affected by the `ungetc()` and `ungetwc()` functions. Calling these functions causes `fflush()` to back up the file position when characters are pushed back. For details, see the `ungetc()` and `ungetwc()` functions respectively. If desired, the `_EDC_COMPAT` environment variable can be set at open time such that `fflush()` discards any pushed-back characters and leaves the file position where it was when the first `ungetc()` or `ungetwc()` function call was issued.

If `fflush()` is used after `ungetwc()` has pushed a wide char on a text stream, the position will be backed up by one wide character from the position the file was at when the `ungetwc()` was issued. For a wide-oriented binary stream, the position will be backed up based on the number of bytes used to represent the wide char in the unget buffer. For this reason, attempting to use `ungetwc()` on a character when the destination is a binary wide-oriented stream that was never read in the first place results in undefined behavior for `fflush()`. Note that the `_EDC_COMPAT` environment variable also changes the behavior of `fflush()` after `ungetwc()`, and will cause any wide char pushed-back to be discarded and the position left at the point where the `ungetwc()` was issued. For details on the `_EDC_COMPAT` environment variable, see the “Environment Variables” in z/OS XL C/C++ Programming Guide.

If `fflush()` fails, the position is left at the point in the file where the first `ungetc()` or `ungetwc()` function call was issued. All pushed-back characters are discarded.

**Note:** The system automatically flushes buffers when you close the stream or when a program ends normally without closing the stream.

The buffering mode and the file type can have an effect on when output data is flushed. For more information, see “Buffering of C Streams” in z/OS XL C/C++ Programming Guide.

`stream` remains open after the `fflush()` call. Because a read operation cannot immediately follow or precede a write operation, the `fflush()` function can be used to allow exchange between these two modes. The `fflush()` function can also be used to refresh the buffer when working with a reader and a simultaneous writer/updater.
Returned Value

If successful in flushing the buffer, fflush() returns 0.

If unsuccessful, fflush() returns EOF. When flushing all open files, a failure to flush any of the files causes EOF to be returned. However, flushing will continue on any other open files that can be flushed successfully.

Example

CELEBF15

/* CELEBF15

This example flushes a stream buffer.
It tests for the returned value of 0 to see if the flushing was successful.

*/
#include <stdio.h>

int retval;
int main(void)
{
    FILE *stream;
    stream = fopen("myfile.dat", "w");

    retval=fflush(stream);
    printf("return value=%i",retval);
}

ffs

ffs() — Find First Set Bit in an Integer

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

int ffs(int i);
```

General Description

The ffs() function finds the first bit set (beginning with the least significant bit) and returns the index of that bit. Bits are numbered starting at one (the least significant bit).

Returned Value

If successful, ffs() returns the index of the first bit set.

If i is 0, ffs() returns 0.

There are no errno values defined.

Related Information

- "strings.h" on page 86
fgetc() — Read a Character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int fgetc(FILE *stream);
```

General Description

Reads a single-byte unsigned character from the input stream pointed to by `stream` at the current position, and increases the associated file pointer so that it points to the next character.

The `fgetc()` function is not supported for files opened with `type=record`.

`fgetc()` has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

If successful, `fgetc()` returns the character read as an integer.

If unsuccessful, `fgetc()` returns EOF to indicate an error or an EOF condition. Use `feof()` or `ferror()` to determine whether the EOF value indicates an error or the end of the file.

Note: EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does not turn on the EOF indicator.

Example

```c
CELEBF16

/* CELEBF16

    This example gathers a line of input from a stream.
    It tests to see if the file can be opened.
    If the file cannot be opened & perror. is called.

    */
#include <stdio.h>
#define MAX_LEN 80

int main(void)
```
```c
fgetc
{
    FILE *stream;
    char buffer[MAX_LEN + 1];
    int i, ch;

    if ((stream = fopen("myfile.dat","r")) != NULL) {
        for (i = 0; (i < (sizeof(buffer)-1)) &
             ((ch = fgetc(stream)) != EOF) &
             (ch != '\n')); i++)
            printf("character is %d\n",ch);
        buffer[i] = ch;
        buffer[i] = '\0';
        if (fclose(stream))
            perror("fclose error");
    } else
        perror("fopen error");
}
```

fgetpos() — Get File Position

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <stdio.h>

int fgetpos(FILE *__restrict__ stream, fpos_t *__restrict__ pos);
```

General Description

Stores the current value of the file pointer associated with `stream` into the object pointed to by `pos`. The value pointed to by `pos` can be used later in a call to `fsetpos()` to reposition the stream pointed to by `stream`.

Both `fgetpos()` and `fsetpos()` functions also save state information for wide-oriented files. The value stored in `pos` is unspecified, and it is usable only by `fsetpos()`.

The position returned by `fgetpos()` is affected by the `ungetc()` and `ungetwc()` functions. Each call to these functions causes the file position indicator to be backed up from the position where the `ungetc()` or `ungetwc()` was issued. For details on how `ungetc()` affects `fgetpos()` behavior, see "ungetc() — Push Character onto Input Stream" on page 2307. For details on how `ungetwc()` affects `fgetpos()` behavior for a wide-oriented stream, see "ungetwc() — Push a Wide Character onto a Stream" on page 2310. Note that the `_EDC_COMPAT` environment variable can be set at open time such that `fgetpos()` will ignore any pushed-back characters. For further details on `_EDC_COMPAT`, see the “Environment Variables” in Z/OS XL C/C++ Programming Guide.

Large Files for HFS

**Note:** Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option LANGLEVEL(LONGLONG) and also define the Feature Test Macro (FTM) _LARGE_FILES before any headers are included will enable this function to operate on HFS files that are larger than 2 gig-1 in size. File size and offset fields will be enlarged to 63 bits in width so any other function operating on this file will have to be enabled with the same FTM.

Multivolume Data Sets Performance

Using the `fgetpos()` and `fsetpos()` functions generally results in better repositioning performance compared to the `ftell()` and `fseek()` functions when working with multivolume data sets.
fgetpos

Returned Value

If successful, fgetpos() returns 0.

If unsuccessful, fgetpos() returns nonzero and sets errno to nonzero.

Special Behavior for XPG4.2

fgetpos() returns -1 and sets errno to ESPIPE if the underlying file type for the stream is a PIPE or a socket.

Example

CELEBF17

/* CELEBF17

This example opens the file myfile.dat for reading.
The current file pointer position is stored into the variable pos.

*/
#include <stdio.h>

int main(void)
{
    FILE *stream;
    int retcode;
    fpos_t pos;
    stream = fopen("myfile.dat", "rb");
    /* The value returned by fgetpos can be used by fsetpos() to set the file pointer if 'retcode' is 0 */
    if ((retcode = fgetpos(stream, &pos)) == 0)
        printf("Current position of file pointer found\n");
    fclose(stream);
}

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

char *fgets(char *__restrict__ string, int n, FILE *__restrict__ stream);
```

General Description

Reads bytes from a stream pointed to by `stream` into an array pointed to by `string`, starting at the position indicated by the file position indicator. Reading continues until the number of characters read is equal to \( n - 1 \), or until a newline character (\( \backslash n \)), or until the end of the stream, whichever comes first. The `fgets()` function stores the result in `string` and adds a NULL character (\( \backslash 0 \)) to the end of the string. The `string` includes the newline character, if read.

The `fgets()` function is not supported for files opened with `type=record`.

`fgets()` has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

If successful, `fgets()` returns a pointer to the `string` buffer.

If unsuccessful, `fgets()` returns NULL to indicate failure.

If \( n \) is less than or equal to 0, it indicates a domain error; `errno` is set to EDOM to indicate the cause of the failure.

When \( n \) equals 1, it indicates a valid result. It means that the string buffer has only room for the NULL terminator; nothing is physically read from the file. (Such an operation is still considered a read operation, so it cannot immediately follow a write operation unless there is an intervening flush or reposition operation first.)

If \( n \) is greater than 1, `fgets()` will only fail if an I/O error occurs or if EOF is reached, and no data is read from the file.

The `ferror()` and `feof()` functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read "past" the last byte of data. Reading up to and including the last byte of data does not turn on the EOF indicator.
fgets

If EOF is reached after data has already been read into the string buffer, fgets() returns a pointer to the string buffer to indicate success. A subsequent call would result in NULL being returned since EOF would be reached without any data being read.

Example

CELEBF18
/* CELEBF18

This example gets a line of input from a data stream. It reads no more than MAX_LEN - 1 characters, or up to a new-line character, from the stream.

*/
#include <stdio.h>
#define MAX_LEN 100

int main(void)
{
    FILE *stream;
    char line[MAX_LEN], *result;
    stream = fopen("myfile.dat","r");
    if ((result = fgets(line,MAX_LEN,stream)) != NULL)
        printf("The string is %s\n", result);
    if (fclose(stream))
        printf("fclose error\n");
}

</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wint_t fgetwc(FILE *stream);
```

General Description

Obtains the next multibyte character from the input stream pointed to by `stream`, converts it to a wide character, and advances the associated file position indicator for the stream (if defined).

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Using non-wide-character functions with `fgetwc()` results in undefined behavior. This happens because `fgetwc()` processes a whole multibyte character and does not expect to be “within” such a character. In addition, `fgetwc()` expects state information to be set already. Because functions like `fgetc()` and `fputc()` do not obey such rules, their results fail to meet the assumptions made by `fgetwc()`.

`fgetwc()` has the same restriction as any read operation for read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

If successful, `fgetwc()` returns the next wide character that corresponds to the multibyte character from the input stream pointed to by `stream`.

If the stream is at EOF, the EOF indicator for the stream is set and `fgetwc()` returns WEOF.

If a read error occurs, the error indicator for the stream is set and `fgetwc()` returns WEOF. If an encoding error occurs (an error converting the multibyte character into a wide character), the value of the macro EILSEQ (illegal sequence) is stored in `errno` and WEOF is returned.

The `ferror()` and `feof()` functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does not turn on the EOF indicator.
Example

CELEBF19
/* CELEBF19 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#include <errno.h>

int main(void)
{
    FILE *stream;
    wint_t wc;
    if ((stream = fopen("myfile.dat", "r")) == NULL) {
        printf("Unable to open file\n");
        exit(1);
    }
    errno = 0;
    while ((wc = fgetwc(stream)) != WEOF)
        printf("wc=0x%X\n", wc);
    if (errno == EILSEQ) {
        printf("An invalid wide character was encountered.\n");
        exit(1);
    }
    fclose(stream);
}

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <wchar.h>

wchar_t *fgetws(wchar_t *__restrict__ wcs, int n, FILE *__restrict__ stream);

General Description

Reads at most one less than the number of the wide characters specified by n, from the stream pointed to by stream, into the array pointed to by wcs. No additional wide characters are read after a newline wide character (which is retained) or after the EOF. A NULL wide character is written immediately after the last wide character read into the array.

The fgetws() function advances the file position unless there is an error, when the file position is undefined.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Using non-wide-character functions with fgetws() results in undefined behavior. This happens because fgetws() processes a whole multibyte character and does not expect to be “within” such a character. In addition, fgetws() expects state information to be set already. Because functions like fgetc() and fputc() do not obey such rules, their results fail to meet the assumptions made by fgetws().

fgetws() has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

If successful, fgetws() returns the new value of wcs.

If EOF is encountered and no wide characters have been read into the array, the contents of the array remain unchanged and fgetws() returns a NULL pointer.

If a read error or an encoding error occurs during the operation, the array contents are indeterminate and fgetws() returns a NULL pointer. An encoding error is one that occurs when a wide character is converted to a multibyte character. If it occurs, errno is set to EILSEQ and fgetws() returns NULL.
fgets

If \( n \) is less than or equal to 0, it indicates a domain error; errno is set to EDOM to indicate the cause of the failure.

When \( n \) equals 1, it indicates a valid result. It means that the string buffer has only room for the NULL terminator; nothing is physically read from the file. (Such an operation is still considered a read operation, so it cannot immediately follow a write operation unless there is an intervening flush or reposition operation first.)

If \( n \) is greater than 1, fgets() will only fail if an I/O error occurs or if EOF is reached, and no data is read from the file. To find out which error has occurred, use either the feof() or the ferror() function. If EOF is reached after data has already been read into the string buffer, fgets() returns a pointer to the string buffer to indicate success. A subsequent call would result in NULL being returned because EOF would be reached without any data being read.

The ferror() and feof() functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does not turn on the EOF indicator.

Example

**CELEBF20**

```c
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
    FILE *stream;
    wchar_t wcs[100];
    wchar_t *ptr;

    if ((stream = fopen("myfile.dat", "r")) == NULL) {
        printf("Unable to open file\n");
        exit(1);
    }

    errno = 0;
    ptr = fgetws(wcs, 100, stream);

    if (ptr == NULL) {
        if (errno == EILSEQ) {
            printf("An invalid wide character was encountered.\n");
            exit(1);
        } else if (feof(stream))
            printf("end of file reached\n");
        else
            perror("read error");
    }

    printf("wcs=\"%ls\"\n", wcs);
    fclose(stream);
}
```

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <stdio.h>

int fileno(const FILE *stream);
```

General Description

Returns the file descriptor number associated with a specified z/OS XL C/C++ I/O stream. The argument `stream` points to a FILE structure controlling a z/OS XL C/C++ I/O stream.

The unistd.h header file defines the following macros, which are constants that map to the file descriptors of the standard streams:

- `STDIN_FILENO` Standard input, `stdin` (value 0)
- `STDOUT_FILENO` Standard output, `stdout` (value 1)
- `STDERR_FILENO` Standard error, `stderr` (value 2)

Note that `stdin`, `stdout`, and `stderr` are macros, not constants.

Returned Value

If successful, fileno() returns the file descriptor number associated with an open HFS stream (that is, one opened with fopen() or freopen()). MVS datasets are not supported, so fileno() of an MVS data set returns −1.

If unsuccessful, fileno() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>One of the following error conditions exists:</td>
</tr>
<tr>
<td></td>
<td>• stream points to a closed stream</td>
</tr>
<tr>
<td></td>
<td>• stream is an incorrect stream pointer</td>
</tr>
<tr>
<td></td>
<td>• stream points to a stream associated with an MVS data set.</td>
</tr>
</tbody>
</table>

Example

```c
CELEBF21
/* CELEBF21

    This example illustrates one use of fileno().

*/
#define _POSIX_SOURCE
#include <errno.h>
#include <stdio.h>
```
main() {
    FILE *stream;
    char hfs_file[]="./hfs_file", mvs_ds[]="/mvs.ds";
    printf("fileno(stdin) = %d\n", fileno(stdin));
    if ((stream = fopen(hfs_file, "w")) == NULL)
        perror("fopen() error for HFS file");
    else {
        printf("fileno() of the HFS file is %d\n", fileno(stream));
        fclose(stream);
        remove(hfs_file);
    }
    if ((stream = fopen(mvs_ds, "w")) == NULL)
        perror("fopen() error for MVS data set");
    else {
        errno = 0;
        printf("fileno() returned %d for MVS data set,\n", fileno(stream));
        printf("errno=%s\n", strerror(errno));
        fclose(stream);
        remove(mvs_ds);
    }
}

Output
fileno(stdin) = 0
fileno() of the HFS file is 3
fileno() returned -1 for the MVS data set,
errno=Bad file descriptor

finite() — Determine the Infinity Classification of a Floating-Point Number

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

```c
#define _AIX_COMPATIBILITY
#include <math.h>

int finite(x)
double x;
```

General Description

The finite() function determines the infinity classification of floating-point number x.

Note: This function works in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

finite() returns nonzero if the x parameter is a finite number, that is, if x is not +-, INF, NaNQ, or NaNS.

finite() does not return errors or set bits in the floating-point exception status, even if a parameter is a NaN.

Special behavior for hex

finite() always returns 1 when it is called from HFP mode.

fldata() — Retrieve File Information

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int fldata(FILE *file, char *filename, fldata_t *info);
```

General Description

Retrieves information about an open stream pointed to by `file`. It returns the file name in `filename` and other information in the structure `info`. The file name returned in `filename` is the name specified in `fopen()` or `freopen()`. If the file is opened with a `ddname` (for example, `fopen("DD:A","w")`), then the `filename` field will contain the `ddname` used to open the file, prefixed with `dd:`. If the file is a DASD data set or a memory file, the field `__dsname` contains the dsname. If the file is an HFS file, the field `__dsname` contains the pathname. For all other files, it is NULL.

After a failure, the contents of the information structure are indeterminate.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use `LANGLVL(EXTENDED)`.

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with `LANGLVL(EXTENDED)`. When you use `LANGLVL(EXTENDED)` any relevant information in the header is also exposed.

For full details about `filename` considerations, see one of the “Opening Files” sections in `z/OS XL C/C++ Programming Guide`.

If `fldata` is the first reference to a standard stream, a call to the `fldata()` function opens the stream.

See `Table 26 on page 602`

Note:

- A filename of NULL indicates that no filename will be returned.
- `FILENAME_MAX` is recommended for the size of the filename buffer.

Special Behavior for POSIX C

Under z/OS UNIX services, if there had been an exec to an application that invokes `fldata()`, the standard streams are opened at the time of the exec. Thus `fldata()`
does not attempt to open them again. See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information about using POSIX support.

Returned Value

If successful, fldata() returns 0.

If unsuccessful, fldata() returns nonzero.

<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int flocate(FILE *stream, const void *key, size_t key_len, int options);
```

General Description

Moves the VSAM file position indicator associated with the stream pointed to by `stream`, according to the rest of the arguments specified.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

`key` points to a key used for positioning.

`key_len` specifies the length of the search key. The `key_len` argument value must always be nonzero, except for `__KEY_FIRST` and `__KEY_LAST`.

KSDS, KSDS PATH, and ESDS PATH

The `key` can point to a field of any storage type except `register`. Typically it points to a character string whose length is `key_len`. The `key_len` must be less than or equal to the key length of the data set. If `key_len` is the same as the file's key length, a full key search is automatically used; otherwise, a generic search is used. A generic key search is one in which the search key is a leading portion of the key field. The record positioned to is the first of the records having the same generic key.

ESDS

The `key` points to a relative byte address that may be stored as 4 or 8 byte value. `key_len` is either 4 or 8.

RRDS

The `key` points to a relative record number stored as an `unsigned long int`. `key_len` is either 4 or 8.

`options` specifies the position options described in Table 27.

<tr>
<td>__RBA_EQ</td>
<td>Positions to the record with the specified RBA. Subsequent reads are in the forward direction. You cannot use __RBA_EQ with an alternative index path. Using this option with RRDS is not recommended. The underlying VSAM utilities do not support seeking to an RBA in an RRDS file. The flocate() function attempts to convert the RBA to a Relative Record Number by dividing the value by the LRECL of the file and using the equivalent __KEY_EQ. Using this option with KSDS is not recommended because the RBA of a given record may change over time, because of inserts, deletions, or updates of other records.</td>
</tr>
<tr>
<td>__RBA_EQ_BWD</td>

The flocate() function attempts to convert the RBA to a Relative Record Number by dividing the value by the LRECL of the file and using the equivalent __KEY_EQ_BWD. Using this option with KSDS is not recommended because the RBA of a given record may change over time, because of inserts, deletions, or updates of other records. Only applies to VSAM files opened in record mode.</td>
</tr>
<tr>
<td>__KEY_EQ_BWD</td>
<td>Positions to the first record with the specified key. Subsequent reads are in backward order. Using this option requires a full key search. key_len must be set equal to the key length as defined for the data set. Only applies to VSAM files opened in record mode.</td>
</tr>
</tbody>
</table>

**Notes:**
- When you are trying to use flocate() in a path to a nonunique key, the resulting position will be at the first physical record of the duplicate key set.
- flocate() releases all record locking.
- Writes to VSAM data sets are not affected by preceding calls to flocate().
If a record was not found, you must successfully relocate to another position before reading or writing (using the flocate() function). The exception to this is that a write that follows a failed flocate() will succeed if the file was opened for initial loading, but no records have been written to it yet.

**Considerations For VSAM extended addressability data sets**

flocate() accepts key lengths of 4 or 8 when relative byte address (RBA) values are used for positioning. A key length of 8 is required only when the working with a VSAM extended addressability data set, because when the address grows past the 4GB boundary, the key needs to be large enough to hold the value.

When using the value 4GB-1 as the key to flocate(), the key length must be 8 and the data type used must be 8 bytes in size (for example, X'00000000FFFFFFFF'). If the key length is 4, flocate() treats the key as -1(EOF).

**Returned Value**

If successful, flocate() returns 0.

If a record was not found or the position is beyond the EOF, flocate() returns EOF.

**Example**

```c
#include <stdio.h>

int main(void)
{
    FILE *stream;
    int vsam_rc;
    char *key = "RECORD 27";

    stream = fopen("DD:MYCLUS", "rb+,type=record");
    vsam_rc = flocate(stream, key, 9, __KEY_EQ);
    ...
}
```

flockfile()—stdio Locking

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R8</td>
</tr>
</tbody>
</table>

Format

```c
#define _UNIX03_SOURCE
#include <stdio.h>

void flockfile(FILE *file);
```

General Description

This function provides explicit application-level locking of stdio (FILE*) objects. The flockfile() family of the functions can be used by a thread to delineate a sequence of I/O statements that are executed as a unit.

The flockfile() function acquires ownership of a (FILE*) object for the thread, waiting if necessary, and increases the internal lock count. If the thread has previously been granted ownership, the internal lock count is increased.

The internal lock count allows matching calls to flockfile() (or successful calls to ftrylockfile()) and funlockfile() to be nested.

z/OS Consideration

The flockfile() family of functions acts upon FILE * objects. It is possible to have the same physical file represented by multiple FILE * objects that are not recognized as being equivalent. For example, fopen() opens a file and open() opens the same file, and then fdopen() creates a FILE * object. In this case, locking the first FILE * does not prevent the second FILE * from also being locked and used.

Returned Value

None.

Note:

- Because the flockfile() function returns void, no error information can be returned.
- It is the application’s responsibility to prevent deadlock (or looping). For example, deadlock (or looping) may occur if a (FILE *) object is closed, or a thread is terminated, before relinquishing all locked (FILE *) objects.

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#include <math.h>

double floor(double x);
float floorf(float x); /* C++ only */
long double floorl(long double x); /* C++ only */
float floor(long double x);
long double floorl(long double x);
```

#### General Description

Calculates the largest integer that is less than or equal to \( x \).

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [IEEE Binary Floating-Point](#) on page 108 for more information about IEEE Binary Floating-Point.

#### Returned Value

Returns the calculated integral value expressed as a double, float, or long double value. The result cannot have a range error.

#### Example

```c
CELEBF24
/* CELEBF24

This example assigns \( y \) the value of the largest integer that is less than or equal to 2.8, and it assigns \( z \) the value of the largest integer that is less than or equal to -2.8.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double y, z;
    y = floor(2.8);
    z = floor(-2.8);
    printf("floor( 2.8 ) = \%f\n", y);
    printf("floor( -2.8 ) = \%f\n", z);
}
```
floor, floorf, floorl

Output

floor( 2.8 ) = 2.000000
floor( -2.8 ) = -3.000000

Related Information

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 floord32(_Decimal32 x);
_Decimal64 floord64(_Decimal64 x);
_Decimal128 floord128(_Decimal128 x);
_Decimal32 floor(_Decimal32 x); /* C++ only */
_Decimal64 floor(_Decimal64 x); /* C++ only */
_Decimal128 floor(_Decimal128 x); /* C++ only */
```

General Description

Calculates the largest integer that is less than or equal to x.

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

Returns the calculated integral value expressed as a _Decimal32, _Decimal64, or _Decimal128 value. The result cannot have a range error.

Example

```c
/* CELEBF78

This example illustrates the floord64() function.

This example assigns y the value of the largest integer that is less than or equal to 2.8, and it assigns z the value of the largest integer that is less than or equal to −2.8.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 y, z;
    y = floord64(+2.8DD);
    z = floord64(-2.8DD);
    printf("floord64(+2.8) = %+Df\n", y);
    printf("floord64(-2.8) = %+Df\n", z);
    return 0;
}
```

fma(), fmaf(), fmal() — Multiply then Add

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <math.h>

double fma(double x, double y, double z);
float fmaf(float x, float y, float z);
long double fmal(long double x, long double y, long double z);
```

General Description

The fma() family of functions compute \((x \cdot y) + z\), rounded as one ternary operation: they compute the value to infinite precision and round once to the resulting format according to the rounding mode characterized by the value of `FLT_ROUNDS`.

Note: The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>fma</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>fmaf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>fmal</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Restriction

The fmaf() function does not support the `_FP_MODE_VARIABLE` feature test macro.

Returned Value

If successful, they return the rounded value of \((x \cdot y) + z\) as one ternary operation.

Related Information

- "math.h" on page 60
fmax, fmaxf, fmaxl

fmax(), fmaxf(), fmaxl() — Calculate the Maximum Numeric Value

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>

```c
#include <math.h>

double fmod(double x, double y);
float fmod(float x, float y); /* C++ only */
long double fmod(long double x, long double y); /* C++ only */
float fmodf(float x, float y);
long double fmodl(long double x, long double y);
```

General Description

Calculates the floating-point remainder of \( \frac{x}{y} \). The absolute value of the result is always less than the absolute value of \( y \). The result will have the same sign as \( x \).

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

If \( y \) is 0, or the result would overflow, then the function returns 0. Errno remains unchanged.

**Special Behavior for IEEE**

If successful, the function returns the floating-point remainder of \( \frac{x}{y} \).

If \( y \) is 0, the function sets errno to EDOM and returns NaNQ. No other errors will occur.

Example

```c
CELEBF25

/* CELEBF25 */

    This example computes \( z \) as the remainder of \( \frac{x}{y} \); here \( \frac{x}{y} \) is \( -3 \) with a remainder of \( -1 \).

    */
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y, z;
```
fmod, fmodf, fmodl

x = -10.0;
y = 3.0;
z = fmod(x,y);  /* z = -1.0 */

printf("fmod( %f, %f) = %lf\n", x, y, z);
}

Output
fmod( -10.000000, 3.000000) = -1.000000

fmtmsg() — Display a Message in the Specified Format

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <fmtmsg.h>

int fmtmsg(long classification, const char *label, int severity,
            const char *text, const char *action, const char *tag);
```

General Description

The fmtmsg() function can be used to display messages in a specified format instead of the traditional printf() function.

Based on a message’s classification component, fmtmsg() writes a formatted message either to standard error, to the console, or to both.

A formatted message consists of up to five components as defined below. The component classification is not part of a message displayed to the user, but defines the source of the message and directs the display of the formatted message.

- **classification**: Contains identifiers from the following groups of major classifications and subclassifications. Any one identifier from a subclass may be used in combination with a single identifier from a different subclass. Two or more identifiers from the same subclass should not be used together, with the exception of identifiers from the display subclass. (Both display subclass identifiers may be used so that messages can be displayed to both standard error and the system console).
  - **Major Classifications**: Identifies the source of the condition. Identifiers are: **MM_HARD** (hardware), **MM_SOFT** (software), and **MM_FIRM** (firmware).
  - **Message Source Subclassifications**: Identifies the type of software in which the problem is detected. Identifiers are: **MM_APPL** (application), **MM_UTIL** (utility), and **MM_OPSYS** (operating system).
  - **Display Subclassifications**: Indicates where the message is to be displayed. Identifiers are: **MM_PRINT** to display the message on the standard error stream, **MM_CONSOLE** to display the message on the system console. One or both identifiers may be used.
  - **Status Subclassifications**: Indicates whether the application will recover from
the condition. Identifiers are: **MM_RECOVER** (recoverable) and **MM_NRECOV** (non-recoverable).

An additional identifier, **MM_NULLMC**, indicates that no classification component is supplied for the message.

**label** Identifies the source of the message. The format is two fields separated by a colon. The first field is up to 10 bytes, the second is up to 14 bytes. The constant `__MM_MXLABELLN` defines the maximum length of label.

**severity** Indicates the seriousness of the condition. Identifiers for the levels of severity are:

- **MM_HALT** indicates that the application has encountered a severe fault and is halting. Produces the string "HALT".
- **MM_ERROR** indicates that the application has detected a fault. Produces the string "ERROR".
- **MM_WARNING** indicates a condition that is out of the ordinary, that might be a problem, and should be watched. Produces the string "WARNING".
- **MM_INFO** provides information about a condition that is not in error. Produces the string "INFO".
- **MM_NOSEV** indicates that no severity level is supplied for the message.
- **Other** provides an unknown severity. Produce the string "SV=n", where n is the severity value specified.

**text** Describes the error condition that produced the message. The character string is not limited to a specific size. If the character string is empty, then the text produced is unspecified.

**action** Describes the first step to be taken in the error-recovery process. The `fmtmsg()` function precedes the action string with the prefix: "TO FIX:". The action string is not limited to a specific size.

**tag** An identifier that references on-line documentation for the message. Suggested usage is that tag includes the label and a unique identifying number. A sample tag is "XSI:cat:146". The constant `__MM_MXTAGLN` defines the maximum length of tag.

The MSGVERB environment variable (for message verbosity) tells `fmtmsg()` which message components it is to select when writing messages to standard error. The value of MSGVERB is a colon-separated list of optional keywords. Valid keywords are: label, severity, text, action, and tag. If MSGVERB contains a keyword for a component and the component’s value is not the component’s NULL value, `fmtmsg()` includes that component in the message when writing the message to standard error. If MSGVERB does not include a keyword for a message component, that component is not included in the display of the message. The keywords may appear in any order. If MSGVERB is not defined, if its value is the NULL string, if its value is not of the correct format, or if it contains keywords other than the valid ones listed above, `fmtmsg()` selects all components.

MSGVERB affects only which components are selected for display to standard error. All message components are included in console messages.
Returned Value

fmtmsg() returns one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MM_OK</td>
<td>The function succeeded.</td>
</tr>
<tr>
<td>MM_NOCON</td>
<td>The function was unable to generate a console message, but otherwise succeeded.</td>
</tr>
<tr>
<td>MM_NOMSG</td>
<td>The function was unable to generate a message on standard error, but otherwise succeeded.</td>
</tr>
<tr>
<td>MM_NOTOK</td>
<td>The function failed completely.</td>
</tr>
</tbody>
</table>

Examples

The following is an example of fmtmsg():

```c
fmtmsg(MM_PRINT, "XSI:cat", MM_ERROR, "illegal option", "refer to cat in user's reference manual", "XSI:cat:001")
```

produces a complete message in the specified message format:

XSI:cat: ERROR: illegal option
TO FIX: refer to cat in user's reference manual XSI:cat:001

The following is another example when the environment variable MSGVERB is set.

```bash
export MSGVERB=severity:text:action
```

```c
fmtmsg(MM_PRINT, "XSI:cat", MM_ERROR, "illegal option", "refer to cat in user's reference manual", "XSI:cat:001")
```

produces a complete message in the specified message format:

ERROR: illegal option
TO FIX: refer to cat in user's reference manual

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <fnmatch.h>

int fnmatch(const char *pattern, const char *string, int flags);
```

General Description

The fnmatch() function matches patterns as described in Section 2.13.1, Patterns Matching a Single Character, and Section 2.13.2, Patterns Matching Multiple Characters. It checks the string specified by the `string` argument to see if it matches the pattern specified by the `pattern` argument.

The `flags` argument modifies the interpretation of `pattern` and `string`. It is the bitwise inclusive-OR of zero or more of the flags defined in the header `<fnmatch.h>`. If the FNM_PATHNAME flag is set in `flags`, then a slash character in `string` will be explicitly matched by a slash in `pattern`; it will not be matched by either the asterisk or question-mark special characters, nor by a bracket expression. If FNM_PATHNAME is set and either of these characters would match a slash, the function returns FNM_ESLASH. If the FNM_PATHNAME flag is not set, the slash character is treated as an ordinary character.

If FNM_NOESCAPE is not set in `flags`, a backslash character (\) in `pattern` followed by any other character will match that second character in `string`. In particular, \ will match a backslash in `string`. If FNM_NOESCAPE is set, a backslash character will be treated as an ordinary character.

If FNM_PERIOD is set in `flags`, then a leading period in `string` will match a period in `pattern`; as described by rule 2 in the XCU specification, Section 2.13.3, Patterns Used for Filename Expansion where the location of “leading” is indicated by the value of FNM_PATHNAME:

- If FNM_PATHNAME is set, a period is “leading” if it is the first character in `string` or if it immediately follows a slash.
- If FNM_PATHNAME is not set, a period is “leading” only if it is the first character of `string`.

If FNM_PERIOD is not set, then no special restrictions are placed on matching a period. If FNM_PERIOD is set, and a pattern wildcard would match a leading period as defined by the above rules, then the function returns FNM_EPERIOD.

Returned Value

If `string` matches the pattern specified by `pattern`, fnmatch() returns 0.

If there is no match, fnmatch() returns FNM_NOMATCH, which is defined in the header `<fnmatch.h>`. 
If an error occurs, fnmatch() returns another nonzero value. See the discussion above for the various possible nonzero returns.

Format

```
#include <stdio.h>

FILE *fopen(const char *__restrict__ filename, const char *__restrict__ mode);
```

General Description

Opens the file specified by filename and associates a stream with it. The mode variable is a character string specifying the type of access requested for the file. The mode variable contains one positional parameter followed by optional keyword parameters. The positional parameters are described in Table 28 and Table 29 on page 628.

The positional parameters must be passed as lowercase characters.

The keyword parameters can be passed in mixed case. They must be separated by commas. Only one instance of a keyword can be specified.

The file name passed to fopen() often determines the type of file that is opened. A set of file-naming rules exist, which allow you to create an application that references both MVS and HFS files specifically. For details on how fopen() determines the type of file from the filename and mode strings, see one of the “Opening Files” sections in z/OS XL C/C++ Programming Guide.

File mode

**Restriction:** When running with POSIX(OFF) and specifying a mode parameter that includes t, for example, rt, rt+, r+t, wt, wt+, w+t, at, at+ or a+t, the fopen() request will fail with a message indicating a non-valid mode was specified.

</tr>
</tbody>
</table>

**Attention:** Use the w, w+, wb, w+b, and w+b+ parameters with care; data in existing files of the same name will be lost.

**Text files** contain printable characters and control characters organized into lines. Each line ends with a newline character. The system may insert or convert control characters in an output text stream. For example, \r written to an MVS DASD text file will be treated as if \n (newline) was written.

**Note:** When compared, data output to a text stream may not be equal to data input from the same text stream.

**Binary files** contain a series of characters. For binary files, the system does not translate control characters on input or output. Under z/OS XL C/C++, some types of files are always treated as binary files, even when opened in text mode.

In such cases, a control character is written to the file as binary data. On input, the control character will be read back as it was written. See “The Byte Stream Model” in z/OS XL C/C++ Programming Guide for more information.
**fopen**

z/OS XL C/C++ has a Record I/O file extension. These files are binary in nature—no data interpretation—and require the additional qualifier: `type=record`. See “Writing to Record I/O Files” in [z/OS XL C/C++ Programming Guide](#) for more information.

When you open a file with `a`, `a+`, `ab`, `a+b`, or `ab+` mode, all write operations take place at the end of the file. Although you can reposition the file pointer using `fseek()`, `fsetpos()`, or `rewind()`, the write functions move the file pointer back to the end of the file before they carry out any output operation. This action prevents you from overwriting existing data.

When you specify the update mode (using `+` in the second or third position), you can both read from and write to the file. However, when switching between reading and writing, you must include an intervening positioning function such as `fseek()`, `fsetpos()`, `rewind()`, or `fflush()`. Output may immediately follow input if the EOF was detected.

**Table 29. Keyword Parameters for File Mode**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>

<tr>
<td><strong>Note:</strong></td>
<td>Using recfm=* is only valid for existing DASD data sets. It is ignored in all other cases.</td>
</tr>
</tbody>
</table>

**recfm=+**

Identical to recfm=* with the following exceptions:

- If there is no record format for the existing DASD data set, defaults are assigned as if the data set did not exist.
- When append mode is used, the fopen() fails.

See [z/OS XL C/C++ Programming Guide](https://publibz.boulder.ibm.com/ps8/0452/0055/04520055b.htm) for more details on fopen() default attributes.

**space**

Space attributes for MVS data sets. Within the parameter, you cannot have any imbedded blanks.

Where:

- u - unit type of space requested
- p - primary amount of space requested
- s - secondary amount of space requested
- d - number of directory space requested

**type=memory**

This parameter identifies this file as a memory file that is accessible only from C programs.

**type=memory(hiperspace)**

If you are using MVS/ESA, you can specify the HIPERSPACE suboption to open a hiperspace memory file.

**Restriction:** For AMODE 64 applications, type=memory(hiperspace) is treated as type=memory.

**type=record**

This parameter specifies that the file is to be opened for sequential record I/O. The file must be opened as a binary file; otherwise, fopen() fails. Read and write operations are done with the fread() and fwrite() functions. This is the default fopen() mode for accessing VSAM clusters.
Table 29. Keyword Parameters for File Mode (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asis</td>
<td>Indicates that the file name is not to be converted to uppercase but used as is. This option is the default under POSIX. It is also the default for HFS file names (see z/OS XL C++ Programming Guide for details).</td>
</tr>
<tr>
<td>password=xxxxxxxx</td>
<td>Specifies the password for a VSAM data set.</td>
</tr>
<tr>
<td>noseek</td>
<td>Indicates that the stream may not use any of the reposition functions. This may improve performance.</td>
</tr>
</tbody>
</table>

Large Files for HFS

**Note:** Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option LANGlvl(LONGLONG) and also define the Feature Test Macro (FTM) _LARGE_FILES before any headers are included will enable this function to operate on HFS files that are larger than 2 gig-1 in size. File size and offset fields will be enlarged to 63 bits in width so any other function operating on this file will have to be enabled with the same FTM.

Named Pipes in Multi-Threaded Environment

Do not use fopen() to open named pipes in multi-threaded environment. If used, a deadlock will occur. See the z/OS XL C++ Programming Guide for a detailed explanation.

Returned Value

If successful, fopen() returns a pointer to the object controlling the associated stream.

If unsuccessful, fopen() returns a NULL pointer.

fopen() generally fails if parameters are mismatched.

Special Behavior for Large Files for HFS

The following is a possible value of errno:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EOVERFLOW</td>
<td>The named file is a regular file and the size of the file cannot be represented correctly in an object of type off_t.</td>
</tr>
</tbody>
</table>

Example

CELEBF26

```c
/* CELEBF26

This example attempts to open two files for reading, myfile.dat and myfile2.dat.
*/
#include <stdio.h>

int main(void)
{
    FILE *stream;
```
The following call opens a text file for reading:

```c
if ((stream = fopen("myfile.dat", "r")) == NULL) {
    printf("Could not open data file for reading\n");
}
```

The following call opens:
- The file `myfile2.dat`,
- A binary file for reading and writing,
- Whose record length is 80 bytes,
- And maximum length of a physical block is 240 bytes,
- Fixed-length, blocked record format for sequential record I/O.

```c
if ((stream = fopen("myfile2.dat", "rb+, lrecl=80,\n    blksize=240, recfm=fb, type=record")) == NULL) {
    printf("Could not open data file for read update\n");
}
```

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <sys/types.h>
#include <unistd.h>

pid_t fork(void);
```

Note: Although POSIX.1 does not require that the `<sys/types.h>` include file be included, XPG4 has it as an optional header. Therefore, it is recommended that you include it for portability.

General Description

Creates a new process. The new process (the child process) is an exact duplicate of the process that calls fork() (the parent process), except for the following:

- The child process has a unique process ID (PID) that does not match any active process group ID.
- The child has a different parent process ID, that is, the process ID of the process that called fork().
- The child has its own copy of the parent's file descriptors. Each file descriptor in the child refers to the same open file description as the corresponding file descriptor in the parent.
- The child has its own copy of the parent's open directory streams. Each child's open directory stream can share directory stream positioning with the corresponding parent's directory stream.
- The following elements in the tms structure are set to 0 in the child:
  ```
  tms_utime
  tms_stime
  tms_cutime
  tms_cstime
  ```
  For more information about these elements, see `times() — Get Process and Child Process Times` on page 2206.
- The child does not inherit any file locks previously set by the parent.
- The child process has no alarms set (similar to the results of a call to alarm() with an argument value of 0).
- The child has no pending signals.
- The child process has only a single thread. That thread is a copy of the thread in the parent that called fork(). The child process has a different thread ID. If the parent process was multi-threaded (invoked pthread_create() at least once), the child process can only safely invoke async-signal-safe functions before it invokes an exec() family function. (This restriction also applies to any process created as the result of the child invoking fork() before it invokes an exec() family function.)
because the child process is still considered multi-threaded.) The child process
does not inherit pthread attributes or pthread security environment. See Table 30
for a list of async-signal-safe functions.

In all other respects, the child is identical to the parent. Because the child is a
duplicate, it contains the same call to fork() that was in the parent. Execution begins
with this fork() call, which returns a value of 0; the child then proceeds with normal
execution.

The child address space inherits the following address space attributes of the
parent address space:

- Region size
- Time limit

If the parent process is multi-threaded, it is the responsibility of the application to
ensure that the application data is in a consistent state when the fork() occurs. For
example, mutexes that are used to serialize updates to application data may need
to be locked before the fork() and unlocked afterwards.

For more information on fork(), refer to 
\[\text{z/OS UNIX System Services Programming: Assembler Callable Services Reference, SA22-7803}\.]

You can use MVS memory files from a z/OS UNIX program. However, use of the
fork() function from the program removes access from a hiperspace memory file for
the child process. Use of an exec function from the program clears a memory file
when the process address space is cleared.

The child process that results from a fork() in a multi-threaded environment can only
invoke async-signal-safe functions.

An async-signal-safe function is defined as a function that may be invoked, without
restriction, from signal-catching functions. All supported async-signal-safe functions
are listed in Table 30.

</tbody>
</table>

Interoperability Restriction

For POSIX resources, fork() behaves as just described. But in general, MVS resources that existed in the parent do not exist in the child. This is true for open streams in MVS data sets and assembler-accessed MVS facilities, such as STIMERS. In addition, MVS allocations (through JCL, SVC99, or ALLOCATE) are not passed to the child process.

Special Behavior for z/OS UNIX Services

Notes:

1. A prior loaded copy of an HFS program in the same address space is reused under the same circumstances that apply to the reuse of a prior loaded MVS unauthorized program from an unauthorized library by the MVS XCTL service with the following exceptions:
   - If the calling process is in Ptrace debug mode, a prior loaded copy is not reused.
   - If the calling process is not in Ptrace debug mode, but the only prior loaded usable copy found of the HFS program is in storage modifiable by the caller, the prior copy is not reused.

2. If the specified file name represents an external link or a sticky bit file, the program is loaded from the caller’s MVS load library search order. For an external link, the external name is only used if the name is eight characters or less, otherwise the caller receives an error from the loadhfs service. For a sticky bit program, the file name is used if it is eight characters or less. Otherwise, the program is loaded from the HFS.

3. If the calling task is in a WLM enclave, the resulting task in the new process image is joined to the same WLM enclave. This allows WLM to manage the old and new process images as one ‘business unit of work’ entity for system accounting and management purposes.

Returned Value

If successful, fork() returns 0 to the child process and the process ID of the newly created child to the parent process.
If unsuccessful, `fork()` fails to create a child process, returns −1 to the parent, and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>There are insufficient resources to create another process, or the process has already reached the maximum number of processes you can run.</td>
</tr>
<tr>
<td>ELEMSGERR</td>
<td>Language Environment message file not available.</td>
</tr>
<tr>
<td>ELEMULTITHREAD</td>
<td>Application contains a language that does not support <code>fork()</code> in a multithreaded environment, or the multithreaded <code>fork()</code> is being attempted while running in a Language Environment preinitialization (CEEPPI) environment.</td>
</tr>
<tr>
<td>ELENOFORK</td>
<td>Application contains a language that does not support <code>fork()</code>.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>The process requires more space than is available.</td>
</tr>
</tbody>
</table>

**Example**

**CELEBF27**

```c
/* CELEBF27 */

#define _POSIX_SOURCE
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>
#include <stdlib.h>
#include <sys/wait.h>

int main() {
    pid_t pid;
    int status;

    if ((pid = fork()) < 0) 
        perror("fork() error");
    else if (pid == 0) {
        puts("This is the child.");
        printf("Child's pid is %d and my parent's is %d\n", 
               (int) getpid(), (int) getppid());
        exit(42);
    } else {
        puts("This is the parent.");
        printf("Parent's pid is %d and my child's is %d\n", 
               (int) getpid(), (int) pid);
        puts("I'm waiting for my child to complete.");
        if (wait(&status) == -1) 
            perror("wait() error");
        else if (WIFEXITED(status))
            printf("The child exited with status of %d\n", 
                   WEXITSTATUS(status));
        else 
            puts("The child did not exit successfully");
    }
}
```

**Output**
This is the parent.
This is the child.
Child's pid is 1114120 and my parent's is 2293766
Parent's pid is 2293766 and my child's is 1114120
I'm waiting for my child to complete.
The child exited with status of 42

fortrc() — Return FORTRAN Return Code

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

int fortrc(void);
```

External Entry Point

@@FORTRC, __fortrc

General Description

Restriction: This function is not supported in AMODE 64.

The fortrc() function returns the value specified on the FORTRAN RETURN statement issued by the last FORTRAN routine called from the C program.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The FORTRAN routine called must be identified to C as a FORTRAN routine using the following preprocessor directive:

```c
#pragma linkage(identifier,FORTRAN,RETURNCODE).
```

The function fortrc() should be called immediately after a call to the FORTRAN routine identifier or else results are unpredictable.

If you do not include stdlib.h in your source code or you use the compile-time option LANGLVL(ANSI), then you must use __fortrc to call the function.

fpathconf

fpathconf() — Determine Configurable Pathname Variables

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

long fpathconf(int fildes, int varcode);
```

General Description

Determines the value of a configuration variable (varcode) associated with a particular file descriptor (fildes).

fpathconf() works exactly like pathconf(), except that it takes a file descriptor as an argument rather than taking a pathname.

The varcode argument can be any one of a set of symbols defined in the unistd.h header file. Each symbol stands for a configuration variable. These are the possible symbols:

- `_PC_LINK_MAX`
  Represents `LINK_MAX`, the maximum number of links the file can have. If `pathname` is a directory, fpathconf() returns the maximum number of links that can be established to the directory itself.

- `_PC_MAX_CANON`
  Represents `MAX_CANON`, the maximum number of bytes in a terminal canonical input line. `pathname` must refer to a character special file for a terminal.

- `_PC_MAX_INPUT`
  Represents `MAX_INPUT`, the minimum number of bytes for which space will be available in a terminal input queue. This input space is the maximum number of bytes that a portable application will allow an end user to enter before the application actually reads the input. `pathname` must refer to a character special file for a terminal.

- `_PC_NAME_MAX`
  Represents `NAME_MAX`, the maximum number of characters in a file name (not including any terminating NULL character if the file name is stored as a string). This limit refers only to the file name itself, that is, the last component of the file’s pathname. fpathconf() returns the maximum length of file names.

- `_PC_PATH_MAX`
  Represents `PATH_MAX`, the maximum number of characters in a complete pathname (not including any terminating NULL if the pathname is stored as a string). fpathconf() returns the maximum length of a relative pathname.
_PC_PIPE_BUF

Represents PIPE_BUF, the maximum number of bytes that can be written to a pipe as one unit. If more than this number of bytes is written to a pipe, the operation can take more than one physical write operation and can require more than one physical read operation to read the data on the other end of the pipe. If pathname is a FIFO special file, fpathconf() returns the value for the file itself. If pathname is a directory, fpathconf() returns the value for any FIFOs that exist or can be created under the directory. If pathname is any other kind of file, an errno of EINVAL (see description below) will be returned.

_PC_CHOWN_RESTRICTED

Represents _POSIX_CHOWN_RESTRICTED defined in the unistd.h header file. This symbol indicates that the use of chown() is restricted; see the callable service chown() for more details. If pathname is a directory, fpathconf() returns the value for any kind of file under the directory, but not for subdirectories of the directory.

_PC_NO_TRUNC

Represents _POSIX_NO_TRUNC defined in the unistd.h header file. This symbol indicates that an error should be generated if a file name is longer than NAME_MAX. If pathname refers to a directory, the value returned by fpathconf() applies to all files under that directory.

_PC_VDISABLE

Represents _POSIX_VDISABLE defined in the unistd.h header file. This symbol indicates that terminal special characters can be disabled using this character value, if it is defined. See the callable service tcsetattr() for details. pathname must refer to a character special file for a terminal.

_PC_ACL

Returns 1 if an access control mechanism is supported by the security product for the file identified by the file descriptor.

_PC_ACL_ENTRIES_MAX

Returns the maximum number of ACL entries in an ACL for the file or directory identified by the file descriptor.

Returned Value

If a particular variable has no limit, fpathconf() returns −1 but does not change errno.

If successful, fpathconf() returns the value of the variable requested in varcode.

If unsuccessful, fpathconf() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>fildes is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>varcode is not a valid variable code, or the given variable cannot be</td>
</tr>
<tr>
<td></td>
<td>associated with the specified file.</td>
</tr>
<tr>
<td></td>
<td>• If varcode refers to MAX_CANON, MAX_INPUT, or _POSIX_VDISABLE, and</td>
</tr>
<tr>
<td></td>
<td>pathname does not refer to a character special file, fpathconf() returns</td>
</tr>
<tr>
<td></td>
<td>−1 and sets errno to EINVAL.</td>
</tr>
</tbody>
</table>
**fpathconf**

- If `varcode` refers to `NAME_MAX`, `PATH_MAX`, or `POSIX_NO_TRUNC`, and `pathname` does not refer to a directory, `fpathconf()` returns the requested information.
- If `varcode` refers to `PC_PIPE_BUF` and `pathname` refers to a pipe or a FIFO, the value returned applies to the referenced object itself. If `pathname` refers to a directory, the value returned applies to any FIFOs that exist or can be created within the directory. If `pathname` refers to any other type of file, the function sets `errno` to `EINVAL`.

**Example**

CELEBF29

```c
/* CELEBF29 */

#define _POSIX_SOURCE
#include <errno.h>
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    long result;
    char fn[]="temp.file";
    int fd;

    if ((fd = creat(fn, S_IRUSR)) < 0)
        perror("creat() error");
    else {
        errno = 0;
        puts("examining NAME_MAX limit for current working directory's");
        puts("filesystem:");
        if ((result = fpathconf(fd, _PC_NAME_MAX)) == -1)
            if (errno == 0)
                puts("There is no limit to NAME_MAX.");
            else perror("fpathconf() error");
        else
            printf("NAME_MAX is %ld\n", result);
        close(fd);
        unlink(fn);
    }
}
```

**Output**

examining NAME_MAX limit for current working directory's filesystem:
NAME_MAX is 255

fpclassify() — Classifies an argument value

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R9</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C/C++ DFP</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <math.h>

int fpclassify (real-floating x);
```

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

int fpclassify(real-floating x or decimal-floating x);
```

General Description

This macro classifies its argument value as NaN, infinite, normal, subnormal or zero based on the type of its argument. If the argument is represented in a format wider than its semantic type, then it is converted to its semantic type and then it is classified.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>fpclassify</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

fpclassify() returns:

- FP_NAN if the argument is Not-a-Number.
- FP_INFINITY if the argument is plus or minus infinity.
- FP_ZERO if the argument is of value zero.
- FP_SUBNORMAL if the argument is too small to be represented in the normal format.
- FP_NORMAL if none of the above.

Special behavior in Hex

- FP_ZERO if the argument is of value zero.
- FP_NORMAL if the argument is a normalized number.
- FP_SUBNORMAL if the argument is an unnormalized number.

fp_clr_flag

fp_clr_flag() — Reset Floating-Point Exception Status Flag

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>both</td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

```c
#include <float.h>
#include <fpxcp.h>

void fp_clr_flag(mask)
    fpflag_t mask;
```

General Description

The fp_clr_flag() function resets the exception status flags defined by the `mask` parameter to 0 (false). The remaining flags in the exception status remain unchanged.

Note: This function works only in IEEE Binary Floating-Point. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

The `fpxcp.h` file defines the following names for the flags indicating floating-point exception status:

- `FP_INVALID` Invalid operation summary
- `FP_OVERFLOW` Overflow
- `FP_UNDERFLOW` Underflow
- `FP_DIV_BY_ZERO` Division by 0
- `FP_INEXACT` Inexact result

Users can reset multiple exception flags using the `fp_clr_flag()` function by OR-ing the names of individual flags. For example, the following resets both the overflow and inexact flags.

```c
fp_clr_flag(FP_OVERFLOW | FP_INEXACT)
```

Returned Value

`fp_clr_flag()` returns no values.

Related Information

- "float.h" on page 46
- "fpxcp.h" on page 48
- "fp_raise_xcp() — Raise a Floating-Point Exception" on page 643
- "fp_read_flag() — Return the Current Floating-Point Exception Status" on page 645
- "__isBFP() — Determine Application Floating-Point Format" on page 1015
The `fp_raise_xcp()` function causes floating-point exceptions defined by the `mask` parameter to be raised immediately.

If the exceptions defined by the `mask` parameter are enabled and the program is running in serial mode, the signal for floating-point exceptions, SIGFPE, is raised.

**Note:** This function works only in IEEE Binary Floating-Point. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

The `fpdxp.h` file defines the following names for the flags indicating floating-point exception status:

- **FP_INVALID**: Invalid operation summary
- **FP_OVERFLOW**: Overflow
- **FP_UNDERFLOW**: Underflow
- **FP_DIV_BY_ZERO**: Division by 0
- **FP_INEXACT**: Inexact result

Users can cause multiple exceptions using `fp_raise_xcp()` by OR-ing the names of individual flags. For example, the following causes both overflow and division by 0 exceptions to occur.

```c
fp_raise_xcp(FP_OVERFLOW | FP_DIV_BY_ZERO)
```

If more than one exception is included in the mask variable, the exceptions are raised in the following order:

1. Non-valid operation
2. Division by zero
3. Underflow
4. Overflow
5. Inexact result

Thus, if the user exception handler does not disable further exceptions, one call to the `fp_raise_xcp()` function can cause the exception handler to be entered many times.
fp_raise_xcp

Returned Value

If successful, fp_raise_xcp() returns 0.

If unsuccessful, fp_raise_xcp() returns nonzero.

Format

#include <float.h>
#include <fp_xcp.h>

fpflag_t fp_read_flag()

General Description

The fp_read_flag() function returns the current floating-point exception status.

These functions aid in determining both when an exception has occurred and the exception type. These functions can be called explicitly around blocks of code that may cause a floating-point exception.

According to the IEEE Standard for Binary Floating-Point Arithmetic, the following types of floating-point operations must be signaled when detected in a floating-point operation:

- Non-valid operation
- Division by zero
- Overflow
- Underflow
- Inexact

A non-valid operation occurs when the result cannot be represented (for example, a square root operation on a number less than 0).

The IEEE Standard for Binary Floating-Point Arithmetic states: “For each type of exception, the implementation shall provide a status flag that shall be set on any occurrence of the corresponding exception when no corresponding trap occurs. It shall be reset only at the user's request. The user shall be able to test and to alter the status flags individually, and should further be able to save and restore all five at one time.”

Floating-point operations can set flags in the floating-point exception status but cannot clear them. Users can clear a flag in the floating-point exception status using an explicit software action such as the fp_clr_flag (0) subroutine.

Note: This function works only in IEEE Binary Floating-Point. See “IEEE Binary Floating-Point” on page 108 for more information about IEEE Binary Floating-Point.

The fp_xcp.h file defines the following names for the flags indicating floating-point exception status:

- FP_INVALID: non-valid operation summary
- FP_OVERFLOW: Overflow
- FP_UNDERFLOW: Underflow
fp_read_flag

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FP_DIV_BY_ZERO</td>
<td>Division by 0</td>
</tr>
<tr>
<td>FP_INEXACT</td>
<td>Inexact result</td>
</tr>
</tbody>
</table>

**Returned Value**

fp_read_flag() returns the current floating-point exception status. The flags in the returned exception status can be tested using the flag definitions above. You can test individual flags or sets of flags.

fp_read_rnd() — Determine Rounding Mode

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>both</td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

```c
#define _AIX_COMPATIBILITY 1
#include <float.h>

fprnd_t fp_read_rnd(void);
```

General Description

For an application running in binary floating-point mode, the `fp_read_rnd()` function returns the current rounding mode indicated by the rounding mode field of the floating-point control (FPC) register. For an application running in hexadecimal floating-point mode, `fp_read_rnd()` returns 0.

Note: This function will not return or update decimal floating-point rounding mode bits.

Returned Value

For an application running in IEEE Binary Floating-Point mode, `fp_read_rnd()` returns the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Rounding Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>_FP_RND_RZ</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>_FP_RND_RN</td>
<td>Round to nearest</td>
</tr>
<tr>
<td>_FP_RND_RP</td>
<td>Round toward +infinity</td>
</tr>
<tr>
<td>_FP_RND_RM</td>
<td>Round toward −infinity</td>
</tr>
</tbody>
</table>

For an application running in hexadecimal floating-point mode, `fp_read_rnd()` returns 0.

</tbody>
</table>

Format

```c
#include <stdio.h>

int fprintf(FILE *__restrict__ stream, const char *__restrict__ format-string, ...);
int printf(const char *__restrict__ format-string, ...);
int sprintf(char *__restrict__ buffer, const char *__restrict__ format-string, ...);
```

General Description

These three related functions are referred to as the `fprintf family`.

The `fprintf()` function formats and writes output to a `stream`. It converts each entry in the `argument list`, if any, and writes to the stream according to the corresponding format specification in the `format-string`. The `fprintf()` function cannot be used with a file that is opened using `type=record`.

The `printf()` function formats and writes output to the standard output stream `stdout`. `printf()` cannot be used if `stdout` has been reopened using `type=record`.

The `sprintf()` function formats and stores a series of characters and values in the array pointed to by `buffer`. Any `argument-list` is converted and put out according to the corresponding format specification in the `format-string`. If the strings pointed to by `buffer` and `format` overlap, behavior is undefined.

`fprintf()` and `printf()` have the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

The `format-string` consists of ordinary characters, escape sequences, and conversion specifications. The ordinary characters are copied in order of their appearance. Conversion specifications, beginning with a percent sign (%) or the sequence (%n$) where n is a decimal integer in the range [1, NL_ARGMAX], determine the output format for any `argument-list` following the `format-string`. The `format-string` can contain multibyte characters beginning and ending in the initial shift state. When the `format-string` includes the use of the optional prefix `ll` to indicate the size expected is a long long datatype then the corresponding value in the argument list should be a long long datatype if correct output is expected.

Special Behavior for XPG4
If the %n$ conversion specification is found, the value of the nth argument after the format-string is converted and output according to the conversion specification. Numbered arguments in the argument list can be referenced from format-string as many times as required.

The format-string can contain either form of the conversion specification, that is, % or %n$ but the two forms cannot be mixed within a single format-string except that %% can be mixed with the %n$ form. When numbered conversion specifications are used, specifying the ‘nth’ argument requires that the first to (n-1)th arguments are specified in the format-string.

The format-string is read from left to right. When the first format specification is found, the value of the first argument after the format-string is converted and output according to the format specification. The second format specification causes the second argument after the format-string to be converted and output, and so on through the end of the format-string. If there are more arguments than there are format specifications, the extra arguments are evaluated and ignored. The results are undefined if there are not enough arguments for all the format specifications. The format specification is illustrated below.

![Format Specification](image)

Each field of the format specification is a single character or number signifying a particular format option. The type character, which appears after the last optional format field, determines whether the associated argument is interpreted as a character, a string, a number, or pointer. The simplest format specification contains only the percent sign and a type character (for example, %s).

**The percent sign**

If a percent sign (%) is followed by a character that has no meaning as a format field, the character is simply copied to stdout. For example, to print a percent sign character, use %%. 

**The flag characters**

The flag characters in [Table 31 on page 650](#) are used for the justification of output and printing of thousands’ grouping characters, signs, blanks, decimal-points, octal, and hexadecimal prefixes, and the semantics for wchar_t precision unit. Notice that more than one flag can appear in a format specification. This is an optional field.
### Table 31. Flag Characters for fprintf() Family

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>'</td>
<td>Added for XPG4: The integer portion of the result of a decimal conversion (%i,%d,%u, %f,%g or %G) will be formatted with the thousands' grouping characters.</td>
<td>No grouping.</td>
</tr>
<tr>
<td>−</td>
<td>Left-justify the result within the field width.</td>
<td>Right-justify.</td>
</tr>
<tr>
<td>+</td>
<td>Prefix the output value with a sign (+ or −) if the output value is of a signed type.</td>
<td>Sign appears only for negative signed values (−).</td>
</tr>
<tr>
<td>blank(' ')</td>
<td>Prefix the output value with a blank if the output value is signed and positive. The + flag overrides the blank flag if both appear, and a positive signed value will be output with a sign.</td>
<td>No blank.</td>
</tr>
<tr>
<td>#</td>
<td>When used with the o, x, or X formats, the # flag prefixes any nonzero output value with 0, 0x, or 0X, respectively. For o conversion, it increases the precision, if and only if necessary, to force the first digit of the result to be a zero (if the value and precision are both 0, a single 0 will be printed). When used with the f, e, or E formats, the # flag forces the output value to contain a decimal-point in all cases. The decimal-point is sensitive to the LC_NUMERIC category of the same current locale. When used with the g or G formats, the # flag forces the output value to contain a decimal-point in all cases and prevents the truncation of trailing zeros. When used with the l, s or S format, the # flag causes precision to be measured in wide characters.</td>
<td>No prefix. Decimal-point appears only if digits follow it. Decimal-point appears only if digits follow it; trailing zeros are truncated. Precision indicates the maximum number of bytes to be output.</td>
</tr>
<tr>
<td>0</td>
<td>When used with the d, i, o, u, x, X, e, E, f, g, or G formats, the 0 flag causes leading 0’s to pad the output to the field width. The 0 flag is ignored if precision is specified for an integer or if the − flag is specified.</td>
<td>Space padding.</td>
</tr>
</tbody>
</table>

The code point for the # character varies between the EBCDIC encoded character sets. The definition of the # character is based on the current LC_SYNTAX category. The default C locale expects the # character to use the code point for encoded character set IBM-1047.

When the LC_SYNTAX category is set using setlocale(), the format strings passed to the printf() functions must use the same encoded character set as is specified for the LC_SYNTAX category.

The # flag should not be used with c, l, 1c, c, d, i, u, s, or p types.

#### The Width of the Output
Width is a nonnegative decimal integer controlling the minimum number of characters printed. If the number of characters in the output value is less than the specified width, blanks are added on the left or the right (depending on whether the – flag is specified) until the minimum width is reached.

Width never causes a value to be truncated; if the number of characters in the output value is greater than the specified width, or width is not given, all characters of the value are output (subject to the precision specification).

The width specification can be an asterisk (*); if it is, an argument from the argument list supplies the value. The width argument must precede the value being formatted in the argument list. This is an optional field.

If format-string contains the %n$ form of conversion specification, width can be indicated by the sequence *m$, where m is a decimal integer in the range [1,NL_ARGMAX] giving the position of an integer argument in the argument list containing the field width.

The Precision of the Output

precision is a nonnegative decimal integer preceded by a period. It specifies the number of characters to be output, or the number of decimal places. Unlike the width specification, the precision can cause truncation of the output value or rounding of a floating-point value.

Be aware that the rounding of floating-point values may not always occur as expected based on the decimal value of the number. This is because the internal binary representation cannot always be an exact representation of the decimal value, so the rounding may occur on an inexact value. This is true of both OS/390 hexadecimal and IEEE 754 binary floating-point formats.

The precision specification can be an asterisk (*); if it is, an argument from the argument list supplies the value. The precision argument must precede the value being formatted in the argument list. The precision field is optional.

If format-string contains the %n$ form of conversion specification, precision can be indicated by the sequence *m$, where m is a decimal integer in the range [1,NL_ARGMAX] giving the position of an integer argument in the argument list containing the field precision.

The interpretation of the precision value and the default when the precision is omitted depend upon the type, as shown in Table 32.

<table>

### Optional prefix

Used to indicate the size of the argument expected:

- **D** Specifies that any following e, E, f, F, g, or G conversions specifier applies to a _Decimal64 argument.
- **DD** Specifies that any following e, E, f, F, g, or G conversions specifier applies to a _Decimal128 argument.
- **H** Specifies that any following e, E, f, F, g, or G conversions specifier applies to a _Decimal32 argument.
- **h** A prefix with the integer types d, i, o, u, x, X means the integer is 16 bits long.
- **hh** Specifies that a following d, i, o, u, x, or X conversion specifier applies to a signed char or unsigned char argument (the argument will have been promoted according to the integer promotions, but its value shall be converted to signed char or unsigned char before printing); or that a following n conversion specifier applies to a pointer to a signed char argument.
- **j** Specifies that a following d, i, o, u, x, or X conversion specifier applies to an intmax_t or uintmax_t argument; or that a following n conversion specifier applies to a pointer to an intmax_t argument.
- **l** A prefix with d, i, o, u, x, X, and n types that specifies that the argument is a long int or unsigned long int.

The l prefix with the c type conversion specifier indicates that the argument is a wint_t. The l prefix with the s type conversion specifier indicates that the argument is a pointer to a wchar_t.
Has no effect on a following a, A, e, E, f, F, g, G conversion specifier.

A prefix with the integer types d, i, o, u, x, X means the integer is 64 bits long.

A prefix with e, E, f, g, or G types that specifies that the argument is long double.

Specifies that a following d, i, o, u, x, or X conversion specifier applies to a ptrdiff_t or the corresponding unsigned type argument; or that a following n conversion specifier applies to a pointer to a ptrdiff_t argument.

Specifies that a following d, i, o, u, x, or X conversion specifier applies to a size_t or the corresponding signed integer type argument; or that a following n conversion specifier applies to a pointer to a signed integer type corresponding to a size_t argument.

**Note:** If you pass a long double value and do not use the L qualifier or if you pass a double value only and use the L qualifier, errors occur.

Table 33 below shows the meaning of the type characters used in the precision argument.

**Table 33. Type Characters and their Meanings**

<table>
<thead>
<tr>
<th>Type</th>
<th>Argument</th>
<th>Output Format</th>

</tbody>
</table>
Table 33. Type Characters and their Meanings (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Argument</th>
<th>Output Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>a, A</td>
<td>Double</td>
<td>A double argument representing a floating-point number is converted to the &quot;[-]0x.hhhhp=dd&quot; format, where there is one hexadecimal digit (non-zero when the argument is a normalized floating-point number; otherwise unspecified) before the decimal-point character and the number of hexadecimal digits after it is equal to the precision. If the precision is missing and FLT_RADIX is a power of 2, then the precision will be sufficient for an exact representation of the value. If the precision is missing and FLT_RADIX is not a power of 2, then the precision will be sufficient to distinguish values of type double, except that trailing zeros may be omitted. If the precision is zero and the '#' flag is not specified, no decimal-point will appear. The letters &quot;abcdef&quot; are used for the a conversion and the letters &quot;ABCDEF&quot; for the A conversion. The A conversion specifier produces a number with letters 'X' and 'P' instead of letters 'x' and 'p'. The exponent always contains at least one digit, and only as many more digits as necessary to represent the decimal exponent of 2. If the value is zero, the exponent is zero. A double argument representing an infinity or NaN is converted in the style of an f or F conversion specifier. If precision is zero, results can be different for Hexadecimal floating point format and IEEE floating point format. For Hexadecimal floating point, a decimal point will not appear in the output. For IEEE floating point, a decimal point will appear.</td>
</tr>
</tbody>
</table>

Note:

1. FLOAT(HEX) normalizes differently than FLOAT(IEEE). FLOAT(HEX) produces output in 0x0.hhhhp+/-dd format, not in the 0x1.hhhhp+/-dd format.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

fprintf Family of Formatted Output Functions

fprintf family functions match e, E, f, F, g or G conversion specifiers to floating-point arguments for which they produce floating-point number substrings in the output stream. fprintf family functions have been extended to determine the floating-point format, hexadecimal floating-point or IEEE Binary Floating-Point, of types e, E, f, F, g or G by using __isBFP().

fprintf family functions convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences.

- The special output sequence for infinity values is a plus or minus sign, then the character sequence INF followed by a white space character (space, tab, or newline), a NULL character (\0) or EOF.
- The special output sequence for NaN values is a plus or minus sign, then the character sequence NANS for a signalling NaN or NANQ for a quiet NaN, then a NaN ordinal sequence, and then a white space character (space, tab, or newline), a NULL character (\0) or EOF.
For Binary Floating Point NANS:
A NaN ordinal sequence is a left-parenthesis character, "(" followed by a digit sequence representing an integer n, where 1 \leq n \leq \text{INT\_MAX}-1, followed by a right-parenthesis character, ")". The integer value, n, is determined by the fraction bits of the NaN argument value as follows:
1. For a signalling NaN value, NaN fraction bits are reversed (left to right) to produce bits (right to left) of an even integer value, 2\(n\). Then formatted output functions produce a (signalling) NaN ordinal sequence corresponding to the integer value n.
2. For a quiet NaN value, NaN fraction bits are reversed (left to right) to produce bits (right to left) of an odd integer value, 2\(n\)-1. Then formatted output functions produce a (quiet) NaN ordinal sequence corresponding to the integer value n.

For Decimal Floating Point NANS:
A NaN ordinal sequence is a left parenthesis character, "(" , followed by a decimal digit sequence of up to 6 digits for a _Decimal32 output number, up to 15 digits for a _Decimal64 output value, or up to 33 digits for a _Decimal128 output value, followed by a right parenthesis, ")" . If the NaN ordinal sequence is omitted, NaN ordinal sequence "(0)" is assumed. If the NaN ordinal sequence is shorter than 6, 15, or 33 digits, it will be padded on the left with '0' digits so that the length becomes 6, 15, or 33 digits for _Decimal32, _Decimal64, and _Decimal128 values respectively.

For Decimal Floating Point numbers, the digits are not reversed, and both odd or even NaN ordinal sequences can be specified for either a Quiet NaN or Signalling NaN.

The C99 standard does not distinguish between the quiet NaN and signaling NaN values. An argument representing a NaN (Not a Number) is to be displayed as [-]nan or [-]nan(n-char-sequence); where the implementation decides the representation. For the A, E, F, and G conversion specifiers, NaN values are displayed as the uppercase versions of the aforementioned character string representations. To get this behavior set the environment variable _EDC_C99_NAN to YES.

Some compatibility with NaN sequences output by AIX formatted output functions can be achieved by setting a new environment variable, _AIX_NAN_COMPATIBILITY, which z/OS formatted output functions recognize, to one of the following (string) values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Output Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Formatted output functions which produce special NaN output sequences omit the NaN ordinal output sequence (1). This results in output NaN sequences of plus or minus sign followed by NANS or NANQ instead of plus or minus sign followed by NANS(1) or NANQ(1). All other NaN ordinal sequences are explicitly output.</td>
</tr>
<tr>
<td>ALL</td>
<td>Formatted output functions which produce special NaN output sequences omit the NaN ordinal output sequence for all NaN values. This results in output NaN sequences of plus or minus sign followed by NANS or NANQ instead of plus or minus sign followed by NANS(n) or NANQ(n) for all NaN values.</td>
</tr>
</tbody>
</table>

_Note:_ _AIX_NAN_COMPATIBILITY_ does not affect the formatting of DFP NaN values. It affects only the formatting of BFP NaN values.
The sprintf() function is available to C applications in a stand-alone System Programming C (SPC) Environment.

**Returned Value**

If successful, fprintf(), printf(), and sprintf() return the number of characters output. The ending NULL character is not counted.

If unsuccessful, they return a negative value.

**Example**

```c
CELEBF30

/* CELEBF30
   This example prints data using &printf. in a variety of formats.
*/

#include <stdio.h>

int main(void)
{
    char ch = 'h', *string = "computer";
    int count = 234, hex = 0x10, oct = 10, dec = 10;
    double fp = 251.7366;
    unsigned int a = 12;
    float b = 123.45;
    int c;
    void *d = "a";

    printf("the unsigned int is %u\n\n", a);
    printf("the float number is %g, and %g\n\n", b, b);
    printf("RAY\n\n", &c);
    printf("last line prints %d characters\n\n", c);
    printf("Address of d is %p\n\n", d);
    printf("%d %d %s %X %x %06d %d\n\n",
            count, count, count, count, count, count);
    printf("12345678901234567890123456789\n\n", &count);
    printf("Value of count should be 13; count = %d\n\n", count);
    printf("%c%c\n\n", ch, ch);
    printf("%s\n\s25.4s\n\n", string, string);
    printf("%f %.2f %e \n\n", fp, fp, fp);
    printf("%i %i %i\n\n", hex, oct, dec);
}
```

**Output**

the unsigned int is 12
the float number is 123.45 and 123.45
RAY
last line prints 3 characters
The following example illustrates the use of printf() to print fixed-point decimal data types.  This example works under C only, not C++.

```c
#include <stdio.h>
#include <decimal.h>

decimal(10,2) pd01 = -12.34d;
decimal(12,4) pd02 = 12345678.9876d;
decimal(31,10) pd03 = 123456789013579246801.9876543210d;

int main(void) {  
    printf("pd01 %D(10,2) = %D(10,2)\n", pd01);
    printf("pd02 %D(12,4) = %D(12,4)\n", pd02);

    printf("pd01 %010.2D(10,2) = %010.2D(10,2)\n", pd01);
    printf("pd02 %20.2D(12,4) = %20.2D(12,4)\n", pd02);
    printf("\n Give strange result if the specified size is wrong!\n");
    printf("pd03 %D(15,3) = %D(15,3)\n\n", pd03);
}
```

**Output**

```
pd01 %D(10,2) = -12.34
pd02 %D(12,4) = 12345678.9876
pd01 %010.2D(10,2) = -00012.34
pd02 %20.2D(12,4) = 12345678.98

Give strange result if the specified size is wrong!
pd03 %D(15,3) = -123456789013.579
```

This example illustrates the use of sprintf() to format and print various data.

```c
#include <stdio.h>

char buffer[200];
int i, j;
double fp;
char *s = "baltimore";
char c;

int main(void) {
```
c = 'l';
i = 35;
fp = 1.7320508;

/* Format and print various data */
j = snprintf(buffer, "%s
", s);
j += snprintf(buffer+j, "%c
", c);
j += snprintf(buffer+j, "%d
", i);
j += snprintf(buffer+j, "%f
", fp);
printf("string:%s\n"character count = %d\n", buffer, j);
}

Output
string:
Baltimore
1
35
1.732051

character count = 24

fp_swap_rnd

fp_swap_rnd() — Swap Rounding Mode

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>both</td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

#define _AIX_COMPATIBILITY 1
#include <float.h>

fprnd_t fp_swap_rnd(RoundMode)
fprnd_t RoundMode

General Description

For an application running in IEEE Binary Floating-Point mode, the fp_swap_rnd() function returns the current rounding mode specified by the rounding mode field of the floating-point control (FPC) register and sets the rounding mode field in the FPC register based on the value of RoundMode as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Rounding Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>_FP_RND_RZ</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>_FP_RND_RN</td>
<td>Round to nearest</td>
</tr>
<tr>
<td>_FP_RND_RP</td>
<td>Round toward +infinity</td>
</tr>
<tr>
<td>_FP_RND_RM</td>
<td>Round toward −infinity</td>
</tr>
</tbody>
</table>

Note:

- When processing IEEE Binary Floating-point values, the z/OS XL C/C++ run-time library math functions require IEEE rounding mode of round to nearest. The z/OS XL C/C++ run-time library takes care of setting round to nearest rounding mode while executing math functions and restoring application rounding mode before returning to the caller.
- This function will not return or update decimal floating-point rounding mode bits.

Returned Value

For an application running in hexadecimal floating-point mode, fp_swap_rnd() returns 0.

For an application running in IEEE Binary Floating-Point mode, fp_swap_rnd() returns the previous (changed from) rounding mode as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Rounding Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>_FP_RND_RZ</td>
<td>Round toward 0</td>
</tr>
<tr>
<td>_FP_RND_RN</td>
<td>Round to nearest</td>
</tr>
<tr>
<td>_FP_RND_RP</td>
<td>Round toward +infinity</td>
</tr>
<tr>
<td>_FP_RND_RM</td>
<td>Round toward −infinity</td>
</tr>
</tbody>
</table>

fputc

fputc() — Write a Character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int fputc(int c, FILE *stream);
```

General Description

Converts c to an unsigned char and then writes c to the output stream pointed to by stream at the current position and advances the file position appropriately. The fputc() function is identical to putc but is always a function, because it is not available as a macro.

If the stream is opened with one of the append modes, the character is appended to the end of the stream regardless of the current file position.

The fputc() function is not supported for files opened with type=record.

fputc() has the same restriction as any write operation for a read immediately following a write, or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

If successful, fputc() returns the character written.

If unsuccessful, fputc() returns EOF.

Example

```c
CELEBF34
/* CELEBF34 */

This example writes the contents of buffer to a file called myfile.dat.
Because the output occurs as a side effect within the second expression of the for statement, the statement body is null.

*/
#include <stdio.h>
#define NUM_ALPHA 26

int main(void)
{
    FILE * stream;
```
int i;
int ch;

char buffer[NUM_ALPHA + 1] = "abcdefghijklmnopqrstuvwxyz";

if ((stream = fopen("myfile.dat", "w")) != NULL)
{
    /* Put buffer into file */
    for (i = 0; (i < sizeof(buffer)) &&
         (ch = fputc(buffer[i], stream)) != EOF); ++i);
    fclose(stream);
}
else
    printf("Error opening myfile.dat\n");

Related Information

- "stdio.h" on page 82
- "fgetc() — Read a Character" on page 587
- "putc(), putchar() — Write a Character" on page 1566
fputs

fputs() — Write a String

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <stdio.h>

int fputs(const char *__restrict__ string, FILE *__restrict__ stream);
```

General Description

 Writes the string pointed to by `string` to the output stream pointed to by `stream`. It does not write the terminating `\0` at the end of the string.

For a text file, truncation may occur if the record is too long. *Truncation* means that excess characters are discarded after the record is full, up to a control character that ends the line (`\n`). Characters after the `\n` start at the next record. For more information, see the section on “Truncation” in [z/OS XL C/C++ Programming Guide](https://www.ibm.com/docs/en/zos/2.5.0). 

`fputs()` is not supported for files opened with `type=record`.

`fputs()` has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

 If successful, `fputs()` returns the number of bytes written.

 If unsuccessful, `fputs()` returns EOF.

Example

```
CELEBF35
/* CELEBF35

 This example writes a string to a stream.

 */
#include <stdio.h>
#define NUM_ALPHA 26

int main(void)
{
 FILE *stream;
 int num;

 /* Do not forget that the '\0' char occupies one character */
```
static char buffer[NUM_ALPHA + 1] = "abcdefghijklmnopqrstuvwxyz";

if ((stream = fopen("myfile.dat", "w")) != NULL )
{
  /* Put buffer into file */
  if ( (num = fputs( buffer, stream )) != EOF )
  {
    /* Note that fputs() does not copy the \0 character */
    printf( "Total number of characters written to file = %i\n", num );
    fclose( stream );
  }
  else  /* fputs failed */
    printf( "fputs failed" );
}
else
  printf( "Error opening myfile.dat" );

fputwc

fputwc() — Output a Wide-Character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

Non-XPG4

```c
#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wchar_t wc, FILE *stream);
```

XPG4

```c
#define _XOPEN_SOURCE
#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wint_t wc, FILE *stream);
```

XPG4 and MSE

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wchar_t wc, FILE *stream);
```

General Description

Converts the wide character specified by `wc` to a multibyte character and writes it to the output stream pointed to by `stream`, at the position indicated by the associated file position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests or if the stream was opened with append mode, the character is appended to the output stream.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. Using non-wide-character functions with `fputwc()` results in undefined behavior.

`fputwc()` has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Special Behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then the compiler assumes that your program is using the XPG4 variety of the `fputwc()` function, unless you also define the `_MSE_PROTOS` feature test macro. Please see Table 4 on page 22 for a list of XPG4 and other feature test macros.
The prototype for the XPG4 variety of the `fputwc()` function is:

```
wint_t fputwc(wint_t wc, FILE *stream);
```

The difference between this variety and the MSE variety of the `fputwc()` function is that the first parameter has type `wint_t` rather than type `wchar_t`.

### Returned Value

If successful, `fputwc()` returns the wide character written.

If a write error occurs, the error indicator for the stream is set and WEOF is returned. If an encoding error occurs during conversion from wide character to a multibyte character, the value of the macro EILSEQ is stored in errno and WEOF is returned.

### Example

```c
CELEBF36
/* CELEBF36 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#include <errno.h>

int main(void)
{
    FILE *stream;
    wchar_t *wcs = L"This test string should not cause a WEOF condition";
    int i;
    int rc;

    if ((stream = fopen("myfile.dat", "w")) == NULL) {
        printf("Unable to open file.\n");
        exit(1);
    }

    for (i=0; wcs[i] != L'\0'; i++) {
        errno = 0;
        if ((rc = fputwc(wcs[i], stream)) == WEOF) {
            printf("Unable to fputwc() the wide character.\n");
            printf("wcs[%d] = 0x%x\n", i, wcs[i]);
            if (errno == EILSEQ)
                printf("An invalid wide character was encountered.\n");
            exit(1);
        }
    }

    fclose(stream);
}
```

fputws

fputws() — Output a Wide-Character String

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <wchar.h>

int fputws(const wchar_t *__restrict__ wcs, FILE *__restrict__ stream);
```

General Description

Converts the wide-character string pointed to by wcs to a multibyte character string and writes it to the stream pointed to by stream, as a multibyte character string. The terminating NULL byte is not written.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. Using non-wide-character functions with fputws() results in undefined behavior.

fputws() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

If successful, fputws() returns a nonnegative value.

If a stream error occurs, fputws() returns −1 and the error indicator for the stream is set.

If an encoding error occurs, fputws() returns −1 and the value of the macro EILSEQ is stored in errno. An encoding error is one that occurs when converting a wide character to a multibyte character.

Example

```
CELEBF37
/* CELEBF37 */
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
    FILE  *stream;
    wchar_t *wcs = L"This test string should not return −1";
    int    rc;

    if ((stream = fopen("myfile.dat", "w")) == NULL) {
```
printf("Unable to open file.\n");
exit(1);
}

errno = 0;
rc = fputws(wcs, stream);
if (rc == EOF) {
    printf("Unable to complete fputws() function.\n");
    if (errno == EILSEQ)
        printf("An invalid wide character was encountered.\n");
    exit(1);
}
fclose(stream);

fread

fread() — Read Items

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

size_t fread(void *__restrict__ buffer, size_t size, size_t count, FILE *__restrict__ stream);
```

General Description

Reads up to `count` items of `size` length from the input stream pointed to by `stream` and stores them in the given `buffer`. The file position indicator advances by the number of bytes read.

If there is an error during the read operation, the file position indicator is undefined. If a partial element is read, the element's value is undefined.

When you are using fread() for record I/O, set `size` to 1 and `count` to the maximum expected length of the record, to obtain the number of bytes. Only one record is read, regardless of `count`, when using record I/O.

fread() has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

fread() returns the number of complete items successfully read.

If `size` or `count` is 0, fread() returns 0, and the contents of the array and the state of the stream remain unchanged. For record I/O, it is possible that the number of complete items can be less than `count`. However, this result does not necessarily indicate that an error has occurred.

The ferror() and feof() functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read "past" the last byte of data. Reading up to and including the last byte of data does not turn on the EOF indicator.

Example

```c
CELEBF38
/* CELEBF38
   This example attempts to read NUM_ALPHA characters from the
```
file myfile.dat.
If there are any errors with either &fread. or &fopen., a
message is printed.

*/
#include <stdio.h>
define NUM_ALPHA 26

int main(void)
{
    FILE * stream;
    int num;  /* number of characters read from stream */
    /* Do not forget that the '\0' char occupies one character too! */
    char buffer[NUM_ALPHA + 1];
    buffer[NUM_ALPHA+1] = '\0';

    if (stream = fopen("myfile.dat", "r"))!= NULL
        num = fread( buffer, sizeof( char ), NUM_ALPHA, stream );
    if (num == NUM_ALPHA) { /* fread success */
        printf("Number of characters read = %i\n", num );
        printf("buffer = %s\", buffer );
        fclose( stream );
    }
    else { /* fread failed */
        if ( ferror(stream) )  /* possibility 1 */
            printf("Error reading myfile.dat" );
        else if ( feof(stream)) { /* possibility 2 */
            printf("EOF found\n");
            printf("Number of characters read %d\n", num );
            printf("buffer = %.5s\", num, buffer);
        }
    }
    else
        printf("Error opening myfile.dat");
}

free

free() — Free a Block of Storage

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

void free(void *ptr);
```

General Description

Frees a block of storage pointed to by `ptr`. The `ptr` variable points to a block previously reserved with a call to `calloc()`, `malloc()`, `realloc()`, or `strdup()`. The number of bytes freed is the number of bytes specified when you reserved (or reallocated, in the case of `realloc()`), the block of storage. If `ptr` is NULL, `free()` simply returns without freeing anything. Since `ptr` is passed by value `free()` will not set `ptr` to NULL after freeing the memory to which it points.

This function is also available to C applications in a stand-alone System Programming C (SPC) Environment.

Note: Attempting to free a block of storage not allocated with `calloc()`, `malloc()`, `realloc()`, `strdup()`, or previously freed storage, can affect the subsequent reserving of storage and lead to an abend.

Special Behavior for C++

Under C++, you cannot use `free()` with an item that was allocated using the C++ new keyword.

Returned Value

`free()` returns no values.

Example

```c
/* This example illustrates the use of `calloc()` to allocate storage for `x` array elements and then calls `free()` to free them. */
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    long *array; /* start of the array */
    long *index; /* index variable */
    int i; /* index variable */
    int num; /* number of entries of the array */

    printf( "Enter the size of the array\n" );
```
scanf( "%i", &num );

/* allocate num entries */
if ( (index = array = (long *)calloc( num, sizeof( long ))) != NULL )
{
  :
  /* do something with the array */
  free( array );           /* deallocates array */
}
else
{ /* Out of storage */
  printf( "Error: out of storage\n" );
  abort();
}

#include <sys/socket.h>
#include <netdb.h>

void *freeaddrinfo(struct addrinfo *ai);
```

SUSV3

```c
#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>
#include <netdb.h>

void *freeaddrinfo(struct addrinfo *ai);
```

General Description

The freeaddrinfo() function frees one or more addrinfo structures returned by getaddrinfo(), along with any additional storage associated with those structures. If the ai_next field of the structure is not null, the entire list of structures is freed.

Returned Value

No return value is defined.

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>
FILE *freopen(const char *__restrict__ filename, const char *__restrict__ mode, FILE *__restrict__ stream);
```

General Description

Closes the file currently associated with `stream` and pointed to by `stream`, opens the file specified by the `filename`, and then associates the stream with it.

The `freopen()` function opens the new file with the type of access requested by the `mode` argument. The `mode` argument is used as in the `fopen()` function. See "fopen() — Open a File" on page 626 for a description of the `mode` parameter.

You can also use the `freopen()` function to redirect the standard stream files `stdin`, `stdout`, and `stderr` to files that you specify. The file pointer input to the `freopen()` function must point to a valid open file. If the file pointer has been closed, the behavior is undefined.

You could use the following `freopen()` call to redirect `stdout` to a memory file `a.b`:

```c
freopen("a.b","wb",type=memory",stdout);
```

If `filename` is an empty string, `freopen()` closes the file and reuses the original file name. For details on how the file name and open mode is interpreted, see `z/OS XL C/C++ Programming Guide`.

A standard stream can be opened by default to a type of file not available to a general `fopen()`. This is true for standard streams under CICS, and also true for the default `stderr` when running a non-POSIX Language Environment application.

The following statement uses `freopen()` to have `stdin` use binary mode instead of text mode:

```c
fp = freopen("", "rb", stdin);
```

You can use the same empty string method to change the mode from binary back to text. This method is not allowed for:

- The default CICS data queues used by the standard streams under CICS
- The Language Environment Message File (MSGFILE), which is the default for `stderr`
- HFS files.
freopen

**Note:** Using the empty string method is included in the SAA C definition, but not in the ANSI C standard.

**Large Files for HFS**

**Note:** Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option LANGLVL(LONGLONG) and also define the Feature Test Macro (FTM) _LARGE_FILES before any headers are included will enable this function to operate on HFS files that are larger than 2 gig-1 in size. File size and offset fields will be enlarged to 63 bits in width so any other function operating on this file will have to be enabled with the same FTM.

**Returned Value**

If successful, freopen() returns the value of `stream`, the same value that was passed to it, and clears both the error and EOF indicators associated with the stream.

A failed attempt to close the original file is ignored.

If an error occurs in reopening the requested file, freopen() closes the original file, and returns a NULL pointer value.

**Special Behavior for Large Files for HFS**

The following is the possible value of errno:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EOVERFLOW</td>
<td>The named file is a regular file and the size of the file cannot be</td>
</tr>
<tr>
<td></td>
<td>represented correctly in an object of type off_t.</td>
</tr>
</tbody>
</table>

**Example**

This example illustrates the z/OS XL C extension that allows you to change characteristics of a file by reopening it.

```c
#include <stdio.h>

int main(void)
{
    FILE *stream, *stream2;
    stream = fopen("myfile.dat","r");
    stream2 = freopen("", "w+", stream);
}
```

This example closes the `stream` data stream and reassigns its stream pointer:

```c
#include <stdio.h>

int main(void)
{
    FILE *stream, *stream2;
    stream = fopen("myfile.dat","r");
    stream2 = freopen("myfile2.dat", "w+", stream);
}
```

**Note:** `stream` and `stream2` will have the same value.

Format

```c
#include <math.h>

double frexp(double x, int *expptr);
float frexp(float x, int *expptr); /* C++ only */
long double frexp(long double x, int *expptr); /* C++ only */
float frexpf(float x, int *expptr);
long double frexpl(long double x, int *expptr);
```

General Description

Breaks down the floating-point value x into a component m for the normalized fraction component and another term n for the exponent, such that the absolute value of m is greater than or equal to 0.5 and less than 1.0 or equal to 0, and \( x = m \times 2^n \). The function stores the integer exponent n at the location to which `expptr` points.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE Binary Floating-Point " on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

Returns the normalized fraction \( m \). If \( x = 0 \), the function returns 0 for both the fraction and exponent. The fraction has the same sign as the argument \( x \). The result of the function cannot have a range error.

Example

```
CELEBF41
/* CELEBF41 */

This example decomposes the floating-point value of \( x, 16.4 \), into its normalized fraction 0.5125, and its exponent 5.
It stores the mantissa in \( y \) and the exponent in \( n \).

*/

#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, m;
```
int n;
x = 16.4;
m = frexp(x, &n);

printf("The fraction is %lf and the exponent is %d\n", m, n);
}

Output
The mantissa is 0.512500 and the exponent is 5

### Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 frexp32(_Decimal32 x, int *expptr);
_Decimal64 frexp64(_Decimal64 x, int *expptr);
_Decimal128 frexp128(_Decimal128 x, int *expptr);
_Decimal32 frexpd32(_Decimal32 x, int *expptr);
_Decimal64 frexpd64(_Decimal64 x, int *expptr);
_Decimal128 frexpd128(_Decimal128 x, int *expptr);
```

### General Description

Breaks down the decimal floating-point value x into a component m for the normalized fraction component and another term n for the exponent, such that the absolute value of m is greater than or equal to 0.1 and less than 1.0 or equal to 0, and x = m * 10^n. The function stores the integer exponent n at the location to which expptr points.

**Note:**
- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See “IEEE Decimal Floating-Point” for more information.

### Returned Value

Returns the normalized fraction m. If x is 0, the function returns 0 for both the fraction and exponent. The fraction has the same sign as the argument x. The result of the function cannot have a range error.

### Example

```c
/* CELEBF81
   This example illustrates the frexp64() function.
*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 x, m;
    int n;

    x = 164.5DD;
    m = frexp64(x, &n);
    ...
printf("The fraction of %df is %df and the exponent is %d\n", 
   x, m, n);
}

Format

```
#include <stdio.h>

int fscanf(FILE *__restrict__ stream, const char *__restrict__ format-string, ...);
int scanf(const char *__restrict__ format-string, ...);
int sscanf(const char *__restrict__ buffer, const char *__restrict__ format, ...);
```

General Description

These three related functions are referred to as the fscanf family.

Reads data from the current position of the specified stream into the locations given by the entries in the argument list, if any. The argument list, if it exists, follows the format string. The fscanf() function cannot be used for a file opened with type=record.

The scanf() function reads data from the standard input stream stdin into the locations given by each entry in the argument list. The argument list, if it exists, follows the format string. scanf() cannot be used if stdin has been reopened as a type=record file.

The sscanf() function reads data from buffer into the locations given by argument-list. Reaching the end of the string pointed to by buffer is equivalent to fscanf() reaching EOF. If the strings pointed to by buffer and format overlap, behavior is undefined.

fscanf() and scanf() have the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

For all three functions, each entry in the argument list must be a pointer to a variable of a type that matches the corresponding conversion specification in format-string. If the types do not match, the results are undefined.

For all three functions, the format-string controls the interpretation of the argument list. The format-string can contain multibyte characters beginning and ending in the initial shift state.

The format string pointed to by format-string can contain one or more of the following:
• White space characters, as specified by isspace(), such as blanks and newline characters. A white space character causes fscanf(), scanf(), and sscanf() to read, but not to store, all consecutive white space characters in the input up to the next character that is not white space. One white space character in format-string matches any combination of white space characters in the input.

• Characters that are not white space, except for the percent sign character (%). A non-white space character causes fscanf(), scanf(), and sscanf() to read, but not to store, a matching non-white space character. If the next character in the input stream does not match, the function ends.

• Conversion specifications which are introduced by the percent sign (%) or the sequence (%n$) where n is a decimal integer in the range [1,NL_ARGMAX]. A conversion specification causes fscanf(), scanf(), and sscanf() to read and convert characters in the input into values of a conversion specifier. The value is assigned to an argument in the argument list.

All three functions read format-string from left to right. Characters outside of conversion specifications are expected to match the sequence of characters in the input stream; the matched characters in the input stream are scanned but not stored. If a character in the input stream conflicts with format-string, the function ends, terminating with a "matching" failure. The conflicting character is left in the input stream as if it had not been read.

When the first conversion specification is found, the value of the first input field is converted according to the conversion specification and stored in the location specified by the first entry in the argument list. The second conversion specification converts the second input field and stores it in the second entry in the argument list, and so on through the end of format-string.

Special Behavior for XPG4.2

• When the %n$ conversion specification is found, the value of the input field is converted according to the conversion specification and stored in the location specified by the nth argument in the argument list. Numbered arguments in the argument list can only be referenced once from format-string.

• The format-string can contain either form of the conversion specification, that is, % or %n$ but the two forms cannot be mixed within a single format-string except that %% or %* can be mixed with the %n$ form.

An input field is defined as:

• All characters until a white space character (space, tab, or newline) is encountered

• All characters until a character is encountered that cannot be converted according to the conversion specification

• All characters until the field width is reached.

If there are too many arguments for the conversion specifications, the extra arguments are evaluated but otherwise ignored. The results are undefined if there are not enough arguments for the conversion specifications.
Each field of the conversion specification is a single character or a number signifying a particular format option. The conversion specifier, which appears after the last optional format field, determines whether the input field is interpreted as a character, a string, or a number. The simplest conversion specification contains only the percent sign and a conversion specifier (for example, `%s`).

Each field of the format specification is discussed in detail below.

Other than conversion specifiers, you should avoid using the percent sign (`%`), except to specify the percent sign: `%%`. Currently, the percent sign is treated as the start of a conversion specifier. Any unrecognized specifier is treated as an ordinary sequence of characters. If, in the future, z/OS XL C/C++ permits a new conversion specifier, it could match a section of your format string, be interpreted incorrectly, and result in undefined behavior. See Table 34 on page 685 for a list of conversion specifiers.

An asterisk (`*`) following the percent sign suppresses assignment of the next input field, which is interpreted as a field of the specified conversion specifier. The field is scanned but not stored.

`width` is a positive decimal integer controlling the maximum number of characters to be read. No more than `width` characters are converted and stored at the corresponding argument.

Fewer than `width` characters are read if a white space character (space, tab, or newline), or a character that cannot be converted according to the given format occurs before `width` is reached.

The optional prefix `l` shows that you use the `long` version of the following conversion specifier, while the prefix `h` indicates that the short version is to be used. The corresponding argument should point to a `long` or `double` object (for the `l` character), a `long double` object (for the `L` character), or a `short` object (with the `h` character). The `l` and `h` modifiers can be used with the `d`, `i`, `o`, `x`, and `u` conversion specifiers. The `l` modifier can also be used with the `e`, `f`, and `g` conversion specifiers. The `L` modifier can be used with the `e`, `f` and `g` conversion specifiers. Note that the `l` modifier is also used with the `c`, `s` and `[]` conversion specifiers to indicate that the corresponding argument is a pointer to an array of wide characters. The `l` and `h` modifiers are ignored if specified for any other conversion specifier.

**Optional prefix**

Used to indicate the size of the argument expected:
Specifies that any following e, E, f, F, g, or G conversions specifier applies to a _Decimal64 argument.

DD Specifies that any following e, E, f, F, g, or G conversions specifier applies to a _Decimal128 argument.

H Specifies that any following e, E, f, F, g, or G conversions specifier applies to a _Decimal32 argument.

hh Specifies that a following d, i, o, u, x, X or n conversion specifier applies to an argument with type pointer to signed char or unsigned char.

j Specifies that a following d, i, o, u, x, X or n conversion specifier applies to an argument with type pointer to intmax_t or uintmax_t.

t Specifies that a following d, i, o, u, x, X or n conversion specifier applies to an argument with type pointer to ptrdiff_t or the corresponding unsigned type.

z Specifies that a following d, i, o, u, x, X or n conversion specifier applies to an argument with type pointer to size_t or the corresponding signed integer type.

The type characters and their meanings are in Table 34.

**fscanf Family of Formatted Input Functions**

`fscanf` family functions match e, E, f, F, g or G conversion specifiers to floating-point number substrings in the input stream. `fscanf` family functions convert each input substring matched by an e, E, f, F, g or G conversion specifier to a `float`, `double` or `long double` value depending on a size modifier preceding the e, E, f, F, g or G conversion specifier.

The floating-point value produced is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking the `fscanf` family function. The `fscanf` family functions use `__isBFP()` to determine the floating-point mode of invoking threads.

Many z/OS XL C/C++ formatted input functions, including the `fscanf` family, recognize special infinity and NaN floating-point number input sequences when the invoking thread is in IEEE Binary Floating-Point mode as determined by `__isBFP()`.

- The special sequence for infinity input is an optional plus or minus sign, then the character sequence INF, where the individual characters may be uppercase or lowercase, and then a white space character (space, tab, or newline), a NULL character (\0) or EOF.
- The special sequence for NaN input is an optional plus or minus sign, then the character sequence NANS for a signalling NaN or NANQ for a quiet NaN, where the individual characters may be uppercase or lowercase, and then a a white space character (space, tab, or newline), a NULL character (\0) or EOF.

**For Binary Floating Point NaNs:**

A NaN ordinal sequence is a left-parenthesis character, “(”, followed by a digit sequence representing an integer n, where 1 <= n <= INT_MAX−1, followed by a right-parenthesis character, “)”. If the NaN ordinal sequence is omitted, NaN ordinal sequence (1) is assumed. The integer value, n, corresponding to a NaN ordinal sequence determines what IEEE Binary Floating-Point NaN fraction bits are produced by formatted input functions.

For a signalling NaN, these functions produce NaN fraction bits (left to right) by reversing the bits (right to left) of the even integer value 2*n.

For a quiet NaN they produce NaN fraction bits (left to right) by reversing the bits (right to left) of the odd integer value 2*n−1.

**For Decimal Floating Point NaNs:**

A NaN ordinal sequence is a left parenthesis character, “(”, followed by a decimal digit sequence of up to 6 digits for a _Decimal32 output number, up to 15 digits for a _Decimal64 output value, or up to 33 digits for a _Decimal128 output value, followed by a right parenthesis, “)”. If the NaN ordinal sequence is omitted, NaN ordinal sequence “0)” is assumed. If the NaN ordinal sequence is shorter than 6, 15, or 33 digits, it will be padded on the left with “0” digits so that the length becomes 6, 15, or, 33 digits for _Decimal32, _Decimal64, and _Decimal128 values respectively.

For Decimal Floating Point numbers, the digits are not reversed, and both odd or even NaN ordinal sequences can be specified for either a Quiet NaN or Signalling NaN.

Each multibyte character in the sequence is converted to a wide character as if by a call to the mbtowc() function, with the conversion state described by the mbstate_t object initialized to zero before the first multibyte character is converted. The corresponding argument is a pointer to the initial array of wchar_t large enough to accept the sequence and the terminating NULL wide character, which is added automatically.</td>
<td></td>
</tr>
</tbody>
</table>

When the LC_SYNTAX category is set using setlocale(), the format strings passed to the fscanf(), scanf(), or sscanf() functions must use the same encoded character set as is specified for the LC_SYNTAX category.

To read strings not delimited by space characters, substitute a set of characters in square brackets ([ ]) for the s (string) conversion specifier. The corresponding input field is read up to the first character that does not appear in the bracketed character set. If the first character in the set is a logical not (~), the effect is reversed: the input field is read up to the first character that does appear in the rest of the character set.

To store a string without storing an ending NULL character (\0), use the specification %ac, where a is a decimal integer. In this instance, the c conversion specifier means that the argument is a pointer to a character array. The next a characters are read from the input stream into the specified location, and no NULL character is added.
The input for a %x conversion specifier is interpreted as a hexadecimal number.

All three functions, fscanf(), scanf(), and sscanf() scan each input field character by character. It might stop reading a particular input field either before it reaches a space character, when the specified width is reached, or when the next character cannot be converted as specified. When a conflict occurs between the specification and the input character, the next input field begins at the first unread character. The conflicting character, if there is one, is considered unread and is the first character of the next input field or the first character in subsequent read operations on the input stream.

**Note:** To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

### Returned Value

All three functions, fscanf(), scanf(), and sscanf() return the number of input items that were successfully matched and assigned. The returned value does not include conversions that were performed but not assigned (for example, suppressed assignments). The functions return EOF if there is an input failure before any conversion, or if EOF is reached before any conversion. Thus a returned value of 0 means that no fields were assigned: there was a matching failure before any conversion. Also, if there is an input failure, then the file error indicator is set, which is not the case for a matching failure.

The ferror() and feof() functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does not turn on the EOF indicator.

### Examples

**CELEBF42**

```c
/* CELEBF42

   This example scans various types of data

*/
#include <stdio.h>

int main(void)
{
    int i;
    float fp;
    char c, s[81];

    printf("Enter an integer, a real number, a character "
           "and a string : \n");
    if (scanf("%d %f %c %s", &i, &fp, &c, s) != 4)
        printf("Not all of the fields were assigned\n");
    else
    {
        printf("integer = %d\n", i);
        printf("real number = %f\n", fp);
        printf("character = %c\n", c);
        printf("string = %s\n", s);
    }
}
```

### Output
If input is: 12 2.5 a yes, then output would be:

Enter an integer, a real number, a character and a string:
integer = 12
real number = 2.500000
character = a
string = yes

CELEBF43

/* CELEBF43
 This example converts a hexadecimal integer to a decimal integer.
 The while loop ends if the input value is not a hexadecimal integer.
 */
#include <stdio.h>

int main(void)
{
    int number;
    printf("Enter a hexadecimal number or anything else to quit:\n");
    while (scanf("%x", &number))
    {
        printf("Hexadecimal Number = %x\n", number);
        printf("Decimal Number = %d\n", number);
    }
}

Output

If input is: 0x231 0xf5e 0x1 q, then output would be:

Enter a hexadecimal number or anything else to quit:
Hexadecimal Number = 231
Decimal Number = 561
Hexadecimal Number = f5e
Decimal Number = 3934
Hexadecimal Number = 1
Decimal Number = 1

CELEBF44

/* CELEBF44
 The next example illustrates the use of scanf() to input fixed-point decimal data types. This example works under C only, not C++.
 */
#include <stdio.h>
#include <decimal.h>

decimal(15, 4) pd01;
decimal(10, 2) pd02;
decimal(5, 5) pd03;

int main(void)
{
    printf("\nFirst time :-------------------------------\n");
    printf("Enter three fixed-point decimal number\n");
    printf(" (15,4) (10,2) (5,5)\n");
    if (scanf("%D(15,4) %D(10,2) %D(5,5)\n", &pd01, &pd02, &pd03) != 3) {
        printf("Error found in scanf\n");
    } else {
        printf("pd01 = %D(15,4)\n", pd01);
        printf("pd02 = %D(10,2)\n", pd02);
        printf("pd03 = %D(5,5)\n", pd03);
    }
    printf("\nSecond time :-------------------------------\n");
    printf("Enter three fixed-point decimal number\n");
    printf(" (15,4) (10,2) (5,5)\n");
    if (scanf("%D(15,4) %D(10,2) %D(5,5)\n", &pd01, &pd02, &pd03) != 3) {

printf("Error found in scanf\n");
} else {
    printf("pd01 = %D(15,4)\n", pd01);
    printf("pd02 = %D(10,2)\n", pd02);
    printf("pd03 = %D(5,5)\n", pd03);
} return(0);
}

Output

First time :-----------------------------
Enter three fixed-point decimal number
   (15,4) (10,2) (5,5)
12345678901.2345 -987.6 .24680
pd01 = 12345678901.2345
pd02 = -987.60
pd03 = 0.24680

Second time :-----------------------------
Enter three fixed-point decimal number
   (15,4) (10,2) (5,5)
123456789013579.24680 123.4567890 987
pd01 = 123456789013579
pd02 = 123.45
pd03 = 0.98700

CELEBF46

/* CELEBF46
   The next example opens the file myfile.dat for reading and then scans
   this file for a string, a long integer value, a character, and a
   floating-point value.
*/
#include <stdio.h>
#define MAX_LEN 80

int main(void)
{
    FILE *stream;
    long l;
    float fp;
    char s[MAX_LEN + 1];
    char c;

    stream = fopen("myfile.dat", "r");

    /* Put in various data. */
    fscanf(stream, "%s", &s[0]);
    fscanf(stream, "%ld", &l);
    fscanf(stream, "%c", &c);
    fscanf(stream, "%f", &fp);

    printf("string = %s\n", s);
    printf("long double = %ld\n", l);
    printf("char = %c\n", c);
    printf("float = %f\n", fp);
}

Output

If myfile.dat contains abcdefghijklmnopqrstuvwxyz 343.2, then the expected output is:
fscanf, scanf, sscanf

string =abcdefgijklmnopqrstuvwxyz
long double = 343
char = .
float = 2.000000

CELEBS32
/

This example uses sscanf() to read various data from the string
tokenstring, and then displays the data.
*/
#include <stdio.h>
#define SIZE 81

int main(void)
{
char *tokenstring = "15 12 14";
int i;
float fp;
char s[SIZE];
char c;

/* Input various data */
printf("No. of conversions=%d\n",
     sscanf(tokenstring, "%s %c%d%f", s, &c, &i, &fp));

/* If there were no space between %s and %c,
/* sscanf would read the first character following */
/* the string, which is a blank space. */

/* Display the data */
printf("string = %s\n",s);
printf("character = %c\n",c);
printf("integer = %d\n",i);
printf("floating-point number = %f\n",fp);
}

Output

You would see this output from example CELEBS32.
No. of conversions = 4
string = 15
character = 1
integer = 2
floating-point number = 14.000000

</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int fseek(FILE *stream, long int offset, int origin);
```

General Description

Changes the current file position associated with `stream` to a new location within the file. The next operation on the `stream` takes place at the new location. On a `stream` open for update, the next operation can be either a reading or a writing operation.

The `origin` must be one of the following constants defined in `stdio.h`:

<table>
<thead>
<tr>
<th>Origin</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEEK_SET</td>
<td>Beginning of file</td>
</tr>
<tr>
<td>SEEK_CUR</td>
<td>Current position of file pointer</td>
</tr>
<tr>
<td>SEEK_END</td>
<td>End of file</td>
</tr>
</tbody>
</table>

**Note:** If you specify SEEK_CUR, any characters pushed back by ungetc() or ungetwc() will have backed up the current position of the file pointer—which is the starting point of the seek. The seek will discard any pushed-back characters before repositioning, but the starting point will still be affected. For more information about calling fseek() after an ungetc() or ungetwc() see "ungetc() — Push Character onto Input Stream" on page 2307 and "ungetwc() — Push a Wide Character onto a Stream on page 2310."

The _EDC_COMPAT environment variable causes fseek() to ignore the effects of ungetc() or ungetwc(). For more details, see “Environment Variables” in z/OS XL C/C++ Programming Guide.

Binary Streams

ANSI states that binary streams use relative byte offsets for both ftell() and fseek(). Under z/OS XL C/C++, this is true except for record-oriented files that have variable length records. For these types of files, the default behavior is to use encoded offsets for ftell() and fseek(), using an origin of SEEK_SET.

Encoded offsets restrict you to seeking only to those positions that are recorded by a previous ftell() or to position 0. If you want to use relative-byte offsets for these types of files, you can either open with the BYTESEEK fopen() option or set the _EDC_BYTESEEK environment variable before opening. For details about BYTESEEK or _EDC_BYTESEEK, see z/OS XL C/C++ Programming Guide.
fseek

With relative-byte offsets, you are free to calculate your own offsets. If the offset exceeds the EOF, your file is extended with NULLs, except for HFS files, for which the file is only extended with NULLs if you subsequently write new data. This is true also under POSIX, using HFS files, where the file is only extended with NULLs if you subsequently write new data.

Attempting to reposition to before the start of the file causes fseek() to fail.

Regardless of whether encoded or relative offsets are returned by ftell(), you can specify relative offsets when using SEEK_CUR and SEEK_END.

If the new position is before the start of the file, fseek() fails. If the relative offset is positioned beyond the EOF, the file is padded with NULLs, except in the case of POSIX, using HFS files, where padding does not occur until a subsequent write of new data.

Text Streams

For text streams, ftell() returns an encoded offset. When seeking with an origin of SEEK_SET, you are restricted to seeking only to 0 or to positions returned by a previous ftell().

Attempting to calculate your own position is not supported, and may result in a non-valid position and the failure of fseek().

When you are using SEEK_CUR or SEEK_END, the offset is a relative byte offset. Attempting to seek to before the start of the file or past the EOF results in failure.

Record I/O

For files opened as type=record, ftell() returns the relative record number. For the origins of SEEK_SET, SEEK_CUR, and SEEK_END, the offset is a relative record number.

Attempting to seek to before the first record or past the EOF results in failure.

For wide-oriented streams, all the above restrictions apply.

Attention: Repositioning within a wide-oriented file and performing updates is strongly discouraged because it is not possible to predict if your update will overwrite part of a multibyte string or character, thereby invalidating subsequent data. For example, you could inadvertently add data that overwrites a shift-out. The following data expects the shift-out to be there, so is not valid if it is treated as if in the initial shift state. Repositioning to the end of the file and adding new data is safe.

For details about wide-oriented streams, see z/OS XL C/C++ Programming Guide.

If successful, the fseek() function clears the EOF indicator, even when origin is SEEK_END, and cancels the effect of any preceding ungetc() or ungetwc() function on the same stream.

If the call to the fseek() function or the fsetpos() function is not valid, the call is treated as a flush and the ungetc characters are discarded.

Large Files for HFS
Note: Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option LANGLVL(LONGLONG) and also define the Feature Test Macro (FTM) _LARGE_FILES before any headers are included will enable operations on HFS files that are larger than 2 gig-1 in size. When this choice has been made then fseek() should be replaced by the neutral function fseeko().

Multivolume Data Sets Performance

Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftell() and fseek() functions when working with multivolume data sets.

Considerations For VSAM extended addressability data sets

As of z/OS V1.8, support is added for extended addressable VSAM data sets, meaning that the VSAM data set can grow beyond 4GB in size and still be able to be read from, written to, or repositioned, in a z/OS XL C/C++ application.

AMODE 31: The fseek() function accepts a signed 4-byte offset and therefore is limited in what direct and relative positions can be achieved. For example, fseek() cannot be used to position directly beyond 2GB-1 when using SEEK_SET as the origin for binary I/O. Applications should use the large files version of fseeko() to avoid the limitations.

AMODE 64: There are no restrictions with fseek() since it accepts a signed 8-byte offset.

See [z/OS XL C/C++ Programming Guide](#) for additional usage information with respect to fseek() and VSAM data sets.

Returned Value

If successful in moving the pointer, fseek() returns 0.

If unsuccessful, or on devices that cannot seek, such as terminals and printers, fseek() returns nonzero.

Special Behavior for XPG4.2

If unsuccessful, fseek() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EOVERFLOW</td>
<td>The resulting file offset would be a value which cannot be represented correctly in an object of type long.</td>
</tr>
</tbody>
</table>

Note: Starting with z/OS V1.9, environment variable _EDC_EOVERFLOW can be used to control behavior of fseek() with respect to detecting an EOVERFLOW condition for UNIX files. By default, fseek() will continue to be able to position beyond a location that ftell() can return. When _EDC_EOVERFLOW is set to YES, fseek() will check if the new position can be returned by ftell().

ESPIPE The underlying file type for the stream is a PIPE or a socket.
fseek

Example

/* This example opens a file myfile.dat for reading.
   After performing input operations (not shown), it moves the file
   pointer to the beginning of the file.
*/
#include <stdio.h>
int main(void)
{
    FILE *stream;
    int result;

    if (stream = fopen("myfile.dat", "r"))
        /* successful */
    if (fseek(stream, 0L, SEEK_SET)); /* moves pointer to */
        /* the beginning of the file */
        /* if not equal to 0 */
        /* then error ... */
    else {
        /* fseek() successful */
    }
}

fseeko() — Change File Position

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R10</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <stdio.h>

int fseeko(FILE *stream, off_t offset, int origin);
```

General Description

Changes the current file position associated with `stream` to a new location within the file. The next operation on the `stream` takes place at the new location. On a stream open for update, the next operation can be either a reading or a writing operation.

The `origin` must be one of the following constants defined in stdio.h:

<table>
<thead>
<tr>
<th>Origin</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEEK_SET</td>
<td>Beginning of file</td>
</tr>
<tr>
<td>SEEK_CUR</td>
<td>Current position of file pointer</td>
</tr>
<tr>
<td>SEEK_END</td>
<td>End of file</td>
</tr>
</tbody>
</table>

**Note:** If you specify SEEK_CUR, any characters pushed back by ungetc() or ungetwc() will have backed up the current position of the file pointer—which is the starting point of the seek. The seek will discard any pushed-back characters before repositioning, but the starting point will still be affected. For more information about calling fseeko() after an ungetc() or ungetwc() see "ungetc() — Push Character onto Input Stream" on page 2307 and "ungetwc() — Push a Wide Character onto a Stream" on page 2310.

The _EDC_COMPAT environment variable causes fseeko() to ignore the effects of ungetc() or ungetwc(). For more details, see “Environment Variables” in z/OS XL C/C++ Programming Guide.

Binary Streams

ANSI states that binary streams use relative byte offsets for both ftello() and fseeko(). Under z/OS XL C/C++, this is true except for record-oriented files that have variable length records. For these types of files, the default behavior is to use encoded offsets for ftello() and fseeko(), using an origin of SEEK_SET.

Encoded offsets restrict you to seeking only to those positions that are recorded by a previous ftello() or to position 0. If you want to use relative-byte offsets for these types of files, you can either open with the BYTESEEK fopen() option or set the _EDC_BYTESEEK environment variable before opening. For details about BYTESEEK or _EDC_BYTESEEK, see z/OS XL C/C++ Programming Guide.

With relative-byte offsets, you are free to calculate your own offsets. If the offset exceeds the EOF, your file is extended with NULLs, except for HFS files, for which
the file is only extended with NULLs if you subsequently write new data. This is true also under POSIX, using HFS files, where the file is only extended with NULLs if you subsequently write new data.

Attempting to reposition to before the start of the file causes fseeko() to fail.

Regardless of whether encoded or relative offsets are returned by ftello(), you can specify relative offsets when using SEEK_CUR and SEEK_END.

If the new position is before the start of the file, fseeko() fails. If the relative offset is positioned beyond the EOF, the file is padded with NULLs, except in the case of POSIX, using HFS files, where padding does not occur until a subsequent write of new data.

**Text Streams**

For text streams, ftello() returns an encoded offset. When seeking with an origin of SEEK_SET, you are restricted to seeking only to 0 or to positions returned by a previous ftello().

Attempting to calculate your own position is not supported, and may result in a non-valid position and the failure of fseeko().

When you are using SEEK_CUR or SEEK_END, the offset is a relative byte offset. Attempting to seek to before the start of the file or past the EOF results in failure.

**Record I/O**

For files opened as type=record, ftello() returns the relative record number. For the origins of SEEK_SET, SEEK_CUR, and SEEK_END, the offset is a relative record number.

Attempting to seek to before the first record or past the EOF results in failure.

For wide-oriented streams, all the above restrictions apply.

**Note:** Repositioning within a wide-oriented file and performing updates is strongly discouraged because it is not possible to predict if your update will overwrite part of a multibyte string or character, thereby invalidating subsequent data. For example, you could inadvertently add data that overwrites a shift-out. The following data expects the shift-out to be there, so is not valid if it is treated as if in the initial shift state. Repositioning to the end of the file and adding new data is safe.

For details about wide-oriented streams, see [z/OS XL C/C++ Programming Guide](#).

If successful, the fseeko() function clears the EOF indicator, even when the origin is SEEK_END, and cancels the effect of any preceding ungetc() or ungetwc() function on the same stream.

If the call to the fseeko() function or the fsetpos() function is not valid, the call is treated as a flush and the ungetc characters are discarded.

**Multivolume Data Sets Performance**
Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftell() and fseek() functions when working with multivolume data sets.

Considerations For VSAM extended addressability data sets

As of z/OS V1.8, support is added for extended addressable VSAM data sets, meaning that the VSAM data set can grow beyond 4GB in size and still be able to be read from, written to, or repositioned, in a z/OS XL C/C++ application.

AMODE 31: The non-large files version of fseeko() is equivalent to fseek(), in that it accepts a signed 4-byte offset and therefore is limited in what direct and relative positions can be achieved. For example, non-large files fseeko() cannot be used to position directly beyond 2GB-1 when using SEEK_SET as the origin for binary I/O. The large files version of fseeko() accepts a signed 8-byte offset and it has been updated to support VSAM extended addressable data sets.

AMODE 64: There are no restrictions with fseeko() since it accepts a signed 8-byte offset.

See [z/OS XL C/C++ Programming Guide](#) for additional usage information with respect to fseek() and VSAM data sets.

Returned Value

If successful, fseeko() returns 0, which means it successfully moved the pointer.

If unsuccessful, fseeko() returns nonzero and sets errno to one of the following values.

On devices that cannot seek, such as terminals and printers, fseeko() returns nonzero.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The file descriptor underlying stream is not an open file descriptor.</td>
</tr>
<tr>
<td>EOVERFLOW</td>
<td>The current file offset cannot be represented correctly in an object of type off_t.</td>
</tr>
<tr>
<td>ESPPIPE</td>
<td>The file descriptor underlying stream is associated with a pipe or FIFO.</td>
</tr>
</tbody>
</table>

Example

```c
/* This example opens a file myfile.dat for reading. After performing input operations (not shown), it moves the file pointer to the beginning of the file. */
#define _LARGE_FILES 1
#include <stdio.h>

int main(void)
{
    FILE *stream;
    int result;

    if (stream = fopen("/myfile.dat", "r"))
        { /* successful */
```
fseeko

```c
if (fseeko(stream, 0LL, SEEK_SET)); /* moves pointer to */
    /* the beginning of the file */
{ /* if not equal to 0 */
    then error ... */
}
else {
    /* fseeko() successful */
}
```

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <stdio.h>

int fsetpos(FILE *stream, const fpos_t *pos);

General Description

Moves the file position associated with stream to a new location within the file according to the value of the object pointed to by pos. The value of pos must be obtained by a call to the fgetpos() library function. If successful, the fsetpos() function clears the EOF indicator, and cancels the effect of any previous ungetc() or ungetwc() function on the same stream.

If the call to the fsetpos() function is not valid, the call is treated as a flush, and the ungetc characters are discarded.

The fsetpos() function handles Double-Byte Character Set (DBCS) state information for wide-oriented files. An fsetpos() call to a position that no longer exists results in an error.

For text streams, the DBCS shift state is recalculated from the start of the record, which has a performance implication. The fsetpos() function repositions to the start of a multibyte character.

For binary streams, the DBCS shift state is set to the state saved by the fsetpos() function. If the record has been updated in the meantime, the shift state may be incorrect.

After the fsetpos() call, the next operation on a stream in update mode may be input or output.

Note: Repositioning within a wide-oriented file and performing updates is strongly discouraged because it is not possible to predict if your update will overwrite part of a multibyte string or character, thereby invalidating subsequent data. For example, you could inadvertently add data that overwrites a shift-out. The following data expects the shift-out to be there, so is not valid if it is treated as if in the initial shift state. Repositioning to the end of the file and adding new data is safe.

Large Files for HFS

Note: Large Files for HFS behavior is automatic for AMODE 64 applications Applications that are compiled with the option LANGLVL(LONGLONG) and also
fsetpos

define the Feature Test Macro (FTM) _LARGE_FILES before any headers are included will enable this function to operate on HFS files that are larger than 2 gig-1 in size. File size and offset fields will be enlarged to 63 bits in width so any other function operating on this file will have to be enabled with the same FTM.

Multivolume Data Sets Performance

Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftell() and fseek() functions when working with multivolume data sets.

Returned Value

If successful in changing the current position of the file, fsetpos() returns 0.

If unsuccessful, fsetpos() returns nonzero and sets errno.

Special Behavior for XPG4.2

If unsuccessful, fsetpos() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESPIPE</td>
<td>The underlying file type for the stream is a PIPE or a socket.</td>
</tr>
</tbody>
</table>

Example

/* This example opens a file called myfile.dat for reading. After performing input operations (not shown), it moves the file pointer to the beginning of the file and rereads the first byte. */
#include <stdio.h>

int main(void)
{
  FILE *stream;
  int retcode;
  fpos_t pos, pos1, pos2, pos3;
  char ptr[20]; /* existing file 'myfile.dat' has 20 byte records */
  /* Open file, get position of file pointer, and read first record */
  stream = fopen("myfile.dat", "rb");
  fgetpos(stream,&pos);
  pos1 = pos;
  if (!fread(ptr,sizeof(ptr),1,stream))
    printf("fread error\n");
  /* Perform a number of read operations. The value of 'pos' changes if 'pos' is passed to fgetpos() */
  ;
  /* Re-set pointer to start of file and re-read first record */
  fsetpos(stream,&pos1);
  if (!fread(ptr,sizeof(ptr),1,stream))
    printf("fread error\n");
  fclose(stream);
}

fstat

fstat() — Get Status Information about a File

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <sys/stat.h>

int fstat(int fildes, struct stat *info);
```

General Description

Gets status information about the file specified by the open file descriptor `fildes` and stores it in the area of memory indicated by the `info` argument. The status information is returned in a `stat` structure, as defined in the `sys/stat.h` header file. The elements of this structure are described in “stat() — Get File Information” on page 2008.

Note: Starting with z/OS V1.9, environment variable `_EDC_EOVERFLOW` can be used to control behavior of `fstat()` with respect to detecting an EOVERFLOW condition for UNIX files. By default, `fstat()` will not set EOVERFLOW when the file size cannot be represented correctly in structure pointed to by `info`. When `_EDC_EOVERFLOW` is set to YES, `fstat()` will check for an overflow condition.

Large Files for HFS

Note: Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option `LANG_LVL(LONGLONG)` and also define the Feature Test Macro (FTM) `_LARGE_FILES` before any headers are included will enable this function to operate on HFS files that are larger than 2 gig-1 in size. File size and offset fields will be enlarged to 63 bits in width so any other function operating on this file will have to be enabled with the same FTM.

Returned Value

If successful, `fstat()` returns 0.

If unsuccessful, `fstat()` returns –1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td><code>info</code> contains a NULL.</td>
</tr>
<tr>
<td>EIO</td>
<td>Added for XPG4.2: An I/O error occurred while reading from the file system.</td>
</tr>
<tr>
<td>EOVERFLOW</td>
<td></td>
</tr>
</tbody>
</table>
The file size in bytes or the number of blocks allocated to the file or the file serial number cannot be represented correctly in the structure pointed to by info.

**Note:** Starting with, z/OS V1R9, the fstat() function may fail with EOVERFLOW if Large Files for HFS is not enabled. The environment variable _EDC_EOVERFLOW controls this behavior. If _EDC_EOVERFLOW is set to YES the new behavior will take place. The default for _EDC_EOVERFLOW is NO.

### Example

**CELEBF47**

/* CELEBF47

This example gets status information for the file called temp.file.

*/

```c
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <time.h>

main() {
    char fn[]="temp.file";
    struct stat info;
    int fd;
    
    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        if (fstat(fd, &info) != 0)
            perror("fstat() error");
        else {
            puts("fstat() returned:");
            printf("inode: %d\n", (int) info.st_ino);
            printf("dev id: %d\n", (int) info.st_dev);
            printf("mode: %08x\n", info.st_mode);
            printf("links: %d\n", info.st_nlink);
            printf("uid: %d\n", (int) info.st_uid);
            printf("gid: %d\n", (int) info.st_gid);
            printf("created: %s", ctime(&info.st_createtime));
        }
        close(fd);
        unlink(fn);
    }
}
```

### Output

fstat() returned:
inode: 3057
dev id: 1
mode: 03000080
links: 1
uid: 25
gid: 500
created: Fri Jun 16 16:03:16 2001

fstatvfs() — Get File System Information

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>C or C++</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td>C or C++</td>
</tr>
</tbody>
</table>

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/statvfs.h>

int fstatvfs(int fildes, struct statvfs *fsinfo);
```

General Description

The fstatvfs() function obtains information about the file system containing the file referenced by fildes and stores it in the area of memory pointed to by the fsinfo argument.

The information is returned in a statvfs structure, as defined in the sys/statvfs.h header file. The elements of this structure are described in "statvfs() — Get File System Information" on page 2012. If fstatvfs() successfully determines this information, it stores it in the area indicated by the fsinfo argument. The size of the buffer determines how much information is stored; data that exceeds the size of the buffer is truncated.

Returned Value

If successful, fstatvfs() returns 0.

If unsuccessful, fstatvfs() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>fildes is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal was caught during the execution of the function.</td>
</tr>
<tr>
<td>EIO</td>
<td>An I/O error has occurred while reading the file system.</td>
</tr>
</tbody>
</table>

Example

```
#include <sys/statvfs.h>
#include <stdio.h>

main()
{
    char fn[]="temp.file";
    int fd;
    struct statvfs buf;

    if ((fd = creat(fn,S_IWUSR)) < 0)
        perror("creat() error");
    else
    {
        if (fstatvfs(fd, &buf) == -1)
            perror("fstatvfs() error");
        else
        {
            printf("each block is \%d bytes big\n", buf.f_bsize);
            printf("there are \%d blocks available\n", buf.f_bavail);
```
```c
printf("out of a total of \%d in bytes,\n", buf.f_blocks);
printf("that's %.0f bytes free out of a total of %.0f\n",
    ((double)buf.f_bavail * buf.f_bsize),
    ((double)buf.f_blocks * buf.f_bsize));
}
close(fd);
unlink(fn);
}
```

**Output**

each block is 4096 bytes big
there are 2089 blocks available
out of a total of 2400 in bytes,
that's 8556544 bytes free out of a total of 9830400

Format

```c
#include <stdio.h>

long int ftell(FILE *stream);
```

General Description

Obtains the current value of the file position indicator for the stream pointed to by `stream`.

Binary Streams

ANSI states that `ftell()` returns relative byte offsets from the beginning of the file for binary files. Under z/OS XL C/C++, this is true except for record-oriented files that have variable length records. For these types of files, `ftell()` returns an encoded offset.

If you want to use relative-byte offsets for these types of files, you can either open your files with the BYTESEEK fopen() option, or set the _EDC_BYTESEEK environment variable before opening them. For details about BYTESEEK or _EDC_BYTESEEK see `z/OS XL C/C++ Programming Guide`.

Text Streams

`ftell()` returns an encoded offset for text streams.

Record I/O

For files opened for record I/O using the `type=record` open mode parameter, `ftell()` returns the relative `record` offset of the current file position from the beginning of the file. All offset values are given in terms of records. For more information about calling `ftell()` after an ungetc() or ungetwc() see `ungetc() — Push Character onto Input Stream` on page 2307 and `ungetwc() — Push a Wide Character onto a Stream` on page 2310.

Large Files for HFS

**Note:** Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option LANGlvl(LONGLONG) and also define the Feature Test Macro (FTM) _LARGE_FILES before any headers are included will enable operations on HFS files that are larger than 2 gig-1 in size. When this choice has been made, then `ftell()` should be replaced by the neutral function `ftello()`.
**Multivolume Data Sets Performance**

Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftell() and fseek() functions when working with multivolume data sets.

**Considerations For VSAM extended addressability data sets**

As of z/OS V1.8, support is added for extended addressable VSAM data sets, meaning that the VSAM data set can grow beyond 4GB in size and still be able to be read from, written to, or repositioned, in a z/OS XL C/C++ application. Being able to report a relative byte address (RBA) beyond 4GB requires the ability to return an 8-byte value back to the application.

**AMODE 31:** The ftell() function returns a signed 4-byte value and therefore has limitations on positions that can be returned. For example, ftell() cannot report an RBA beyond 2GB-1. Applications should use the large files version of ftello() to avoid the limitations.

**AMODE 64:** There is no restriction with ftell() since it returns a signed 8-byte value.

See [z/OS XL C/C++ Programming Guide](https://www.ibm.com/) for additional usage information with respect to ftell() and VSAM data sets.

**Returned Value**

If successful, ftell() returns the calculated value.

If unsuccessful, ftell() returns -1 and sets errno to a positive value.

**Special Behavior for XPG4.2**

If unsuccessful, ftell() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EOVERFLOW</td>
<td>For ftell(), the current file offset cannot be represented correctly in an object of type long.</td>
</tr>
</tbody>
</table>

**Note:** Starting with z/OS V1.9, environment variable _EDC_EOVERFLOW can be used to control behavior of ftell() with respect to detecting an EOVERFLOW condition for UNIX files. By default, ftell() will not set EOVERFLOW when the file offset can not be represented correctly. When _EDC_EOVERFLOW is set to YES, ftell() will check for an overflow condition.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESPIPE</td>
<td>The underlying file type for the stream is a PIPE or a socket.</td>
</tr>
</tbody>
</table>

**Example**

```c
/* This example opens the file myfile.dat for reading. 
   The current file pointer position is stored in the variable pos.
*/
#include <stdio.h>

int main(void)
{
    FILE *stream
    long int pos;
```
stream = fopen("myfile.dat", "rb");

/* The value returned by ftell can be used by fseek() to set the file pointer if 'pos' is not -1 */

if ((pos = ftell(stream)) != EOF)
    printf("Current position of file pointer found\n");
fclose(stream);
}

ftello

**ftello() — Get Current File Position**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R10</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE 500
#include <stdio.h>

off_t ftello(FILE *stream);
```

**General Description**

Obtains the current value of the file position indicator for the stream pointed to by `stream`.

**Binary Streams**

ANSI states that `ftello()` returns relative byte offsets from the beginning of the file for binary files. Under z/OS XL C/C++, this is true except for record-oriented files that have variable length records. For these types of files, `ftello()` returns an encoded offset.

If you want to use relative-byte offsets for these types of files, you can either open your files with BYTESEEK fopen() option, or set the _EDC_BYTESEEK environment variable before opening them. For details about BYTESEEK see [z/OS XL C/C++ Programming Guide](http://www.ibm.com).  

**Text Streams**

`ftello()` returns an encoded offset for text streams.

**Record I/O**

For files opened for record I/O using the type=record open mode parameter, `ftello()` returns the relative record offset of the current file position from the beginning of the file. All offset values are given in terms of records. For more information about calling `ftello()` after an ungetwc() see "ungetc() — Push Character onto Input Stream" on page 2307 and "ungetwc() — Push a Wide Character onto a Stream" on page 2310.

**Multivolume Data Sets Performance**

Using the `fgetpos()` and `fsetpos()` functions generally results in better repositioning performance compared to the `ftell()` and `fseek()` functions when working with multivolume data sets.

**Considerations For VSAM extended addressability data sets**

As of z/OS V1.8, support is added for extended addressable VSAM data sets, meaning that the VSAM data set can grow beyond 4GB in size and still be able to be read from, written to, or repositioned, in a z/OS XL C/C++ application. Being
able to report a relative byte address (RBA) beyond 4GB requires the ability to return an 8-byte value back to the application.

AMODE 31: The non-large files version of ftello() is equivalent to ftell(), in that it returns a signed 4-byte value and therefore has limitations on positions that can be returned. For example, non-large files ftello() cannot report an RBA beyond 2GB-1. The large files version of ftello() returns a signed 8-byte value and it has been updated to support VSAM extended addressable data sets.

AMODE 64: There is no restriction with ftello() since it returns a signed 8-byte value.

### Returned Value

If successful, ftello() returns the calculated value.

If unsuccessful, ftello() returns (off_t)-1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The file descriptor underlying stream is not an open file descriptor.</td>
</tr>
<tr>
<td>EOVERFLOW</td>
<td>The current file offset cannot be represented correctly in an object of type off_t.</td>
</tr>
<tr>
<td>ESPIPE</td>
<td>The file descriptor underlying stream is associated with a pipe or FIFO.</td>
</tr>
</tbody>
</table>

### Example

```c
/* This example opens the file myfile.dat for reading.
   The current file pointer position is stored in the variable pos. */

#define _LARGE_FILES 1
#include <stdio.h>

int main(void)
{
    FILE *stream
    off_t pos;

    stream = fopen("/myfile.dat", "rb");

    /* The value returned by ftello() can be used by fseeko()
       to set the file pointer if 'pos' is not -1 */

    if((pos = ftello(stream)) != -1LL)
        printf("Current position of file pointer found\n");
    fclose(stream);
}
```

ftime() — Set the Date and Time

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/timeb.h>

int ftime(struct timeb *tp);
```

General Description

The ftime() function sets the time and millitm members of the timeb structure pointed to by tp to contain seconds and milliseconds, respectively, of the current time in seconds since 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.

Note: The ftime() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The time() function is preferred for portability.

Returned Value

If successful, ftime() returns 0.

If overflow occurs, ftime() returns -1. ¹

Related Information

- "limits.h" on page 55
- "sys/timeb.h" on page 89
- "ctime() — Convert Time to Character String" on page 389

- "time() — Determine current UTC time" on page 2204

¹ Overflow occurs when the current time in seconds since 00:00:00 UTC, January 1, 1970 exceeds the capacity of the time member of the timeb structure pointed to by tp. The time member is type time_t.
ftok

ftok() — Generate an Interprocess Communication (IPC) key

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/ipc.h>

key_t ftok(const char *path, int id);
```

General Description

The ftok() function returns a key based on `path` and `id` that is usable in subsequent calls to msgget(), semget(), and shmget(). The `path` argument must be the pathname of an existing file that the process is able to stat().

The ftok() function returns the same key value for all paths that name the same file, when called with the same `id` value. If a different `id` value is given, or a different file is given, a different key is returned. Only the low-order 8-bits of `id` are significant, and must be nonzero.

Returned Value

If successful, ftok() returns a key.

If unsuccessful, ftok() returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for a component of the path prefix.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The low-order 8-bits of <code>id</code> are zero.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>Too many symbolic links were encountered in resolving path.</td>
</tr>
</tbody>
</table>
| ENAMETOOLONG | One of the following error conditions exists:  
  • The length of the `path` argument exceeds `PATH_MAX` or a pathname component is longer than `NAME_MAX`.  
  • The pathname resolution of a symbolic link produced an intermediate result whose length exceeds `PATH_MAX`. |
| ENOENT     | A component of `path` does not name an existing file or `path` is an empty string. |
| ENOTDIR    | A component of the path prefix is not a directory. |

ftruncate() — Truncate a File

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1a</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX1_SOURCE 2
#include <unistd.h>

int ftruncate(int fildes, off_t length);
```

General Description

Truncates the file indicated by the open file descriptor `fildes` to the indicated `length`. `fildes` must be a regular file that is open for writing. If the file size exceeds `length`, any extra data is discarded. If the file size is smaller than length, bytes between the old and new lengths are read as zeros. A change to the size of the file has no impact on the file offset.

Special Behavior for XPG4.2

If `ftruncate()` would cause the file size to exceed the soft file size limit for the process, `ftruncate()` will fail and a SIGXFSZ signal will be generated for the process.

If successful, `ftruncate()` marks the `st_ctime` and `st_mtime` fields of the file.

If unsuccessful, `ftruncate()` leaves the file unchanged.

Large Files for HFS

**Note:** Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option LANGLEVEL(LONGLONG) and also define the Feature Test Macro (FTM) `_LARGE_FILES` before any headers are included will enable this function to operate on HFS files that are larger than 2 gig-1 in size. File size and offset fields will be enlarged to 63 bits in width so any other function operating on this file will have to be enabled with the same FTM.

Returned Value

If successful, `ftruncate()` returns 0.

If unsuccessful, `ftruncate()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EFBIG</td>
<td>The length argument was greater than the maximum file size.</td>
</tr>
<tr>
<td>EINTR</td>
<td>Added for XPG4.2: A signal was caught during execution.</td>
</tr>
<tr>
<td>EINVAL</td>
<td><code>fildes</code> does not refer to a regular file, it is opened read-only, or the length specified is incorrect.</td>
</tr>
</tbody>
</table>
**ftruncate**

EIO **Added for XPG4.2:** An I/O error occurred while reading from or writing to a file system.

EROFS The file resides on a read-only file system.

**Example**

**CELEBF49**

/* CELEBF49 */

```c
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#define string_len 1000

main() {
    char *mega_string;
    int fd, ret;
    char fn[]="write.file";
    struct stat st;

    if ((mega_string = (char*) malloc(string_len)) == NULL)
        perror("malloc() error");
    else if (fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        memset(mega_string, '0', string_len);
        if ((ret = write(fd, mega_string, string_len)) == -1)
            perror("write() error");
        else {
            printf("write() wrote %d bytes\n", ret);
            fstat(fd, &st);
            printf("the file has %ld bytes\n", (long) st.st_size);
            if (ftruncate(fd, 1) != 0)
                perror("ftruncate() error");
            else {
                fstat(fd, &st);
                printf("the file has %ld bytes\n", (long) st.st_size);
            }
        }
        close(fd);
        unlink(fn);
    }
}
```

**Output**

write() wrote 1000 bytes
the file has 1000 bytes
the file has 1 bytes

ftrylockfile() — stdio Locking

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R8</td>
</tr>
</tbody>
</table>

Format

```c
#define _UNIX03_SOURCE
#include <stdio.h>

int ftrylockfile(FILE *file);
```

General Description

This function provides explicit application-level locking of stdio (FILE*) objects. The flockfile() family of functions can be used by a thread to delineate a sequence of I/O statements that are executed as a unit.

If the (FILE*) object specified by the ftrylockfile() function is available, ownership is granted to the thread for the (FILE*) object and the internal lock count is increased. If the thread has previously been granted ownership, the internal lock count is increased. If another thread has been granted ownership, ftrylockfile() does not grant ownership to the calling thread and returns a non-zero value. ftrylockfile() is a non-blocking version of flockfile().

The internal lock count allows matching calls to flockfile() (or successful calls to ftrylockfile()) and funlockfile() to be nested.

z/OS Consideration

The flockfile() family of functions acts upon FILE * objects. It is possible to have the same physical file represented by multiple FILE * objects that are not recognized as being equivalent. For example, fopen() opens a file and open() opens the same file, and then fdopen() creates a FILE * object. In this case, locking the first FILE * does not prevent the second FILE * object from also being locked and used.

Returned Value

The ftrylockfile() function returns zero for success and non-zero to indicate that the lock cannot be acquired.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The input (FILE *) object is not valid.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>The input (FILE *) object is locked by another thread.</td>
</tr>
</tbody>
</table>

Note: It is the application’s responsibility to prevent deadlock (or looping). For example, deadlock (or looping) may occur if a (FILE *) object is closed, or a thread is terminated, before relinquishing all locked (FILE *) objects.

ftw

ftw() — Traverse a File Tree

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <ftw.h>

int ftw(const char *path,
         int (*fn)(const char *, const struct stat *, int),
         int ndirs);
```

General Description

The ftw() function recursively descends the directory hierarchy rooted in `path`. For each object in the hierarchy, ftw() calls the function pointed to by `fn`, passing it a pointer to a NULL-terminated string containing the name of the object, a pointer to a `stat` structure containing information about the object, and an integer. Possible values of the integer, defined in the `<ftw.h>` header, are:

- **FTW_D** for a directory
- **FTW_DNR** for a directory that cannot be read
- **FTW_F** for a file
- **FTW_SL** for a symbolic link
- **FTW_NS** for an object other than a symbolic link on which `stat()` could not be successfully executed. If the object is a symbolic link, and `stat()` failed, it is unspecified whether `ftw()` passes `FTW_SL` or `FTW_NS` to the user-supplied function.

If the integer is `FTW_DNR`, descendants of that directory will not be processed. If the integer is `FTW_NS`, the `stat` structure will contain undefined values. An example of an object that would cause `FTW_NS` to be passed to the function pointed to by `fn` would be a file in a directory with read but without execute (search) permission.

The `ftw()` function visits a directory before visiting any of its descendants.

The `ftw()` function uses at most one file descriptor for each level in the tree.

The argument `ndirs` should be in the range of 1 to `OPEN_MAX`.

The tree traversal continues until the tree is exhausted, an invocation of `fn` returns a nonzero value, or some other error, other than [EACCES], is detected within `ftw()`.

The `ndirs` argument specifies the maximum number of directory streams or file descriptors or both available for use by `ftw()` while traversing the tree. When `ftw()` returns it closes any directory streams and file descriptors it uses not counting any opened by the application-supplied `fn` function.
Note: When working with Large Files, the function pointed to by fn should be compiled with Large Files support or else data may be inaccurate in the stat structure.

Returned Value

If the tree is exhausted, ftw() returns 0. If the function pointed to by fn returns a nonzero value, ftw() stops its tree traversal and returns whatever value was returned by the function pointed to by fn().

If ftw() detects an error, it returns −1 and sets errno to one of the following values. All other errnos returned by ftw() are unchanged.

<table>

funlockfile() — stdio Unlocking

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R8</td>
</tr>
</tbody>
</table>

Format

```c
#define _UNIX03_SOURCE
#include <stdio.h>

void funlockfile(FILE *file);
```

General Description

This function provides explicit application-level unlocking of stdio (FILE*) objects. The flockfile() family of functions can be used by a thread to delineate a sequence of I/O statements that are executed as a unit.

The funlockfile() function reduces the internal lock count. When the count is reduced to zero, the funlockfile() function relinquishes the ownership granted to the thread, of a (FILE *) object. If a call to funlockfile() is made by a thread which has not been granted ownership of a (FILE *) object, the call is ignored and the lock count is not reduced.

The internal lock count allows matching calls to flockfile() (or successful calls to ftrylockfile()) and funlockfile() to be nested.

z/OS Consideration

The flockfile() family of functions acts upon FILE * objects. It is possible to have the same physical file represented by multiple FILE * objects that are not recognized as being equivalent. For example, fopen() opens a file and open() opens the same file, and then fdopen() creates a FILE * object. In this case, locking the first FILE * does not prevent the second FILE * from also being locked and used.

Returned Value

None.

Note:

- Because the funlockfile() function returns void, no error information can be returned. If an invalid (FILE *) object is input, it will be ignored.
- It is the application's responsibility to prevent deadlock (or looping). For example, deadlock (or looping) may occur if a (FILE *) object is closed, or a thread is terminated, before relinquishing all locked (FILE *) objects.

Related Information

- "flockfile()—stdio Locking" on page 608

fupdate() — Update a VSAM Record

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

size_t fupdate(const void *buffer, size_t size, FILE *stream);
```

General Description

Replaces the last record read from the VSAM cluster pointed to by `stream`, with the contents of `buffer` for a length of `size`. See “Performing VSAM I/O Operations” in [z/OS XL C/C++ Programming Guide](#) for details.

The `fupdate()` function can be used only with a VSAM data set opened in update mode (rb+/r+b, ab+/a+b, or wb+/w+b) with the type=record option.

The `fupdate()` function can only be used after an `fread()` call has been performed and before any other operation on that file pointer. For example, if you need to acquire the file position using `ftell()` or `fgetpos()`, you can do it either before the `fread()` or after the `fupdate()`. An `fread()` after an `fupdate()` retrieves the next updated record.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use `LANGLVL(EXTENDED)`.

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with `LANGLVL(EXTENDED)`. When you use `LANGLVL(EXTENDED)` any relevant information in the header is also exposed.

**KSDS or KSDS PATH**

The size of the record can be changed by a call to `fupdate()`. If the size is greater than the existing record size but less than or equal to the maximum record length of the file, a call to `fupdate()` will lengthen the record up to the maximum record length of the file. If the size is greater than the maximum record length of the file, the record is truncated and `errno` is set. If the size is less than or equal to the existing record length, all size bytes of the record are written, and no padding or overlaying occurs. The records will be shortened and not partially updated.

**ESDS, ESDS PATH, or RRDS**

The size of a record cannot be changed by a call to `fupdate()`. If you call `fupdate()` with `size` smaller than the size of the existing record, `size` bytes of the record are updated; the remaining bytes are unchanged, and the record length remains unchanged.
fupdate

The key of reference (the prime key if opened as a cluster, the alternative index key if opened as a path) cannot be changed by an update. If a data set is opened as a path, the prime key cannot be changed by an update. For RRDS files, the buffer must be an RRDS record structure, which includes an rrds_key.

Returned Value

If successful, fupdate() returns the size of the updated record.

If the update operation is not successful, fupdate() returns 0.

Example

CLEBEF50
/* CLEBEF50 */
#include <stdio.h>

int main(void)
{
    FILE *stream;
    struct record { char name[20];
                    char address[40];
                    int age;
                    } buffer;
    int vsam_rc, numread;

    stream = fopen("DD:MYCLUS", "rb+,type=record");
    numread = fread(&buffer, 1, sizeof(buffer), stream);
    /* ... Update fields in the record ... */
    vsam_rc = fupdate(&buffer, sizeof(buffer), stream);
}

#include <stdio.h>
#include <wchar.h>

int fwide(FILE *stream, int mode);

General Description

fwide() determines the orientation of the stream pointed to by stream. If mode is greater than 0, the function attempts to make the stream wide-oriented. If mode is less than 0, the function attempts to make the stream byte-oriented. Otherwise, mode is 0 and the function does not alter the orientation of the stream, rather the function returns the current orientation of the stream.

If the orientation of the stream has already been determined, fwide() will not change it.

Streams opened as type=record do not have orientation.

VSAM data sets and CICS transient data queues do not have orientation. Use of fwide() against streams referring to VSAM data sets or CICS transient data queues will be unsuccessful.

An application wishing to check for error situations should set errno to 0, then call fwide(), then check errno. If errno is non-zero assume an error has occurred.

Special Considerations for C++

The interaction of fwide() and a C++ I/O stream is undefined.

Usage Note

The run-time library does not prevent using byte-oriented I/O functions on a wide-oriented stream, using wide-oriented I/O functions on a byte-oriented stream, or any other mixed orientation usage. The behavior of an application doing so is undefined. As a result, the orientation of a stream reported by fwide() might not be consistent with the I/O functions that are being used. The stream orientation first set using fwide() itself, or through the first I/O operation on the stream is what will be returned. For example, if fwide() is used to set the orientation as byte-oriented, but only wide-oriented I/O functions are used on the stream, the orientation of the stream remains byte-oriented even though no mixing of I/O functions has occurred.
fwide

Returned Value

If successful, fwide() returns a value greater than 0 if the stream has wide-orientation after the call. It returns a value less than 0 if the stream has byte-orientation, or 0 if the stream has no orientation after the call.

When unsuccessful, fwide() returns 0 and sets errno to one of the following:

**EBADF** – The stream specified by stream was not valid.

**EINVAL** – The stream specified by stream was opened type=record, or the stream refers to a VSAM data set or CICS transient data queue.

Format

Non-XPG4

```c
#include <wchar.h>

int fwprintf(FILE *__restrict__ stream, const wchar_t *__restrict__ format, ...);
int swprintf(wchar_t *__restrict__ wcs, size_t n, const wchar_t *__restrict__ format, ...);
int wprintf(const wchar_t *__restrict__ format, ...);
```

XPG4

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int fwprintf(FILE *__restrict__ stream, const wchar_t *__restrict__ format, ...);
int swprintf(wchar_t *__restrict__ wcs, size_t n, const wchar_t *__restrict__ format, ...);
int wprintf(const wchar_t *__restrict__ format, ...);
```

General Description

The fwprintf(), swprintf() and wprintf() functions are equivalent to fprintf(), sprintf() and printf(), respectively, except for the following:

- For swprintf(), the argument wcs specifies an array of type wchar_t into which the generated output is to be written, rather than an array of type char.
- The argument format specifies an array of type wchar_t that describes how subsequent arguments are converted for output, rather than an array of type char.
- %c without an l prefix means an int arg is to be converted to wchar_t, as if mbtowc() were called, and then written.
- %c with l prefix means a wint_t is converted to wchar_t and then written.
- %s without an l prefix means a character array containing a multibyte character sequence is to be converted to an array of wchar_t and then written. The conversion will take place as if mbtowc() were called repeatedly.
- %s with l prefix means an array of wchar_t will be written. The array is written up to but not including the terminating NULL character, unless the precision specifies a shorter output.

For swprintf(), a NULL wide character is written at the end of the wide characters written; the NULL wide character is not counted as part of the returned sum. If copying takes place between objects that overlap, the behavior is undefined.

Special Behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the fwprintf(),
fwprintf(), swprintf, wprintf()

swprintf() or wprintf() function in the wchar header available when you compile your program. Please see Table 4 on page 22 for a list of XPG4 and other feature test macros.

Note: The fwprintf() and wprintf() functions have a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII Support” on page 2495 for details.

Returned Value

If successful, fwprintf(), wprintf(), and swprintf() return the number of wide characters written, not counting the terminating NULL wide character.

If unsuccessful, a negative value is returned.

If \( n \) or more wide characters were requested to be written, swprintf() returns a negative value and sets errno to indicate the error.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

size_t fwrite(const void *__restrict__ buffer, size_t size, size_t count, FILE *__restrict__ stream);
```

General Description

Writes up to `count` items of size `size` from the location pointed to by `buffer` to the stream pointed to by `stream`.

When you are using fwrite() for record I/O output, set `size` to 1 and `count` to the length of the record to be written. You can only write one record at a time when you are using record I/O. Any string longer than the record length is cut off at the record length. A flush or reposition is required before a subsequent read.

Because fwrite() may buffer output before writing it out to the stream, data from prior fwrite() calls may be lost where a subsequent call to fwrite() causes a failure when the buffer is written to the stream.

fwrite() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

fwrite() returns the number of items that were successfully written.

This number can be smaller than `count` only if a write error occurred.

Example

```c
CELEBF51

/* CELEBF51

This example writes NUM long integers to a stream in binary format.
It checks that the fopen function is successful and that 100 items are written to the stream.

*/
#include <stdio.h>
define NUM 100

int main(void)
```
fwrite

```c
{ 
    FILE *stream;
    long list[NUM];
    int numwritten, number;

    if((stream = fopen("myfile.dat", "w+b")) != NULL )
    { 
        for (number = 0; number < NUM; ++number)
            list[number] = number;
        numwritten = fwrite(list, sizeof(long), NUM, stream);
        printf("number of long characters written is %d\n",numwritten);
    }
    else
        printf("fopen error\n");
}
```

Format

Non-XPG4

```c
#define _MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

int fwscanf(FILE *__restrict__ stream,
            const wchar_t *__restrict__ format, ...);

int swscanf(const wchar_t *__restrict__ wcs,
            const wchar_t *__restrict__ format, ...);

int wscanf(const wchar_t *__restrict__ format, ...);
```

XPG4 and swscanf()

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int swscanf(const wchar_t *__wcs, const wchar_t *__format, ...);
```

General Description

The fwscanf(), swscanf(), and wscanf() functions are equivalent to fscanf(), scanf(), and sscanf() respectively, except for the following:

- The argument `wcs` specifies an array of type `wchar_t` from which the input is to be obtained, rather than an array of type `char`.
- The `format` argument specifies an array of type `wchar_t` that describes the admissible input sequences and how they are to be converted for assignment, rather than an array of type `char`.
- `%c` with no `/` prefix means one or more (depending on precision) `wchar_t` is converted to multibyte characters and copied to the character array pointed to by the corresponding argument.
- `%c` with the `/` prefix means one or more (depending on precision) `wchar_t` is copied to the array of `wchar_t` pointed to by the corresponding argument.
- `%s` with no `/` prefix means a sequence of non-white `wchar_t` will be converted and copied, including the terminating NULL character, to the character array pointed to by the corresponding argument.
- `%s` with the `/` prefix means an array of `wchar_t` will be copied, including the terminating NULL wide-character, to the array of `wchar_t` pointed to by the corresponding argument.
fwscanf, swscanf, wscanf

- %l with no / prefix means a sequence of non-white wchar_t will be converted and copied, including the terminating NULL character, to the character array pointed to by the corresponding argument.
- %l with the / prefix means an array of wchar_t will be copied, including the terminating NULL wide-character, to the array of wchar_t pointed to by the corresponding argument.

**Note:** Reaching the end of a wide-character string is equivalent to reaching the end of a char string for the fscanf() and scanf() functions. If copying takes place between objects that overlap, the behavior is undefined.

**Special Behavior for XPG4 and swscanf()**

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the swscanf() function in the wchar header available when you compile your program. Please see [Table 4 on page 22](#) for a list of XPG4 and other feature test macros.

**Returned Value**

If successful, they either return the number of input items assigned, which can be fewer than provided for, or 0 in the event of an early matching failure. If an input failure occurs before any conversion, EOF is returned.

<td>both</td>
<td>z/OS V1R4</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netdb.h>

char *gai_strerror(int ecode);
```

```c
#define _POSIX_C_SOURCE 200112L
#include <netdb.h>

const char *gai_strerror(int ecode);
```

General Description

The `gai_strerror()` function returns a pointer to a text string describing the error value returned by a failure return from either the `getaddrinfo()` or `getnameinfo()` function. If the `ecode` is not one of the EAI_xxx values from the `<netdb.h>` header, then `gai_strerror()` returns a pointer to a string indicating an unknown error.

Subsequent calls to `gai_strerror()` will overwrite the buffer containing the text string.

Returned Value

When successful, `gai_strerror()` returns a pointer to a string describing the error. Upon failure, `gai_strerror()` will return NULL and set `errno` to one of the following:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>Insufficient memory to allocate buffer for text string describing the error.</td>
</tr>
</tbody>
</table>

</tr>
</tbody>
</table>

Format

```c
#include <math.h>

double gamma(double x);
```

Compiler Option

LANGLVL(SAA), LANGLVL(SAAL2), or LANGLVL(EXTENDED)

General Description

gamma() provides the same function as lgamma(), including the use of signgam. Use of lgamma() instead of gamma() is suggested by XPG4.2.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use lgamma() instead of gamma().

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

gcvt() — Convert Double to String

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *gcvt(double x, int ndigit, char *buf);
```

General Description

The gcvt() function converts double floating-point argument values to floating-point output strings. The gcvt() function has been extended to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of double argument values by using __isBFP().

z/OS XL C/C++ formatted output functions, including the gcvt() function, convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences. See “fprintf Family of Formatted Output Functions” on page 655 for a description of the special infinity and NaN output sequences.

The gcvt() function converts `x` to a NULL-terminated string (similar to the %g format of `fprintf()`, `printf()`, `sprintf()` — Format and Write Data” on page 648) in the array pointed to by `buf` and returns `buf`. It produces `ndigit` significant digits (limited to an unspecified value determined by the precision of a double) in %f if possible, or %e (scientific notation) otherwise. A minus sign is included in the returned string if `value` is less than 0. A radix character is included in the returned string if `value` is not a whole number. Trailing zeros are suppressed where `value` is not a whole number. The radix character is determined by the current locale. If `setlocale()` — Set Locale” on page 1811 has not been called successfully, the default locale, “POSIX”, is used. The default locale specifies a period (.) as the radix character. The LC_NUMERIC category determines the value of the radix character within the current locale.

Note: This function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The sprintf() function is preferred for portability.

Returned Value

If successful, gcvt() returns the character equivalent of `x` as specified above.

If unsuccessful, gcvt() returns NULL.

<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <sys/socket.h>
#include <netdb.h>

int getaddrinfo(const char *nodename,
    const char *servname,
    const struct addrinfo *hints,
    struct addrinfo **res);
```

SUSV3

```c
#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>
#include <netdb.h>

int getaddrinfo(const char *__restrict__ nodename,
    const char *__restrict__ servname,
    const struct addrinfo *__restrict__ hints,
    struct addrinfo *__restrict__ res);
```

General Description

The `getaddrinfo()` function translates the name of a service location (for example, a host name) and/or service name and returns a set of socket addresses and associated information to be used in creating a socket with which to address the specified service.

The `nodename` and `servname` arguments are either pointers to null-terminated strings or null pointers. One or both of these two arguments must be specified as a non-null pointer.

The format of a valid name depends on the protocol family or families. If a specific family is not given and the name could be interpreted as valid within multiple supported families, the function attempts to resolve the name in all supported families. When no errors are detected, all successful results will be returned.

If the `nodename` argument is not null, it can be a descriptive name or it can be an address string. If the specified address family is AF_INET, AF_INET6, or AF_UNSPEC, valid descriptive names include host names. If the specified address family is AF_INET or AF_UNSPEC, address strings using standard dot notation as specified in `inet_addr()` are valid. If the specified address family is AF_INET6 or AF_UNSPEC, standard IPv6 text forms described in `inet_pton()` are valid. In addition, scope information can be appended to the descriptive name or the address string using the format `nodename%scope` information. Scope information can be either an interface name or the numeric representation of an interface index suitable for use on this system.

If `nodename` is not null, the requested service location is named by `nodename`; otherwise, the requested service location is local to the caller.
If `servname` is null, the call returns network-level addresses for the specified `nodename`. If `servname` is not null, it is a null-terminated character string identifying the requested service. This can be either a descriptive name or a numeric representation suitable for use with the address family or families. If the specified address family is AF_INET, AF_INET6, or AF_UNSPEC, the service can be specified as a string specifying a decimal port number.

If the argument `hints` is not null, it refers to a structure containing input values that may direct the operation by providing options and by limiting the returned information to a specific socket type, address family and/or protocol. In the hints structure every member other than `ai_flags`, `ai_family`, `ai_socktype`, and `ai_protocol` must be zero or a null pointer. A value of AF_UNSPEC for `ai_family` means that the caller will accept any protocol family. A value of zero for `ai_socktype` means that the caller will accept any socket type. A value of zero for `ai_protocol` means that the caller will accept any protocol. If `hints` is a null pointer, the behavior must be as if it referred to a structure containing the value zero for the `ai_flags`, `ai_socktype`, and `ai_protocol` fields, and AF_UNSPEC for the `ai_family` field.

The `ai_flags` member to which the hints argument points can be set to 0 or be the bitwise inclusive OR of one or more of the following values:

- AI_PASSIVE
- AI_CANONNAME
- AI_NUMERICHOST
- AI_NUMERICSERV
- AI_V4MAPPED
- AI_ALL
- AI_ADDRCONFIG

If the AI_PASSIVE bit is set in the `ai_flags` member of the hints structure, then the caller plans to use the returned socket address structure in a call to `bind()`. In this case, if the `nodename` argument is a null pointer, then the IP address portion of the socket address structure will be set to INADDR_ANY for an IPv4 address or IN6ADDR_ANY_INIT for an IPv6 address. If the AI_PASSIVE bit is not set in the `ai_flags` member of the hints structure, then the returned socket address structure will be ready for a call to `connect()` (for a connection-oriented protocol) or either `connect()`, `sendto()`, or `sendmsg()` (for a connectionless protocol). In this case, if the `nodename` argument is a null pointer, then the IP address portion of the socket address structure will be set to the loopback address.

If the AI_CANONNAME bit is set in the `ai_flags` member of the hints structure, then upon successful return the `ai_canonname` member of the first addrinfo structure in the linked list will point to a null-terminated string containing the canonical name of the specified nodename.

If the AI_NUMERICHOST bit is set in the `ai_flags` member of the hints structure, then a non-null `nodename` string must be a numeric host address string. Otherwise an error code of EAI_NONAME is returned. This flag prevents any type of name resolution service (for example, the DNS) from being called.

If the AI_NUMERICSERV flag is specified then a non-null `servname` string must be a numeric port string. Otherwise an error code EAI_NONAME is returned. This flag prevents any type of name resolution service (for example, NIS+ from being invoked.

If the AI_V4MAPPED flag is specified along with the AF field with the value of AF_INET6, or a value of AF_UNSPEC when IPv6 is supported on the system, then
the caller will accept IPv4-mapped IPv6 addresses. When the AI_ALL flag is not also specified and no IPv6 addresses are found, then a query is made for IPv4 addresses. If any IPv4 addresses are found, they are returned as IPv4-mapped IPv6 addresses.

If the AF field does not have a value of AF_INET6 or the AF field contains AF_UNSPEC but IPv6 is not supported on the system, this flag is ignored.

When the AF field has a value of AF_INET6 and AI_ALL is set, the AI_V4MAPPED flag must also be set to indicate that the caller will accept all addresses (IPv6 and IPv4-mapped IPv6 addresses). When the AF field has a value of AF_UNSPEC when the system supports IPv6 and AI_ALL is set, the caller accepts IPv6 addresses and either IPv4 (if AI_V4MAPPED is not set) or IPv4-mapped IPv6 (if AI_V4MAPPED is set) addresses. A query is first made for IPv6 addresses and if successful, the IPv6 addresses are returned. Another query is then made for IPv4 addresses and any found are returned as IPv4 addresses (if AI_V4MAPPED was not set) or as IPv4-mapped IPv6 addresses (if AI_V4MAPPED was set). If the AF field does not have the value of AF_INET6, or the value of AF_UNSPEC when the system supports IPv6, the flag is ignored.

If the AI_ADDRCONFIG flag is specified then a query for IPv6 address records should occur only if the node has at least one IPv6 source address configured. A query for IPv4 address records will always occur, whether or not any IPv4 addresses are configured. The loopback address is not considered for this case as valid as a configured sources address.

All of the information returned by getaddrinfo() is dynamically allocated: the addrinfo structures, and the socket address structures and canonical node name strings pointed to by the addrinfo structures. To return this information to the system the function freeaddrinfo() is called.

Application Usage Notes

1. If the caller handles only TCP and not UDP, for example, then the ai_protocol member of the hints structure should be set to IPPROTO_TCP when getaddrinfo() is called.
2. If the caller handles only IPv4 and not IPv6, then the ai_family member of the hints structure should be set to AF_INET when getaddrinfo() is called.
3. Scope information is only pertinent to IPv6 link-local addresses. It is ignored for resolved IPv4 addresses and IPv6 addresses that are not link-local addresses.

Returned Value

When successful, getaddrinfo() returns 0 and a pointer to a linked list of one or more addrinfo structures through the res argument. The caller can process each addrinfo structure in this list by following the ai_next pointer, until a null pointer is encountered. In each returned addrinfo structure the three members ai_family, ai_socktype, and ai_protocol are the corresponding arguments for a call to the socket() function. In each addrinfo structure the ai_addr member points to a filled-in socket address structure whose length is specified by the ai_addrlen member. Upon failure, getaddrinfo() returns a non-zero error code. The error codes are as follows:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAI_AGAIN</td>
<td>The name specified by the Node_Name or Service_Name</td>
</tr>
</tbody>
</table>
parameter could not be resolved within the configured time interval, or the resolver address space has not been started. The request can be retried later.

EAI_BADFLAGS
The flags parameter had an incorrect setting.

EAI_FAIL An unrecoverable error occurred.

EAI_FAMILY The family parameter had an incorrect setting.

EAI_MEMORY A memory allocation failure occurred during an attempt to acquire an Addr_INFO structure.

EAI_NONAME One of the following conditions occurred:
1. The name does not resolve for the specified parameters. At least one of the Name or Service operands must be specified.
2. The request name parameter is valid, but it does not have a record at the name server.

EAI_SERVICE The service that was passed was not recognized for the specified socket type.

EAI_SOCKTYPE The intended socket type was not recognized.

EAI_SYSTEM A system error occurred.

For more information about the above return codes, see z/OS Communications Server: IP and SNA Codes.

Format

#include <stdio.h>

int getc(FILE *stream);
int getchar(void);

General Description

Reads a single character from the current stream position and advances the stream position to the next character. The getchar() function is identical to getc(stdin).

The getc() and fgetc() functions are identical. However, getc() and getchar() are provided in a highly efficient macro form. For performance purposes, it is recommended that the macro forms be used rather than the functional forms or fgetc(). By default, stdio.h provides the macro versions of these functions.

However, to get the functional forms, do one or more of the following:
  • For C only: do not include stdio.h.
  • Specify #undef, for example, #undef getc
  • Surround the call statement by parentheses, for example, (getc)

getc() and getchar() are not supported for files opened with type=record.

getc() and getchar() have the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

If the application is not multithreaded, then setting the _ALL_SOURCE_NO_THREADS feature test macro may improve performance of the application, because it allows use of the inline version of this function.

Special Behavior for POSIX

In a multithreaded C application that uses POSIX(ON), in the presence of the feature test macro, _OPEN_THREADS, these macros are in an #undef status because they are not thread-safe.

Note: Because the getc() macro reevaluates its input argument more than once, you should never pass a stream argument that is an expression with side effects.
**Returned Value**

getc() and getchar() return the character read.

A returned value of EOF indicates either an error or an EOF condition. If a read error occurs, the error indicator is set. If an EOF is encountered, the EOF indicator is set.

Use ferror() or feof() to determine whether an error or an EOF condition occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does not turn on the EOF indicator.

**Example**

**CELEBG02**

/* CELEBG02

This example gets a line of input from the stdin stream. You can also use getc(stdin) instead of getchar. In the for statement to get a line of input from stdin.

*/
#include <stdio.h>
define LINE 80

int main(void)
{
    char buffer[LINE+1];
    int i;
    int ch;

    printf( "Please enter string\n" );

    /* Keep reading until either:
        1. the length of LINE is exceeded or
        2. the input character is EOF or
        3. the input character is a new-line character
    */

    for ( i = 0; ( i < LINE ) && (( ch = getchar() ) != EOF) &&
        ( ch != '\n' ); ++i )
        buffer[i] = ch;
    buffer[i] = '0'; /* a string should always end with '0' */
    printf( "The string is %s\n", buffer );
}

**Output**

Please enter string
hello world
The string is hello world

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R8</td>
</tr>
</tbody>
</table>

Format

```c
#define _UNIX03_SOURCE
#include <stdio.h>

int getc_unlocked(FILE *stream);
int getchar_unlocked(void);
int putc_unlocked(int c, FILE *stream);
int putchar_unlocked(int c);
```

General Description

Versions of the functions getc(), getchar(), putc(), and putchar() respectively named getc_unlocked(), getchar_unlocked(), putc_unlocked(), and putchar_unlocked() are functionally equivalent to the original versions, with the exception that they are not thread-safe. These functions may safely be used in a multi-threaded program if and only if they are called while the invoking thread owns the (FILE*) object, as is the case after a successful call to the flockfile() or ftrylockfile() functions.

getc_unlocked, getchar_unlocked, putc_unlocked, putchar_unlocked are provided in a highly efficient macro form. For performance purposes, it is recommended that the macro forms be used rather than the functional forms. By default, stdio.h provides the macro versions of these functions.

However, to get the functional forms, do one or more of the following:

- Surround the call statement by parentheses, for example, `(getc_unlocked)`
- Specify `#undef`, for example, `#undef getc_unlocked`
- For C only: do not include stdio.h.

getc_unlocked, getchar_unlocked, putc_unlocked, putchar_unlocked are not supported for files that are opened with type=record.

getc_unlocked, getchar_unlocked, putc_unlocked, putchar_unlocked have the same restrictions as any read or write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

**Note:** Because the macro forms of these functions reevaluate their input arguments more than once, you must not pass an argument that is an expression with side effects.

Returned Value

See [getc(3), getchar(3) — Read a Character](#) on page 742 and [putc(3), putchar(3) — Write a Character(3)](##) on page 1566.

getclientid

getclientid() — Get the Identifier for the Calling Application

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>
#include <sys/types.h>

int getclientid(int domain, struct clientid *clientid);
```

General Description

The `getclientid()` function call returns the identifier by which the calling application is known to the TCP/IP address space. The `clientid` can be used in the `givesocket()` and `takesocket()` calls. However, this function is supplied for use by existing programs that depend on the address space name returned. Even for these programs it is recommended that the name be saved for its later use and the `__getclientid()` function be issued to reconstruct the `clientid` structure for use by `givesocket()` and `takesocket()`.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>domain</code></td>
<td>The address domain requested.</td>
</tr>
<tr>
<td><code>clientid</code></td>
<td>The pointer to a <code>clientid</code> structure to be filled.</td>
</tr>
</tbody>
</table>

The `clientid` structure is filled in by the call and returned as follows:

```c
struct clientid {
    int domain;
    union {
        char name[8];
        struct {
            int NameUpper;
            pid_t pid;
        } c_pid;
        } c_name;
    char subtaskname[8];
    struct {
        char type;
        union {
            char specific[19];
            struct {
                char unused[3];
                int SockToken;
            } c_close;
        } c_func;
        } c_reserved;
    };
```

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>domain</code></td>
<td>The input <code>domain</code> value returned in the domain field of the <code>clientid</code> structure.</td>
</tr>
</tbody>
</table>
getclientid

c_name.name  The application program's address space name, left-justified and padded with blanks.

subtaskname  The calling program's task identifier.

c_reserv  Specifies binary zeros.

Returned Value

If successful, getclientid() returns 0.

If unsuccessful, getclientid() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>Using the clientId parameter as specified would result in an attempt to access storage outside the caller's address space, or storage not modifiable by the caller.</td>
</tr>
</tbody>
</table>

<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>
#include <sys/types.h>

int __getclientid(int domain, struct clientid *clientid);
```

General Description

The __getclientid() function call returns the process identifier (PID) by which the calling application is known to the TCP/IP address space. The clientid is used in the givesocket() and takesocket() calls. Use the __getclientid() function call to transfer sockets between the caller and the selected application. The __getclientid() function provides improved performance and integrity over the getclientid() function for applications that use the output of __getclientid() as input clientids for givesocket() and takesocket().

Parameter Description

domain The address domain requested.

clientid The pointer to a clientid structure to be filled.

The clientid structure:

```c
struct clientid {
    int domain;
    union {
        char name[8];
        struct {
            int NameUpper;
            pid_t pid;
        } c_pid;
    } c_name;
    char subtaskname[8];

    struct {
        char type;
        union {
            char specific[19];
            struct {
                char unused[3];
                int SockToken;
            } c_close;
        } c_func;
        } c_reserved;
};
```

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>domain</td>
<td>The input domain value returned in the domain field of the clientid structure.</td>
</tr>
<tr>
<td>c_pid.pid</td>
<td>Is the label in the clientid structure that is filled in by the function</td>
</tr>
</tbody>
</table>
call to the PID of the requester (caller of __getclientid()). It should be left as set because it is used by the takesocket() and givesocket() functions.

<table>
<thead>
<tr>
<th>subtaskname</th>
<th>Blanks</th>
</tr>
</thead>
<tbody>
<tr>
<td>c_reserved</td>
<td>Binary zeros</td>
</tr>
</tbody>
</table>

**Returned Value**

If successful, __getclientid() returns 0.

If unsuccessful, __getclientid() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>

getcontext

getcontext() — Get User Context

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ucontext.h>

int getcontext(ucontext_t *ucp);
```

General Description

The getcontext() function initializes the structure pointed to by `ucp` to the current user context of the calling process. The `ucontext_t` type that `ucp` points to defines the user context and includes the contents of the calling process’s machine registers, the signal mask, and the current execution stack. A subsequent call to `setcontext()` restores the saved context and returns control to a point in the program corresponding to the `getcontext()` call. Execution resumes as if the `getcontext()` call had just returned. The return value from `getcontext()` is the same regardless of whether the return is from the initial invocation or using a call to `setcontext()`.

The context created by `getcontext()` may be modified by the `makecontext()` function. Refer to `makecontext` for details.

`getcontext()` is similar in some respects to `sigsetjmp()` (and `setjmp()` and `_setjmp()`). The `getcontext()`–`setcontext()` pair, the `sigsetjmp()`–`siglongjmp()` pair, the `setjmp()`–`longjmp()` pair, and the `_setjmp()`–`_longjmp()` pair cannot be intermixed. A context saved by `getcontext()` should be restored only by `setcontext()`.

**Note:** Some compatibility exists with `siglongjmp()`, so it is possible to use `siglongjmp()` from a signal handler to restore a context created with `getcontext()`, but it is not recommended.

Portable applications should not modify or access the `uc_mcontext` member of `ucontext_t`. A portable application cannot assume that context includes any process-wide static data, possibly including `errno`. Users manipulating contexts should take care to handle these explicitly when required.

This function is supported only in a POSIX program.

The `<ucontext.h>` header file defines the `ucontext_t` type as a structure that includes the following members:

- `mcontext_t uc_mcontext`: A machine-specific representation of the saved context.
- `ucontext_t *uc_link`: Pointer to the context that will be resumed when this context returns.
- `sigset_t uc_sigmask`: The set of signals that are blocked when this context is active.
- `stack_t uc_stack`: The stack used by this context.

**Special Behavior for C++**
If `getcontext()` and `setcontext()` are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic objects is undefined. This applies to both z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of `getcontext()` and `setcontext()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Do not issue `getcontext()` in a C++ constructor or destructor, since the saved context would not be usable in a subsequent `setcontext()` or `swapcontext()` after the constructor or destructor returns.

Special Behavior for XPLINK-compiled C++

Restrictions concerning `setjmp.h` and `ucontext.h`:

Notes:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the `jmp_buf`, `sigjmp_buf` or `ucontext_t` types must not be compiled with C headers from Language Environment V2R9 or earlier.

2. Non-XPLINK functions compiled with any level of Language Environment headers must not define `jmp_buf`, `sigjmp_buf` or `ucontext_t` data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.

3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger `jmp_buf`, `sigjmp_buf` or `ucontext_t` area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Language Environment V2R10 and later headers define a shorter `jmp_buf`, `sigjmp_buf` or `ucontext_t` area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short `jmp_buf`, `sigjmp_buf` or `ucontext_t` area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned Value

If successful, `getcontext()` returns 0.

If unsuccessful, `getcontext()` returns −1.

There are no `errno` values defined.

Example

This example saves the context in main with the `getcontext()` statement. It then returns to that statement from the function `func` using the `setcontext()` statement. Since `getcontext()` always returns 0 if successful, the program uses the variable `x` to determine if `getcontext()` returns as a result of `setcontext()` or not.

```c
/* This example shows the usage of getcontext() and setcontext(). */
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdio.h>
#include <ucontext.h>

void func(void);

int x = 0;
```
getcontext

ucontext_t context, *cp = &context;

int main(void) {
    getcontext(cp);
    if (!x) {
        printf("getcontext has been called\n");
        func();
    } else {
        printf("setcontext has been called\n");
    }
}

void func(void) {
    x++;
    setcontext(cp);
}

Output
getcontext has been called
setcontext has been called

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

char *getcwd(char *buffer, size_t size);
```

General Description

Determines the pathname of the working directory and stores it in `buffer`.

- `size` The number of characters in the `buffer` area.
- `buffer` The name of the buffer that will be used to hold the path name of the working directory. `buffer` must be big enough to hold the working directory name, plus a terminating NULL to mark the end of the name.

Returned Value

If successful, `getcwd()` returns a pointer to the buffer.

If unsuccessful, `getcwd()` returns a NULL pointer and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The process did not have read or search permission on some component of the working directory’s pathname.</td>

getdate

getcode() — Convert User Format Date and Time

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <time.h>

struct tm *getdate(const char *string);

extern int getdate_err;
```

General Description

The `getdate()` function converts definable date and/or time specifications pointed to by `string` into a `tm` structure. The `tm` structure declaration is in the header `<time.h>`. Templates are used to parse and interpret the input string. The templates are contained in text files created by the process and identified using the environment variable `DATEMSK`. The `DATEMSK` variable should be set to indicate the full pathname of the file that contains the templates. The first line in the template that matches the input specification is used for the interpretation and conversion into the internal time format.

The following field descriptors are supported:

- `%%` same as `%`
- `%a` abbreviated weekday name
- `%A` full weekday name
- `%b` abbreviated month name
- `%B` full month name
- `%c` locale’s appropriate date and time representation
- `%C` Century number [00,99]; leading zeros are permitted but not required. Used in conjunction with `%y`
- `%d` day of month (01-31; the leading 0 is optional)
- `%D` date as %m/%d/%y
- `%e` same as `%d`
- `%h` same as `%b`
- `%H` hour (00-23; the leading 0 is optional)
- `%I` hour (01-12; the leading 0 is optional)
- `%m` month number (00-11; the leading 0 is optional)
- `%n` minute (00-59; the leading 0 is optional)
- `same as \n`
locale’s equivalent of either AM or PM
locale’s 12 hour time representation. In the POSIX locale this is equivalent to %I:%M:%S %p
time as %H:%M
Seconds [00,60]. The range goes to 60 (rather than stopping at 59) to allow positive leap seconds to be expressed. Since leap seconds cannot be predicted by any algorithm, leap second data must come from some external source.
same as \t (tab)
time as %H:%M:%S
weekday number (0-6; 0 indicates Sunday)
locale’s date representation. In the POSIX locale this is equivalent to %m/%d/%y.
locale’s time representation. In the POSIX locale this is equivalent to %H:%M:%S.
year within century. When a century is not otherwise specified, values in the range 69-99 refer to years in the twentieth century (1969 to 1999 inclusive); values in the range 00-68 refer to years in the twenty-first century (2000 to 2068 inclusive).
year as ccyy (1969-9999)
time zone name or no characters if no time zone exists. If the time zone supplied for %Z is not the time zone getdate() expects, a non-valid input specification error will result. The getdate() function calculates an expected time zone based on time and date information supplied to it.

The match between the template and input specification performed by getdate() is case insensitive.

The month and weekday names can consist of any combination of uppercase or lowercase letters. The process can request that the input date and time specification be in a specific language by setting the LC_TIME category (see setlocale()).

Leading 0’s are not necessary for the descriptors that allow leading 0’s. However, at most two digits are allowed for those descriptors, including leading 0’s. Extra white space in either the template file or in string is ignored.

The field descriptors %c, %x, and %X will not be supported if they include unsupported field descriptors.

The following rules apply for converting the input specification into a tm structure:
• If only weekday is given, today is assumed if the given day is equal to the current day and next week if it is less,
• If only the month is given, the current month is assumed if the given month is equal to the current month and next year if it is less and no year is given (the first day of the month is assumed if no day is given),
• If no hour, minute, and second are given, the current hour, minute and second are assumed,
If no date is given, today is assumed if the given hour is greater than the current hour and tomorrow is assumed if it is less.

**Returned Value**

If successful, `getdate()` returns a pointer to a `tm` structure.

If unsuccessful, `getdate()` returns a NULL pointer and sets the external variable `getdate_err` to a value indicating the error.

The `tm` structure to which `getdate()` returns a pointer is not shared with any other functions. Also, the `getdate()` function produces a `tm` structure unique to the thread on which it runs.

As is true for all external variables, C/370 allocates storage for the `getdate_err` external variable in writable static storage which is shared among all threads. Thus, `getdate_err` is not intrinsically “thread-safe”.

C/370 allocates storage on a per thread basis for an analog of `getdate_err`. The `__gderr()` function returns a pointer to this storage. It is recommended that multithread applications and applications running from a DLL use the `__gderr()` function rather than `getdate_err` if `getdate()` returns a NULL pointer to determine in a thread-safe manner why `getdate()` was unsuccessful.

The `__gderr()` is defined as follows:

```c
#include <time.h>

int *__gderr(void);
```

The `__gderr()` function returns a pointer to the thread-specific value of `getdate_err`.

The following is a list of `getdate_err` settings and their description:

1. The `DATEMSK` environment variable is NULL or undefined.
2. The template file cannot be opened for reading.
3. Failed to get file status information.
4. The template file is not a regular file.
5. An error was encountered while reading the template file.
6. Memory allocation failed (not enough memory available).
7. No line in the template file matches the input specification.
8. Non-valid input specification. For example, February 31; or a time that can not be represented in a `time_t` (representing the time is seconds since Epoch - midnight, January 1, 1970 (UTC)).
9. Unable to determine current time.

**Note:** This value is unique for z/OS UNIX services.

<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int getdtablesize(void);
```

General Description

The `getdtablesize()` function is equivalent to `getrlimit()` with the RLIMIT_NOFILE option.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `getrlimit()` instead of `getdtablesize()`.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned Value

`getdtablesize()` returns the current soft limit as if obtained from a call to `getrlimit()`.

There are no `errno` values defined.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

gid_t getegid(void);
```

General Description

Finds the effective group ID (GID) of the calling process.

Returned Value

Returns the effective group ID (GID). It is always successful.

There are no documented errno values.

Example

**CELEBG04**

```c
/* CELEBG04

   This example finds the group ID.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <unistd.h>

main() {
   printf("my group id is %d\n", (int) getgid());
}
```

Output

my group id is 500

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

char *getenv(const char *varname);
```

General Description

Searches the table of environment variables for an entry corresponding to `varname` and returns a pointer to a buffer containing the current string value of `varname`.

Special Behavior for POSIX

Under POSIX, the value of the `char *environ` pointer is honored and used by `getenv()`. You can declare and use this pointer. Under POSIX(OFF) this is not the case: the table start cannot be modified. See “z/OS XL C/C++ applications with z/OS UNIX System Services C functions” on page 13 for more information.

Returned Value

If successful, `getenv()` returns a pointer to a buffer containing the current string value of `varname`. You should copy the string that is returned because a subsequent call to `getenv()` will overwrite it.

If the `varname` is not found, `getenv()` returns a NULL pointer. The returned value is NULL if the given variable is not currently defined.

Example

**CELEBG05**

```c
/* CELEBG05

   In this example, *pathvar points to the value of the PATH environment variable. 
   In a POSIX environment, this variable would be from the CENV group ID.

   */
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    char *pathvar;
```

Chapter 3. Part 3. Library Functions  761
```c
pathvar = getenv("PATH");
printf("pathvar=%s", pathvar);
}
```

__getenv() — Get an Environment Variable

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

char *__getenv(const char *varname);
```

General Description

__getenv() returns a unique character pointer for each environmental variable. For single-threaded applications, this eliminates the need to copy the string returned by previous __getenv() calls.

This function should not be used by multithreaded applications. Updates to the environmental variable on another thread may invalidate the address returned by __getenv() before the application copies the returned value.

The format of an environment variable is made up of three parts that are combined to form:

```
name=value
```

Where:

1. The first part, `name`, is a character string that represents the name of the environment variable. It is this part of the environment variable that __getenv() tries to match with `varname`.
2. The second part, `=`, is a separator character (since the equal sign is used as a separator character it cannot appear in the `name`).
3. The third part, `value`, is a NULL-terminated character string that represents the value that the environment variable, `name`, is set to. This is the part of the environment variable that __getenv() returns a pointer to.

There are several ways to establish a set of environment variables.

- Set at program initialization time from the Language Environment run-time option ENVAR.
- Set at program initialization time from a data set.
- If the program was invoked with a system() call, they can be inherited from the calling enclave.
- In the z/OS UNIX environment they can also be inherited from the parent process if the program was invoked with one of the exec functions.
- During the running of a program they can be set with the setenv() function or the putenv() function.

For a list of the environment variables that z/OS UNIX services support, see the chapter “Using Environment Variables” in [z/OS XL C/C++ Programming Guide](#).

Special Behavior for POSIX
__getenv

Under POSIX, the value of the char **environ pointer is honored and used by getenv(). You can declare and use this pointer. Under POSIX(OFF) this is not the case: the table start cannot be modified. See “z/OS XL C/C++ applications with z/OS UNIX System Services C functions” on page 13 for more information.

Note: The __getenv() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII Support” on page 2495 for details.

Returned Value

If successful, __getenv() returns a pointer to the string containing the value of the environment variable specified by varname.

If unsuccessful, __getenv() returns a NULL pointer. The returned value is NULL if the given variable is not currently defined or if the system does not support environment variables.

Related Information

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

uid_t geteuid(void);
```

General Description

Finds the effective user ID (UID) of the calling process.

Returned Value

Returns the effective user ID of the calling process. It is always successful.

There are no documented errno values.

Example

```c
CELEBG06
/* CELEBG06 */

#define _POSIX_SOURCE
#include <sys/types.h>
#include <pwd.h>
#include <unistd.h>

main() { 
  struct passwd *p;
  uid_t uid;

  if ((p = getpwuid(uid = geteuid())) == NULL) 
    perror("getpwuid() error");
  else {
    puts("getpwuid() returned the following info for your user id:");
    printf(" pw_name : %s\n", p->pw_name);
    printf(" pw_uid : %d\n", (int) p->pw_uid);
    printf(" pw_gid : %d\n", (int) p->pw_gid);
    printf(" pw_dir : %s\n", p->pw_dir);
    printf(" pw_shell : %s\n", p->pw_shell);
  }
}
```

Output

getpwuid() returns the following information for your user ID:
geteuid

    pw_name : MVSUSR1
    pw_uid : 25
    pw_gid : 500
    pw_dir : /u/mvsusr1
    pw_shell : /bin/sh

</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

gid_t getgid(void);
```

General Description

Finds the real group ID (GID) of the calling process.

Returned Value

Returns the real group ID of the calling process. It is always successful.

There are no documented errno values.

Example

```c
CELEBG07
/* CELEBG07

   This example gets the real group ID.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>

main() {

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <grp.h>

struct group *getgrgid(gid_t gid);
```

General Description

Provides information about the group specified by `gid` and its members.

Returned Value

If successful, getgrgid() returns a pointer to a group structure containing an entry from the group database with the specified `gid`. The return value may point to static data that is overwritten by each call. This group structure, defined in the `grp.h` header file, contains the following members:

- **gr_name**: The name of the group
- **gr_gid**: The numerical group ID (GID)
- **gr_mem**: A NULL-terminated vector of pointers to the individual member names

If unsuccessful, getgrgid() returns a NULL pointer.

There are no documented errno values.

Example

```c
CELEBG08
/* CELEBG08

This example provides the root GID and group name.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>
#include <sys/stat.h> /*FIX: used to be <stat.h>*/

main() {
    struct stat info;
    struct group *grp;

    if (stat("/", &info) < 0)
        perror("stat() error");
    else {
        printf("The root is owned by gid \%d\n", info.st_gid);
        if ((grp = getgrgid(info.st_gid)) == NULL)
            perror("getgrgid() error");
    }
}```
getgrgid

```c
else
   printf("This group name is %s\n", grp->gr_name);
}
}

Output
The root is owned by gid 500
This group name is SYS1

getgrgid_r() — Get Group Database Entry for a Group ID

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <grp.h>

int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);
```

General Description

The getgrgid_r() function updates the group structure pointed to by `grp` and stores a pointer to that structure at the location pointed to by `result`. The structure contains an entry from the group database with a matching `gid`. Storage referenced by the group structure is allocated from the memory provided with the `buffer` parameter, which is `bufsize` bytes in size. A NULL pointer is returned at the location pointed to by `result` on error or if the requested entry is not found.

Returned Value

If successful, getgrgid_r() returns 0.

If unsuccessful, getgrgid_r() sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERANGE</td>
<td>Insufficient storage was supplied in <code>buffer</code> and <code>bufsize</code> to contain the data to be referenced by the resulting group structure.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <grp.h>

struct group *getgrnam(const char *name);
```

General Description

Accesses the group structure containing an entry from the group database with the specified name.

Returned Value

If successful, getgrnam() returns a pointer to a group structure. The return value may point to static data that is overwritten by each call.

The group structure, defined in the grp.h header file, contains the following members:

- `gr_name`: The name of the group
- `gr_gid`: The numerical group ID (GID)
- `gr_mem`: A NULL-terminated vector of pointers to the individual member names.

If unsuccessful or if the requested entry is not found, getgrnam() returns a NULL pointer.

There are no documented errno values.

Example

```c
CELEBG09
/* CELEBG09

  This example provides the members of a group.

  */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>

main()
{
    struct group *grp;
    char  grpname[]="USERS", **curr;
    if ((grp = getgrnam(grpname)) == NULL)
      perror("getgrnam() error");
    else {
```
printf("The following are members of group %s:\n", grpname);
    for (curr=grp->gr_mem; (*curr) != NULL; curr++)
        printf(" %s\n", *curr);
}
}

Output
The following are members of group USERS:

MVSUSR1
MVSUSR2
MVSUSR3
MVSUSR4
MVSUSR5
MVSUSR6
MVSUSR7
MVSUSR8
MVSUSR9

Format

```
#include <sys/types.h>
#include <grp.h>

int getgrnam_r(const char *name, struct group *grp, char *buffer,
    size_t bufsize, struct group **result);
```

General Description

The getgrnam_r() function updates the group structure pointed to by `grp` and stores a pointer to that structure at the location pointed to by `result`. The structure contains an entry from the group database with a matching gid or name. Storage referenced by the group structure is allocated from the memory provided with the `buffer` parameter, which is `bufsize` bytes in size. A NULL pointer is returned at the location pointed to by `result` on error or if the requested entry is not found.

Returned Value

If successful, `getgrnam_r()` returns 0.

If unsuccessful, `getgrnam_r()` sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERANGE</td>
<td>Insufficient storage was supplied in <code>buffer</code> and <code>bufsize</code> to contain the data to be referenced by the resulting group structure.</td>

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

int getgroups(int size, gid_t list[]);
```

General Description

Stores the supplementary group IDs of the calling process in the `list` array. `size` gives the number of `gid_t` elements that can be stored in the `list` array.

Returned Value

If successful, `getgroups()` returns the number of supplementary group IDs that it puts into `list`. This value is always greater than or equal to 1 and less than or equal to the value of `NGROUPS_MAX` (which is defined in the limits.h header file).

If `size` is zero, `getgroups()` returns the total number of supplementary group IDs for the process. `getgroups()` does not try to store group IDs in `list`.

If unsuccessful, `getgroups()` returns −1 and sets `errno` to one of the following values.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td><code>size</code> was not equal to 0 and is less than the total number of supplementary group IDs for the process. <code>list</code> may or may not contain a subset of the supplementary group IDs for the process.</td>
</tr>
</tbody>
</table>

Example

```c
CELEBG10
/* CELEBG10

   This example provides a list of the supplementary group IDs.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>
#include <unistd.h>

#define dim(x) (sizeof(x)/sizeof(x[0]))

main()
{
  gid_t gids[500];
  struct group *grp;
  int count, curr;
```
if ((count = getgroups(dim(gids), gids)) == -1)
    perror("getgroups() error");
else {
    puts("The following is the list of my supplementary groups:");
    for (curr=0; curr<count; curr++) {
        if ((grp = getgrgid(gids[curr])) == NULL)
            perror("getgrgid() error");
        else
            printf(" %8s (%d)\n", grp−>gr_name, (int) gids[curr]);
    }
}

Output
The following is the list of my supplementary groups:
  SYS1 (500)
  KINGS (512)
  NOBLES (513)
  KNIGHTS (514)
  WIZARDS (515)
  SCRIBES (516)
  JESTERS (517)
  PEASANTS (518)

</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

int getgroupsbyname(char username[], int size, gid_t list[]);
```

General Description

Stores the supplementary group IDs of the specified `username` in the array, `list`. `size` gives the number of `gid_t` elements that can be stored in the array, `list`.

Returned Value

If successful, `getgroupsbyname()` returns the number of supplementary group IDs that it puts into `list`. This value is always greater than or equal to one, and less than or equal to the value of `NGROUPS_MAX`.

If `size` is zero, `getgroupsbyname()` returns the total number of supplementary group IDs for the process. `getgroupsbyname()` does not try to store group IDs in `list`.

If unsuccessful, `getgroupsbyname()` returns −1 and sets `errno` to one of the following values.

<td>EINVAL</td>
<td><code>size</code> was less than or equal to the total number of supplementary group IDs for the process. <code>list</code> may or may not contain a subset of the supplementary group IDs for the process.</td>
</tr>
</tbody>
</table>

Example

```c
CELEBG11

/* CELEBG11

   This example provides a list of the supplementary group IDs for MVSUSR1.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>
#include <unistd.h>

#define dim(x) (sizeof(x)/sizeof(x[0]))

main() {
    gid_t gids[500];
    struct group *grp;
    int count, curr;
    char user[]="MVSUSR1";

    if ((count = getgroupsbyname(user, dim(gids), gids)) == -1)
```
getgroupsbyname

```c
perror("getgroups() error");
else {
    printf("The following is the list of %s's supplementary groups:\n", user);
    for (curr=0; curr<count; curr++) {
        if ((grp = getgrgid(gids[curr])) == NULL)
            perror("getgrgid() error");
        else
            printf(" %8s (%d)\n", grp->gr_name, (int) gids[curr]);
    }
}
```

Output

The following is the list of MVSUSR1's supplementary groups:

SYS1 (900)
USERS (523)

Format

X/Open

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>
extern int h_errno;

struct hostent *gethostbyaddr(const void *address, size_t len, int type);
```

Berkeley Sockets

```c
#define _OE_SOCKETS
#include <netdb.h>

struct hostent *gethostbyaddr(char *address, int address_len, int domain);
```

General Description

The gethostbyaddr() call tries to resolve the host address through a name server, if one is present. gethostbyaddr() searches the local host tables until a matching host address is found or an EOF marker is reached.

Parameter | Description
---|---
address | The pointer to a structure containing the address of the host. (An unsigned long for AF_INET.)
address_len | The size of address in bytes.
domain | The address domain supported (AF_INET).

If you want gethostbyaddr() to bypass the name server and instead resolve the host address using the local host tables, you must define the RESOLVE_VIA_LOOKUP symbol before including any sockets-related include files in your source program.

You can use the X_ADDR environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization.

Note: For more information on these local host tables or the environment variables, see [z/OS Communications Server: IP Configuration Guide, SC31-8775](#).

The gethostbyaddr() call returns a pointer to a hostent structure for the host address specified on the call.

gethostent(), gethostbyaddr(), and gethostbyname() all use the same static area to return the hostent structure. This static area is only valid until the next one of these functions is called on the same thread.

The netdb.h include file defines the hostent structure and contains the following elements:
### gethostbyaddr

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>h_addr_list</td>
<td>A pointer to a NULL-terminated list of host network addresses.</td>
</tr>
<tr>
<td>h_addrtype</td>
<td>The type of address returned; currently, it is always set to AF_INET.</td>
</tr>
<tr>
<td>h_aliases</td>
<td>A zero-terminated array of alternative names for the host.</td>
</tr>
<tr>
<td>h_length</td>
<td>The length of the address in bytes.</td>
</tr>
<tr>
<td>h_name</td>
<td>The official name of the host.</td>
</tr>
</tbody>
</table>

The following function (X/Open sockets only) is defined in netdb.h and should be used by multithreaded applications when attempting to reference h_errno return on error:

```c
int *__h_errno(void);
```

Also use this function when you invoke gethostbyaddr() in a DLL.

This function returns a pointer to a thread-specific value for the h_errno variable.

### Special Behavior for C++

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

**Note:** The gethostbyaddr() and gethostbyname() functions have been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The getaddrinfo() and getnameinfo() functions are preferred for portability.

### Returned Value

The return value points to static data that is overwritten by subsequent calls. A pointer to a hostent structure indicates success. A NULL pointer indicates an error or End Of File (EOF).

If unsuccessful in X/Open, gethostbyaddr() sets h_errno to indicate the error as follows:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOST_NOT_FOUND</td>
<td>No such host is known.</td>
</tr>
<tr>
<td>NO_DATA</td>
<td>The server recognized the request and the name but no address is available.</td>
</tr>
<tr>
<td>NO_RECOVERY</td>
<td>An unexpected server failure occurred from which there is no recovery.</td>
</tr>
<tr>
<td>TRY_AGAIN</td>
<td>A temporary error such as no response from a server, indicating the information is not available now but may be at a later time.</td>
</tr>
</tbody>
</table>

X/Open

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>
extern int h_errno;
struct hostent *gethostbyname(const char *name);
```

Berkeley Sockets

```c
#define _OE_SOCKETS
#include <netdb.h>
struct hostent *gethostbyname(char *name);
```

General Description

The gethostbyname() call tries to resolve the host name through a name server, if one is present. If a name server is not present, gethostbyname() searches the local host tables until a matching host name is found or an EOF marker is reached.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the host.</td>
</tr>
</tbody>
</table>

The gethostbyname() call returns a pointer to a hostent structure for the host name specified on the call.

gethostent(), gethostbyaddr(), and gethostbyname() all use the same static area to return the hostent structure. This static area is only valid until the next one of these functions is called on the same thread.

If you want gethostbyname() to bypass the name server and instead resolve the host name using the local host tables, you must define the RESOLVE_VIA_LOOKUP symbol before including any sockets-related include files in your source program.

If the name server is not present or the RESOLVE_VIA_LOOKUP option is in effect, you can use the X_SITE environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization.

Note: For more information on these local host tables or the environment variables, see z/OS Communications Server: IP Configuration Guide, SC31-8775.

gethostent(), gethostbyaddr(), and gethostbyname() all use the same static area to return the HOSTENT structure. This static area is only valid until the next one of these functions is called on the same thread.
The **netdb.h** include file defines the **hostent** structure and contains the following elements:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>h_addr_list</code></td>
<td>A pointer to a NULL-terminated list of host network addresses.</td>
</tr>
<tr>
<td><code>h_addrtype</code></td>
<td>The type of address returned; currently, it is always set to AF_INET.</td>
</tr>
<tr>
<td><code>h_aliases</code></td>
<td>A zero-terminated array of alternative names for the host.</td>
</tr>
<tr>
<td><code>h_length</code></td>
<td>The length of the address in bytes.</td>
</tr>
<tr>
<td><code>h_name</code></td>
<td>The official name of the host.</td>
</tr>
</tbody>
</table>

The following function (X/Open sockets only) is defined in **netdb.h** and should be used by multithreaded applications when attempting to reference `h_errno` return on error:

```c
int *__h_errno(void);
```

Also use this function when you invoke `gethostbyname()` in a DLL. This function returns a pointer to a thread-specific value for the `h_errno` variable.

**Special Behavior for C++**

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` feature test macro.

**Note:** The `gethostbyaddr()` and `gethostbyname()` functions have been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `getaddrinfo()` and `getnameinfo()` functions are preferred for portability.

**Returned Value**

The return value points to static data that is overwritten by subsequent calls. A pointer to a **hostent** structure indicates success. A NULL pointer indicates an error or End Of File (EOF).

If unsuccessful in X/Open, `gethostbyname()` sets `h_errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOST_NOT_FOUND</td>
<td>No such host is known.</td>
</tr>
<tr>
<td>NO_DATA</td>
<td>The server recognized the request and the name but no address is available. Another type of request to the name server might return an answer.</td>
</tr>
<tr>
<td>NO_RECOVERY</td>
<td>An unexpected server failure occurred from which there is no recovery.</td>
</tr>
<tr>
<td>TRYAGAIN</td>
<td>A temporary error such as no response from a server, indicating the information is not available now but may be at a later time.</td>
</tr>
</tbody>
</table>

struct hostent *gethostent(void);
```

**Berkeley Sockets**

```c
#define _OE_SOCKETS
#include <netdb.h>

struct hostent *gethostent(void);
```

General Description

The gethostent() call reads the next line of the local host tables.

The gethostent() call returns a pointer to the next entry in the local host tables. gethostent() uses the local host tables to get aliases.

You can use the `X_SITE` environment to specify different local host tables and override those supplied by the z/OS resolver during initialization.

**Note:** For more information on these local host tables or the environment variables, see [z/OS Communications Server: IP Configuration Guide, SC31-8775](https://www.ibm.com).

gethostent(), gethostbyaddr(), and gethostbyname() all use the same static area to return the `hostent` structure. This static area is only valid until the next one of these functions is called on the same thread.

<td>The official name of the host.</td>
</tr>
</tbody>
</table>

Special Behavior for C++

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.
gethostent

Returned Value

If successful, gethostent() returns a pointer to a *hostent* structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, gethostent() returns a NULL pointer, indicating an error or End Of File (EOF).

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

**X/Open**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

long gethostid(void);
```

**Berkeley Sockets**

```c
#define _OE_SOCKETS
#include <unistd.h>

int gethostid();
```

General Description

The `gethostid()` call gets the unique 32-bit identifier for the current host. This value is the default home Internet address.

**Special Behavior for C++**

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned Value

If successful, `gethostid()` returns the 32-bit identifier of the current host, which should be unique across all hosts.

If unsuccessful, `gethostid()` returns −1 and stores the error value in `errno`. For return codes, see [z/OS UNIX System Services Messages and Codes](https://www.ibm.com/support/documentation/en/systems/z/os/zos/infocenter.html).

</tr>
</tbody>
</table>

Format

X/Open

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int gethostname(char *name, size_t namelen);
```

Berkeley Sockets

```c
#define _OE_SOCKETS
#include <unistd.h>

int gethostname(char *name, int namelen);
```

General Description

The gethostname() call returns the name of the host processor that the program is running on. Up to `namelen` characters are copied into the name array. The returned name is NULL-terminated unless there is insufficient room in the name array.

**Parameter**

- `name`  The character array to be filled with the host name.
- `namelen`  The length of `name`.

**Special Behavior for C++**

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned Value

If successful, gethostname() returns 0.

If unsuccessful, gethostname() returns -1 and sets errno to one of the following values:

**Error Code**

- `EFAULT`  Using `name` and `namelen` would result in an attempt to copy the address into a portion of the caller’s address space to which data cannot be written.
- `EMVSPARM`  Incorrect parameters were passed to the service.

getibmsockopt

getibmsockopt() — Get the Options Associated with a Bulk Mode Socket

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int getibmsockopt(int s, int level, int optname, char *optval, int *optlen);
```

General Description

Like getsockopt(), the getibmsockopt() gets the options associated with a socket in the AF_INET or AF_INET6 domain. Only SOL_SOCKET is supported. This call is for options specific to the IBM implementation of sockets. Currently, only the SOL_SOCKET level and the socket options SO_BULKMODE, SO_NONBLOCKLOCAL, and SO_IGNOREINCOMINGPUSH are supported.

Bulk mode is supported only for receive-type socket calls. Currently, send-type socket calls are not supported for bulk mode.

Use getibmsockopt() with the socket option SO_BULKMODE to test whether the UDP socket s is in bulk mode. Normally, UNIT transactions occur between the socket application and the TCP/IP address space for every receive (read(), recv(), recvfrom(), or recvmsg()) or send (send(), sendto(), sendmsg(), or write()) issued on a socket. The bulk mode socket option enables an application to queue multiple datagrams, sending all of the datagrams in one UNIT transaction. This reduces the CPU consumption for each datagram.

This call is used only in the AF_INET domain.

Parameter Description

- **s** The socket descriptor.
- **level** The level for which the option is set.
- **optname** The name of a specified socket option.
- **optval** The pointer to option data.
- **optlen** The pointer to the length of the option data.

For SO_BULKMODE, **optval** should point to an ibm_bulkmode_struct, which is defined in SOCKET.H. The ibm_bulkmode_struct contains the following fields:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b_onoff</td>
<td>1 means bulk mode is on; 0 means bulk mode is off.</td>
</tr>
<tr>
<td>b_max_receive_queue_size</td>
<td>The maximum receiving queue size in bytes.</td>
</tr>
<tr>
<td>b_max_send_queue_size</td>
<td>The maximum sending queue size in bytes. This</td>
</tr>
</tbody>
</table>
value is set to zero, since send-type socket calls are not currently supported for bulk mode.

b_move_data
For outbound sockets, if b_move_data is nonzero, the data is moved into buffers in the queue. The client's buffers can be reused right away. If b_move_data is zero, pointers to the data are saved in the queue. The buffers should not be reused until the queue has been flushed (generally by issuing an ibmsflush()).

b_teststor
If this element is nonzero, the message buffer address and the message buffer are checked for addressability during each socket call. errno is set to EFAULT if either address or buffer cannot be addressed. If this element is zero, no checking is performed.

b_max_send_queue_size_avail
The maximum send queue size in bytes that can be set for the b_max_send_queue_size field of ibm_bulkmode_struct. This value will be set to zero, since send-type socket calls are not currently supported for bulk mode.

b_num_UNITs_sent
The number of actual UNITs issued in sending datagrams to TCP/IP. This value will be set to zero, since send-type socket calls are not currently supported for bulk mode.

b_num_UNITs_received
The number of actual UNITs issued in receiving datagrams from TCP/IP.

The fields b_num_UNITs_sent and b_num_UNITs_received represent cumulative totals for this socket since the time the application was started.

For SO_NONBLOCKLOCAL, optval should point to an integer. getibmsockopt() returns 0 in optval if the socket is in blocking mode, and returns 1 in optval if the socket is in nonblocking mode.

For SO_IGNOREINCOMINGPUSH, optval should point to an integer. getibmsockopt() returns 0 in optval if the option is not set, and returns 1 in optval if the option is set.

Returned Value
If successful, getibmsockopt() returns 0.

If unsuccessful, getibmsockopt() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The s parameter is not a valid socket descriptor (outside the range of descriptors as specified with maxdesc() ).</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using optval and optlen parameters would result in an attempt to access storage outside the caller's address space.</td>
</tr>
</tbody>
</table>
The optname parameter is unrecognized, or the level parameter is not SOL_SOCKET.

Example

The following is an example of the getibmsockopt() call.

```c
#include <stdio.h>
#include <sys/socket.h>

{ struct ibm_bulkmode_struct bulkstr;
  int optlen, rc, s;
  FILE *stream;

  /* Create, bind, etc done for socket s */
  .
  .
  .
  optlen = sizeof(bulkstr);    
  rc = getibmsockopt(s, SOL_SOCKET, SO_BULKMODE, (char *) &bulkstr, &optlen);
  if (rc < 0)
  { tcperror("on getibmsockopt()");
    exit(-1);   
  }
  fprintf(stream,"%d byte buffer available for outbound queue.\n",
          bulkstr.b_max_send_queue_size_avail);
}
```

__getipc() — Query Interprocess Communications

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _XOPEN_SOURCE
#include <sys/__getipc.h>

int __getipc(int token_id, IPCQPROC *bufptr, size_t buflen, int cmd);
```

General Description

The __getipc() function provides means for obtaining information about the status of interprocess communications (IPC) resources, message queues, semaphores, shared memory, and map service memory.

The argument `token_id` is a number that identifies the relative position of an IPC member in the system or specifies a message queue ID, semaphore ID, or shared memory ID. Zero represents the first IPC member ID in the system. On the first call to __getipc(), pass the a `token_id` of zero; the function will return the token that identifies the next IPC resource to which the caller has access. Use this token on the next call to __getipc().

The argument `bufptr` is the address where the data is to be stored.

The argument `buflen` is the length of the buffer.

The argument `cmd` specifies one of the following commands:

- IPCQALL: Retrieve the next shared memory, semaphore, or message queue
- IPCQMSG: Retrieve the next message member
- IPCQSEM: Retrieve the next semaphore member
- IPCQSHM: Retrieve the next shared memory member
- IPCQMAP: Retrieve the next map service memory currently allocated
- IPCQOVER: Overview of system variables. Ignores the value of the first argument `token_id`.

Returned Value

If successful, __getipc() returns 0.

If unsuccessful, __getipc() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Operation permission (read) is denied to the calling process for the member ID specified by <code>token_id</code>.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>The argument <code>bufptr</code> contains an non-valid address.</td>
</tr>
</tbody>
</table>
EINVAL The member ID specified in the argument `token_id` is not valid for the command specified, or the argument `cmd` is not a valid command.

getipv4sourcefilter — Get source filter

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3678</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>

int getipv4sourcefilter(int s, struct in_addr interface, struct in_addr group,
                          uint32_t *fmode, uint32_t *numsrc, struct in_addr *slist);
```

General Description

This function allows applications to get a previously set multicast filtering state for a tuple consisting of socket, interface, and multicast group values.

A multicast filter is described by a filter mode, which is MCAST_INCLUDE or MCAST_EXCLUDE, and a list of source addresses which are filtered.

This function is IPv4-specific, must be used only on AF_INET sockets with an open socket of type SOCK_DGRAM or SOCK_RAW.

If the function is unable to obtain the required storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

Argument Description

- **s** Identifies the socket.
- **interface** Holds the local IP address of the interface.
- **group** Holds the IP multicast address of the group.
- **fmode** Points to an integer that will contain the filter mode on a successful return. The value of this field will be either MCAST_INCLUDE or MCAST_EXCLUDE, which are likewise defined in <netinet/in.h>.
- **numsrc** It is a pointer that on input, points to the number of source addresses that will fit in the slist array. On return, points to the total number of sources associated with the filter.
- **slist** Points to buffer into which an array of IP addresses of included or excluded (depending on the filter mode) sources will be written. If numsrc was 0 on input, a NULL pointer may be supplied.

Returned Value

If successful, the function returns 0. Otherwise, it returns -1 and sets errno to one of the following values.

- **errno** Description
getipv4sourcefilter

- **EADDRNOTAVAIL**
  The tuple consisting of socket, interface, and multicast group values does not exist, or the specified interface address is incorrect for this host, or the specified interface address is not multicast capable.

- **EBADF**
  s is not a valid socket descriptor.

- **EINVAL**
  Interface or group is not a valid IPv4 address, or the socket s has already requested multicast setsockopt options.

- **EPROTOTYPE**
  The socket s is not of type SOCK_DGRAM or SOCK_RAW.

getitimer() — Get Value of an Interval Timer

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/time.h>

int getitimer(int which, struct itimerval *value);
```

General Description

getitimer() gets the current value of an (previously set) interval timer. An interval timer is a timer which sends a signal after each repetition (interval) of time.

The `which` argument indicates what kind of time is being controlled. Values for `which` are:

**ITIMER_REAL**  This timer is marking real (clock) time. A SIGALRM signal is generated after each interval of time.

**Note:** alarm() also sets the real interval timer.

**ITIMER_VIRTUAL**  This timer is marking process virtual time. Process virtual time is the amount of time spent while executing in the process, and can be thought of as a CPU timer. A SIGVTALRM signal is generated after each interval of time.

**ITIMER_PROF**  This timer is marking process virtual time plus time spent while the system is running on behalf of the process. A SIGPROF signal is generated after each interval of time.

**Note:** In a multithreaded environment, each of the above timers is specific to a thread of execution for both the generation of the time interval and the measurement of time. For example, an ITIMER_VIRTUAL timer will mark execution time for just the thread, not the entire process.

The `value` argument is a pointer to a structure containing:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>it_interval</td>
<td>timer interval</td>
</tr>
<tr>
<td>it_value</td>
<td>current timer value (time remaining)</td>
</tr>
</tbody>
</table>

Each of these fields is a timeval structure, and contains:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tv_sec</td>
<td>seconds since January 1, 1970 (UTC)</td>
</tr>
<tr>
<td>tv_usec</td>
<td>microseconds</td>
</tr>
</tbody>
</table>

Returned Value

If successful, getitimer() returns 0, and `value` points to the itimerval structure.

If unsuccessful, getitimer() returns −1 and sets errno to one of the following values:
getitimer

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td><em>which</em> is not a valid timer type.</td>
</tr>
</tbody>
</table>

Format

```c
_POSIX_SOURCE
#define _POSIX_SOURCE
#include <unistd.h>
char *getlogin(void);

_XOPEN_SOURCE
#define _XOPEN_SOURCE
#include <unistd.h>
char *getlogin(void);
```

General Description

Finds the name that the login process associated with the current terminal. This string is stored in a static data area and, therefore, may be overwritten with every call to getlogin().

Special Behavior for _POSIX_SOURCE

If called from a batch program, a TSO command, or a shell command, getlogin() returns the MVS user name associated with the program. With z/OS UNIX services, this name is a TSO/E user ID. When _POSIX_SOURCE is defined and _XOPEN_SOURCE is not defined, then getlogin() is the same as __getlogin1().

Special Behavior for XPG4.2

You must have a TTY at file descriptor 0, 1, or 2, and the TTY must be recorded in the /etc/utmpx database. Someone must have logged in using the TTY. Also, the program must be invoked from a shell session, and file descriptors 0, 1, and 2 are not all redirected.

If getlogin() cannot determine the login name, you can call getuid() to get the user ID of the process, and then call getpwuid() to get a login name associated with that user ID. getpwuid() always returns the passwd struct for the same user, even if multiple users have the same UID.

Returned Value

If successful, getlogin() returns a pointer to a string that has the login name for the current terminal.

Special Behavior for _POSIX_SOURCE

Chapter 3. Part 3. Library Functions 799
getlogin

If unsuccessful, getlogin() returns the NULL pointer.

There are no documented errno values.

Special Behavior for XPG4.2

If unsuccessful, getlogin() returns a NULL pointer and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EMFILE</td>
<td>OPEN_MAX file descriptors are currently open in the calling process.</td>
</tr>
<tr>
<td>ENFILE</td>
<td>The maximum allowable number of files is currently open in the system.</td>
</tr>
<tr>
<td>ENXIO</td>
<td>The calling process has no controlling terminal.</td>
</tr>
</tbody>
</table>

Example

CELEBG12
/

This example gets the user login name.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <unistd.h>

main()
{
    char *user;

    if ((__getlogin1()) == NULL)
        perror("__getlogin1() error");
    else printf("__getlogin1() returned %s\n", user);
}

Output
getlogin() returned MEGA

<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <unistd.h>

int getlogin_r(char *name, size_t namesize);
```

General Description

The `getlogin_r()` function puts the name associated by the login activity with the control terminal of the current process in the character array pointed to by `name`. The array is `namesize` characters long and should have space for the name and the terminating NULL character. The maximum size of the login name is `LOGIN_NAME_MAX`.

If `getlogin_r()` is successful, `name` points to the name the user used at login, even if there are several login names with the same user ID.

Returned Value

If successful, `getlogin_r()` returns 0.

If unsuccessful, `getlogin_r()` sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERANGE</td>
<td>The value of <code>namesize</code> is smaller than the length of the string to be returned including the terminating NULL character.</td>

<td></td>
</tr>
</tbody>
</table>

Format

```c
_POSIX_SOURCE
#define _POSIX_SOURCE
#include <unistd.h>

char *__getlogin1(void);
```

General Description

Finds the name that the login process associated with the current terminal. If called from batch, __getlogin1() finds the name associated with the batch program. With z/OS UNIX services, this name is a TSO/E user ID unless the USERIDALISTABLE is in use. If the USERIDALISTABLE is setup and a UNIX alias name exists for a given MVS(TSO, batch user, etc.) userid, then that will be returned.

If __getlogin1() cannot determine the login name, you can call getuid() to get the user ID of the process, and then call getpwuid() to get a login name associated with that user ID. getpwuid() always returns the passwd struct for the same user, even if multiple users have the same UID.

Returned Value

If successful, __getlogin1() returns a pointer to a string that has the login name for the current terminal.

If unsuccessful, __getlogin1() returns the NULL pointer.

There are no documented errno values.

getmccoll

getmccoll() — Get Next Collating Element from String

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <collate.h>

collel_t getmccoll(char **src);
```

General Description

If the object pointed to by `src` is not a NULL pointer, the getmccoll() library function determines the longest sequence of bytes in the array pointed to by `src` that constitute a valid multicharacter collating element. It then produces the value of type `collel_t` corresponding to that collating element. The object pointed to by `src` is assigned the address just past the last byte of the multicharacter collating element processed.

Returned Value

If successful, getmccoll() returns the value of type `collel_t` that represents the collating element found.

If the object pointed to by `src` is a NULL pointer, or if it points to NULL character, getmccoll() returns 0.

getmsg(), getpmsg() — Receive Next Message from a STREAMS File

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int getmsg(int fildes, struct strbuf *ctlptr, 
            struct strbuf *dataptr, int *flagsp);
int getpmsg(int fildes, struct strbuf *ctlptr, 
            struct strbuf *dataptr, int *bandp, int *flagsp);
```

General Description

The getmsg() function retrieves the contents of a message located at the head of the STREAM head read queue associated with a STREAMS file and places the contents into one or more buffers. The message contains either a data part, a control part, or both. The data and control parts of the message are placed into separate buffers, as described below. The semantics of each part is defined by the originator of the message.

The getpmsg() function does the same thing as getmsg(), but provides finer control over the priority of the messages received. Except where noted, all requirements on getmsg() also pertain to getpmsg().

The `fildes` argument specifies a file descriptor referencing a STREAMS-based file.

The `ctlptr` and `dataptr` arguments each point to a `strbuf` structure, in which the `buf` member points to a buffer in which the data or control information is to be placed, and the `maxlen` member indicates the maximum number of bytes this buffer can hold. On return, the `len` member contains the number of bytes of data or control information actually received. The `len` member is set to 0 if there is a zero-length control or data part and `len` is set to -1 if no data or control information is present in the message.

When getmsg() is called, `flagsp` should point to an integer that indicates the type of message the process is able to receive. This is described further below.

The `ctlptr` argument is used to hold the control part of the message, and `dataptr` is used to hold the data part of the message. If `ctlptr` (or `dataptr`) is a NULL pointer or the `maxlen` member is -1, the control (or data) part of the message is not processed and is left on the STREAM head read queue. If the `ctlptr` (or `dataptr`) is not a NULL pointer, `len` is set to -1. If the `maxlen` member is set to 0 and there is a zero-length control (or data) part, that zero-length part is removed from the read queue and `len` is set to 0. If the `maxlen` member is set to 0 and there are more than 0 bytes of control (or data) information, that information is left on the read queue and `len` is set to 0. If the `maxlen` member in `ctlptr` (or `dataptr`) is less than the control (or data) part of the message, `maxlen` bytes are retrieved. In this case, the remainder of the message is left on the STREAM head read queue and a nonzero return value is provided.
By default, getmsg() processes the first available message on the STREAM head read queue. However, a process may choose to retrieve only high-priority messages by setting the integer pointed to by `flagsp` to `RS_HIPRI`. In this case, getmsg() and getpmsg() will only process the next message if it is a high-priority message. When the integer pointed to by `flagsp` is 0, any message will be retrieved. In this case, on return, the integer pointed to by `flagsp` will be set to `RS_HIPRI` if a high-priority message was retrieved, or 0 otherwise.

For getpmsg(), the flags are different. The `flagsp` argument points to a bitmask with the following mutually-exclusive flags defined: `MSG_HIPRI`, `MSG_BAND`, and `MSG_ANY`. Like getmsg(), getpmsg() processes the first available message on the STREAM head read queue. A process may choose to retrieve only high-priority messages by setting the integer pointed to by `flagsp` to `MSG_HIPRI` and the integer pointed to by `bandp` to 0. In this case, getpmsg() will only process the next message if it is a high-priority message. In a similar manner, a process may choose to retrieve a message from a particular priority band by setting the integer pointed to by `flagsp` to `MSG_BAND` and the integer pointed to by `bandp` to the priority band of interest. In this case, getpmsg() will only process the next message if it is in a priority band equal to, or greater than, the integer pointed to by `bandp`, or if it is a high-priority message. If a process just wants to get the first message off the queue, the integer pointed to by `flagsp` should be set to `MSG_ANY` and the integer pointed to by `bandp` should be set to 0. On return, if the message retrieved was a high-priority message, the integer pointed to by `flagsp` will be set to `MSG_HIPRI` and the integer pointed to by `bandp` will be set to 0. Otherwise, the integer pointed to by `flagsp` will be set to `MSG_BAND` and the integer pointed to by `bandp` will be set to the priority band of the message.

If `O_NONBLOCK` is not set, getmsg() and getpmsg() will block until a message of the type specified by `flagsp` is available at the front of the STREAM head read queue. If `O_NONBLOCK` is set and a message of the specified type is not present at the front of the read queue, getmsg() and getpmsg() fail and set `errno` to `EAGAIN`.

If a hang-up occurs on the STREAM from which messages are to be retrieved, getmsg() and getpmsg() continue to operate normally, as described above, until the STREAM head read queue is empty. Thereafter, they return 0 in the `len` members of `ctlptr` and `dataptr`.

The following symbolic constants are defined under `_XOPEN_SOURCE_EXTENDED 1` in `<stropts.h>`.

- **MSG_ANY**: Receive any message.
- **MSG_BAND**: Receive message from specified band.
- **MSG_HIPRI**: Send/Receive high priority message.
- **MORECTL**: More control information is left in message.
- **MOREDATA**: More data is left in message.

### Returned Value

If successful, getmsg() and getpmsg() return a nonnegative value. A value of 0 indicates that a full message was read successfully. A return value of MORECTL indicates that more control information is waiting for retrieval. A return value of MOREDATA indicates that more data is waiting for retrieval. A return value of the bitwise logical OR of MORECTL and MOREDATA indicates that both types of information remain. Subsequent getmsg() and getpmsg() calls retrieve the remainder of the message. However, if a message of higher priority has come in on the STREAM head read queue, the next call to getmsg() or getpmsg() retrieves that higher-priority message before retrieving the remainder of the previous message.
If unsuccessful, getmsg() and getpmsg() return -1 and set errno to one of the following values.

**Note:** z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for getmsg() and getpmsg() to get a message from a STREAMS file. It will always return -1 with errno set to indicate the failure. See “open() — Open a File” on page 1313 for more information.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The _O_NONBLOCK flag is set and no messages are available.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The <em>fildes</em> argument is not a valid file descriptor open for reading.</td>
</tr>
<tr>
<td>EBADMSG</td>
<td>The queued message to be read is not valid for getmsg() or getpmsg() or a pending file descriptor is at the STREAM head.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal was caught during getmsg() or getpmsg()</td>
</tr>
<tr>
<td>EINVAL</td>
<td>An illegal value was specified by <em>flagsp</em>, or the STREAM or multiplexer referenced by <em>fildes</em> is linked (directly or indirectly) downstream from a multiplexer.</td>
</tr>
<tr>
<td>ENOSTR</td>
<td>A STREAM is not associated with <em>fildes</em>.</td>
</tr>
</tbody>
</table>

In addition, getmsg() and getpmsg() will fail if the STREAM head had processed an asynchronous error before the call. In this case, the value of errno does not reflect the result of getmsg() or getpmsg() but reflects the prior error.

```c
#define _OPEN_SYS_SOCK_IPV6
#include <sys/socket.h>
#include <netdb.h>

int getnameinfo(const struct sockaddr *sa, socklen_t salen,
                 char *host, socklen_t hostlen,
                 char *serv, socklen_t servlen,
                 int flags);
```

```c
#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>
#include <netdb.h>

int getnameinfo(const struct sockaddr *__restrict__ sa, socklen_t salen,
                 char *__restrict__ host, socklen_t hostlen, char *__restrict__ serv,
                 socklen_t servlen, int flags);
```

General Description

The getnameinfo() function translates a socket address to a node name and service location. The getnameinfo() function looks up an IP address and port number provided by the caller in the DNS and system-specific database, and returns text strings for both in buffers provided by the caller.

The `sa` argument points to either a `sockaddr_in` structure (for IPv4) or a `sockaddr_in6` structure (for IPv6) that holds the IP address and port number. The `sockaddr_in6` structure may also contain a zone index value, if the IPv6 address represented by this `sockaddr_in6` structure is a link-local address. The `salen` argument gives the length of the `sockaddr_in` or `sockaddr_in6` structure.

If the socket address structure contains an IPv4-mapped IPv6 address or an IPv4-compatible IPv6 address, the embedded IPv4 address is extracted and the the lookup is performed on the IPv4 address.

**Note:** The IPv6 unspecified address ("::") and the IPv6 loopback address ("::1") are not IPv4-compatible addresses. If the address is the IPv6 unspecified address, a lookup is not performed, and the EAI_NONAME error code is returned.

The node name associated with the IP address is returned in the buffer pointed to by the `host` argument. The caller provides the size of this buffer in the `hostlen` argument. The caller specifies not to return the node name by specifying a zero value for `hostlen` or a null `host` argument. If the node's name cannot be located, the numeric form of the node's address is returned instead of its name. If a zone index value was present in the `sockaddr_in6` structure, the numeric form of the zone index, or the interface name associated with the zone index, is appended to the node name returned, using the format node name%scope information.
If the size of the buffer specified in the `hostlen` argument is insufficient to contain
the entire node name, or node name and scope information combination, up to
`hostlen` characters will be copied into the buffer as a null terminated string.

The service name associated with the port number is returned in the buffer pointed
to by the `serv` argument, and the `servlen` argument gives the length of this buffer.
The caller specifies not to the service name by specifying a zero value for `servlen`
or a null `serv` argument. If the service’s name cannot be located, the numeric of the
service address (for example, its port number) will be returned instead of its name.

If the size of the buffer specified in the `servlen` argument is insufficient to contain
the entire service name, up to `servlen` characters will be copied into the buffer as a
null terminated string.

The final argument, `flags`, is a flag that changes the default actions of this function.
By default the fully-qualified domain name (FQDN) for the host is returned.

If the flag bit `NI_NOFQDN` is set, only the node name portion of the FQDN is
returned for local hosts.

If the flag bit `NI_NUMERICHOST` is set, the numeric form of the host’s address is
returned instead of its name.

If the flag bit `NI_NAMEREQD` is set, an error is returned if the host’s name cannot
be located.

If the flag bit `NI_NUMERICSERV` is set, the numeric form of the service address is
returned (for example, its port number) instead of its name.

If the flag bit `NI_NUMERICSCOPE` is set, the numeric form of the scope identifier is
returned (for example, zone index) instead of its name. This flag is ignored if the `sa`
argument is not an IPv6 address.

If the flag bit `NI_DGRAM` is set, this specifies that the service is a datagram
service, and causes `getservbyport()` to be called with a second argument of "udp"
instead of its default of "tcp". This flag is required for the few ports (for example,
[512,514]) that have different services for UDP and TCP.

**Note:** The three `NI_NUMERICxxx` flags are required to support the "-n" flag that
many commands provide.

**Special Behavior for SUSv3:**

Starting with z/OS V1.9, environment variable `_EDC_SUSV3` can be used to control
the behavior of `getnameinfo()` with respect to detecting if the buffer pointed to by
the host or serv argument is too small to contain the entire resolved name. The
function will fail and return `EAI_OVERFLOW`. By default, `getnameinfo()` will truncate
the values pointed to by host or serv and return successfully. When `_EDC_SUSV3`
is set to 1, `getnameinfo()` will check for insufficient size buffers to contain the
resolved name.

**Returned Value**

Upon successful completion, `getnameinfo()` returns the node and service names, if
requested, in the buffers provided. The returned names are always null-terminated
strings.
A zero return value for `getnameinfo()` indicates successful completion; a non-zero return value indicates failure. The possible values for the failures are listed as follows.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAI_AGAIN</td>
<td>The specified host address could not be resolved within the configured time interval, or the resolver address space has not been started. The request can be retried later.</td>

Format

XPG4.2

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct netent *getnetbyaddr(ip_addr_t net, int type);
```

SUSV3

```c
#define _POSIX_C_SOURCE 200112L
#include <netdb.h>

struct netent *getnetbyaddr(uint32_t net, int type);
```

Berkeley Sockets

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <netdb.h>

struct netent *getnetbyaddr(unsigned long net, int type);
```

General Description

The getnetbyaddr() call searches the tcpip.HOSTS.ADDRINFO data set for the specified network address.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>net</td>
<td>The network address.</td>
</tr>
<tr>
<td>type</td>
<td>The address domain supported (AF_INET).</td>
</tr>
</tbody>
</table>

If the name server is not present or the RESOLVE_VIA_LOOKUP option is in effect, you can use the X_ADDR environment variable to specify a data set other than tcpip.HOSTS.ADDRINFO.

Note: For more information on these data sets and environment variables, tcpip.HOSTS.LOCAL, tcpip.HOSTS.ADDRINFO, and tcpip.HOSTS.SITEINFO, see [z/OS Communications Server: IP Configuration Guide, SC31-8775](https://www.ibm.com/support/docview.wss?uid=swg27033422).

getnetbyaddr(), getnetbyname(), and getnetent() all use the same static area to return the netent structure. This static area is only valid until the next one of these functions is called on the same thread.

The netent structure is defined in the `netdb.h` include file and contains the following elements:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n_addrtype</td>
<td>The type of network address returned. The call always sets this value to AF_INET.</td>
</tr>
</tbody>
</table>
getnetbyaddr

n_aliases An array, terminated with a NULL pointer, of alternative names for the network.

n_name The official name of the network.

n_net The network number, returned in host byte order.

Special Behavior for C++

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned Value

If successful, getnetbyaddr() returns a pointer to a netent structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, getnetbyaddr() returns a NULL pointer, indicating an error or End Of File (EOF).

</table>

Format

**X/Open**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct netent *getnetbyname(const char *name);
```

**Berkeley Sockets**

```c
#define _OE_SOCKETS
#include <netdb.h>

struct netent *getnetbyname(name);
```

General Description

The getnetbyname() call searches the `tcpip.HOSTS.SITEINFO` data set for the specified network name.

**Parameter** | **Description**
--- | ---
name | The pointer to a network name.

You can use the `X_SITE` environment variable to specify a data set other than `tcpip.HOSTS.SITEINFO`.

**Note:** For more information on these data sets and environment variables, `tcpip.HOSTS.LOCAL`, `tcpip.HOSTS.SITEINFO`, and `tcpip.HOSTS.SITEINFO`, see [z/OS Communications Server: IP Configuration Guide, SC31-8775](#).

The getnetbyname() call returns a pointer to a `netent` structure for the network name specified on the call. `getnetbyaddr()`, `getnetbyname()`, and `getnetent()` all use the same static area to return the `netent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `netent` structure is defined in the `netdb.h` include file and contains the following elements:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n_addrtype</td>
<td>The type of network address returned. The call always sets this value to <code>AF_INET</code>.</td>

#include <netdb.h>

struct netent *getnetent(void);

Berkeley Sockets
#define _OE_SOCKETS
#include <netdb.h>

struct netent *getnetent(void);

General Description

The getnetent() call reads the next entry of the tcpip.HOSTS.ADDRINFO data set.

You can use the X_ADDR environment variable to specify a data set other than tcpip.HOSTS.ADDRINFO.

Note: For more information on these data sets and environment variables, tcpip.HOSTS.LOCAL, tcpip.HOSTS.ADDRINFO, and tcpip.HOSTS.SITEINFO, see z/OS Communications Server: IP Configuration Guide, SC31-8775.

The getnetent() call returns a pointer to the next entry in the tcpip.HOSTS.SITEINFO data set.

getnetbyaddr(), getnetbyname(), and getnetent() all use the same static area to return the netent structure. This static area is only valid until the next one of these functions is called on the same thread.

The netent structure is defined in the netdb.h include file and contains the following elements:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n_addrtype</td>
<td>The type of network address returned. The call always sets this value to AF_INET.</td>

</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdio.h>
int getopt(int argc, char *const argv[], const char *optstring);

extern char *optarg;
extern int optind, opterr, optopt;
```

```c
#define _XOPEN_SOURCE 600
#include <unistd.h>
int getopt(int argc, char *const argv[], const char *optstring);

extern char *optarg;
extern int optind, opterr, optopt;
```

General Description

The getopt() function is a command-line parser that can be used by applications that follow Utility Syntax Guidelines 3, 4, 5, 6, 7, 9 and 10 in X/Open CAE Specification, System Interface Definitions, Issue 4, Version 2 Section 10.2, Utility Syntax Guidelines. The getopt() function provides the identical functionality described in the X/Open CAE Specification System Interfaces and Headers, Issue 4, Version 2 for the getopt() function with the following extensions:

- If the external variable optind is set to zero, the getopt() function treats this as an indication to restart the scan at the first byte of argv[1].

If getopt() encounters an option character that is not contained in optstring, it returns the question-mark (?) character. If it detects a missing option-argument, it returns the colon character (:) if the first character of optstring was a colon, or a question-mark character (?) otherwise. In either case, getopt() sets the variable optopt to the option character that caused the error. If the application has not set the variable opterr to 0 and the first character of optstring is not a colon, getopt() also prints a diagnostic message to stderr in the format specified for the getopts utility.

Because the getopt() function returns thread-specific data the getopt() function can be used safely from a multithreaded application.

Returned Value

If successful, getopt() returns the value of the next option character from argv that matches a character in optstring.

A colon (:) is returned if getopt() detects a missing argument and the first character of optstring was a colon (:).
getopt

A question-mark (?) is returned if getopt() encounters an option character not in optstring or detects a missing argument and the first character of optstring was not a colon (:).

Otherwise getopt() returns -1 when all command line arguments have been parsed or an unexpected error is encountered in the command line.

getopt() sets the external variables optind, optarg and optopt as described in the X/Open CAE Specification System Interfaces and Headers, Issue 4, Version 2 for the getopt() function.

The following functions defined in <stdio.h> should be used by multithreaded applications when attempting to reference or change the optind, optopt, optarg and opterr external variables:

```c
int *__opindf(void);
int *__opoptf(void);
char **__opargf(void);
int *__operrf(void);
```

Also use these functions when you invoke getopt() in a DLL. These functions return a pointer to a thread-specific value for each variable.

getopt() does not return any errno values.

If getopt() detects a missing argument or an option character not in optstring it will write an error message to stderr describing the option character in error and the invoking program.

getpagesize() — Get the Current Page Size

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int getpagesize(void);
```

General Description

The `getpagesize()` function returns the current page size. The `getpagesize()` function is equivalent to `sysconf(_SC_PAGE_SIZE)` and `sysconf(_SC_PAGESIZE)`.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `sysconf(_SC_PAGESIZE)` instead of `getpagesize()`.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned Value

`getpagesize()` returns the current page size.

Related Information

- [“unistd.h” on page 96](#)
- [“sysconf() — Determine System Configuration Options” on page 2111](#)
getpass

getpass() — Read a String of Characters Without Echo

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <unistd.h>

char *getpass(const char *prompt);
```

General Description

The getpass() function opens the process’s controlling terminal, writes to that device the NULL-terminated string `prompt`, disables echoing, reads a string of characters up to the next newline character or EOF, restores the terminal state and closes the terminal.

getpass() only works in an environment where either a controlling terminal exists, or stdin and stderr refer to tty devices. Specifically, it does not work in a TSO environment.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro __UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned Value

If successful, getpass() returns a pointer to a NULL-terminated string of at most PASS_MAX bytes that were read from the terminal device.

If unsuccessful, getpass() returns a NULL pointer and the terminal state is restored.

Related Information

- "unistd.h" on page 96
getpeername() — Get the Name of the Peer Connected to a Socket

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int getpeername(int socket, struct sockaddr *__restrict__ name, socklen_t *__restrict__ namelen);
```

Berkeley Sockets

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int getpeername(int socket, struct sockaddr *name, int *namelen);
```

General Description

The getpeername() call returns the name of the peer connected to socket descriptor `socket`. `namelen` must be initialized to indicate the size of the space pointed to by `name` and is set to the number of bytes copied into the space before the call returns. The size of the peer name is returned in bytes. If the actual length of the address is greater than the length of the supplied `sockaddr`, the stored address is truncated. The `sa_len` member of the store structure contains the length of the untruncated address.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>socket</code></td>
<td>The socket descriptor.</td>
</tr>
<tr>
<td><code>name</code></td>
<td>The Internet address of the connected socket that is filled by getpeername() before it returns. The exact format of <code>name</code> is determined by the domain in which communication occurs.</td>
</tr>
<tr>
<td><code>namelen</code></td>
<td>Must initially point to an integer that contains the size in bytes of the storage pointed to by <code>name</code>. On return, that integer contains the size required to represent the address of the connecting socket. If this value is larger than the size supplied on input, then the information contained in sockaddr is truncated to the length supplied on input. If <code>name</code> is NULL, <code>namelen</code> is ignored.</td>
</tr>
</tbody>
</table>

Sockets in the AF_INET6 Domain

For an AF_INET6 socket, the address is returned in a sockaddr_in6 address structure. The sockaddr_in6 structure is defined in the header file `netinet/in.h`.

Special Behavior for C++
getpeername

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

**Note:** The getpeername() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII Support” on page 2495 for details.

**Returned Value**

If successful, getpeername() returns 0.

If unsuccessful, getpeername() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The socket parameter is not a valid socket descriptor.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using the name and namelen parameters as specified would result in an attempt to access storage outside of the caller’s address space.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The namelen parameter is not a valid length. The socket has been shut down.</td>
</tr>
<tr>
<td>ENOBUFS</td>
<td>getpeername() is unable to process the request due to insufficient storage.</td>
</tr>
<tr>
<td>ENOTCONN</td>
<td>The socket is not in the connected state.</td>
</tr>
<tr>
<td>ENOTSOCK</td>
<td>The descriptor is for a file, not for a socket.</td>
</tr>
<tr>
<td>EOPTNOTSUPP</td>
<td>The operation is not supported for the socket protocol.</td>
</tr>
</tbody>
</table>

getpgid() — Get Process Group ID

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

pid_t getpgid(pid_t pid);
```

General Description

The getpgid() function returns the process group ID of the process whose process ID is equal to `pid`. If `pid` is 0, getpgid() returns the PID of the calling process.

Returned Value

If successful, getpgid() returns a process group ID.

If unsuccessful, getpgid() returns (pid_t)-1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPERM</td>
<td>The process whose process ID is equal to <code>pid</code> is not the same session as the calling process, and the implementation does not allow to the process group ID of that process from the calling process.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>There is no process with a process ID equal to <code>pid</code>.</td>
</tr>
</tbody>
</table>

getpgid() may fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of the <code>pid</code> argument is not valid.</td>
</tr>
</tbody>
</table>

</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

pid_t getpgrp(void);
```

General Description

Finds the process group ID of the calling process.

Returned Value

Returns the found value. It is always successful.

There are no documented errno values.

Example

```c
CELEBG13
/* CELEBG13 */

This example gets all the process group IDs.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <sys/wait.h>

main()
{
    int status;

    if (fork() == 0) {
        if (fork() == 0) {
            printf("grandchild's pid is %d, process group id is %d\n",
                    (int) getpid(), (int) getpgrp());
            exit(0);
        }
        printf("child's pid is %d, process group id is %d\n",
                (int) getpid(), (int) getpgrp());
        wait(&status);
        exit(0);
    }
    printf("parent's pid is %d, process group id is %d\n",
            (int) getpid(), (int) getpgrp());
    printf("the parent's parent's pid is %d\n", (int) getppid());
    wait(&status);
}
```

Output
parent's pid is 5373959, process group id is 5111816
the parent's parent's pid is 5111816
child's pid is 5832710, process group id is 5111816
grandchild's pid is 196617, process group id is 5111816

There are no documented errno values.

Example

```
CELEBG15
/* CELEBG15 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <signal.h>
#include <unistd.h>
#include <sys/wait.h>
/*FIX: used to be <wait.h>*

volatile short footprint=0;

void catcher(int signum) {
  switch (signum) {
    case SIGALRM: puts("caught SIGALRM");
      break;
    case SIGUSR2: puts("caught SIGUSR2");
      break;
    default: printf("caught unexpected signal %d\n", signum);
  }
  footprint++;
}

main() {
  struct sigaction sact;
  int status;

  sigemptyset(&sact.sa_mask);
  sact.sa_flags = 0;
  sact.sa_handler = catcher;
  sigaction(SIGUSR2, &sact, NULL);
  sigemptyset(&sact.sa_mask);
  sact.sa_flags = 0;
```
getppid

sact.sa_handler = catcher;

sigaction(SIGALRM, &sact, NULL);

printf("parent (pid %d) is about to fork child\n", (int) getpid());

if (fork() == 0) {
    printf("child is sending SIGUSR2 to pid %d\n", (int) getppid());
    kill(getppid(), SIGUSR2);
    exit(0);
}

alarm(30);
while (footprint == 0);
wait(&status);
puts("parent is exiting");

Output

parent (pid 6094854) is about to fork child
child is sending SIGUSR2 to pid 6094854
caught SIGUSR2
parent is exiting

getpriority() — Get Process Scheduling Priority

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int getpriority(int which, id_t who);
```

General Description

getpriority() obtains the current priority of a process, process group or user.

Processes are specified by the values of the `which` and `who` arguments. The `which` argument may be any one of the following set of symbols defined in the `sys/resource.h` include file:

- `PRIO_PROCESS`: indicates that the `who` argument is to be interpreted as a process ID
- `PRIO_PGRP`: indicates that the `who` argument is to be interpreted as a process group ID
- `PRIO_USER`: indicates that the `who` argument is to be interpreted as a user ID

The `who` argument specifies the ID (process, process group, or user). A 0 (zero) value for the `who` argument specifies the current process, process group or user ID.

Returned Value

If successful, `getpriority()` returns the priority of the process, process group, or used ID requested in `who`. The priority is returned as an integer in the range -20 to 19 (the lower the numerical value, the higher the priority).

If more than one process is specified, `getpriority()` returns the highest priority pertaining to any of the specified processes.

If unsuccessful, `getpriority()` returns –1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The symbol specified in the <code>which</code> argument was not recognized, or the value of the <code>who</code> argument is not a valid process ID, process group ID or user ID.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>No process could be located using the <code>which</code> and <code>who</code> argument values specified.</td>
</tr>
</tbody>
</table>
getpriority

Because getpriority() can return the value -1 on successful completion, it is necessary to set the external variable errno to 0 before a call to getpriority(). If getpriority() returns -1, then errno can be checked to see if an error occurred or if the value is a legitimate priority.

Format

**X/Open**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct protoent *getprotobynumber(const char *name);
```

**Berkeley Sockets**

```c
#define _OE_SOCKETS
#include <netdb.h>

struct protoent *getprotobynumber(char name);
```

General Description

The getprotobynumber() call searches the `/etc/protocol` or `tcpip.ETC.PROTO` data set for the specified protocol name.

**Parameter Description**

- **name**: The name of the protocol.

The getprotobynumber() call returns a pointer to a `protoent` structure for the network protocol specified on the call. `getprotobynumber()`, `getprotobynumber()`, and `getprotoent()` all use the same static area to return the `protoent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `protoent` structure is defined in the `netdb.h` include file and contains the following elements:

- **p_aliases**: An array, terminated with a NULL pointer, of alternative names for the protocol.
- **p_name**: The official name of the protocol.
- **p_proto**: The protocol number.

**Special Behavior for C++**

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned Value

If successful, getprotobynumber() returns a pointer to a `protoent` structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.
getprotobyname

If unsuccessful, getprotobyname() returns a NULL pointer, indicating an error or End Of File (EOF).

struct protoent *getprotoent(void);
```

**Berkeley Sockets**

```c
#define _OE_SOCKETS
#include <netdb.h>

struct protoent *getprotoent(void);
```

General Description

The getprotoent() call reads `/etc/protocol` or the `tcpip.ETC.PROTO` data set.

The getprotoent()> call returns a pointer to the next entry in the `/etc/protocol` or the `tcpip.ETC.PROTO` data set.

getprotobyname(), getprotobynumber(), and getprotoent() all use the same static area to return the `protoent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `protoent` structure is defined in the `netdb.h` include file and contains the following elements:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_aliases</code></td>
<td>An array, terminated with a NULL pointer, of alternative names for the protocol.</td>

</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <pwd.h>

struct passwd *getpwnam(const char *name);
```

General Description

Accesses the passwd structure (defined in the pwd.h header file), which contains the following members:

- `pw_name`: User name
- `pw_uid`: User ID (UID) number
- `pw_gid`: Group ID (GID) number
- `pw_dir`: Initial working directory
- `pw_shell`: Initial user program

Returned Value

If successful, getpwnam() returns a pointer to a passwd structure containing an entry from the user database with the specified *name*. Return values may point to the static data that is overwritten on each call.

If unsuccessful, getpwnam() returns a NULL pointer and sets *errno* to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>A non-valid user <em>name</em> is detected.</td>
</tr>
</tbody>
</table>

Example

```c
CELEBG16

/* CELEBG16

   This example provides information for the user data base, MEGA.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <pwd.h>

main()
{
    struct passwd *p;
    char user[]="MEGA";

    if ((p = getpwnam(user)) == NULL)
        perror("getpwnam() error");
    else {
```
printf("getpwnam() returned the following info for user \%s: \n", user);
printf(" pw_name : \%s\n", p->pw_name);
printf(" pw_uid : \%d\n", (int) p->pw_uid);
printf(" pw_gid : \%d\n", (int) p->pw_gid);
printf(" pw_dir : \%s\n", p->pw_dir);
printf(" pw_shell : \%s\n", p->pw_shell);
"
};

Output
pw_name : MEGA
pw_uid : 0
pw_gid : 512
pw_dir : /u/mega
pw_shell : /bin/sh

getpwnam_r() — Search User Database for a Name

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <pwd.h>

int getpwnam_r(const char *nam, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result);
```

General Description

The getpwnam_r() function updates the passwd structure pointed to by `pwd` and stores a pointer to that structure at the location pointed to by `result`. The structure will contain an entry from the user database with a matching name. Storage referenced by the structure is allocated from the memory provided with the `buffer` parameter, which is `bufsize` characters in size. A NULL pointer is returned at the location pointed to by `result` on error or if the requested entry is not found.

Returned Value

If successful, getpwnam_r() returns 0.

If unsuccessful, getpwnam_r() sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERANGE</td>
<td>Insufficient storage was supplied in <code>buffer</code> and <code>bufsize</code> to contain the data to be referenced by the resulting <code>passwd</code> structure.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <pwd.h>

struct passwd *getpwuid(uid_t uid);
```

General Description

Gets information about a user with the specified `uid`. `getpwuid()` returns a pointer to a `passwd` structure containing an entry from the user database for the specified `uid`. This structure (defined in the `pwd.h` header file), contains the following members:

- `pw_name`  User name
- `pw_uid`   User ID (UID) number
- `pw_gid`   Group ID (GID) number
- `pw_dir`   Initial working directory
- `pw_shell` Initial user program

Return values may point to the static data that is overwritten on each call.

Returned Value

If successful, `getpwuid()` returns a pointer.

If unsuccessful, `getpwuid()` returns a NULL pointer.

There are no documented `errno` values.

Example

```c
CELEBG17
/* CELEBG17

   This example provides information for user ID 0.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <pwd.h>

main() {  
  struct passwd *p;
  uid_t  uid=0;

  if ((p = getpwuid(uid)) == NULL)  
    perror("getpwuid() error");
  else {  
    printf("getpwuid() returned the following info for uid %d: 
           (int) uid);
    printf(" pw_name : %s\n", p->pw_name);
```
getpwuid

    printf("  pw_uid  : %d
", (int) p->pw_uid);
    printf("  pw_gid  : %d
", (int) p->pw_gid);
    printf("  pw_dir  : %s
",    p->pw_dir);
    printf("  pw_shell: %s
",   p->pw_shell);
  }
}

Output

getpwuid() returned the following info for uid 0:
  pw_name  : MEGA
  pw_uid  : 0
  pw_gid  : 512
  pw_dir  : /u/mega
  pw_shell : /bin/sh

getrlimit

getrlimit() — Get Current/Maximum Resource Consumption.

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int getrlimit(int resource, struct rlimit *rlp);
```

General Description

The getrlimit() function gets resource limits for the calling process. A resource limit is a pair of values; one specifying the current (soft) limit, the other a maximum (hard) limit.

The value `RLIM_INFINITY` defined in `<sys/resource.h>`, is considered to be larger than any other limit value. If a call to getrlimit() returns `RLIM_INFINITY` for a resource, it means the implementation does not enforce limits on that resource.

The `resource` argument specifies which resource to get the hard and/or soft limits for, and may be one of the following values:

**RLIMIT_CORE**

The maximum size of a dump of memory (in bytes) allowed for the process. A value of 0 (zero) prevents file creation. Dump file creation will stop at this limit.

**RLIMIT_CPU**

The maximum amount of CPU time (in seconds) allowed for the process. If the limit is exceeded, a SIGXCPU signal is sent to the process and the process is granted a small CPU time extension to allow for signal generation and delivery. If the extension is used up, the process is terminated with a SIGKILL signal.

**RLIMIT_DATA**

The maximum size of the break value for the process, in bytes. In this implementation, this resource always has a hard and soft limit value of `RLIM_INFINITY`.

**RLIMITFSIZE**

The maximum file size (in bytes) allowed for the process. A value of 0 (zero) prevents file creation. If the size is exceeded, a SIGXFSZ signal is sent to the process. If the process is blocking, catching, or ignoring SIGXFSZ, continued attempts to increase the size of a file beyond the limit will fail with an errno of EFBIG.

**RLIMIT_NOFILE**

The maximum number of open file descriptors allowed for the process. This number is one greater than the maximum value that may be assigned to a newly created descriptor. (That is, it is one-based.) Any function that attempts to create a new file descriptor beyond the limit will fail with an EMFILE errno.

**RLIMIT_STACK**

The maximum size of the stack for a process, in bytes. Note that in
z/OS UNIX services, the stack is a per-thread resource. In this implementation, this resource always has a hard and soft limit value of RLIM_INFINITY. A call to setrlimit() to set this resource to any value other than RLIM_INFINITY will fail with an errno of EINVAL.

**RLIMIT_AS** The maximum address space size for the process, in bytes. If the limit is exceeded, malloc() and mmap() functions will fail with an errno of ENOMEM. Automatic stack growth will also fail.

The *rip* argument points to a *rlimit* structure. This structure contains the following members:

- **rlim_cur** The current (soft) limit
- **rlim_max** The maximum (hard) limit

Refer to the `<sys/resource.h>` header for more detail.

The resource limit values are propagated across exec and fork.

**Special Behavior for z/OS UNIX Services**

An exception exists for exec processing in conjunction with daemon support. If a daemon process invokes exec and it had previously invoked setuid() before exec, the RLIMIT_CPU, RLIMIT_AS, RLIMIT_CORE, RLIMITFSIZE, and RLIMIT_NOFILE limit values are set based on the limit values specified in the kernel parmlib member BPXPRMxx.

For processes which are not the only process within an address space, the RLIMIT_CPU and RLIMIT_AS limits are shared with all the processes within the address space. For RLIMIT_CPU, when the soft limit is exceeded, action will be taken on the first process within the address space. If the action is termination, all processes within the address space will be terminated.

In addition to the RLIMIT_CORE limit values, the dump file defaults are set by SYSMDUMP defaults. Refer to [z/OS MVS Initialization and Tuning Reference](https://www.ibm.com/support/docview.wss?uid=swg27029014) for information on setting up SYSMDUMP defaults using the IEADMR00 parmlib member.

Dumps of memory are taken in 4160 byte increments. Therefore, RLIMIT_CORE values affect the size of memory dumps in 4160 byte increments. For example, if the RLIMIT_CORE soft limit value is 4000, the dump will contain no data. If the RLIMIT_CORE soft limit value is 8000, the maximum size of a memory dump is 4160 bytes.

**Large Files for HFS**

**Note:** Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option LANGLEVEL(LONGLONG) and also define the Feature Test Macro (FTM) _LARGE_FILES before any headers are included will enable this function to operate on memory sizes of 2 gig and larger. File size and offset fields will be enlarged to 63 bits in width so any other function operating on this file will have to be enabled with the same FTM.
getrlimit

Returned Value

If successful, getrlimit() returns 0.

If unsuccessful, getrlimit() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>A non-valid resource was specified.</td>
</tr>
</tbody>
</table>

</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int getrusage(int who, struct rusage *r_usage);
```

General Description

The getrusage() function provides measures of the resources used by the current process or its terminated and waited-for-child processes. If the value of the `who` argument is RUSAGE_SELF, information is returned about resources used by the current process. If the value of the `who` argument is RUSAGE_CHILDREN, information is returned about resources used by the terminated and waited-for-children of the current process. If the child is never waited for (for instance, if the parent has SA_NOCLDWAIT set or sets SIGCHLD to SIG_IGN), the resource information for the child process is discarded and not included in the resource information provided by getrusage()

The `r_usage` argument is a pointer of an object of type struct rusage in which the returned information is stored.

Returned Value

If successful, getrusage() returns 0.

If unsuccessful, getrusage() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of the <code>who</code> argument is not valid.</td>
</tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

char *gets(char *buffer);
```

General Description

Reads bytes from the standard input stream stdin, and stores them in the array pointed to by buffer. The line consists of all characters up to and including the first newline character (\n) or EOF. The gets() function discards any newline character, and the NULL character (\0) is placed immediately after the last byte read. If there is an error, the value stored in buffer is undefined.

gets() is not supported for files opened with type=record.

gets() has the same restriction as any read operation, such as a read immediately following a write, or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

If successful, gets() returns its argument.

If unsuccessful, gets() returns a NULL pointer to indicate an error or an EOF condition with no characters read.

Use ferror() or feof() to determine which of these conditions occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does not turn on the EOF indicator.

Example

```c
CELEBG18
/* CELEBG18

   This example gets a line of input from stdin.

*/
#include <stdio.h>
#define MAX_LINE 100

int main(void)
```

850 z/OS V1R9.0 XL C/C++ Run-Time Library Reference
{  
    char line[MAX_LINE];
    char *result;

    printf("Enter string:\n");
    if ((result = gets(line)) != NULL)
        printf("string is %s\n", result);
    else
        if (ferror(stdin))
            printf("Error\n");
}

Format

X/Open

#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct servent *getservbyname(const char *name, const char *proto);

Berkeley Sockets

#define _OE_SOCKETS
#include <netdb.h>

struct servent *getservbyname(char *name, char *proto);

General Description

The getservbyname() call searches the /etc/services or tcpip.ETC.SERVICES data set for the first entry that matches the specified service name and protocol name. If proto is NULL, only the service name must match.

Parameter Description

name The service name.
proto The protocol name.

The getservbyname() call returns a pointer to a servent structure for the network service specified on the call. getservbyname(), getservbyport(), and getservent() all use the same static area to return the servent structure. This static area is only valid until the next one of these functions is called on the same thread.

The servent structure is defined in the netdb.h include file and contains the following elements:

Element Description

s_aliases An array, terminated with a NULL pointer, of alternative names for the service.
s_name The official name of the service.
s_port The port number of the service.
s_proto The protocol required to contact the service.

Special Behavior for C++

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.
Returned Value

The return value points to data that is overwritten by subsequent calls returning the same data structure.

If successful, getservbyname() returns a pointer to a servent structure.

If unsuccessful or End Of File (EOF), getservbyname() returns a NULL pointer.

</tr>
</tbody>
</table>

Format

#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

pid_t getsid(pid_t pid);

General Description

The getsid() function obtains the process group ID of the process specified by pid. If pid is 0, the system uses the PID of the process calling getsid().

Returned Value

If successful, getsid() returns the process group ID of the session leader of the specified process.

If unsuccessful, getsid() returns (pid_t)-1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPERM</td>
<td>The process specified by pid is not in the same session as the calling process, and the implementation does not allow access to the process group ID of the session leader of that process from the calling process.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>There is no process with a process ID equal to pid.</td>
</tr>
</tbody>
</table>

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int getsockname(int socket, struct sockaddr *__restrict__ name,
                 socklen_t *__restrict__ namelen);
```

Berkeley Sockets

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int getsockname(int socket, struct sockaddr *name,
                 int *namelen);
```

General Description

The getsockname() call stores the current name for the socket specified by the `socket` parameter into the structure pointed to by the `name` parameter. It returns the address to the socket that has been bound. If the socket is not bound to an address, the call returns with the family set, and the rest of the structure set to zero. For example, an unbound socket in the Internet domain would cause the name to point to a `sockaddr_in` structure with the `sin_family` field set to AF_INET and all other fields zeroed.

If the actual length of the address is greater than the length of the supplied `sockaddr`, the stored address is truncated. The `sa_len` member of the store structure contains the length of the untruncated address.

Parameter | Description
---|---
socket | The socket descriptor.
name | The address of the buffer into which getsockname() copies the name of `socket`.
namelen | Must initially point to an integer that contains the size in bytes of the storage pointed to by `name`. On return, that integer contains the size required to represent the address of the connecting socket. If this value is larger than the size supplied on input, then the information contained in `sockaddr` is truncated to the length supplied on input. If `name` is NULL, `namelen` is ignored.

The getsockname() call is often used to discover the port assigned to a socket after the socket has been implicitly bound to a port. For example, an application can call `connect()` without previously calling `bind()`. In this case, the `connect()` call completes the binding necessary by assigning a port to the socket. This assignment can be discovered with a call to `getsockname()`. 
Sockets in the AF_INET6 Domain

For an AF_INET6 socket, the address is returned in a sockaddr_in6 address structure. The sockaddr_in6 structure is defined in the header file netinet/in.h.

Special Behavior for C++

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The getsockname() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII Support " on page 2495 for details.

Returned Value

If successful, getsockname() returns 0.

If unsuccessful, getsockname() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The socket parameter is not a valid socket descriptor.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using the name and namelen parameters as specified would result in an attempt to access storage outside of the caller’s address space.</td>
</tr>

</tbody>
</table>

Format

**X/Open**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int getsockopt(int socket, int level, int option_name, 
void *__restrict__ option_value, 
socklen_t *__restrict__ option_len);
```

**Berkeley Sockets**

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int getsockopt(int socket, int level, int option_name, 
char *option_value, 
int *option_len);
```

General Description

The `getsockopt()` call gets options associated with a socket. Not all options are supported by all address families. See each option for details. Options can exist at multiple protocol levels.

**Parameter** | **Description**
--- | ---
socket | The socket descriptor.
level | The level for which the option is set.
option_name | The name of a specified socket option.
option_value | The pointer to option data.
option_len | The pointer to the length of the option data.

When manipulating socket options, you must specify the level at which the option resides and the name of the option. To manipulate options at the socket or IP level, the `level` parameter must be set to SOL_SOCKET or IPPROTO_IP as defined in `sys/socket.h`. To manipulate options at any other level, such as the TCP level, supply the appropriate protocol number for the protocol controlling the option. The `getprotobyname()` call can be used to return the protocol number for a named protocol.

The `option_value` and `option_len` parameters are used to return data used by the particular get command. The `option_value` parameter points to a buffer that is to receive the data requested by the `get` command. The `option_len` parameter points to the size of the buffer pointed to by the `option_value` parameter. It must be initially set to the size of the buffer before calling `getsockopt()`. On return it is set to the actual size of the data returned.
All the socket level options except SO_LINGER expect option_value to point to an integer and option_len to be set to the size of an integer. When the integer is nonzero, the option is enabled. When it is zero, the option is disabled. The SO_LINGER option expects option_value to point to a linger structure as defined in sys/socket.h. This structure is defined in the following example:

```c
struct linger
    {
    int l_onoff;       /* option on/off */
    int l_linger;      /* linger time */
    };
```

The l_onoff field is set to zero if the SO_LINGER option is being disabled. A nonzero value enables the option. The l_linger field specifies the amount of time to linger on close.

The following options are recognized at the IP level:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_MULTICAST_TTL</td>
<td>Used to get the IP time-to-live of outgoing multicast datagrams. The TTL value is passed back as u_char.</td>
</tr>
<tr>
<td>IP_MULTICAST_LOOP</td>
<td>Used to determine whether loopback is enabled or disabled. The loopback indicator is passed back as u_char. 0 means loopback is disabled and 1 means it is enabled.</td>
</tr>
<tr>
<td>IP_MULTICAST_IF</td>
<td>Used to get the interface IP address used for sending outbound multicast datagrams. The IP address is passed back using struct in_addr.</td>
</tr>
</tbody>
</table>

The following options are recognized at IPv6 level:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPV6_CHECKSUM</td>
<td>Used to determine if checksum processing is enabled for a RAW (non-ICMPv6) socket. The option value returned is the offset into the user data where the checksum is located. It is passed back as int. A value of -1 means the function is disabled.</td>
</tr>
<tr>
<td>IPV6_DONTFRAG</td>
<td>This option turns off the automatic inserting of a fragment header in the packet for UDP and raw sockets.</td>
</tr>
<tr>
<td>IPV6_DSTOPTS</td>
<td>The application can remove any sticky destination options header by calling setsockopt() for this option with a zero option length.</td>
</tr>
<tr>
<td>IPV6_HOPOPTS</td>
<td>The application can remove any sticky hop-by-hop options header by calling setsockopt() for this option with a zero option length.</td>
</tr>
<tr>
<td>IPV6_MULTICAST_HOPS</td>
<td>Returns the hop limit value for outbound multicast datagrams. The hop limit value is passed back as int.</td>
</tr>
</tbody>
</table>
IPV6_MULTICAST_IF
Returns the interface index for the interface used for sending
outbound multicast datagrams. The interface index is passed back
using struct u_int.

IPV6_MULTICAST_LOOP
Used to determine whether loopback of outgoing multicast packets
is enabled or disabled. The loopback indicator is passed back as
u_int. 0 means the function is disabled and 1 means it is enabled.

IPV6_NEXTHOP
Specifies the next hop for the datagram as a socket address
structure.

IPV6_PATHMTU
This is a getsockopt() option only. It is used to retrieve the current
path MTU value for the destination of a connected socket.

IPV6_PKTINFO
Returns the source IP address for an outgoing packet and the
outgoing interface. If a setsockopt() has been done for this option,
the value from the setsockopt() will be returned. It is passed back in
an in6_pktinfo structure as defined in netinet/in.h.

IPV6_RECV DSTOPTS
To receive destination options header this option must be enabled.

IPV6_RECVHOPLIMIT
Indicates whether the function to return the received hop limit as
ancillary data is enabled or disabled. The option value is passed
back as int. 0 means the function is disabled and 1 means it is
enabled.

IPV6_RECVHOPOPTS
To receive a hop-by-hop options header this option must be
enabled.

IPV6_RECVPATHMTU
Enables the receipt of of the IPV6_PATHMTU ancillary data item.

IPV6_RECVPKTINFO
Indicates whether the function is to return the destination IP
address and incoming interface is enabled or disabled. The option
value is passed back as int. 0 means the function is disabled and 1
means it is enabled.

IPV6_RECVRTHDR
To receive a routing header this option must be enabled.

IPV6_RECVTCLASS
To receive the traffic class this option must be enabled.

IPV6_RTHDR
The application can remove any sticky routing header by calling
setsockopt() for this option with a zero option length.

IPV6_RTHDRDSTOPTS
The application can remove any sticky destination options header
by calling setsockopt() for this option with a zero option length.

IPV6_TCLASS
To specify the traffic class value this option must be enabled.
getsockopt

IPV6_UNICAST_HOPS
Returns the hop limit value for outbound unicast datagrams. The hop limit value is passed back as int.

IPV6_USE_MIN_MTU
Indicates whether the IP layer will use the minimum MTU size (1280) for sending packets, bypassing path MTU discovery. The option value is passed back as int. A value of -1 causes the default values for unicast (disabled) and multicast (enabled) destinations to be used. A value of 0 disables this option for unicast and multicast destinations. A value of 1 enables this option for unicast and multicast destinations and the minimum MTU size will be used. If a setsockopt() call has not been made prior to a getsockopt() call, the default value of -1 is returned.

IPV6_V6ONLY Used to determine whether a socket is restricted to IPv6 communications only. The option value is passed back as int. A non-zero value means the option is enabled (socket can only be used for IPv6 communications). 0 means the option is disabled.

The following option is recognized at ICMPv6 level:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP6_FILTER</td>
<td>Used to filter ICMPv6 messages. It returns the filter value being used for this socket. It is passed back in an icmp6_filter structure as defined in netinet/icmp6.h.</td>
</tr>
</tbody>
</table>

The following options are recognized at the socket level:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SO_ACCEPTCONN</td>
<td>The socket had a listen() call.</td>
</tr>
<tr>
<td>SO_BROADCAST</td>
<td>Toggles the ability to broadcast messages. If this option is enabled, it allows the application to send broadcast messages over socket, if the interface specified in the destination supports the broadcasting of packets. This option has no meaning for stream sockets. This option is valid only for the AF_INET domain.</td>
</tr>
<tr>
<td>SO_DEBUG</td>
<td>Reports whether debugging information is being recorded. This option stores an int value.</td>
</tr>
<tr>
<td>SO_ERROR</td>
<td>Returns any pending error on the socket and clears the error status. You can use SO_ERROR to check for asynchronous errors on connected datagram sockets or for other asynchronous errors (errors that are not returned explicitly by one of the socket calls).</td>
</tr>
<tr>
<td>SO_KEEPALIVE</td>
<td>Toggles the TCP keep-alive mechanism for a stream socket. When activated, the keep-alive mechanism periodically sends a packet on an otherwise idle connection. If the remote TCP does not respond to the packet or to retransmissions of the packet, the connection is ended with the error ETIMEDOUT. Processes writing to that socket are notified with a SIGPIPE signal. This option stores an int value. This option is valid only for the AF_INET and AF_INET6 domains.</td>
</tr>
</tbody>
</table>
| SO_LINGER     | Lingers on close if data is present. When this option is enabled and
there is unsent data present when close() is called, the calling application is blocked during the close() call until the data is transmitted or the connection has timed out. If this option is disabled, the TCP/IP address space waits to try to send the data. Although the data transfer is usually successful, it cannot be guaranteed, because the TCP/IP address space waits only a finite amount of time trying to send the data. The close() call returns without blocking the caller. This option has meaning only for stream sockets.

SO_OOBINLINE
Toggles reception of out-of-band data. When this option is enabled, out-of-band data is placed in the normal data input queue as it is received; it is then available to recv(), recvfrom(), and recvmsg() without the need to specify the MSG_OOB flag in those calls. When this option is disabled, out-of-band data is placed in the priority data input queue as it is received; it is then available to recv(), recvfrom(), and recvmsg() only if the MSG_OOB flag is specified in those calls. This option has meaning only for stream sockets.

_SO_PROPAGATEUSERID
Toggles propagating a user ID (UID) over a socket. When enabled, user (UID) information is extracted from the system when the connect() function is invoked and presented over the socket when the accept() function is invoked.

SO_RCVBUF Reports receive buffer size information. This option stores an int value.

SO_REUSEADDR
Toggles local address reuse. When enabled, this option allows local addresses that are already in use to be bound. SO_REUSEADDR alters the normal algorithm used in the bind() call.

The system checks at connect time to ensure that the local address and port do not have the same foreign address and port. The error EADDRINUSE is returned if the association already exists.

After the 'SO_REUSEADDR' option is active, the following situation is supported:

A server can bind() the same port multiple times as long as every invocation uses a different local IP address and the wildcard address INADDR_ANY is used only one time per port.

This option is valid only for the AF_INET and AF_INET6 domains.

SO_SECINFO Toggles receiving security information. When enabled on an AF_UNIX UDP socket, the recvmsg() function will return security information about the sender of each datagram as ancillary data. This information contains the sender's user ID, uid, gid, and jobname and it is mapped by the secsinfo structure in sys/socket.h.

SO_SNDBUF Reports send buffer size information. This option stores an int value.

SO_TYPE This option returns the type of the socket. On return, the integer pointed to by option_value is set to SOCK_STREAM or SOCK_DGRAM. This option is valid for the AF_UNIX, AF_INET and AF_INET6 domains.
getsockopt

Special Behavior for C++

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned Value

If successful, getsockopt() returns 0.

If unsuccessful, getsockopt() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The socket parameter is not a valid socket descriptor.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using option_value and option_len parameters would result in an attempt to access storage outside the caller’s address space.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The specified option is not valid at the specified socket level.</td>
</tr>
<tr>
<td>ENOBUFS</td>
<td>Buffer space is not available to send the message.</td>
</tr>
<tr>
<td>ENOPROTOOPT</td>
<td>The option_name parameter is unrecognized, or the level parameter is not SOL_SOCKET.</td>
</tr>
<tr>
<td>ENOSYS</td>
<td>The function is not implemented. You attempted to use a function that is not yet available.</td>
</tr>
<tr>
<td>ENOTSOCK</td>
<td>The descriptor is for a file, not for a socket.</td>
</tr>
<tr>
<td>EOPNOTSUPP</td>
<td>The operation is not supported by the socket protocol. At least the following options are not supported:</td>
</tr>
<tr>
<td></td>
<td>• IPV6_JOIN_GROUP</td>
</tr>
<tr>
<td></td>
<td>• IPV6_LEAVE_GROUP</td>
</tr>
<tr>
<td></td>
<td>• IP_ADD_SOURCE_MEMBERSHIP</td>
</tr>
<tr>

</tr>
<tr>
<td></td>
<td>• MCAST_LEAVE_SOURCE_GROUP</td>
</tr>
</tbody>
</table>

Example

The following are examples of the getsockopt() call. See "setsockopt() — Set Options Associated with a Socket" on page 1843 for examples of how the setsockopt() call options are set.

```c
int rc;
int s;
int option_value;
int option_len;
struct linger l;
int getsockopt(int s, int level, int option_name, char *option_value, int *option_len);
```
/* Is out-of-band data in the normal input queue? */
option_len = sizeof(int);
rc = getsockopt(
    s, SOL_SOCKET, SO_OOBINLINE, (char *)&option_value, &option_len);
if (rc == 0)
{
    if (option_len == sizeof(int))
    {
        if (option_value)
            /* yes it is in the normal queue */
        else
            /* no it is not */
    }
}

/* Do I linger on close? */
option_len = sizeof(l);
rc = getsockopt(
    s, SOL_SOCKET, SO_LINGER, (char *)&l, &option_len);
if (rc == 0)
{
    if (option_len == sizeof(l))
    {
        if (l.l_onoff)
            /* yes I linger */
        else
            /* no I do not */
    }
}

getsourcefilter — Get source filter

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3678</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```
#define _XOPEN_SYS_SOCK_EXT3
#include <netinet/in.h>

int getsourcefilter(int s, uint32_t interface, struct sockaddr *group,
    socklen_t grouplen, uint32_t *fmode, uint32_t *numsrc,
    struct sockaddr_storage *slist);
```

General Description

This function allow applications to get a previously set multicast filtering state for a tuple consisting of socket, interface, and multicast group values.

A multicast filter is described by a filter mode, which is MCAST_INCLUDE or MCAST_EXCLUDE, and a list of source addresses which are filtered.

This function is protocol-independent. It can be on either AF_INET or AF_INET6 sockets of the type SOCK_DGRAM or SOCK_RAW.

If the function is unable to obtain the required storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

Argument

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
</tr>
</tbody>
</table>

Identifies the socket.

interface

Holds the index of the interface.

group

Points to either a sockaddr_in structure for IPv4 or a sockaddr_in6 structure for IPv6 that holds the IP multicast address of the group.

grouplen

Gives the length of the sockaddr_in or sockaddr_in6 structure.

fmode

Points to an integer that will contain the filter mode on a successful return. The value of this field will be either MCAST_INCLUDE or MCAST_EXCLUDE, which are likewise defined in <netinet/in.h>.

numsrc

It is a pointer that on input, points to the number of source addresses that will fit in the slist array. On return, points to the total number of sources associated with the filter.

slist

Points to buffer into which an array of IP addresses of included or excluded (depending on the filter mode) sources will be written. If numsrc was 0 on input, a NULL pointer may be supplied.
Returned Value

If successful, the function returns 0. Otherwise, it returns -1 and sets errno to one of the following values.

errno Description

EADDRNOTAVAIL
The tuple consisting of socket, interface, and multicast group values does not exist; or the specified interface address is not multicast capable.

EAFNOSUPPORT
The address family of the input sockaddr is not AF_INET or AF_INET6.

EBADF
s is not a valid socket descriptor.

EINVAL
Interface or group is not a valid address, or the socket s has already requested multicast setsockopt options (refer to z/OS Communications Server: IP Sockets Application Programming Interface Guide and Reference for details.) Or if the group address family is AF_INET and grouplen is not at least size of sockaddr_in or if the group address family is AF_INET6 and grouplen is not at least size of sockaddr_in6 or if grouplen is not at least size of sockaddr_in.

ENXIO
The specified interface index provided in the interface parameter does not exist.

EPROTOTYPE
The socket s is not of type SOCK_DGRAM or SOCK_RAW.

getstablesize

getstablesize() — Get the Socket Table Size

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int getstablesize(void);
```

General Description

The getstablesize() function obtains the number of sockets that are allowed for use in bulk mode operations for a process.

Returned Value

If successful, getstablesize() returns the current limit for this process.

If it has not been changed by the maxdesc() function, then the default is returned. The default is the hard limit returned by getrlimit() for RLIMIT_NOFILE. This is the value set by a BPXPRMnn parmlib member on its MAXFILEPROC statement.

There are no errno values defined.

Related Information

getsubopt() — Parse Suboption Arguments

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int getsubopt(char **optionp, char *const *tokens, char **valuep);
```

General Description

The `getsubopt()` function parses suboption arguments in a flag argument that was initially parsed by `getopt()`. These suboption arguments must be separated by commas and may consist of either a single token, or a token-value pair separated by an equal sign. Because commas delimit suboption arguments in the option string, they are not allowed to be part of the suboption arguments or the value of a suboption argument. Similarly, because the equal sign separates a token from its value, a token must not contain an equal sign.

The `getsubopt()` function takes the address of a pointer to the option argument string, a vector of possible tokens, and the address of a value string pointer. If the option argument string at `optionp` contains only one suboption argument, `getsubopt()` updates `optionp` to point to the NULL at the end of the string. Otherwise, it isolates the suboption argument by replacing the comma separator with a NULL, and updates `optionp` to point to the start of the next suboption argument. If the suboption argument has an associated value, `getsubopt()` updates `valuep` to point to the value’s first character. Otherwise it sets `valuep` to a NULL pointer.

The token vector is organized as a series of pointers to strings. The end of the token vector is identified by a NULL pointer.

When `getsubopt()` returns, if `valuep` is not a NULL pointer, then the suboption argument processed included a value. The calling program may use this information to determine if the presence or lack of a value for the suboption is an error.

Additionally, when `getsubopt()` fails to match the suboption argument with the tokens in the `tokens` array, the calling program should decide if this is an error, or if the unrecognized option should be passed on to another program.

Because the `getsubopt()` function returns thread-specific data the `getsubopt()` function can be used safely from a multithreaded application.

Returned Value

If successful, `getsubopt()` returns the index of the matched token string.

If no token strings were matched, `getsubopt()` returns -1.

`getsubopt()` does not return any errno values.
getsubopt

getsyntx() — Return LC_SYNTAX Characters

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <variant.h>

struct variant *getsyntx(void);
```

General Description

Determines the encoding of the special characters defined in the LC_SYNTAX category of the current locale, and stores the encoding values in the structure of type `variant`. For details of the variant structure, see [variant.h](#) on page 98.

Returned Value

Returns the pointer to the structure containing the values of the special characters.

If the information about the special characters is not available in the current locale, `getsyntx()` returns a NULL pointer.

The structure returned is not modified by the program that this function is used in. The structure may be invalidated by calls to the setlocale() function with LC_ALL, LC_CTYPE, LC_COLLATE, or LC_SYNTAX.

Example

```c
CELEBG19
/* CELEBG19 */
#include <stdio.h>
#include <stdlib.h>
#include <variant.h>
#include <wchar.h>

int main(void)
{
    struct variant *var;
    var = getsyntx();
    printf("codeset : %s\n", var->codeset);
    printf("backslash : %3d\n", var->backslash);
    printf("right_bracket : %3d\n", var->right_bracket);
    printf("left_bracket : %3d\n", var->left_bracket);
    printf("right_brace : %3d\n", var->right_brace);
    printf("left_brace : %3d\n", var->left_brace);
    printf("circumflex : %3d\n", var->circumflex);
    printf("tilde : %3d\n", var->tilde);
    printf("exclamation_mark : %3d\n", var->exclamation_mark);
    printf("number_sign : %3d\n", var->number_sign);
    printf("vertical_line : %3d\n", var->vertical_line);
    printf("dollar_sign : %3d\n", var->dollar_sign);
    printf("commercial_at : %3d\n", var->commercial_at);
    printf("grave_accent : %3d\n", var->grave_accent);
}
```

__get_system_settings() — Retrieves System Parameters

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R10</td>
</tr>
</tbody>
</table>

Format

```
#define _OPEN_SYS_EXT 1
#include <sys/ps.h>

struct _Optn *__get_system_settings(void);
```

General Description

The __get_system_settings() function retrieves system parameter information from the BPXPRM member used during IPL, or updated by the OMVS operator command.

Returned Value

If successful, __get_system_settings() returns a pointer to an _Optn structure containing the values set for the BPXPRMxx member process during IPL, or updated by the OMVS operator command.

If unsuccessful, __get_system_settings() returns NULL and may set errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>Insufficient memory available to allocate _Optn structure.</td>
</tr>
</tbody>
</table>

gettimeofday

gettimeofday() — Get Date and Time

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1

#undef _ALL_SOURCE
#include <sys/time.h>

int gettimeofday(struct timeval *__restrict__ tp,
                  void *__restrict__ tzp);

#define _ALL_SOURCE
#include <sys/time.h>

int gettimeofday(struct timeval *__restrict__ tp,
                  struct timezone *__restrict__ tzp);
```

General Description

The gettimeofday() function obtains the current time, expressed as seconds and microseconds since 00:00:00 Coordinated Universal Time (UTC), January 1, 1970, and stores it in the timeval structure pointed to by tp.

Special Behavior for _ALL_SOURCE

The gettimeofday() function has two prototypes. Which one is used depends on whether or not you define the _ALL_SOURCE feature test macro when you compile your program. If _ALL_SOURCE is NOT defined when the C/370 preprocessor processes the <sys/time.h> header, it includes a prototype for gettimeofday() which defines the second argument, tzp, as a void pointer and includes a C/370 pragma map statement for a C/370 version of gettimeofday() which ignores tzp.

If _ALL_SOURCE is defined, the C/370 preprocessor includes a prototype for gettimeofday() which defines tzp as a pointer to a timezone structure and includes a pragma map statement for a C/370 version of gettimeofday() which stores time zone information in the timezone structure to which the second argument points. The timezone structure contains the following members:

```c
int tz_minuteswest; /* Time west of Greenwich in minutes */
int tz_dsttime;    /* Type of DST correction to apply */
```

When _ALL_SOURCE is defined, the gettimeofday() function:
1. invokes tzset() to set the values of the timezone and daylight external variables.
2. converts the value of the timezone external variable to minutes and stores the converted value, rounded up to the nearest minute, in tzp->tz_minuteswest.
3. stores the value of the daylight external variable in tzp->tz_dsttime.

Returned Value

If successful, gettimeofday() returns 0.
If overflow occurs, gettimeofday() returns nonzero. Overflow occurs when the current time in seconds since 00:00:00 UTC, January 1, 1970 exceeds the capacity of the `tv_sec` member of the timeval structure pointed to by `tp`. The `tv_sec` member is type `time_t`.

</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

uid_t getuid(void);
```

General Description

Finds the real user ID (UID) of the calling process.

Returned Value

getuid() returns the found value. It is always successful.

There are no documented errno values.

Example

```c
CELEBG20

/* CELEBG20

   This example provides information for your user ID.

*/
#define _POSIX_SOURCE
#include <pwd.h>
#include <sys/types.h>
#include <unistd.h>

main() {
   struct passwd *p;
   uid_t uid;

   if ((p = getpwuid(uid = getuid())) == NULL)
      perror("getpwuid() error");
   else {
      puts("getpwuid() returned the following info for your userid:");
      printf(" pw_name : %s\n", p->pw_name);
      printf(" pw_uid : %d\n", (int)p->pw_uid);
      printf(" pw_gid : %d\n", (int)p->pw_gid);
      printf(" pw_dir : %s\n", p->pw_dir);
      printf(" pw_shell : %s\n", p->pw_shell);
   }
}
```

Output

878  z/OS V1R9.0 XL C/C++ Run-Time Library Reference
pw_name : MVSUSR1
pw_uid  : 25
pw_gid  : 500
pw_dir  : /u/mvsusr1

getutxent() — Read Next Entry in utmpx Database

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *getutxent(void);
```

General Description

The getutxent() function reads in the next entry from the utmpx database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.

The pututxline() function obtains an exclusive lock in the utmpx database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions getutxent(), getutxid(), and getutxline() might continue to read and are not affected by pututxline().

Because the getutxent() function returns thread-specific data the getutxent() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread’s database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

The name of the database file defaults to /etc/utmpx. To process a different database file name use the __utmpxname() function.

For all entries that match a request, the ut_type member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the ut_type member as follows:

- **EMPTY**
  - No other members have meaningful data.

- **BOOT_TIME**
  - ut_tv is meaningful.

- **__RUN_LVL**
  - ut_tv and ut_line are meaningful

- **OLD_TIME**
  - ut_tv is meaningful.

- **NEW_TIME**
  - ut_tv is meaningful.

- **USER_PROCESS**
  - ut_id, ut_user (login name of the user), ut_line, ut_pid, and ut_tv are meaningful.

- **INIT_PROCESS**
  - ut_id, ut_pid, and ut_tv are meaningful.

- **LOGIN_PROCESS**
  - ut_id, ut_user (implementation-specific name of the login process), ut_pid, and ut_tv are meaningful.
DEAD_PROCESS
ut_id, ut_pid, and ut_tv are meaningful.

Returned Value

If successful, getutxent() returns a pointer to a utmpx structure containing a copy of the requested entry in the user accounting database.

If unsuccessful, getutxent() returns a NULL pointer.

No errors are defined for this function.

<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *getutxid(const struct utmpx *id);
```

General Description

The getutxid() function searches forward from the current point in the utmpx database. If the database is not already open, it opens it. If the ut_type value of the utmpx structure pointed to by id is BOOT_TIME, __RUN_LVL, OLD_TIME, or NEW_TIME, then it stops when it finds an entry with a matching ut_type value. If the ut_type value is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then it stops when it finds an entry whose type is one of these four and whose ut_id member matches the ut_id member of the utmpx structure pointed to by id. If the UT_type value is EMPTY, getutxid() fails (returns NULL) without repositioning the utmpx database to the end. If the end of the of the database is reached without a match, getutxid() fails.

The pututxline() function obtains an exclusive lock in the utmpx database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions getutxent(), getutxid(), and getutxline() might continue to read and are not affected by pututxline().

Because the getutxid() function returns thread-specific data the getutxid() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread’s database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

The name of the database file defaults to /etc/utmpx. To process a different database file name use the __utmpxname() function.

For all entries that match a request, the ut_type member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the ut_type member as follows:

- **EMPTY**: No other members have meaningful data.
- **BOOT_TIME**: ut_tv is meaningful.
- **__RUN_LVL**: ut_tv and ut_line are meaningful
- **OLD_TIME**: ut_tv is meaningful.
- **NEW_TIME**: ut_tv is meaningful.
- **USER_PROCESS**: ut_id, ut_user (login name of the user), ut_line, ut_pid, and ut_tv are meaningful.
getutxid

INIT_PROCESS
   ut_id, ut_pid, and ut_tv are meaningful.

LOGIN_PROCESS
   ut_id, ut_user (implementation-specific name of the login process),
   ut_pid, and ut_tv are meaningful.

DEAD_PROCESS
   ut_id, ut_pid, and ut_tv are meaningful.

Returned Value
If successful, getutxid() returns a pointer to a utmpx structure containing a copy of
the requested entry in the user accounting database.

If unsuccessful, getutxid() returns a NULL pointer.

No errors are defined for this function.

</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *getutxline(const struct utmpx *line);
```

General Description

The getutxline() function searches forward from the current point in the utmpx database until it finds an entry of the type `LOGIN_PROCESS` or `USER_PROCESS` which also has a `ut_line` value matching that in the utmpx structure pointed to by argument `line`. If the database is not already open, it opens it. If it reaches the end of the database, it fails.

The pututxline() function obtains an exclusive lock in the utmpx database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions getutxent(), getutxid(), and getutxline() might continue to read and are not affected by pututxline().

Because the getutxline() function returns thread-specific data the getutxline() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

The name of the database file defaults to `/etc/utmpx`. To process a different database file name use the __utmpxname() function.

The functions getutxent(), getutxid(), and getutxline() cache the last entry read from the database. For this reason, to use getutxline() function to search for multiple occurrences, it is necessary to zero out the utmpx structure pointed to by the return value from these functions.

For all entries that match a request, the `ut_type` member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the `ut_type` member as follows:

- **EMPTY**: No other members have meaningful data.
- **BOOT_TIME**: `ut_tv` is meaningful.
- **__RUN_LVL**: `ut_tv` and `ut_line` are meaningful
- **OLD_TIME**: `ut_tv` is meaningful.
- **NEW_TIME**: `ut_tv` is meaningful.
- **USER_PROCESS**: `ut_id`, `ut_user` (login name of the user), `ut_line`, `ut_pid`, and `ut_tv` are meaningful.
getutxline

INIT_PROCESS
   ut_id, ut_pid, and ut_tv are meaningful.

LOGIN_PROCESS
   ut_id, ut_user (implementation-specific name of the login process),
   ut_pid, and ut_tv are meaningful.

DEAD_PROCESS
   ut_id, ut_pid, and ut_tv are meaningful.

Returned Value

If successful, getutxline() returns a pointer to a utmpx structure containing a copy of
the requested entry in the user accounting database.

If unsuccessful, getutxline() returns a NULL pointer.

No errors are defined for this function.

getw() — Get a Machine Word from a Stream

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdio.h>

int getw(FILE *stream);
```

General Description

The `getw()` function reads the next word from the `stream`. The size of the word is the size of an int, and varies from machine to machine. The `getw()` function presumes no special alignment in the file.

The `getw()` function may mark the `st_atime` field of the file associated with `stream` for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc()`, `fgets()`, `fread()`, `getc()`, `getchar()`, `gets()`, `fscanf()` or `scanf()` using `stream` that returns data not supplied by a prior call to `ungetc()`.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use character-based input functions to replace `getw()` for portability.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned Value

If successful, `getw()` returns the next word from the input stream pointed to by `stream`. If the stream is at End Of File (EOF), the End Of File indicator for the stream is set and `getw()` returns EOF. If a read error occurs, the error indicator for the stream is set, `getw()` returns EOF and sets `errno` to indicate the error.

Refer to "getc() — Read a Character" on page 587 for `errno` values.

Because the representation of EOF is a valid integer, applications wishing to check for errors should use `ferror()` and `feof()`.

<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wint_t getwc(FILE *stream);
```

General Description

Obtains the next multibyte character from stdin, converts it to a wide character, and advances the associated file position indicator for stdin.

The getwc() function is equivalent to the fgetwc() function. Therefore, the argument should never be an expression with side effects.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Using non-wide-character functions with getwc() results in undefined behavior. This happens because getwc() processes a whole multibyte character and does not expect to be “within” such a character. In addition, getwc() expects state information to be set already. Because functions like fgetc() and fputc() do not obey such rules, their results fail to meet the assumptions made by getwc().

getwc() has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Returned Value

Returns the next wide character from the input stream pointed to by stream or else the function returns WEOF.

If there is an error, getwc() sets the error indicator. If the EOF is encountered, it sets the EOF indicator. If an encoding error is encountered, it sets EILSEQ in errno.

Use ferror() or feof() to determine whether an error or an EOF condition occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does not turn on the EOF indicator.

Example

CELEBG21
/* CELEBG21 */
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
  FILE *stream;
  wint_t wc;

  if ((stream = fopen("myfile.dat", "r")) == NULL) {
    printf("Unable to open file.");
    exit(1);
  }

  errno = 0;
  while ((wc = getwc(stream)) != WEOF)
    printf("wc=0x%lx\n", wc);

  if (errno == EILSEQ) {
    printf("An invalid wide character was encountered.\n");
    exit(1);
  }

  fclose(stream);
}

<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wint_t getwchar(void);
```

General Description

The `getwchar()` function is equivalent to `getwc()` with the argument `stdin`. The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned Value

Returns the next wide character from the input stream pointed to by `stdin` or else the function returns WEOF. If the stream is at EOF, the EOF indicator for the stream is set and `fgetwc()` returns WEOF. If a read error occurs, the error indicator for the stream is set and `fgetwc()` returns WEOF. If an encoding error occurs, the value of the macro EILSEQ is stored in `errno` and WEOF is returned.

Use `ferror()` or `feof()` to determine whether an error or an EOF condition occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does not turn on the EOF indicator.

Example

**CELEBG22**

```c
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
    wint_t wc;

    errno = 0;
    while ((wc = getwchar()) != WEOF)
        printf("wc=0x%X\n", wc);

    if (errno == EILSEQ) {
        printf("An invalid wide character was encountered.\n");
        exit(1);
    }
}
```

getwd

getwd() — Get the Current Working Directory

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

char *getwd(char *path_name);
```

General Description

The getwd() function determines an absolute pathname of the current working directory of the calling process, and copies that pathname into the array pointed to by `path_name` argument.

If the length of the pathname of the current working directory is greater than (`PATH_MAX`+1) including the NULL byte, getwd() fails and returns a NULL pointer.

For portability to implementations conforming to earlier versions of the standards, getcwd() is preferred over this function.

Note: The getwd() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The getcwd() function is preferred for portability.

Returned Value

If successful, getwd() returns a pointer to the string containing the absolute pathname of the current working directory.

If unsuccessful, getwd() returns a NULL pointer and the contents of the array pointed to by `path_name` are undefined.

There are no errno values defined.

getwmccoll() — Get Next Collating Element from Wide String

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <collate.h>

collel_t getwmccoll(wchar_t **src);
```

General Description

If the object pointed to by `src` is not a NULL pointer, the getwmccoll() library function determines the longest sequence of wide characters in the array pointed to by `str` that constitute a valid multi-wide-character collating element. It then produces the value of type `collel_t` corresponding to that collating element. The object pointed to by `src` is assigned the address just past the last wide character of the multi-wide-character collating element processed.

Returned Value

If successful, getwmccoll() returns the value of type `collel_t` that represents the collating element found.

If the object pointed to by `src` is a NULL pointer or if it points to a NULL wide character, getwmccoll() returns 0.

If the object pointed to by `src` points to a non-valid wide character, getwmccoll() returns −1 and sets `errno` to EILSEQ.

**givesocket() — Make the Specified Socket Available**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int givesocket(int d, struct clientid *clientid);
```

**General Description**

The `givesocket()` call makes the specified socket available to a `takesocket()` call issued by another program. Any socket can be given. Typically, `givesocket()` is used by a master program that obtains sockets by means of `accept()` and gives them to application programs that handle one socket at a time.

**Parameter Description**

- **d**: The descriptor of a socket to be given to another application.
- **clientid**: A pointer to a client ID structure specifying the program to which the socket is to be given.

To pass a socket, the giving program first calls `givesocket()` with the client ID structure filled in as follows:

The `clientid` structure:

```c
struct clientid {
    int domain;
    union {
        char name[8];
        struct {
            int NameUpper;
            pid_t pid;
        } c_pid;
        } c_name;
        char subtaskname[8];

        struct {
            char type;
            union {
                char specific[19];
                struct {
                    char unused[3];
                    int SocketToken;
                } c_close;
                } c_func;
            } c_reserved;
    }
};
```

**Element Description**

- **domain**: The domain of the input socket descriptor.
- **c_name.name**: If the `clientid` was set by a `getclientid()` call, `c_name.name` can be
  - set to the application program's address space name, left-justified and padded with blanks. The application program
can run in the same address space as the master program, in which case this field is set to the master program’s address space.

- set to blanks, so any z/OS address space can take the socket.

**subtaskname**

If the `clientid` was set by a `getclientid()` call, `subtaskname` can be

- set to the task identifier of the taker. This, combined with a `c_name.name` value, allows only a process with this `c_name.name` and `subtaskname` to take the socket.
- set to blanks. If `c_name.name` has a value and `subtaskname` is blank, any task with that `c_name.name` can take the socket.

**c_pid.pid**

If the `clientid` was set by a `_getclientid()` call, `c_pid.pid` should be set to the process id (PID) of the taker, so only a process with that PID can take the socket. The `subtaskname` field is ignored when the `c_pid` has a value.

**c_reserved.type**

When set to SO_CLOSE, this indicates the socket should be automatically closed by `givesocket()`, and a unique socket identifying token is to be returned in `c_close.SockToken`. The `c_close.SockToken` should be passed to the taking program to be used as input to `takesocket()` instead of the socket descriptor. The now closed socket descriptor could be re-used by the time the `takesocket()` is called, so the `c_close.SockToken` should be used for `takesocket()`.

When set to _SO_SELECT, this indicates that the application intends to block on the `select()` for exception, waiting for the `takesocket()` to occur before closing the socket. If `c_reserved.type` is set to _SO_SELECT and the caller of `givesocket()` closes the socket before it has been taken, the connection will be severed. _SO_SELECT also allows `select()` to return exception status if `select()` is done after the socket was taken with `takesocket()`.

**c_close.SockToken**

The unique socket identifying token returned by `givesocket()` to be used as input to `takesocket()`, instead of the socket descriptor when `c_reserved.type` has been set to SO_CLOSE.

**c_reserved**

Specifies binary zeros if an automatic close of a socket is not to be done by `givesocket()`.

**Using name and subtaskname for givesocket/takesocket:**

1. The giving program calls `getclientid()` to obtain its client ID. The giving program calls `givesocket()` to make the socket available for a `takesocket()` call. The giving program passes its client ID along with the descriptor of the socket to be given to the taking program by the taking program’s startup parameter list.
2. The taking program calls `takesocket()`, specifying the giving program’s client ID and socket descriptor.
3. Waiting for the taking program to take the socket, the giving program uses `select()` to test the given socket for an exception condition. When `select()` reports that an exception condition is pending, the giving program calls `close()` to free the given socket.
4. If the giving program closes the socket before a pending exception condition is indicated, the connection is immediately reset, and the taking program’s call to

takesocket() is unsuccessful. Calls other than the close() call issued on a given socket return -1, with errno set to EBADF.

**Note:** For backward compatibility, a client ID can point to the struct client ID structure obtained when the target program calls getclientid(). In this case, only the target program, and no other programs in the target program’s address space, can take the socket.

**Using process id (PID) for givesocket/takesocket:**

1. The giving program calls __getclientid() to obtain its client ID. The giving program sets the `c_pid.pid` in the clientid structure to the PID of the taking program that will take the socket (that is, issue the takesocket() call). This ensures only a process that has obtained the giver’s PID can take the specified socket. If the giving program wants the socket to be automatically closed by givesocket(), `c_reserved.type` should be set to SO_CLOSE. The giving program calls givesocket() to make the socket available for a takesocket() call. The giving program passes its client ID, the descriptor of the socket to be given, and the giving program’s PID to the taking program by the taking program’s startup parameter list.

2. The taking program sets the `c_pid.pid` in the clientid structure to the PID of the giving program to identify the process from which the socket is to be taken. If the `c_reserved.type` field was set to SO_CLOSE on givesocket(), the `c_close.SockToken` should be used as input to the takesocket() instead of the normal socket descriptor. The taking program calls takesocket(), specifying the giving program’s client ID and either the socket descriptor or `c_close.SockToken`.

3. If the `c_reserved.type` field in the clientid structure was set to SO_CLOSE on the givesocket() call, the socket is closed and the giving program does not have to wait for the taking program to issue the takesocket(). Otherwise, steps 3 and 4 of “Using name and subtaskname for givesocket/takesocket” should be followed.

**Returned Value**

If successful, givesocket() returns 0.

If unsuccessful, givesocket() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The <code>d</code> parameter is not a valid socket descriptor. The socket has already been given.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using the <code>clientid</code> parameter as specified would result in an attempt to access storage outside the caller’s address space.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The <code>clientid</code> parameter does not specify a valid client identifier or the clientid domain does not match the domain of the input socket descriptor.</td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <glob.h>

int glob(const char *__restrict__ pattern, int flags,
         int (*errfunc)(const char *__path, int eerrno),
         glob_t *__restrict__ pglob);
```

General Description

The `glob()` function is a pathname generator that implements the rules defined in `X/Open CAE Specification, Commands and Utilities, Issue 4, Version 2 Section 2.13, Pattern Matching Notation`, with optional support for rule 3 in Section 2.13.3, Patterns Used for Filename Expansion.

The structure `glob_t` is defined in the header `<glob.h>` and includes at least the following members:

- `gl_pathc` Count of paths matched by `pattern`.
- `gl_pathv` Pointer to a list of matched filenames.
- `gl_offs` Slots to reserve at the beginning of `gl_pathv`.

The argument `pattern` is a pointer to a pathname pattern to be expanded. The `glob()` function matches all accessible pathnames against this pattern and develops a list of all pathnames that match. In order to have access to a pathname, `glob()` requires search permission on every component of a path except the last, and read permission on each directory of any filename component of `pattern` that contains any of the following special characters:

- `*`  
- `?`  
- `[`  

The `glob()` function stores the number of matched pathnames into `pglob->gl_pathc` and a pointer to a list of pointers to pathnames into `pglob->gl_pathv`. The pathnames are in sort order as defined by the current setting of the `LC_COLLATE` category, see `X/Open CAE Specification, System Interface Definitions, Issue 4, Version 2 Section 5.3.2`, `LC_COLLATE`. The first pointer after the last pathname is a NULL pointer. If the pattern does not match any pathnames, the returned number of matched paths is set to 0, and the contents of `pglob->gl_pathv` are implementation-dependent.

It is the caller’s responsibility to create the structure pointed to by `pglob`. The `glob()` function allocates other space as needed, including the memory pointed to by `gl_pathv`. 
The flags argument is used to control the behavior of glob(). The value of flags is a bitwise inclusive-OR of zero or more of the following constants, which are defined in the header <glob.h>:

**GLOB_APPEND**

Append pathnames generated to the ones from a previous call to glob().

**GLOB_DOOFFS**

Make use of pglob->gl_offs. If this flag is set, pglob->gl_offs is used to specify how many NULL pointers to add to the beginning of pglob->gl_pathv. In other words, pglob->gl_pathv will point to pglob->gl_offs NULL pointers, followed by pglob->gl_pathc pathname pointers, followed by a NULL pointer.

**GLOB_ERR**

Causes glob() to return when it encounters a directory that it cannot open or read. Ordinarily, glob() continues to find matches.

**GLOB_MARK**

Each pathname that is a directory that matches pattern has a slash appended.

**GLOB_NOCHECK**

Support rule 3 in the XCU specification, Section 2.13.3, Patterns Used for Filename Expansion. If pattern does not match any pathname, then glob() returns a list consisting of only pattern, and the number of matched pathnames is 1.

**GLOB_NOESCAPE**

Disable backslash escaping.

**GLOB_NOSORT**

Ordinarily, glob() sorts the matching pathnames according to the current setting of the LC_COLLATE category, see the XBD specification, Section 5.3.2, LC_COLLATE. When this flag is used the order of pathnames returned is unspecified.

The GLOB_APPEND flag can be used to append a new set of pathnames to those found in a previous call to glob(). The following rules apply when two or more calls to glob() are made with the same value of pglob and without intervening calls to globfree():

1. The first such call must not set GLOB_APPEND. All subsequent calls must set it.
2. All calls must set GLOB_DOOFFS, or all must not set it.
3. After the second call, pglob->gl_pathv points to a list containing the following:
   a. Zero or more NULL pointers, as specified by GLOB_DOOFFS and pglob->gl_offs.
   b. Pointers to the pathnames that were in the pglob->gl_pathv list before the call, in the same order as before.
   c. Pointers to the new pathnames generated by the second call, in the specified order.
4. The count returned in pglob->gl_pathc will be the total number of pathnames from the two calls.
5. The application can change any of the fields after a call to glob(). If it does, it must reset them to the original value before a subsequent call, using the same pglob value, to globfree() or glob() with the GLOB_APPEND flag.
If, during the search, a directory is encountered that cannot be opened or read and `errfunc` is not a NULL pointer, `glob()` calls (`*errfunc`) with two arguments:

1. The `epath` argument is a pointer to the path that failed.
2. The `eerrno` argument is the value of `errno` from the failure, as set by `opendir()`, `readdir()` or `stat()`. (Other values may be used to report other errors not explicitly documented for those functions.)

### Returned Value

If successful, `glob()` returns 0. The argument `pglob->gl_pathc` returns the number of matched pathnames and the argument `pglob->gl_pathv` contains a pointer to a NULL-terminated list of matched and sorted pathnames. However, if `pglob->gl_pathc` is 0, the content of `pglob->gl_pathv` is undefined.

If `glob()` terminates due to an error, it returns one of the following nonzero constants defined in `<glob.h>` as error return values for `glob()`:

- **GLOB_ABORTED**
  - The scan was stopped because `GLOB_ERR` was set or (`*errfunc`) returned nonzero.

- **GLOB_NOMATCH**
  - The pattern does not match any existing pathname, and `GLOB_NOCHECK` was set in `flags`.

- **GLOB_NOSPACE**
  - An attempt to allocate memory failed.

If (`*errfunc`) is called and returns nonzero, or if the `GLOB_ERR` flag is set in `flags`, `glob()` stops the scan and returns `GLOB_ABORTED` after setting `gl_pathc` and `gl_pathv` in `pglob` to reflect the paths already scanned. If `GLOB_ERR` is not set and either `errfunc` is a NULL pointer or (`*errfunc`) returns 0, the error is ignored.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <glob.h>

void globfree(glob_t *pglob);
```

General Description

The globfree() function frees storage associated with `pglob` by a previous call to `glob()`.

Returned Value

globfree() returns no values.

Related Information

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <time.h>

struct tm *gmtime(const time_t *timer);
```

General Description

Converts the calendar time pointed to by `timer` into a broken-down time, expressed as Coordinated Universal Time (UTC). ²

The value pointed to by `timer` is usually obtained by a call to the `time()` function.

The relationship between a time in seconds since the Epoch used as an argument to `gmtime()` and the `tm` structure (defined in the `<time.h>` header) is that the result is as specified in the expression given in the definition of seconds since the Epoch, where the names in the structure and in the expression correspond.

Returned Value

Returns a pointer to a `tm` structure containing the broken-down time, expressed in Coordinated Universal Time (UTC) corresponding to calendar time pointed to by `timer`. The fields in `tm` are shown in Table 19 on page 94. If the calendar time pointed to by `timer` cannot be converted to broken-down time (in UTC), `gmtime()` returns a NULL pointer.

Error code

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EOVERFLOW</td>
</tr>
</tbody>
</table>

The result cannot be represented.

Notes:

- The range (0-60) for `tm_sec` allows for as many as one leap second.
- The `gmtime()` and `localtime()` functions may use a common, statically allocated buffer for the conversion. Each call to one of these functions may alter the result of the previous call.
- The calendar time returned by the `time()` function begins at the epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.

². Coordinated Universal Time (UTC) was formerly known as Greenwich Mean Time (GMT).
Example

CELEBG23

/* CELEBG23

This example uses the &gt;gmtime&lt; function to convert a
time_t representation to a Coordinated Universal Time
character string and then converts it to a printable string
using &lt;asct..

*/
#include &lt;stdio.h&gt;
#include &lt;time.h&gt;

int main(void)
{
    time_t ltime;
    time(&lt;ltime&gt;);
    printf (&quot;Coordinated Universal Time is %s
&quot;,
            asctime(gmtime(&lt;ltime&gt;)));
}

Output

Coordinated Universal Time (UTC) is Fri Jun 16 21:01:44 2001

gmtime_r

gmtime_r() — Convert a Time Value to Broken-Down UTC Time

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <time.h>

struct tm *gmtime_r(const time_t *__restrict__ clock,
                                   struct tm *__restrict__ result);
```

General Description

The `gmtime_r()` function converts the calendar time pointed to by `clock` into a broken-down time expressed as Coordinated Universal Time (UTC). The broken-down time is stored in the structure referred to by `result`. The `gmtime_r()` function also returns the address of the same structure.

The relationship between a time in seconds since the Epoch used as an argument to `gmtime()` and the `tm` structure (defined in the `<time.h>` header) is that the result is as specified in the expression given in the definition of seconds since the Epoch, where the names in the structure and in the expression correspond.

Returned Value

If successful, `gmtime_r()` returns the address of the structure pointed to by the argument `result`.

If an error is detected or UTC is not available, `gmtime_r()` returns a NULL pointer.

There are no documented errno values.

Error Code

**EOVERFLOW**

The result cannot be represented.

grantpt

grantpt() — Grant Access to the Slave Pseudoterminal Device

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int grantpt(int fildes);
```

General Description

The `grantpt()` function changes the mode and ownership of the slave pseudoterminal device. `fildes` should be the file descriptor of the corresponding master pseudoterminal. The user ID of the slave is set to the real UID of the calling process and the group ID is set to the group ID associated with the group name specified by the installation in the TTYGROUP() initialization parameter. The permission mode of the slave pseudoterminal is set to readable and writable by the owner, and writable by the group.

You can provide secure connections by either using `grantpt()` and `unlockpt()`, or by simply issuing the first open against the slave pseudoterminal from the first userid or process that opened the master terminal.

Returned Value

If successful, `grantpt()` returns 0.

If unsuccessful, `grantpt()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The slave pseudoterminal was opened before <code>grantpt()</code>, or a <code>grantpt()</code> was already issued. In either case, slave pseudoterminal permissions and ownership have already been updated. If you use <code>grantpt()</code> to change slave pseudoterminal permissions, you must issue <code>grantpt()</code> between the master open and the first pseudoterminal open, and <code>grantpt()</code> can only be issued once.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The <code>fildes</code> argument is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The <code>fildes</code> argument is not associated with a master pseudoterminal device.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>The slave pseudoterminal device was not found during lookup.</td>
</tr>
</tbody>
</table>

hcreate() — Create Hash Search Tables

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <search.h>

int hcreate(size_t nel);
```

General Description

The hcreate() function allocates sufficient space for a hash table containing `nel` elements, and must be called before hsearch() is used.

The `nel` argument is an estimate of the maximum number of entries that the table will contain. This number may be adjusted upward by hcreate() for the actual table allocation in order to obtain certain mathematically favorable circumstances.

Threading Behavior: see "hsearch() — Search Hash Tables" on page 911.

Returned Value

If successful, hcreate() returns nonzero.

If hcreate() cannot allocate sufficient space for the table, it returns 0 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>Insufficient storage space is available.</td>
</tr>
</tbody>
</table>

<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE
#include <search.h>

void hdestroy(void);
```

**General Description**

The hdestroy() function disposes of the search table, and may be followed by another call to hcreate(). After the call to hdestroy(), the data can no longer be considered accessible.

Threading Behavior: see “hsearch() — Search Hash Tables” on page 911.

**Returned Value**

hdestroy() returns no values.

**Related Information**

__heaprpt() — Obtain Dynamic Heap Storage Report

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

typedef struct
{
  int __uheap_size;
  int __uheap_bytes_alloc;
  int __uheap_bytes_free;
} hreport_t;

int __heaprpt(hreport_t *heap_report_structure);
```

General Description

__heaprpt() returns to the caller the address of a structure that contains the user heap storage report. The storage report is similar in content to the user heap storage report that is generated with the RPTSTG(ON) Run-Time option.

To use this function, the calling program must obtain storage where the user's heap storage report will be stored. The address of this storage is passed as an argument to __heaprpt().

Returned Value

If successful, __heaprpt() fills the struct hreport_t with the user's heap storage report information.

If the address is not valid, __heaprpt() returns -1 and sets errno to EFAULT.

Example

```c
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
  hreport_t *strptr;
  strptr = (hreport_t *) malloc(sizeof(hreport_t));
  if (__heaprpt(strptr) != 0)
    perror("__heaprpt() error");
  else
  {
    printf("Total amount of user heap storage: \%d\n", strptr->__uheap_size);
    printf("Amount of user heap storage in use: \%d\n", strptr->__uheap_bytes_alloc);
    printf("Amount of available user heap storage: \%d\n", strptr->__uheap_bytes_free);
  }
}
```
__heaprpt

hsearch() — Search Hash Tables

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <search.h>
ENTRY *hsearch(ENTRY item, ACTION action);
```

General Description

The hsearch() function is a hash-table search routine. It returns a pointer into a hash table indicating the location at which an entry can be found. The `item` argument is a structure of type `ENTRY` (defined in the `<search.h>` header) containing two pointers: `item.key` points to the comparison key (a `char *`), and `item.data` (a `void *`) points to any other data to be associated with that key. The comparison function used by hsearch() is `strcmp()`. The `action` argument is a member of an enumeration type `ACTION` indicating the disposition of the entry if it cannot be found in the table. `ENTER` indicates that the item should be inserted in the table at an appropriate point. `FIND` indicates that no entry should be made.

Threading Behavior: The hcreate() function allocates a piece of storage for use as the hash table. This storage is not exposed to the user, and is referred to by all threads. In other words, these functions operate on one hash table global to the process. The library serializes access to the table and attendant data across threads using an internal mutex.

Returned Value

hsearch() returns a NULL pointer if either the action is `FIND` and the item could not be found or the action is `ENTER` and the table is full.

If an error occurs, hsearch() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>Insufficient storage space is available.</td>
</tr>
</tbody>
</table>

htonl() — Translate Address Host to Network Long

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

XPG4.2

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_addr_t htonl(in_addr_t hostlong);
```

SUSV3

```c
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>

uint32_t htonl(uint32_t hostlong);
```

Berkeley Sockets

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <arpa/inet.h>
#include <netinet/in.h>

unsigned long htonl(unsigned long a);
```

General Description

The htonl() function translates a long integer from host byte order to network byte order.

Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>The unsigned long integer to be put into network byte order.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>in_addr_t hostlong</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is typed to the unsigned long integer to be put into network byte order.</td>
</tr>
</tbody>
</table>

Notes:

1. For MVS, host byte order and network byte order are the same.
2. Since this function is implemented as a macro, you need one of the feature test macros and the inet header file.

Returned Value

htonl() returns the translated long integer.

**Format**

SAA

**Compiler Option** LANGVL(EXTENDED), LANGVL(SAA), or LANGVL(SAAL2)

```c
#include <math.h>
double hypot(double side1, double side2);
```

XPG4

```c
#define _XOPEN_SOURCE
#include <math.h>
double hypot(double side1, double side2);
```

C99

```c
#define _ISOC99_SOURCE
#include <math.h>
float hypotf(float side1, float side2);
long double hypotl(long double side1, long double side2);
```

**General Description**

The hypot() family of functions calculates the length of the hypotenuse of a right-angled triangle based on the lengths of two sides `side1` and `side2`. A call to hypot() is equal to:

\[
\sqrt{side1^2 + side2^2};
\]

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>SPC</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>hypot</td>
<td>X</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>hypotf</td>
<td></td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>hypotl</td>
<td></td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

**Restriction**

The hypotf() function does not support the _FP_MODE_VARIABLE feature test macro.
Returned Value

The hypot() family of functions returns the calculated length of the hypotenuse.

If the correct value is outside the range of representable values, ±HUGE_VAL is returned, according to the sign of the value. The value of the macro ERANGE is stored in errno, to show the calculated value is out of range. If the correct value would cause an underflow, zero is returned and the value of the macro ERANGE is stored in errno.

Special Behavior for IEEE

If successful, The hypot() family of functions returns the calculated length of the hypotenuse.

If the correct value overflows, hypot() sets errno to ERANGE and returns HUGE_VAL.

Example

CELEBH01

/* CELEBH01
   * This example calculates the hypotenuse of a right-angled triangle with sides of 3.0 and 4.0.
*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y, z;
    x = 3.0;
    y = 4.0;
    z = hypot(x,y);
    printf("The hypotenuse of the triangle with sides %lf and %lf is %lf\n", x, y, z);
}

Output

The hypotenuse of the triangle with sides 3.000000 and 4.000000 is 5.000000

Related Information

ibmsflush

ibmsflush() — Flush the Application-side Datagram Queue

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int ibmsflush(int s);
```

General Description

Bulk mode is supported only for receive-type socket calls. Currently, send-type socket calls are not supported for bulk mode. Until bulk mode send is supported, ibmsflush() simply returns to the calling program with a zero return code.

For outbound sockets, the application-side datagram queue is flushed (transferred to the TCP/IP address space) if any one of the following occur:

- An ibmsflush() is issued on the socket.
- The queue is full and another send-type socket call is issued.
- The socket is closed.
- Another setibmssockopt() is issued.

Parameter

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
</tr>
</tbody>
</table>

Returned Value

If successful, ibmsflush() returns 0.

If unsuccessful, ibmsflush() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The s parameter is not a valid socket descriptor.</td>
</tr>
</tbody>
</table>

Example

The following is an example of the ibmsflush() call.

```c
char buffer[1000];
int rc, sizeofbuf;
struct ibm_bulkmode_struct mybulkstr;

/* Create, bind, etc done for socket sd */
.
.
mybulkstr.b_onoff = 1;
mybulkstr.b_max_receive_queue_size = 0;
mybulkstr.b_max_send_queue_size = 2100;
mybulkstr.b_move_data = 1;
rc = setibmssockopt(sd, SOL_SOCKET, SO_BULKMODE,
            (char *)&mybulkstr, sizeof(mybulkstr));
```
strcpy(buffer, "Buffer info that fills up to 1000" );
sizeofbuf = 1000;
write(sd, buffer, sizeofbuf);

strcpy(buffer, "More buffer info that fills up to 1000" );
sizeofbuf = 1000;
write(sd, buffer, sizeofbuf);

strcpy(buffer, "Even more buffer info that fills up to 1000" );
sizeofbuf = 1000;
write(sd, buffer, sizeofbuf);

/* Issue ibmsflush() to make sure everything in buffer has been sent.*/
rc = ibmsflush(sd);
.
.
.

iconv

iconv() — Code Conversion

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <iconv.h>

size_t iconv(iconv_t cd, char **__restrict__ inbuf,
              size_t *__restrict__ inbytesleft, char **__restrict__ outbuf,
              size_t *__restrict__ outbytesleft);
```

General Description

Converts a sequence of characters, indirectly pointed to by `inbuf`, from one encoded character set into a sequence of corresponding characters in another encoded character set. The resulting character sequence is then stored into the array indirectly pointed to by `outbuf`. The encoded character sets are those specified in the `iconv_open()` call that returned the conversion descriptor, `cd`. If the descriptor refers to the state-dependent encoding, then before it is first used, the `cd` descriptor is in its initial shift state.

The `inbuf` argument points to a variable that points to the first character in the input buffer. `inbytesleft` indicates the number of bytes to the end of the buffer to be converted. The `outbuf` argument points to a variable that points to the first character in the output buffer. `outbytesleft` indicates the number of available bytes to the end of the buffer.

If the output character set refers to the state-dependent encoding—if it contains the multibyte characters with shift-states—the conversion descriptor `cd` is placed in its initial state by a call for which `inbuf` is a NULL pointer, or for which `inbuf` points to a NULL pointer. When `iconv()` is called in this way, and if `outbuf` is not a NULL pointer or a pointer to a NULL pointer, and `outbytesleft` points to a positive value, `iconv()` places in the output buffer the byte sequence to change the output buffer to the initial shift state. If the output buffer is not large enough to hold the entire reset sequence, `iconv()` fails, and sets `errno` to `E2BIG`. Subsequent calls with `inbuf` as other than a NULL pointer or a pointer to a NULL pointer cause conversion from the current state of the conversion descriptor.

If a sequence of input bytes does not form a valid character in the specified encoded character set, conversion stops after the previous successfully converted character, and `iconv()` sets `errno` to `EILSEQ`. If the input buffer ends with an incomplete character or shift sequence, conversion stops after the previous successfully converted bytes, and `iconv()` sets `errno` to `EINVAL`. If the output buffer is not large enough to hold the entire converted input, conversion stops just before the input bytes that would cause the output buffer to overflow.

The variable pointed to by `inbuf` is updated to point to the byte following the last byte of a successfully converted character. The value pointed to by `inbytesleft` is decremented to reflect the number of bytes still not converted in the input buffer. The variable pointed to by `outbuf` is updated to point to the byte following the last
byte of converted output data. The value pointed to by `outbytesleft` is decremented to reflect the number of bytes still available in the output buffer. For state-dependent encoding, the conversion descriptor is updated to reflect the shift state in effect at the end of the last successfully converted byte sequence.

If `iconv()` encounters a character in the input buffer that is valid, but for which a conversion is not defined in the conversion descriptor, `cd`, then `iconv()` performs a nonidentical conversion on this character. The conversion is implementation-defined.

The `<iconv.h>` header file declares the `iconv_t` type that is a pointer to the object capable of storing the information about the converters used to convert characters in one coded character set to another. For state-dependent encoding, the object must be capable of storing the encoded information about the current shift state.

### Special Considerations for Bidirectional Language Support

If the `_BIDION` environment variable is set to TRUE, `iconv()` performs bidirectional layout transformation to the converted characters. The required attributes for bidirectional layout transformation can be specified using the environment variable `_BIDIATTR` (e.g., `export _BIDIATTR="@Is typeof:text=visual:implicit, orientation=lt:lt, numerals=nominal:national"`). For a detailed description of the bidirectional layout transformation, see “Bidirectional Language Support” in the `C/C++ Programming Guide`. If the environment variable `_BIDIATTR` is not set, the default values will be used.

`iconv()` can perform bidirectional layout transformation while converting the data from the fromCodePage to the toCodePage. Bidirectional layout transformation will take place only if bidirectional language support is activated, see “Allocate Code Conversion Descriptor” on page 925 for more information about activating bidirectional layout transformation. In case `iconv` encounters any error in input or output buffers in the bidirectional part it will bypass the bidirectional layout transformation and continue its normal function as usual.

### Special Behavior for POSIX C

In the POSIX environment, a conversion descriptor returned from a successful `iconv_open()` may be used safely within a single thread. In addition, it may be opened on one thread, used on a second thread (`iconv()`), and closed (`iconv_close()`) on a third thread. However, you must ensure correct cross-thread sequencing and synchronization (that is: `iconv_open()`, followed by optional `iconv()` calls, followed by `iconv_close()`). The use of a shared conversion descriptor by `iconv()` across multiple threads may result in undefined behavior.

See “z/OS XL C/C++ applications with z/OS UNIX System Services C functions” on page 13 for more information about using POSIX support.

### Returned Value

If successful, `iconv()` updates the variables pointed to by the arguments to reflect the extent of the conversion and returns the number of nonidentical conversions performed.
If the entire string in the input buffer is converted, the value pointed to by `inbytesleft` will be 0. If the input conversion is stopped because of any conditions mentioned above, the value pointed to by `inbytesleft` will be nonzero and `errno` is set to indicate the condition.

If an error occurs, `iconv()` returns `(size_t)-1` and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>cd</code> is not a valid descriptor.</td>
</tr>
<tr>
<td>ECUNNOENV</td>
<td>A CUN_RS_N0_UNI_ENV error was issued by Unicode Conversion Services. Refer to <code>z/OS Support for Unicode: Using Unicode Services</code> documentation for user action.</td>
</tr>
<tr>
<td>ECUNNOCONV</td>
<td>A CUN_RS_NO_CONVERSION error was issued by Unicode Conversion Services. Refer to <code>z/OS Support for Unicode: Using Unicode Services</code> documentation for user action.</td>
</tr>
<tr>
<td>ECUNNOTALIGNED</td>
<td>A CUN_RS_TABLE_NOT_ALIGNED error was issued by Unicode Conversion Services. Refer to <code>z/OS Support for Unicode: Using Unicode Services</code> documentation for user action.</td>
</tr>
<tr>
<td>ECUNERR</td>
<td>Function <code>iconv()</code> encountered an unexpected error while using Unicode Conversion Services. Refer to message EDC6258 for additional information.</td>
</tr>
<tr>
<td>EILSEQ</td>
<td>Input conversion stopped due to an input byte that does not belong to the input codeset.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Input conversion stopped due to an incomplete character or shift sequence at the end of the input buffer.</td>
</tr>
<tr>
<td>E2BIG</td>
<td>Input conversion stopped due to lack of space in the output buffer.</td>
</tr>
</tbody>
</table>

**Example**

**CELEBI01**

```c
/* CELEBI01

This example converts an array of characters coded in encoded character set IBM-1047 to an array of characters coded in encoded character set IBM-037.
Input is in inbuf, output will be in outbuf.

*/
#include <iconv.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
```
main ()
{
    char *inptr; /* Pointer used for input buffer */
    char *outptr; /* Pointer used for output buffer */
    char inbuf[20] = "ABCDEFGH!@#$1234"; /* input buffer */
    unsigned char outbuf[20]; /* output buffer */
    iconv_t cd; /* conversion descriptor */
    size_t inleft; /* number of bytes left in inbuf */
    size_t outleft; /* number of bytes left in outbuf */
    int rc; /* return code of iconv() */

    if ((cd = iconv_open("IBM-037", "IBM-1047")) == (iconv_t)(−1)) {
        fprintf(stderr, "Cannot open converter from %s to %s\n",
                "IBM-1047", "IBM-037");
        exit(8);
    }

    inleft = 16;
    outleft = 20;
    inptr = inbuf;
    outptr = (char*)outbuf;

    rc = iconv(cd, &inptr, &inleft, &outptr, &outleft);
    if (rc == -1) {
        fprintf(stderr, "Error in converting characters\n");
        exit(8);
    }
    iconv_close(cd);
}

</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <iconv.h>

int iconv_close(iconv_t cd);
```

General Description

Deallocates the conversion descriptor `cd` and all other associated resources allocated by the `iconv_open()` function. For an illustration of using `iconv_open()`, see "Example" on page 922.

Returned Value

If successful, `iconv_close()` returns 0.

If unsuccessful, `iconv_close()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>cd</code> is not a valid descriptor.</td>

<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <iconv.h>

iconv_t iconv_open(const char *tocode, const char *fromcode);
```

General Description

Performs all the initialization needed to convert characters from the encoded character set specified in the array pointed to by the `fromcode` argument to the encoded character set specified in the array pointed to by the `tocode` argument.

The conversion descriptor relates the two encoded character sets.

For state-dependent encodings, the conversion descriptor will be in an encoded-character-set-dependent initial shift state, ready for immediate use with `iconv()`. The conversion descriptor remains valid until it is closed with `iconv_close()`.

Settings of `fromcode`, `tocode`, and their permitted combinations are implementation-dependent.

Note:

The `iconv()` family of functions has been modified to utilize character conversion services provided by Unicode Services. `iconv_open()`, `iconv()` and `iconv_close()`’s function interfaces will remain unchanged with the exception of the addition of four new errno values and two new environment variables described in the following paragraphs. There are differences in externals between the `iconv()` family of functions and Unicode Services. However, the differences in externals will be managed by the `iconv()` family of functions except where noted in the `z/OS XL C/C++ Compiler and Run-Time Migration Guide for the Application Programmer`. All conversions listed in tables 74 and table 75 in the section of the `z/OS XL C/C++ Programming Guide` entitled “Code Set Converters Supplied” will continue to work as they do today. However, Unicode Services supports conversions between thousands of additional character sets not listed in tables 74 and table 75 of the `z/OS XL C/C++ Programming Guide`. A complete list of conversions supported by Unicode Services can be found in tables 25 an tables 26 in the `z/OS Support for Unicode: Using Unicode Services`. To set up a conversion using `iconv_open()` for any of the character sets listed in tables 25 an tables 26 the user needs to use a character string representing the CCSID’s for `fromcode/tocode`. For example, to set up a conversion from CCSID 00256 to CCSID 00870 using conversion technique R, the user would set the `_ICONV_TECHNIQUE` environment variable to R and call `iconv_open()` as follows:

```c
    cd = iconv_open("00870", "00256");
```
and continue to use iconv() and iconv_close() as in previous releases.

iconv() uses the following environment variables.

- **_ICONV_UCS2**
  Tells iconv_open(Y, X) what type of conversion method to setup when there is a choice between “direct” conversion from X to Y and “indirect” X to UCS-2 to Y.

- **_ICONV_UCS2_PREFIX**
  Tells iconv_open() what z/OS dataset name prefix to use to find UCS-2 tables if they cannot be found in the HFS.

- **_ICONV_MODE**
  Selects the behavior mode for iconv_open(), iconv() and iconv_close().

- **_ICONV_TECHNIQUE**
  This is the technique value used while using Unicode Conversion Services. For more information regarding the Unicode Conversion Services technique value, refer to Chapter 3 - Creating a Unicode Environment section of the z/OS Support for Unicode: Using Unicode Services.

For illustration of using iconv_close(), see "Example" on page 922.

Special Considerations for Bidirectional Language Support

Performs all the initialization needed to activate the bidirectional layout transformation to be used by iconv. The following three conditions must be satisfied to enable the bidirectional layout transformation:

1. The _BIDION environment variable must be set to TRUE.
2. The current locale environment at iconv_open() time must be an Arabic or Hebrew locale (eg. Ar_AA or Iw_IL).
3. The conversion code set must be an Arabic or Hebrew code set.

Conversion code sets differ in the following three cases:

1. Case fromCodeSet is UCS-2 and toCodeSet is single byte code set. In this case toCodeSet must be an Arabic or Hebrew code set.
2. Case fromCodeSet is single byte code set and toCodeSet is UCS-2. In this case fromCodeSet must be an Arabic or Hebrew code set.
3. Case both fromCodeSet and toCodeSet are single byte code sets. In this case toCodeSet must be an Arabic or Hebrew code set.

iconv_open() checks for the existence of the environment variable _BIDIATTR to get the bidirectional layout transformation attributes. It will use default values in case _BIDIATTR is not defined, is unset, or in case of the existence of some erroneous values in the _BIDIATTR environment variable. The default values are code set dependent according to the Arabic or Hebrew code set used. For the Arabic 420 code set the default values will be: orientation RTL, type of text visual, shaping shaped, numerals national and swapping on. For the Hebrew 424 code set the default values will be: orientation RTL, type of text implicit, shaping nominal, numerals national and swapping on.

iconv_open() uses the following environment variables.

- **_BIDION**
  Tells iconv_open() whether to activate bidirectional handling of the...
converted data or not. _BIDION can be assigned either the value TRUE, if you want to turn on bidirectional layout transformation, or the value FALSE, if you want to turn off the BiDi layout transformation. Bidirectional layout transformation can also be turned off if the variable_BIDION is not defined in the environment.

_BIDIATTR Holds the bidirectional layout transformation attributes which will be used later by iconv. _BIDIATTR will be read only in iconv_open() time. The _BIDIATTR environment variable is in the form of input/output pairs separated by colon, at the beginning of the string there is an @ that identifies the beginning of the attributes list, then followed by the attributes in the form of <attribute_name1>=<input1>:<output1>, <attribute_name2>=<input2>:<output2> ..... (eg. export _BIDIATTR="@01s typeoftext=visual:implicit,orientation=ltr:ltr, numerals=nominal:national").

Returned Value

If successful, iconv_open() returns a conversion descriptor.

If unsuccessful, iconv_open() returns (iconv_t)−1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>

```

```
#define _POSIX_C_SOURCE 200112L
#include <net/if.h>
char *if_indextoname(unsigned int ifindex, char *ifname);
```

General Description

The if_indextoname() function maps an interface index to its corresponding interface name. When this function is called, ifname must point to a buffer of at least IF_NAMESIZE bytes into which the interface name corresponding to interface index ifindex is returned. Otherwise, the function shall return a NULL pointer and set errno to indicate the error.

Returned Value

<table>
<thead>

<tbody>
<tr>
<td>RFC2553</td>
<td>both</td>
<td>z/OS V1R4</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <net/if.h>

struct if_nameindex *if_nameindex(void);
```

SUSV3

```c
#define _POSIX_C_SOURCE 200112L
#include <net/if.h>
struct if_nameindex *if_nameindex(void);
```

General Description

The if_nameindex() function returns an array of if_nameindex structures, one structure per interface. The end of the array is indicated by a structure with an if_index of zero and an if_name of NULL.

The if_nameindex structure holds the information about a single interface and is defined as a result of including the <net/if.h> header.

```c
struct if_nameindex {
    unsigned int if_index; /* 1, 2, ... */
    char          *if_name; /* null terminated name: "le0", ... */
};
```

The memory used for this array of structures along with the interface names pointed to by the if_name members is obtained dynamically. This memory is freed by calling the if_freenameindex() function.

Return Value

When successful, if_nameindex() returns a pointer to an array of if_nameindex structures. Upon failure, if_nameindex() returns NULL and sets errno to one of the following:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>Insufficient storage is available to supply the array.</td>
</tr>
</tbody>
</table>

#include <math.h>

int ilogbf(float x);
int ilogbl(long double x);
```

General Description

The ilogb() functions returns the unbiased exponent of its argument \( x \) as an integer.

Note: The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point " on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ilogb</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>ilogbf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>ilogbl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

If successful, the ilogb() functions return the unbiased exponent of \( x \) as an integer.

- If \( x \) is 0, the value FP_ILOGB0 is returned.
- If \( x \) is a NaN, ilogb() will return FP_ILOGBNAN
- If \( x \) is infinity, ilogb() will return INT_MAX
- If the correct value is greater than \{INT_MAX\}, \{INT_MAX\} is returned and a domain error occurs.
- If the correct value is less than \{INT_MIN\}, \{INT_MIN\} is returned and a domain error occurs.

Special Behavior for hex
ilogb

This function will return the unbiased exponent minus 1 (Because hex representation has no hidden bit, this treatment is needed to satisfy the logb() inequality).

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EDOM</td>
<td>The x argument is zero, NaN, or ±inf, or the correct value is not representable as an integer.</td>
</tr>
</tbody>
</table>

ilogbd32, ilogbd64, ilogbd128 — Integer Unbiased Exponent

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

int ilogbd32(_Decimal32 x);
int ilogbd64(_Decimal64 x);
int ilogbd128(_Decimal128 x);
int ilogb(_Decimal32 x); /* C++ only */
int ilogb(_Decimal64 x); /* C++ only */
int ilogb(_Decimal128 x); /* C++ only */
```

General Description

Returns the unbiased exponent of its argument `x` as an integer. For typical numbers, the value returned is the logarithm of `|x|` rounded down (toward -INFINITY) to the nearest integer value.

Note:
- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

If successful, these functions return the unbiased exponent of `x` as an integer.

If `x` is equal to 0.0, `ilogb()` will return _FP_DEC_ILOGB0 (= -INT_MAX).

If `x` is a NaN or infinity, `ilogb()` will return INT_MAX.

Example

```c
/* CELEBI11

This example illustrates the ilogbd128() function.
*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x = -12345.678901DL;
    int y;

    y = ilogbd128(x);

    printf("The result of ilogbd128(\%DDf) is \%d\n", x, y);
    return 0;
}
```
ilogbd32, ilogbd64, ilogbd128

imaxabs() — Absolute value for intmax_t

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <inttypes.h>

intmax_t imaxabs(intmax_t j);
```

Compile requirement

Function imaxabs() requires long long to be available.

General Description

The imaxabs() function computes the absolute value of \( j \). When the input value is INTMAX_MIN, the value is undefined. The imaxabs() function is similar to llabs() and labs(). The only difference being that the return value and the argument passed in are of type intmax_t.

Returned Value

The imaxabs function returns the absolute value of \( j \).

Example

```c
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>
int main(void)
{
    intmax_t a = -1234;
    intmax_t b = imaxabs(a);

    printf("%jd \n", b);
}
```

Output:

1234

imaxdiv

imaxdiv() — quotient and remainder for intmax_t

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <inttypes.h>

imaxdiv_t imaxdiv(intmax_t numer, intmax_t denom);
```

Compile requirement

Function imaxdiv() requires long long to be available.

General Description

The imaxdiv() function computes numer / denom and numer % denom in a single operation. The imaxdiv function is similar to lldiv() and ldiv(). The only difference being that the return value is of type imaxdiv_t and those being passed in are of type intmax_t.

Returned Value

imaxdiv() returns a structure of type imaxdiv_t comprising both the quotient and the remainder. If either part of the result cannot be represented, the behavior is undefined. if the denominator is zero, a divide by zero exception is raised.

Example

```c
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    intmax_t num = 45;
    intmax_t den = 7;
    imaxdiv_t res;
    printf("Original numerator: %jd and denominator: %jd "
           ,num,den);
    res = imaxdiv(num,den);
    printf("Quotient: %jd  Remainder: %jd\n"    , res.quot,res.rem);
}
```

Output

Original numerator: 45 and denominator: -7 Quotient: -6  Remainder: 3

Related Information

- lldiv()
ImportWorkUnit() — WLM Import Service

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX System Services</td>
<td>both</td>
<td>OS/390 V2R9</td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__wlm.h>

int ImportWorkUnit(wlmxtok_t *exporttoken,
                   wlmetok_t *enclavetoken,
                   unsigned int *conntoken);
```

General Description

Imports an enclave that has been previously exported using the ExportWorkUnit() function. The caller must invoke UnDoImportWorkUnit() when it no longer needs access to the enclave.

The ImportWorkUnit() function uses the following parameters:

* `enclavetoken` Points to a work unit export token that was returned from a call to ExportWorkUnit().

* `exporttoken` Points to a data field of type wlmetok_t where the ImportWorkUnit() function is to return the WLM work unit enclave token.

* `conntoken` Specifies the connect token that represents the WLM connection.

Returned Value

If successful, ImportWorkUnit() returns 0.

If unsuccessful, ImportWorkUnit() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>An argument of this function contained a value that is not correct.</td>
</tr>
<tr>
<td>EMVSSAF2ERR</td>
<td>An error occurred in the security product.</td>
</tr>
<tr>
<td>EMVSWLMERROR</td>
<td>A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller’s address space must be permitted to the BPX.WLMSERVER Facility class, if the BPX.WLMSERVER class is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).</td>
</tr>
</tbody>
</table>

index() — Search for Character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

char *index(const char *string, int c);

General Description

The index() function locates the first occurrence of c (converted to an unsigned char) in the string pointed to by string. The character c can be the NULL character (\0); the ending NULL is included in the search.

The string argument to the function must contain a NULL character (\0) marking the end of the string.

The index() function is identical to "strchr() — Search for Character" on page 2020.

Note: The index() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The strchr() function is preferred for portability.

Returned Value

If successful, index() returns a pointer to the first occurrence of c (converted to an unsigned character) in the string pointed to by string.

If unsuccessful because c was not found, index() returns a NULL pointer.

There are no errno values defined.

inet6_opt_append

inet6_opt_append() — Add an Option with Length "len" and Alignment "align"

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3542</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_append(void *extbuf, socklen_t extlen, int offset,
        uint8_t type, socklen_t len, uint8_t align,
        void **databufp);
```

General Description

inet6_opt_append() returns the updated total length after adding an option with length `len` and alignment `align`. If `extbuf` is not NULL, it inserts any necessary padding and sets the type and length fields. A pointer to the location for the option content in `databufp` is then returned.

`offset` should be the length returned by inet6_opt_init() or the previous inet6_opt_append(). `type` is the 8-bit option type and `len` is the length of the option data (excluding the option type and option length fields).

Returned Value

If successful, inet6_opt_append() returns the updated total length of the extension header.

Upon failure, returns -1 and errno is set to one of the following:

**EINVAL** If one of the following is true:
- `extbuf` is NULL and `extlen` is non-zero;
- `extbuf` is non-NULL and `extlen` is not a positive multiple of 8;
- `offset` is less than the size of the empty extension header;
- `type` is not valid (specifies one of the PAD options);
- `len` is less than 0 or greater than 255;
- `align` is not 1, 2, 4, or 8;
- `align` is greater than `len`;
- new updated total length would exceed `extlen` (extbuf is non-NULL);
- `databufp` is NULL (extbuf is non-NULL).

Usage Note

1. The option, `type`, must have a value from 2 to 255 (0 and 1 are reserved for the Pad1 and PadN options).
2. The option data length must have a value between 0 and 255, including the values 0 and 255. It is the length of the option data that follows.
3. The `align` parameter must have a value of 1, 2, 4, or 8 and can not exceed the value of `len`.
4. Once inet6_opt_append() has been called, the application can use databufp
   directly or use inet6_opt_set_val() to specify the content of the option.

inet6_opt_find

inet6_opt_find() — Search for an Option Specified by the Caller

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3542</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_find(void *extbuf, socklen_t extlen, int offset,
                    uint8_t type, socklen_t *lenp, void **databufp);
```

General Description

inet6_opt_find() is similar to inet6_opt_next(), except it lets the caller specify the option type to be searched for.

Returned Value

If successful, inet6_opt_find() returns the updated "previous" total length computed by advancing past the option that was returned and past any options that did not match the type.

Upon failure, returns -1 and errno is set to one of the following:

**EINVAL** If one of the following is true:
- `extbuf` is NULL;
- `extlen` is not a positive multiple of 8;
- `offset` is less than 0 or greater than or equal to `extlen`;
- `lenp` or `databufp` is NULL;
- the option was not located;
- the extension header is malformed.

Usage Note

The returned "previous" length can be passed to subsequent calls of inet6_opt_find() for finding the next occurrence of the same option type.

Related Information

- "inet6_opt_find" on page 68

</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include "netinet/in.h"

int inet6_opt_finish(void *extbuf, socklen_t extlen, int offset);
```

General Description

inet6_opt_finish() returns the updated total length taking into account the final padding of the extension header to make it a multiple of 8 bytes. If `extbuf` is not NULL the function also initializes the option by inserting a Pad1 or PadN option of the proper length.

Returned Value

If successful, `inet6_opt_finish()` returns the total length of the extension header including the final padding.

Upon failure, returns -1 and errno is set to one of the following:

**EINVAL** If one of the following is true:
- `extbuf` is NULL and `extlen` is non-zero;
- `extbuf` is non-NULL and `extlen` is not a positive multiple of 8;
- `extbuf` is non-NULL and offset is greater than `extlen`;
- `offset` is less than the size of the empty extension header.

Usage Note

`offset` should be the length returned by `inet6_opt_init()` or `inet6_opt_append()`.

int inet6_opt_get_val(void *databuf, int offset,
                      void *val, socklen_t vallen);
```

**General Description**

`inet6_opt_get_val()` extracts data items of various sizes in the data portion of the option.

**Returned Value**

If successful, `inet6_opt_get_val()` returns the offset for the next field (`offset + vallen`) that can be used when extracting option content with multiple fields.

Upon failure, returns -1 and sets `errno` to one of the following:

**EINVAL** If one of the following is true:
- `databuf` is `NULL`;
- `val` is null;
- `offset` is less than 0;
- `offset + vallen` is greater than the option length.

**Usage Note**

1. `databuf` should be a pointer returned by `inet6_opt_next()` or `inet6_opt_find()`.
2. `val` should point to the destination for the extracted data.
3. `offset` specifies from where in the data portion of the option the value should be extracted; the first byte after the option type and length is accessed by specifying an `offset` of zero.

</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_init(void *extbuf, socklen_t extlen);
```

General Description

`inet6_opt_init()` returns the number of bytes needed for the empty extension header. If `extbuf` is not NULL, the extension header is initialized to have the correct length field and the `extlen` value must be a positive, non-zero, multiple of 8, or the function will fail.

Returned Value

If successful, `inet6_opt_init()` returns the number of bytes needed for the empty extension header.

Upon failure, returns -1 and `errno` is set to one of the following:

- **EINVAL** If one of the following is true:
  - `extbuf` is NULL and `extlen` is non-zero;
  - `extbuf` is non-NULL and `extlen` is not a positive multiple of 8.

inet6_opt_next

inet6_opt_next() — Parse Received Option Headers Returning the Next Option

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3542</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_opt_next(void *extbuf, socklen_t extlen, int offset,
                    uint8_t *typep, socklen_t *lenp, void **databufp);
```

General Description

inet6_opt_next() parses received option extension headers and returns the next option.

Returned Value

If successful, `inet6_opt_next()` returns the updated "previous" length computed by advancing past the option that was returned. This returned "previous" length can then be passed to subsequent calls to `inet6_opt_next()`. This function does not return any PAD1 or PADN options.

Upon failure, returns -1 and `errno` is set to one of the following:

- **EINVAL** If one of the following is true:
  - `extbuf` is NULL;
  - `extlen` is not a positive multiple of 8;
  - `offset` is less than 0 or greater than or equal to `extlen`;
  - `typep`, `lenp`, or `databufp` is NULL;
  - there are no more options;
  - the extension header is malformed.

Usage Note

1. `extbuf` and `extlen` specifies the extension header.
2. `offset` should either be zero (for the first option) or the length returned by a previous call to `inet6_opt_next()` or `inet6_opt_find()`. It specifies the position to continue scanning the extension buffer. The next option is returned by updating `typep`, `lenp`, and `databufp`.
3. `typep` points to the option type field.
4. `lenp` stores the length of the option data (excluding the option type and option length fields).
5. `databufp` points to the data field of the of the option.

int inet6_opt_set_val(void *databuf, int offset,
                      void *val, socklen_t vallen);
```

General Description

inet6_opt_set_val() inserts items of various sizes in the data portion of the option.

Returned Value

If successful, inet6_opt_set_val() returns the `offset` for the next field (`offset + vallen`) that can be used when composing option content with multiple fields.

Upon failure, returns -1 and errno is set to one of the following:

- **EINVAL** If one of the following is true:
  - `databuf` is NULL;
  - `val` is NULL;
  - `offset` is less than 0;
  - `offset` + `vallen` is greater than the option length.

Usage Note

1. `databuf` should be a pointer returned by inet6_opt_append().
2. `val` should point to the data to be inserted.
3. `offset` specifies where in the data portion of the option the value should be inserted; the first byte after the option type and length is accessed by specifying an `offset` of 0.

</tr>
</thead>
<tbody>
<tr>
<td>RFC3542</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_rth_add(void *bp, const struct in6_addr *addr);

General Description

inet6_rth_add() adds the IPv6 address pointed to by addr to the end of the routing header that is being constructed.

Returned Value

If successful, inet6_rth_add() returns 0 and the segleft member of the routing header is updated to account for the new address.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:
- bp is NULL;
- the routing header indicates an unsupported header type;
- the routing header contains a non-valid number of segments for the type;
- there is not enough room to add the address.

Related Information

inet6_rth_getaddr() — Return Pointer to the IPv6 Address Specified

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3542</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

struct in6_addr *inet6_rth_getaddr(const void *, int index);
```

General Description

`inet6_rth_getaddr()` returns a pointer to the IPv6 address specified by `index` in the routing header described by `bp`.

Returned Value

If successful, `inet6_rth_getaddr()` returns a pointer to the IPv6 address.

Upon failure, returns NULL and errno is set to one of the following:

**EINVAL** If one of the following is true:
- `bp` is NULL;
- the routing header indicates an unsupported header type;
- the routing header contains a non-valid number of segments;
- `index` is less than 0 or greater than or equal to the number of segments.

Usage Note

1. To obtain the number of segments in the routing header, a call to `inet6_rth_segments()` should be made first.
2. `index` must have a value between 0 and one less than the value returned by `inet6_rth_segments()`.

Related Information

inet6_rth_init

inet6_rth_init() — Initialize an IPv6 Routing Header Buffer

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3542</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

void *inet6_rth_init(void *bp, socklen_t bp_len,
               int type, int segments);
```

General Description

`inet6_rth_init()` initializes the buffer pointed to by `bp` to contain a routing header of the specified `type` and sets ip6r_len based on the `segments` parameter.

Returned Value

When successful, `inet6_rth_init()` returns the pointer to the buffer, `bp`. This is then used as the first argument to the `inet6_rth_add()` function.

Upon failure, returns NULL and errno is set to one of the following:

- **EINVAL** If one of the following is true::
  - `bp` is NULL;
  - `type` indicates an unsupported header type;
  - `segments` is not valid for the `type`;
  - the buffer is not large enough, `bp_len` is too small.

Usage Note

1. The caller must allocate the buffer; its size can be determined by calling `inet6_rth_space()`.
2. Any cmsghdr fields must be initialized when the application uses ancillary data.

Related Information

inet6_rth_reverse() — Reverse the Order of the Addresses

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3542</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_rth_reverse(const void *in, void *out);
```

General Description

inet6_rth_reverse() takes a routing header, pointed to by in, and writes a new routing header that sends datagrams along the reverse of that route. It reverses the order of the addresses and sets the segleft member in the new routing header to the number of segments required to send the datagram back to where it originated. Both arguments are allowed to point to the same buffer (the reversal can occur in place).

Returned Value

If successful, inet6_rth_reverse() returns 0.

Upon failure, returns -1 and errno is set to one of the following:

- **EINVAL** If one of the following is true:
  - *in* is NULL or *out* is NULL;
  - the input routing header indicates an unsupported header type;
  - the input routing header contains a non-valid number of segments;
  - *in* and *out* overlap, but *in* and *out* are not the same buffer.

</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_rth_segments(const void *bp);
```

General Description

inet6_rth_segments() returns the number of segments (addresses) contained in the routing header described by `bp`.

Returned Value

If successful, inet6_rth_segments() returns the number of segments or 0, if there are none in the header.

Upon failure, returns -1 and errno is set to one of the following:

- **EINVAL** If one of the following is true:
  - `bp` is NULL;
  - the routing header indicates an unsupported header type;
  - the routing header contains a non-valid number of segments.

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3542</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

socklen_t inet6_rth_space(int type, int segments);
```

General Description

inet6_rth_space() calculates the number of bytes required to hold a routing header for the specified type containing the specified number of segments (addresses).

Returned Value

If successful, inet6_rth_space() returns the number of bytes, space required, for the routing header.

Upon failure, returns 0 and errno is set to one of the following:

- **EINVAL** If one of the following is true:
  - `type` indicates an unsupported header type;
  - `segments` is not valid for the `type`.

Usage Note

1. This function returns the size but does not allocate the space required for the ancillary data. This allows an application to allocate a larger buffer, if other ancillary data objects are desired, because all the ancillary data objects must be specified to sendmsg() as a single msg_control buffer.

2. For an IPv6 Type 0 routing header, the number of `segments` must be between 0 and 127, inclusive. When the application uses ancillary data it must pass the returned length to CMSG_SPACE() to determine how much memory is needed for the ancillary data object (including the cmsghdr structure).

<td></td>
</tr>
</tbody>
</table>

Format

X/Open

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_addr_t inet_addr(const char *cp);
```

Berkeley Sockets

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned long inet_addr(char *cp);
```

General Description

The inet_addr() function interprets character strings representing host addresses expressed in standard dotted-decimal notation and returns host addresses suitable for use as an Internet address.

To provide an ASCII input/output format for applications using this function, define the feature test macro __LIBASCII as described [24].

Parameter

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cp</td>
</tr>
</tbody>
</table>

A character string in standard dotted-decimal (.) notation.

Values specified in standard dotted-decimal notation take one of the following forms:

- a.b.c.d
- a.b.c
- a.b
- a

When a 4-part address is specified, each part is interpreted as a byte of data and assigned, from left to right, to one of the 4 bytes of an Internet address.

When a three-part address is specified, the last part is interpreted as a 16-bit quantity and placed in the two rightmost bytes of the network address. This makes the three-part address format convenient for specifying class-B network addresses as 128.net.host.

When a two-part address is specified, the last part is interpreted as a 24-bit quantity and placed in the three rightmost bytes of the network address. This makes the two-part address format convenient for specifying class-A network addresses as net.host.
When a one-part address is specified, the value is stored directly in the network address space without any rearrangement of its bytes.

Numbers supplied as address parts in standard dotted-decimal notation can be decimal, hexadecimal, or octal. Numbers are interpreted in C language syntax. A leading 0x implies hexadecimal; a leading 0 implies octal. A number without a leading 0 implies decimal.

**Special Behavior for C++**

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

**Note:** The inet_addr() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII Support” on page 2495 for details.

**Returned Value**

If successful, inet_addr() returns the Internet address in network byte order.

If the Internet address is returned in error—for example, not in the correct format—INADDR_NONE is the returned value. INADDR_NONE is defined in the netinet/in.h include file.

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

struct in_addr inet_makeaddr(unsigned long net, unsigned long lna);
```

General Description

The `inet_makeaddr()` function takes a network number and a local network address and constructs an Internet address.

Parameter

```c
net  The network number.
lna  The local network address.
```

Special Behavior for C++

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` feature test macro.

Returned Value

The Internet address is returned in network byte order.

#include <arpa/inet.h>

in_addr_t inet_network(const char *cp);
```

Berkeley Sockets

```c
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned long inet_network(char cp);
```

General Description

The inet_network() function interprets character strings representing addresses expressed in standard dotted-decimal notation and returns numbers suitable for use as a network number.

Parameter

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cp</code></td>
</tr>
</tbody>
</table>

Note: The input value is handled as an octal value when there are 3 integers within the dotted-decimal notation. For example: the input value of `inet_network("40.001.016.000")` validly returns 0x28010e00 (40.1.14.0) since the 016 is treated as an octet.

Special Behavior for C++

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Note: The `inet_network()` function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII Support" on page 2495 for details.

Returned Value

The network number is returned in host byte order.

#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

char *inet_ntoa(struct in_addr in);
```

General Description

The inet_ntoa() function returns a pointer to a string expressed in the
dotted-decimal notation. inet_ntoa() accepts an Internet address expressed as a
32-bit quantity in network byte order and returns a string expressed in
dotted-decimal notation.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>in</td>
<td>The host Internet address.</td>
</tr>
</tbody>
</table>

To provide an ASCII input/output format for applications using this function, define
feature test macro __LIBASCII as described on page 24.

Note: The inet_ntoa() function has a dependency on the level of the Enhanced
ASCII Extensions. See “Enhanced ASCII Support ” on page 2495 for details.

Special Behavior for C++

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1
feature test macro.

Returned Value

Returns a pointer to the Internet address expressed in dotted-decimal notation. The
storage pointed to exists on a per-thread basis and is overwritten by subsequent
calls.

- "inet_ntop() — Convert Internet Address Format from Binary to Text" on page 970
- "inetpton() — Convert Internet Address Format from Text to Binary" on page 972
The `inet_ntop()` function converts from an Internet address in binary format, specified by `src`, to standard text format, and places the result in `dst`, when `size`, the space available in `dst`, is sufficient. The argument `af` specifies the family of the Internet address. This can be AF_INET or AF_INET6.

The argument `src` points to a buffer holding an IPv4 Internet address if the `af` argument is AF_INET, or an IPv6 Internet address if the `af` argument is AF_INET6.

The argument `dst` points to a buffer where the function will store the resulting text string. The `size` argument specifies the size of this buffer. The application must specify a non-NULL `dst` argument. For IPv6 addresses, the buffer must be at least 46 bytes. For IPv4 addresses, the buffer must be at least 16 bytes.

In order to allow applications to easily declare buffers of the proper size to store IPv4 and IPv6 addresses in string form, the following two constants are defined in `<netinet/in.h>`:

```
#define INET_ADDRSTRLEN 16
#define INET6_ADDRSTRLEN 46
```

**Note:** The `inet_ntop()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII Support” on page 2495](#) for details.

**Returned Value**

If successful, `inet_ntop()` returns a pointer to the buffer containing the converted address.

If unsuccessful, `inet_ntop()` returns NULL and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>

---

**Standards**

<table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_SYS_SOCK_IPV6
#include <arpa/inet.h>
const char *inet_ntop(int af, const void *src, char *dst, socklen_t size);
```

**SUSV3**

```c
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>
const char *inet_ntop(int af, const void *__restrict__ src, char *__restrict__ dst, socklen_t size);
```
EAFNOSUPPORT
The address family specified in af is unsupported.

ENOSPC The destination buffer size is too small.

Note: For Enhanced ASCII usage, the inet_ntop() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII Support" on page 2495 for details.

inet_pton

inet_pton() — Convert Internet Address Format from Text to Binary

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC2553</td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <arpa/inet.h>

int inet_pton(int af, const char *src, void *dst);
```

```c
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>

int inet_pton(int af, const char *__restrict__ src, void *__restrict__ dst);
```

General Description

The inet_pton() function converts an Internet address in its standard text format into its numeric binary form. The argument `af` specifies the family of the address.

**Note:** AF_INET and AF_INET6 address families are currently supported.

The argument `src` points to the string being passed in. The argument `dst` points to a buffer into which `inet_pton()` stores the numeric address. The address is returned in network byte order. The caller must ensure that the buffer pointed to by `dst` is large enough to hold the numeric address.

If the `af` argument is AF_INET, `inet_pton()` accepts a string in the standard IPv4 dotted-decimal form:

```
ddd.ddd.ddd.ddd
```

where `ddd` is a 1 to 3 digit decimal number between 0 and 255.

If the `af` argument is AF_INET6, the `src` string must be in one of the following standard IPv6 text forms:

1. The preferred form is `x:x:x:x:x:x:`, where the `x`'s are the hexadecimal values of the eight 16-bit pieces of the address. Leading zeros in individual fields can be omitted, but there should be at least one numeral in every field.
2. A string of contiguous zero fields in the preferred form can be shown as `::`. The `::` can only appear once in an address. Unspecified addresses (0:0:0:0:0:0:0:0) may be represented simply as `::`.
3. A third form that is sometimes more convenient when dealing with a mixed environment of IPv4 and IPv6 is `x:x:x:x:d.d.d.d`, where `x`'s are the hexadecimal values of the six high-order 16-bit pieces of the address, and the `d`s are the decimal values of the four low-order 8-bit pieces of the address (standard IPv4 representation).

Notes:
inet_pton

- A more extensive description of the IPv6 standard representations can be found in RFC2373.
- The inet_pton() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII Support " on page 2495 for details.

Returned Value

If successful, inet_pton() returns 1 and stores the binary form of the Internet address in the buffer pointed to by dst.

If unsuccessful because the input buffer pointed to by src is not a valid string, inet_pton() returns 0.

If unsuccessful because the af argument is unknown, inet_pton() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAFNOSUPPORT</td>
<td>The address family specified in af is unsupported.</td>
</tr>
</tbody>
</table>

**initgroups() — Initialize the Supplementary Group ID List for the Process**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_SYS
#include <sys/types.h>
#include <grp.h>

int initgroups(const char *user, const gid_t basegid);
```

**General Description**

The `initgroups()` function obtains the supplementary group membership of `user`, and sets the current process supplementary group IDs to that list. The `basegid` is also included in the supplementary group IDs list.

The caller of this function must be a superuser or must specify the password of the target user name specified on the `initgroups()` call - issue the `passwd()` function before `initgroups()`.

**Returned Value**

If successful, `initgroups()` returns 0.

If unsuccessful, `initgroups()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The number of supplementary groups for the specified user plus the basegid group exceeds the maximum number of groups allowed, or a non-valid <code>user</code> is specified.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>An MVS environmental or internal error occurred.</td>
</tr>
<tr>
<td>EMVSSAF2ERR</td>
<td>The Security Authorization Facility (SAF) had an error.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The caller is not authorized, only authorized users are allowed to alter the supplementary group IDs list.</td>
</tr>
</tbody>
</table>

initstate() — Initialize Generator for random()

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *initstate(unsigned seed, char *state, size_t size);
```

General Description

The `initstate()` function allows a state array, pointed to by the `state` argument, to be initialized for future use in calls to the `random()` functions by the calling thread. The `size` argument, which specifies the size in bytes of the state array, is used by the `initstate()` function to decide how sophisticated a random-number generator to use; the larger the state array, the more random the numbers. Values for the amount of state information are 8, 32, 64, 128, and 256 bytes. While other amounts are rounded down to the nearest known value. The `seed` argument specifies a starting point for the random-number sequence and provides for restarting at the same point. The `initstate()` function returns a pointer to the previous state information array.

Returned Value

If successful, `initstate()` returns a pointer to the previous state array.

If unsuccessful, `initstate()` returns a NULL pointer. If `initstate()` is called with `size` less than 8, it will return NULL.

insque

insque() — Insert an Element into a Doubly-linked List

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <search.h>

void insque(void *element, void *pred);
```

General Description

The insque() function inserts the element pointed to by `element` into a doubly-linked list immediately after the element pointed to by `pred`. The function operates on pointers to structures which have a pointer to their successor in the list as their first element, and a pointer to their predecessor as the second. The application is free to define the remaining contents of the structure, and manages all storage itself. To insert the first element into a linear (non-circular) list, an application would call `insque(element, NULL);`. To insert the first element into a circular list, the application would set the element’s forward and back pointers to point to the element.

Returned Value

`insque()` returns no values.

Format

Terminals

#include <sys/ioctl.h>

int ioctl(int fildes int cmd, ... /* arg */);

Sockets

#define _XOPEN_SOURCE_EXTENDED 1

/** OR **/
#define _OE_SOCKETS

#include <sys/ioctl.h>
#include <net/route.h>
#include <net/if.h>

int ioctl(int fildes, int cmd, ... /* arg */);

STREAMS

#define _XOPEN_SOURCE_EXTENDED 1

#include <stropts.h>

int ioctl(int fildes int cmd, ... /* arg */);

General Description

ioctl() performs a variety of control functions on devices. The cmd argument and an optional third argument (with varying type) are passed to and interpreted by the device associated with fildes.

The cmd argument selects the control function to be performed and will depend on the device being addressed.

The arg argument represents additional information that is needed by this specific device to perform the requested function. The type of arg depends upon the particular control request, but it is either an integer or a pointer to a device-specific data structure.

ioctl() information is divided into the following sections:
- Terminals
- Sockets
- STREAMS
- ACLs

Terminals

The following ioctl() commands are used with terminals:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>

Chapter 3. Part 3. Library Functions 977
TIOCSWINSZ Set window size. Used as the second operand in an ioctl() against a terminal. The window size information pointed to by the third operand is copied into an area in the kernel associated with the terminal, and a SIGWINCH signal is generated against the foreground process group.

TIOCGWINSZ Get window size. Used as the second operand in an ioctl() against a terminal. The current window size is returned in the area pointed to by the third operand - a winsize structure.

The winsize structure is the third operand in an ioctl() call when you use TIOCSWINSZ or TIOCGWINSZ. The structure contains four unsigned short integers:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ws_row</td>
<td>Number of rows in the window, in characters.</td>
</tr>
<tr>
<td>ws_col</td>
<td>Number of columns in the window, in characters.</td>
</tr>
<tr>
<td></td>
<td>This assumes single-byte characters. Multibyte</td>
</tr>
<tr>
<td></td>
<td>characters may take more room.</td>
</tr>
<tr>
<td>ws_xpixel</td>
<td>Horizontal size of the window, in pixels.</td>
</tr>
<tr>
<td>ws_ypixel</td>
<td>Vertical size of the window, in pixels.</td>
</tr>
</tbody>
</table>

Sockets

The following ioctl() commands are used with sockets:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIONBIO</td>
<td>Sets or clears nonblocking I/O for a socket. arg is a pointer to an integer. If the integer is 0, nonblocking I/O on the socket is cleared. Otherwise, the socket is set for nonblocking I/O.</td>
</tr>
<tr>
<td>FIONREAD</td>
<td>Gets the number of immediately readable bytes for the socket. arg is a pointer to an integer. Sets the value of the integer to the number of immediately readable characters for the socket.</td>
</tr>
<tr>
<td>FIONWRITE</td>
<td>Returns the number of bytes that can be written to the connected peer AF_UNIX stream socket before the socket blocks or returns EWOULDBLOCK. The number of bytes returned is not guaranteed unless there is serialization by the using applications.</td>
</tr>
<tr>
<td>FIOGETOWN</td>
<td>Returns the PID that has been set that designates the recipient of signals.</td>
</tr>
<tr>
<td>FIOSETOWN</td>
<td>Sets the PID to be used when sending signals</td>
</tr>
<tr>
<td>FIOGETOWN and FIOSETOWN are equivalent to the F_GETOWN and F_SETOWN commands of fcntl(). For information on the values for pid, refer to that function. This function is only valid for AF_INET stream sockets.</td>
<td></td>
</tr>
<tr>
<td>SECIGET</td>
<td>Gets the peer socket’s security identity values for an AF_UNIX connected stream socket. The MVS user ID, effective UID, and effective GID of the peer process are returned in the seci structure, which is mapped by BPXYSECI. This option is valid only for the AF_UNIX domain.</td>
</tr>
<tr>
<td>SECIGET_T</td>
<td>Returns both the process and, if available, the task level security information of the peer for an AF_UNIX stream connected to the socket. The task level security information is from the task that issued the connect() or accept(). The security information is</td>
</tr>
</tbody>
</table>
returned in a struct __sect_s as defined in <sys/ioctl.h>. The security information is not available until accept() completes. The availability of the peer’s task level security data is determined by the task level userid length field. If zero, the peer does not have task level security data.

**SIOCADDRT** Adds a routing table entry. *arg* is a pointer to a `rtentry` structure, as defined in <net/route.h>. The routing table entry, passed as an argument, is added to the routing tables. This option is valid only for the AF_INET domain.

**SIOCATMARK** Queries whether the current location in the data input is pointing to out-of-band data. *arg* is a pointer to an integer. SIOCATMARK sets the argument to 1 if the socket points to a mark in the data stream for out-of-band data; otherwise, it sets the argument to 0. Refer to recv(), recvfrom(), and recvmsg() for more information on receiving out-of-band data.

**SIOCDELRT** Deletes a routing table entry. *arg* is a pointer to a `rtentry` structure, as defined in <net/route.h>. If it exists, the routing table entry passed as an argument is deleted from the routing tables. This option is valid only for the AF_INET domain.

**SIOCGIFADDR** Gets the network interface address. *arg* is a pointer to an `ifreq` structure, as defined in <net/if.h>. The interface address is returned in the argument. This option is valid only for the AF_INET domain.

**SIOCGIFBRDADDR** Gets the network interface broadcast address. *arg* is a pointer to an `ifreq` structure, as defined in <net/if.h>. The interface broadcast address is returned in the argument. This option is valid only for the AF_INET domain.

**SIOCGIFCONF** Gets the network interface configuration. *arg* is a pointer to an `ifconf` structure, as defined in <net/if.h>. The interface configuration is returned in the buffer pointed to by the `ifconf` structure. The returned data’s length is returned in the field that had originally contained the length of the buffer. This option is valid only for the AF_INET domain.

**SIOCGIFCONF6**

Gets the name, address, and other information about the IPv6 network interfaces that are configured. This is similar to the SIOCGIFCONF command for IPv4.

A struct __net_ifconf6header_s is passed as the argument of the ioctl. This structure specifies the buffer where the configuration information is to be written and is returned with the number of entries and entry length of each struct, and __net_ifconf6header_s that was written to the output buffer. These structures are defined in <sys/ioctl.h>.

If __nif6h_buflen and __nif6h_buffer are both zero, a query function is performed and the header is returned with:

```
__nif6h_version
```

The maximum supported version.
Note: If the version number is supplied (not zero), the entry length returned will be for the specified version. (If it is supported)

__nif6h_entries
The total number of entries that will be output.

__nif6h_entrylen
The length of each individual entry.

If a call to get information fails with either
errno = ERANGE, or
errno = EINVAL and __nif6h_version has changed

The call was converted into a query function and the header has been filled in as described above. In these cases, the content of the output buffer is undefined.

If Common INET is configured and multiple TCP/IP stacks are attached to the socket, the output from each stack that is enabled for IPv6 will be concatenated in the output buffer and the header will contain the total number of entries returned from all the stacks.
The version returned with the query function will be the highest version supported by all the stacks.

This ioctl can be issued on an AF_INET or AF_INET6 socket.

Error Code Description
EAFNOSUPPORT
No IPv6 enabled TCP/IP stacks are active.
EINVAL
The input version number is not supported.
ERANGE
The buffer is too small to contain all of the IPv6 network interface entries.

SIOCGIFDSTADDR
Gets the network interface destination address. arg is a pointer to an ifreq structure, as defined in <net/if.h>. The interface destination (point-to-point) address is returned in the argument. This option is valid only for the AF_INET domain.

SIOCGIFFLAGS
Gets the network interface flags. arg is a pointer to an ifreq structure, as defined in <net/if.h>. The interface flags are returned in the argument. This option is valid only for the AF_INET domain.

SIOCGIFMETRIC
Gets the network interface routing metric. arg is a pointer to an ifreq structure, as defined in <net/if.h>. The interface routing metric is returned in the argument. This option is valid only for the AF_INET domain.

SIOCGIFNETMASK
Gets the network interface network mask. arg is a pointer to an ifreq structure, as defined in <net/if.h>. The interface network mask is returned in the argument. This option is valid only for the AF_INET domain.

SIOCGSPLXFQDN
Gets the fully qualified domain name for a given server and domain
name in a sysplex. This is an special purpose command to support applications that have registered with WorkLoad Manager (WLM) for connection optimization services using the Domain Name System (DNS). 'arg' is a pointer to sysplexFqDn structure, as defined in <ezbzsdnc.h>. sysplexFqDn contains pointer to sysplexFqDnData structure, as defined in <ezbzsdnc.h>.

sysplexFqDnData structure contains server name(input), group name(input) and fully qualified domain name(output).

ioctl() with the SIOCGSPLXFQDN command will fail if:

**Error Code** | **Description**
--- | ---
EFAULT | Write user storage failed
EINVAL | One of the following:
  - Group name required
  - Buffer length not valid
  - Socket call parameter error
ENXIO | One of the following:
  - Sysplex address not found
  - Res not found In DNS
  - Time out
  - Time Unexpected Error

**Example**

The following is an example of the ioctl() call used with SIOCGSPLXFQDN.

```c
#include <ezbzsdnc.h>
sysplexFqDn splxFqDn;
sysplexFqDnData splxData;
int rc;

splxFqDn.splxVersion = splxDataVersion;
splxFqDn.splxBufLen = sizeof(sysplexFqDnData);
splxFqDn.splxBufAddr = &splxData;

/* Assign values to splxData.groupName, */
/* splxData.serverName if required */

/* Get the fully qualified domain name */
rc = ioctl(s, SIOCGSPLXFQDN, (char *) &splxFqDn);

/* splxData.domainName contains the fully*/
/* qualified domain name. */
```

**SIOCSECEVR**

Used to SET or GET the security environment for a server socket. arg points to a struct __seco_s where element __seco_argument is set to 1 for a SET and 2 for a GET request.

When used with the SET argument, the AF_UNIX stream socket server will designate the server socket as one that requires the full security environment of the connecting client to be available before the connect will complete successfully. During connect processing, connect obtains the security environment of the connector and anchors it off the connector’s socket for use by the server. If the
security environment cannot be obtained during connect processing, the connect will fail. This command has no effect on sockets that do not become server sockets.

When used with the GET argument, the AF_UNIX stream socket server will copy the previously SET security environment from the connector’s address space to the server’s address space so it can be used as input on calls to the security product. This command has meaning only for server sockets that previously issued SIOCSECENV with the SET argument.

SIOCSIFMETRIC
Sets the network interface routing metric. arg is a pointer to an ifreq structure, as defined in <net/if.h>. SIOCSIFMETRIC sets the interface routing metric to the value passed in the argument. This option is valid only for the AF_INET domain.

SIOCSVIPA
Defines or deletes a dynamic VIPA. arg is a pointer to a dvreq structure as defined in <ezbzdvpc.h>. This option is valid only for the AF_INET domain.

SIOCTIEDESTHRD
Associates (ties) or disassociates (unties) a descriptor with a thread. arg is a pointer to an int. When *arg is 1, the descriptor is tied to the calling thread. When *arg is 0, the descriptor is untied from the calling thread. If the task should terminate before the descriptor is closed or untied from the task, UNIX file system thread termination processing will close the descriptor. This command can be used on both heavy weight and medium weight threads.

SIOCGIFCONF6
Gets the name, address, and other information about the IPV6 network interfaces that are configured. This is similar to the SIOCGIFCONF command for IPV4.

A struct _NET_IFCONF6HEADER_S is passed as the argument of the IOCTL. This structure specifies the buffer where the configuration information is to be written and is returned with the number of entries and entry length of each struct _NET_IFCONF6ENTRY_S that was written to the output buffer. These structures are defined in <sys/ioctl.h>.

If _NIF6H_BUFLEN and _NIF6H_BUFFER are both zero, a query function is performed and the header is returned with _NIF6H_VERSION. The maximum supported version note. If the version number is supplied (not zero), the entry length returned will be for the specified version if it is supported.

_NIF6H_ENTRIES is the total number of entries that will be outputed. _NIF6H_ENTRYLEN is the length of each individual entry.

If a call to get information fails with either ERRNO = ERANGE or ERRNO = EINVAL and _INF6H_VERSION has changed, the call was converted into a query function and the header has been filled in as described above. In these cases, the content of the output buffer is undefined.

If common INET is configured and multiple TCP/IP stacks are attached to the socket, the output from each stack that is enabled for IPV6 will be concatenated in the output buffer and the header
will contain the total number of entries returned from all the stacks. The version returned with the query function will be the highest version supported by all the stacks.

This IOCTL can be issued on an AF_INET or AF_INET6 socket.

### Error Code Description

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAFNOSUPPORT</td>
<td>No IPV6 enabled TCP/IP stacks are active.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The input version number is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The buffer is too small to contain all of the IPV6 network interface and entries.</td>
</tr>
</tbody>
</table>

**Special Behavior for C++**

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

**Terminal and Sockets Returned Value**

If successful, `ioctl()` returns 0.

If unsuccessful, `ioctl()` returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The <code>fd</code> parameter is not a valid socket descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The request is not valid or not supported.</td>
</tr>
<tr>
<td>EIO</td>
<td>The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.</td>
</tr>
<tr>
<td>EMVSPARM</td>
<td>Incorrect parameters were passed to the service.</td>
</tr>
<tr>
<td>ENODEV</td>
<td>The device is incorrect. The function is not supported by the device driver.</td>
</tr>
<tr>
<td>ENOTTY</td>
<td>An incorrect file descriptor was specified. The file type was not character special.</td>
</tr>
</tbody>
</table>

**Example**

The following is an example of the `ioctl()` call.

```c
int s;
int dontblock;
int rc;
...  
/* Place the socket into nonblocking mode */
dontblock = 1;
rc = ioctl(s, FIONBIO, (char *) &dontblock);
...  
```

**STREAMS**

The following `ioctl()` commands are used with STREAMS:

- **L_PUSH** Pushes the module whose name is pointed to by `arg` onto the top of the current STREAM, just below the STREAM head. It then calls the `open()` function of the newly-pushed module.
ioctl

ioctl() with the _I_PUSH command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Non-valid module name.</td>
</tr>
<tr>
<td>ENXIO</td>
<td>Open function of new module failed.</td>
</tr>
<tr>
<td>ENXIO</td>
<td>Hang-up received on fildes</td>
</tr>
</tbody>
</table>

_L_POP
Removes the module just below the STREAM pointed to by fildes. The arg argument should be 0 in an _I_POP request.

ioctl() with the _I_POP command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>No module present in the STREAM.</td>
</tr>
<tr>
<td>ENXIO</td>
<td>Hang-up received on fildes</td>
</tr>
</tbody>
</table>

_L_LOOK
Retrieves the name of the module just below the STREAM head of the STREAM pointed to by fildes and places it in a character string pointed to by arg. The buffer pointed to by arg should be at least FMNAMESZ+1 bytes long, where FMNAMESZ is defined in <stropts.h>.

ioctl() with the _I_LOOK command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>No module present in the STREAM.</td>
</tr>
</tbody>
</table>

_L_FLUSH
This request flushes read and/or write queues, depending on the value of arg. Valid arg values are:

- FLUSHR: Flush all read queues.
- FLUSHW: Flush all write queues.
- FLUSHRW: Flush all read and all write queues.

ioctl() with the _I_FLUSH command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>Unable to allocate buffers for flush message.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Non-valid arg value.</td>
</tr>
<tr>
<td>ENXIO</td>
<td>Hang-up received on fildes</td>
</tr>
</tbody>
</table>

_I_FLUSHBAND
Flushes a particular band of messages. The arg argument points to a bandinfo structure. The bi_flag member may be one of FLUSHER, FLUSHW, or FLUSHRW as described above. The bi_pri member determines the priority band to be flushed.

_I_SETSIG
Requests that the STREAMS implementation send the SIGPOLL signal to the calling process when a particular event has occurred on the STREAM associated with fildes. I_SETSIG supports an asynchronous processing capability in STREAMS. The value of arg is a bitmask that specifies the events for which the process should be signaled. It is the bitwise OR of any combination of the following constants:

- S_RDNORM: A normal (priority band set to 0) message has
arrived at the head of a STREAM head read queue. A signal will be generated even if the message is of zero length.

**S_RDBAND**  A message with a nonzero priority band has arrived at the head of a STREAM head read queue. A signal will be generated even if the message is of zero length.

**S_INPUT**  A message, other than a high-priority message, has arrived at the head of a STREAM head read queue. A signal will be generated even if the message is of zero length.

**S_HIPRI**  A high-priority message is present on a STREAM head read queue. A signal will be generated even if the message is of zero length.

**S_OUTPUT**  The write queue for normal data (priority band 0) just below the STREAM head is no longer full. This notifies the process that there is room on the queue for sending (or writing) normal data downstream.

**S_WRNORM**  Same as S_OUTPUT.

**S_WRBAND**  The write queue for a nonzero priority band just below the STREAM head is no longer full. This notifies the process that there is no room on the queue for sending (or writing) priority data downstream.

**S_MSG**  A STREAMS signal message that contains the SIGPOLL signal has reached the front of the STREAM head read queue.

**S_ERROR**  Notification of an error condition has reached the STREAM head.

**S_HANGUP**  When used in conjunction with S_RDBAND, SIGURG is generated instead of SIGPOLL when a priority message reaches the front of the STREAM head read queue.

If **arg** is 0, the calling process will be unregistered and will not receive further SIGPOLL signals for the STREAM associated with **fdles**.

Processes that wish to receive SIGPOLL signals must explicitly register to receive them using I_SETSIG. If several processes register to receive this signal for the same event on the same STREAM, each process will be signaled when the event occurs.

**ioctl()** with the I_SETSIG command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>There were insufficient resources to store the signal request.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of <strong>arg</strong> is not valid.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of <strong>arg</strong> is 0 and the calling process is not registered to receive the SIGPOLL signal.</td>
</tr>
</tbody>
</table>
I_GETSIG  Returns the events for which the calling process is currently registered to be sent a SIGPOLL signal. The events are returned as a bitmask in an int pointed to by `arg`, where the events are those specified in the description of I_SETSIG above.

ioctl() with the I_GETSIG command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Process is not registered to receive the SIGPOLL signal.</td>
</tr>
</tbody>
</table>

I_FIND  This request compares the names of all modules currently present in the STREAM to the name pointed to by `arg`, and returns 1 if the name module is present in the STREAM, or returns 0 if the named module is not present.

ioctl() with the I_FIND command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td><code>arg</code> does not contain a valid module name.</td>
</tr>
</tbody>
</table>

I_PEEK  This request allows a process to retrieve the information in the first message on the STREAM head read queue without taking the message off the queue. It is analogous to getmsg() except that this command does not remove the message from the queue. The `arg` argument points to a strpeek structure.

The maxlen member in the ctlbuf and databuf strbuf structure must be set to the number of bytes of control information and/or data information, respectively, to retrieve. The flags member may be marked RS_HIPRI or 0, as described by getmsg() - getpmsg(). If the process sets flags to RS_HIPRI, for example, I_PEEK will only look for a high-priority message on the STREAM head read queue.

I_PEEK returns 1 if a message was retrieved, and returns 0 if no message was found on the STREAM head read queue, or if the RS_HIPFI flag was set in flags and a high-priority message was not present on the STREAM head read queue. It does not wait for a message to arrive. On return, ctlbuf specifies information in the control buffer, databuf specifies information in the data buffer, and flags contains the value RS_HIPRI or 0.

I_SRDOPT  Sets the read mode using the value of the argument `arg`. Read modes are described in read(). Valid `arg` flags are:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RNORM</td>
<td>Byte-stream mode, the default.</td>
</tr>
<tr>
<td>RMSGD</td>
<td>Message-discard mode.</td>
</tr>
<tr>
<td>RMSGN</td>
<td>Message-nondiscarded mode.</td>
</tr>
</tbody>
</table>

The bitwise inclusive-OR of RMSGD and RMSGN will return EINVAL. The bitwise inclusive-OR of RNORM and either RMSGD or RMSGN will result in the other flag overriding RNORM which is the default.

In addition, treatment of control messages by the STREAM head may be changed by setting any of the following flag in `arg`:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RPROTNORM</td>
<td>Fail read() with EBADMSG if a message containing a control part is at the front of the STREAM head read queue.</td>
</tr>
</tbody>
</table>
RPROTDAT Deliver the control part of a message as data when a process issues a read().

RPROTDIS Discard the control part of a message, delivery any data portion, when a process issues a read().

ioctl() with the I_SRDOPT command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The arg argument is not valid.</td>
</tr>
</tbody>
</table>

I_GRDOPT Returns the current read mode setting, as described above, in an int pointed to by the argument arg. Read modes are described in read().

I_NREAD Counts the number of data bytes in the data part of the first message on the STREAM head read queue and places this value in the init pointed to by arg. The return value for the command is the number of messages on the STREAM head read queue. For example, if 0 is returned in arg, but the ioctl() return value is greater than 0, this indicates that a zero-length message is next on the queue.

I_FDINSERT Creates a message from specified buffer(s), adds information about another STREAM, and sends the message downstream. The message contains a control part and an optional data part. The data and control parts to be sent are distinguished by placement in separate buffers, as described below. The arg argument points to a strfdinsert structure.

The len member in the ctlbuf strbuf structure must be set to the size of a pointer plus the number of bytes of control information to be sent with the message. The fildes member specifies the file descriptor of the other STREAM, and the offset member, which must be suitably aligned for use as a pointer, specifies the offset from the start of the control buffer where I_FDINSERT will store a pointer whose interpretation is specific to the STREAM end. The len member in the databuf strbuf structure must be set to the number of bytes of data information to be sent with the message, or 0 if no data part is to be sent.

The flags member specifies the type of message to be created. A normal message is created if flags is set to 0, and a high-priority message is created if flags is set to RS_HIPRI. For non-priority messages, I_FDINSERT will block if the STREAM write queue is full due to internal flow control conditions. For priority messages, I_FDINSERT does not block on this condition. For non-priority messages, I_FDINSERT does not block when the write queue is full and O_NONBLOCK is set. Instead, it fails and sets errno to EAGAIN.

I_FDINSERT also blocks, unless prevented by lack of internal resources, waiting for the availability of message blocks in the STREAM, regardless of priority or whether O_NONBLOCK has been specified. No partial message is sent.

ioctl() with the I_FDINSERT command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>
| EAGAIN     | A non-priority message is specified, the
O_NONBLOCK flag is set, and the STREAM write queue is full due to internal flow control conditions.

EAGAIN or ENOSR
Buffers can not be allocated for the message that is to be created.

EINVAL One of the following:
• The \texttt{fd} member of the \texttt{strfinsert} structure is not a valid, open STREAM file descriptor.
• The size of a pointer plus \texttt{offset} is greater than the \texttt{len} member for the buffer specified through \texttt{ctlptr}
• the \texttt{offset} member does not specify a properly-aligned location in the data buffer.
• An undefined value is stored in \texttt{flags}

ENXIO Hang-up received for \texttt{fd} or \texttt{fildes}.

ERANGE The \texttt{len} member for the buffer specified through \texttt{databuf} does not fall within the range specified by the maximum and minimum packet sizes of the topmost STREAM module or the \texttt{len} member for the buffer specified through \texttt{databuf} is larger than the maximum configured size of the data part of a message; or the \texttt{len} member for the buffer specified through \texttt{ctlbuf} is larger than the maximum configured size of the control part of a message.

I_STR Constructs an internal STREAMS ioctl() message from the data pointed to by \texttt{arg}, and sends that message downstream.

This mechanism is provided to send ioctl() requests to downstream modules and drivers. It allows information to be sent with ioctl(), and returns to the process any information sent upstream by the downstream recipient. I_STR blocks until the system responds with either a positive or negative acknowledgement message, or until the request “times out” after some period of time. If the request times out, it fails with \texttt{errno} set to ETIME.

At most, one I_STR can be active on a STREAM. Further I_STR calls will block until the active I_STR completes at the STREAM head. The default timeout interval for these requests is 15 seconds. The O_NONBLOCK flag has no effect on this call.

To send requests downstream, \texttt{arg} must point to a \texttt{striodctl} structure.

The \texttt{ic_cmd} member is the internal ioctl() command intended for a downstream module or driver and \texttt{ic_timeout} is the number of seconds (-1 = infinite, 0 = use implementation-dependent timeout interval, >0 = as specified) an I_STR request will wait for acknowledgement before timing out. \texttt{ic_len} member has two uses: on input, it contains the length of the data argument passed in, and on return from the command, it contains the number of bytes being returned to the process (the \texttt{buffer} pointed to by \texttt{ic_dp} should be large enough to contain the maximum amount of data that any module or the driver in the STREAM can return.)
The STREAM head will convert the information pointed to by the `strioctl` structure to an internal `ioctl()` command message and send it downstream.

`ioctl()` with the _I_STR_ command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN or ENOSR</td>
<td>Unable to allocate buffers for the <code>ioctl()</code> message.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>This <code>ic_len</code> member is less than 0 or larger than the maximum configured size of the data part of a message, or <code>ic_timeout</code> is less than -1.</td>
</tr>
<tr>
<td>ENXIO</td>
<td>Hang-up received on <code>fildes</code>.</td>
</tr>
<tr>
<td>ETIME</td>
<td>A downstream <code>ioctl()</code> timed out before acknowledgement was received.</td>
</tr>
</tbody>
</table>

An _I_STR_ can also fail while waiting for an acknowledgement if a message indicating an error or a hang-up is received at the STREAM head. In addition, an error code can be returned in the positive or negative acknowledgement message, in the event the `ioctl()` command sent downstream fails. For these cases, _I_STR_ fails with `errno` set to the value in the message.

**I_SWROPT**

Sets the write mode using the value of the argument `arg`. Valid bit settings for `arg` are:

- **SNDZERO**
  - Send a zero-length message downstream when a `write()` if 0 bytes occurs. To not send a zero-length message when a `write()` of 0 bytes occurs, this bit must not be set in `arg` (for example, `arg` would be set to 0).

`ioctl()` with the _I_SWROPT_ command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td><code>arg</code> is not the above value.</td>
</tr>
</tbody>
</table>

**I_GWROPT**

Returns the current write mode setting as described above, in the int that is pointed to by the argument `arg`.

**I_SENDFD**

`I_SENDFD` creates a new reference to the open file description associated with the file descriptor `arg` and writes a message on the STREAMS-based pipes `fildes` containing the reference, together with the user ID and group ID of the calling process.

`ioctl()` with the _I_SENDFD_ command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The sending STREAM is unable to allocate a message block to contain the file pointer; or the read queues of the receiving STREAM head is full and cannot accept the message sent by <em>I_SENDFD</em>.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The <code>arg</code> argument is not a valid, open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The <code>fildes</code> argument is not connected to a STREAM pipe.</td>
</tr>
</tbody>
</table>
ENXIO  Hang-up received on fildes.

I_RECVFD  Retrieves the reference to an open file description from a message within a STREAMS-based pipe using the I_SENDFD command, and allocates a new file descriptor in the calling process that refers to this open file description. The arg argument is a pointer to an strrecvfd data structure as defined in <stropts.h>.

The fd member is a file descriptor. The uid and gid members are the effective user ID and effective group ID, respectively, of the sending process.

If O_NONBLOCK is not set I_RECVFD blocks until a message is present at the STREAM head. If O_NONBLOCK is set, I_RECVFD fails with errno set to EAGAIN if no message is present at the STREAM head.

If the message at the STREAM head is a message sent by an I_SENDFD, a new file descriptor is allocated for the open file descriptor referenced in the message. The new file descriptor is placed in the fd member of the strrecvfd structure pointed to by arg.

ioctl() with the I_RECVFD command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>A message is not present at the STREAM head read queue and the O_NONBLOCK flag is set.</td>
</tr>
<tr>
<td>EBADMSG</td>
<td>The message at the STREAM head read queue is not a message containing a passed file descriptor.</td>
</tr>
<tr>
<td>EFILE</td>
<td>The process has the maximum number of file descriptors currently open that is allowed.</td>
</tr>
<tr>
<td>ENXIO</td>
<td>Hang-up received on fildes.</td>
</tr>
</tbody>
</table>

I_LIST  This request allows the process to list all the module names on the STREAM, up to and including the topmost driver names. If arg is a NULL pointer, the return value is the number of modules, including the driver, that are on the STREAM pointed to by fildes. This lets the process allocate enough space for the module names. Otherwise, it should point to an str_list structure.

The sl_nmods member indicates the number of entries the process has allocated in the array. Upon return, the sl_modlist member of the str_list structure contains the list of module names. The number of entries that have been filled into the sl_modlist array is found in the sl_nmode member (the number includes the number of module including the driver). The return value from ioctl() is 0. The entries are filled in starting at the top of the STREAM and continuing downstream until either the end of the STREAM is reached, or the number of requested modules (sl_nmods) is satisfied.

ioctl() with the I_LIST command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN or ENOSR</td>
<td>Unable to allocate buffers.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The sl_nmods member is less than 1.</td>
</tr>
</tbody>
</table>
I_ATMARK  This request allows the process to see if the message at the head of the STREAM head read queue is marked by some module downstream. The arg argument determines how the checking is done when there may be multiple marked messages on the STREAM head read queue. It may take on the following values:

ANYMARK  Check if the message is marked.

LASTMARK  Check if the message is the last one marked on the queue.

The bitwise inclusive-OR of the flags ANYMARK and LASTMARK is permitted.

The return value is 1 if the mark condition is satisfied and 0 otherwise.

ioctl() with the I_ATMARK command will fail if:

EINVAL  Non-valid arg value.

I_CKBAND  Check if a message of a given priority band exists on the STREAM head read queue. This returns 1 if a message of the given priority exists, 0 if no message exists, or -1 on error. arg should be of type int.

ioctl() with the I_CKBAND command will fail if:

EINVAL  Non-valid arg value.

I_GETBAND  Return the priority band of the first message on the STREAM head read queue in the integer referenced by arg.

ioctl() with the I_GETBAND command will fail if:

ENODATA  No message on the STREAM head read queue.

I_CANPUT  Check if a certain band is writable. arg is set to the priority band in question. The return value is 0 if the band is flow-controlled, 1 if the band is writable, or -1 on error.

ioctl() with the I_CANPUT command will fail if:

EINVAL  Non-valid arg value.

I_SETCLTIME  This request allows the process to set the time the STREAM head will delay when a STREAM is closing and there is data on the write queues. Before closing each module or driver, if there is data on its write queue, the STREAM head will delay for the specified amount of time to allow the data to drain. If, after the delay, data is still present, it will be flushed. The arg argument is a pointer to an integer specifying the number of milliseconds to delay, rounded up to the nearest valid value. If I_SETCLTIME is not performed on a STREAM, an implementation-dependent default timeout interval is used.

ioctl() with the I_SETCLTIME command will fail if:

EINVAL  Non-valid arg value.

I_GETCLTIME  This request returns the close time delay in the integer pointed to by arg

Multiplexed STREAMS Configurations
The following four commands are used for connecting and disconnecting multiplexed STREAMS configurations. These commands use an implementation-dependent default timeout interval.

**I_LINK**

Connects two STREAMS, where `fildes` is the file descriptor of the STREAM connected to the multiplexing driver, and `arg` is the file descriptor of the STREAM connected to another driver. The STREAM designated by `arg` gets connected below the multiplexing driver. `I_LINK` requires the multiplexing driver to send an acknowledgement message to the STREAM head regarding the connection. This call returns a multiplexer ID number (an identifier used to disconnect the multiplexer; see (I_UNLINK) on success, and -1 on failure.

`ioctl()` with the `I_LINK` command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN or ENOSR</td>
<td>Unable to allocate STREAMS storage to perform the <code>I_LINK</code>.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The <code>arg</code> argument is not a valid, open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The <code>fildes</code> does not support multiplexing; or <code>arg</code> is not a STREAM or is already connected downstream from a multiplexer, or the specified <code>I_LINK</code> operation would connect the STREAM head in more than one place in the multiplexed STREAM.</td>
</tr>
<tr>
<td>ENXIO</td>
<td>Hang-up received on <code>fildes</code>.</td>
</tr>
<tr>
<td>ETIME</td>
<td>Time out before acknowledgement message was received at STREAM head.</td>
</tr>
</tbody>
</table>

An `I_LINK` can also fail while waiting for the multiplexing driver to acknowledge the request, if a message indicating an error or a hang-up is received at the STREAM head of `fildes`. In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, `I_LINK` fails with `errno` set to the value in the message.

**I_UNLINK**

Disconnects the two STREAMs specified by `fildes` and `arg`. `fildes` is the file descriptor of the STREAM connected to the multiplexing driver. The `arg` argument is the multiplexer ID number that was returned by the `I_LINK` `ioctl()` command when a STREAM was connected downstream from the multiplexing driver. If `arg` is `MUXID_ALL`, then all STREAMs that were connected to `fildes` are disconnected. As in `I_LINK`, this command requires acknowledgement.

`ioctl()` with the `I_UNLINK` command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN or ENOSR</td>
<td>Unable to allocate buffers for the acknowledgement message.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Non-valid multiplexer ID number.</td>
</tr>
<tr>
<td>ENXIO</td>
<td>Hang-up received on <code>fildes</code>.</td>
</tr>
</tbody>
</table>
ETIME Time out before acknowledgement message was received at STREAM head.

An I_UNLINK can also fail while waiting for the multiplexing driver to acknowledge the request if a message indicating an error or a hang-up is received at the STREAM head of fildes. In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, I_UNLINK fails with errno set to the value in the message.

I_PLINK

Creates a persistent connection between two STREAMs, where fildes is the file descriptor of the STREAM connected to another driver. This call creates a persistent connection which can exist even if the file descriptor fildes associated with the upper STREAM to the multiplexing driver is closed. The STREAM designated by arg gets connected using a persistent connection below the multiplexing driver. I_PLINK requires the multiplexing driver to send an acknowledgement message to the STREAM head. This call returns a multiplexer ID number (an identifier that may be used to disconnect the multiplexer, see I_PUNLINK) on success, and -1 on failure.

ioctl() with the I_PLINK command will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN or ENOSR</td>
<td>Unable to allocate STREAMS storage to perform the I_PLINK.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The arg argument is not valid, open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The fildes argument does not support multiplexing; or arg is not a STREAM or is already connected downstream from a multiplexer; or the specified I_PLINK operation would connect the STREAM head in more than one place in the multiplexed STREAM.</td>
</tr>
<tr>
<td>ENXIO</td>
<td>Hang-up received on fildes.</td>
</tr>
<tr>
<td>ETIME</td>
<td>Time out before acknowledgement message was received at STREAM head.</td>
</tr>
</tbody>
</table>

An I_PLINK can also fail while waiting for the multiplexing driver to acknowledge the request, if a message indicating an error or a hang-up is received at the STREAM head of fildes. In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, I_PLINK fails with errno set to the value in the message.

I_PUNLINK

Disconnects the two STREAMs specified by fildes and arg from a persistent connection. The fildes argument is the file descriptor of the STREAM connected to the multiplexing driver. The arg argument is the multiplexer ID number that was returned by the I_PLINK ioctl() command when a STREAM was connected downstream from the multiplexing driver. If arg is MUXID_ALL then all STREAMs which are persistent connections to fildes are disconnected. As in I_PLINK, this command requires the multiplexing driver to acknowledge the request.
ioctl

ioctl() with the I_PUNLINK command will fail if:

### Error Code | Description
--- | ---
EAGAIN or ENOSR | Unable to allocate buffers for the acknowledgement message.
EINVAL | Non-valid multiplexer ID number.
ENXIO | Hang-up received on `fildes`.
ETIME | Time out before acknowledgement message was received at STREAM head.

An I_PUNLINK can also fail while waiting for the multiplexing driver to acknowledge the request if a message indicating an error or a hang-up is received at the STREAM head of `fildes`. In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, I_PUNLINK fails with errno set to the value in the message.

### STREAMS Returned Value

If successful, ioctl() returns a value other than -1 that depends upon the STREAMS device control function.

If unsuccessful, ioctl() returns -1 and sets errno to one of the following values.

**Note:** It is impossible for ioctl() to perform any STREAMS type commands successfully, since z/OS UNIX services do not provide any STREAMS-based files. The function will always return -1 with errno set to indicate the failure. See [open() — Open a File](https://publib.boulder.ibm.com/epub/books/redbookrv4/0667-2556-en.html#open-function) for more information.

Under the following general conditions, ioctl() will fail if:

### Error Code | Description
--- | ---
EBADF | The `fildes` argument is not a valid open file descriptor.
EINTR | A signal was caught during the ioctl() operation.
EINVAL | The STREAM or multiplexer referenced by `fildes` is linked (directly or indirectly) downstream from a multiplexer.

If an underlying device driver detects an error, ioctl() will fail if:

### Error Code | Description
--- | ---
EINVAL | The `cmd` or `arg` argument is not valid for this device.
EIO | Some physical I/O error has occurred.
ENODEV | The `fildes` argument refers to a valid STREAMS device, but the corresponding device driver does not support ioctl().
ENOTTY | The `fildes` argument is not associated with a STREAMS device that accepts control functions.
ENXIO | The `cmd` or `arg` argument is not valid for this device driver, but the service requested can not be performed on this particular sub-device.
If a STREAM is connected downstream from a multiplexer, any ioctl() command except I_UNLINK and I_PUNLINK will set errno to EINVAL.

**ACLs**

The following ioctl() commands are used with ACLs:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETFACL</td>
<td>Set ACL. Used to set information into an Access Control List. arg specifies the user buffer containing the input ACL which is mapped by struct ACL_buf followed immediately by an array of struct ACL_entries. arglen specifies the combined length of the struct ACL_buf and the array of struct ACL_entries. See <a href="https://www.ibm.com/support/knowledgecenter/en_US/zos91/rftoc69_.htm">z/OS UNIX System Services Programming: Assembler Callable Services Reference</a> for more information about ACL_buf and the ACL_entries.</td>
</tr>
<tr>
<td>GETFACL</td>
<td>Get ACL. Used to retrieve information from an Access Control List. arg specifies the user buffer into which the requested ACL will be returned. The data is mapped by struct ACL_BUF followed immediately by an array of struct ACL_entries. See <a href="https://www.ibm.com/support/knowledgecenter/en_US/zos91/rftoc69_.htm">z/OS UNIX System Services Programming: Assembler Callable Services Reference</a> for more information about ACL_buf and the ACL_entries. Arglen specifies the combined length of the struct ACL and the array of struct ACL_entries in the user buffer.</td>
</tr>
</tbody>
</table>

**ACLs Returned Value**

If successful, ioctl() returns 0.

If unsuccessful, ioctl() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The fildes parameter is not a valid file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The request is not valid or not supported.</td>
</tr>
<tr>
<td>EMVSPARM</td>
<td>Incorrect parameters were passed to the service.</td>
</tr>
<tr>
<td>ENODEV</td>
<td>The device is incorrect. The function is not supported by the device driver.</td>
</tr>
</tbody>
</table>

**Example**

The following is an example of the ioctl() call.

```c
int s;
int rc;
int aclrlen;
ext_acl_t aclbufp;
s = open("datafile", O_RDWR);
aclrlen = sizeof struct ACL_buf + (1024 * sizeof ACL_entry);
aclbufp = (ext acl_t)malloc(aclrlen);
rc = ioctl(s, GETFACL, aclrlen, aclbufp)
```

</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <__ftp.h>

struct __ipdbcss *__ipdbcs(void);
```

General Description

The __ipdbcs() function determines the values that IP address resolution initialization found in the resolver configuration data set for the keywords LoadDBCSTables. If the LoadDBCSTables keywords are not found in the resolver configuration data set, the structure returned has a count of zero and each element in the structure list points to a NULL string.

Returned Value

If successful, __ipdbcs() returns a NULL-terminated character string containing the complete structure __ipdbcss with each entry in __ip_dbcs_list[] initialized either to a valid name or to a NULL string. The number of valid names, up to the maximum of 8, is placed in __ipdbcsnum. If no table names are specified then __ipdbcsnum is set to zero.

If unsuccessful, __ipdbcs() returns NULL and stores one of the following error values in h_errno. __ipdbcs() is only unsuccessful if IP Address Resolution initialization fails to complete.

</table>

Format

```
#include <__ftp.h>

char *__ipDomainName(void);
```

General Description

Lets an application get the values which IP address resolution initialization established for the domain name (supplied by keywords Domain or DomainOrigin).

Returned Value

If successful, __ipDomainName() returns the NULL-terminated character string which is the name found for the domain name or a NULL string if no domain name was found in the IP address resolution initialization.

If unsuccessful, __ipDomainName() returns NULL and stores one of the following error values in h_errno. The __ipDomainName() function is only unsuccessful if IP address resolution initialization fails to complete.

Format

```c
#include <__ftp.h>

char *__ipdspx(void);
```

General Description

The __ipdspx() function determines the value that IP address resolution initialization found in the resolver configuration data set for the keyword DataSetPrefix. If no DataSetPrefix keyword is found in the resolver configuration data set, then the default value is returned.

Returned Value

If successful, __ipdspx() returns the NULL-terminated character string that was supplied in the configuration data set. If the configuration data set did not supply a value for the keyword DataSetPrefix, then __ipdspx() returns the string TCPIP.

If unsuccessful, __ipdspx() returns NULL and stores one of the following error values in h_errno. __ipdspx() is only unsuccessful if IP Address Resolution initialization fails to complete.

Format

```
#include <__ftp.h>

char *__iphost(void);
```

General Description

The __iphost() function lets an application determine the values that IP address resolution initialization found in the resolver configuration data set for the keyword HOSTname. If the keyword is not found in the resolver configuration data set, the char string returned will be a NULL string.

Returned Value

If successful, __iphost() returns the NULL-terminated character string, which is the name supplied on the HOSTname keyword found in the resolver configuration file.

If unsuccessful, __iphost() returns NULL and stores one of the following error values in h_errno. __iphost() is only unsuccessful if IP Address Resolution initialization fails to complete.

</tbody>
</table>

Format

```
#include <__ftp.h>

int __ipmsgc(void);
```

General Description

The __ipmsgc() function determines the value that IP address resolution initialization found in the resolver configuration data set for the keyword MessageCase. If no MessageCase keyword is found in the resolver configuration data set, then the default value is returned.

The `init` argument returned is one of the following set of symbols defined in the __ftp.h header file, each one stands for a message case selection.

- __MIXED: Represents mixed case value selected for the messages FTP will send.
- __UPPER: Represents uppercase value selected for the messages FTP will send.

Returned Value

__ipmsgc() is always successful and returns either the value of the __MIXED or the value of __UPPER for all requests. __MIXED is the default value.

</table>

Format

```
#include <__ftp.h>

char *__ipnode(void);
```

General Description

The __ipnode() function lets an application determine the values that IP address resolution initialization found as the NodeID name used by the VMCF platform. If the VMCF nodeID name is not found, the char string returned will be a NULL string.

Returned Value

If successful, __ipnode() returns the NULL-terminated character string, which is the name found for the VMCF platform.

If unsuccessful, __ipnode() returns NULL and stores one of the following error values in h_errno. __ipnode() is only unsuccessful if IP Address Resolution initialization fails to complete.

</tbody>
</table>

Format

```
#include <__ftp.h>

char *__iptcpn(void);
```

General Description

The __iptcpn() function lets an application determine the values that IP address resolution initialization found in the resolver configuration data set for either of the keywords TCPIPuserid or TCPIPjobname, whichever is the last one read. If neither keyword is found in the resolver configuration data set, the char string returned will be a NULL string.

Returned Value

If successful, __iptcpn() returns the NULL-terminated character string which is the name supplied on the TCPIPuserid or TCPIPjobname keyword found in the resolver configuration file.

If unsuccessful, __iptcpn() returns NULL and stores one of the following error values in h_errno. __iptcpn() is only unsuccessful if IP Address Resolution initialization fails to complete.

Format

```c
#include <ctype.h>

int isalnum(int c);
int isalpha(int c);
int iscntrl(int c);
int isdigit(int c);
int isgraph(int c);
int islower(int c);
int isprint(int c);
int ispunct(int c);
int isspace(int c);
int isupper(int c);
int isxdigit(int c);
```

General Description

The functions listed above, which are all declared in ctype.h, test a given integer value. The valid integer values for `c` are those representable as an `unsigned char` or EOF.

The functions in ctype.h are also available as macros. For better performance, the macro forms are recommended over the functional forms.

However, to get the functional forms, do one or more of the following:

- For C only: do not include ctype.h.
- Specify `#undef`, for example, `#undef islower`
- Surround the call statement by parentheses, for example, `(islower)('a')`

Here are descriptions of each function in this group.

- **isalnum()** Test for an upper- or lowercase letter, or a decimal digit, as defined in the `alnum` locale source file and in the `alnum` class of the LC_CTYPE category of the current locale.
- **isalpha()** Test for an alphabetic character, as defined in the `alpha` locale source file and in the `alpha` class of the LC_CTYPE category of the current locale.
- **iscntrl()** Test for any control character, as defined in the `cntrl` locale source file and in the `cntrl` class of the LC_CTYPE category of the current locale.
- **isdigit()** Test for a decimal digit, as defined in the `digit` locale source file and in the `digit` class of the LC_CTYPE category of the current locale.
isgraph()  Test for a printable character excluding space, as defined in the
        graph locale source file and in the graph class of the LC_CTYPE
        category of the current locale.

islower()  Test for a lowercase character, as defined in the lower locale
        source file and in the lower class of the LC_CTYPE category of the
        current locale.

isprint()  Test for a printable character including space, as defined in the
        print locale source file and in the print class of the LC_CTYPE category of the
        current locale.

ispunct()  Test for any nonalphanumeric printable character, excluding space,
        as defined in the punct locale source file and in the punct class of
        the LC_CTYPE category of the current locale.

isspace()  Test for a white space character, as defined in the space locale
        source file and in the space class of the LC_CTYPE category of the
        current locale.

isupper()  Test for an uppercase character, as defined in the upper locale
        source file and in the upper class of the LC_CTYPE category of the
        current locale.

isxdigit() Test for a hexadecimal digit, as defined in the xdigit locale source
        file and in the xdigit class of the LC_CTYPE category of the
        current locale.

The space, uppercase, and lowercase characters can be redefined by their
respective class of the LC_CTYPE in the current locale. The LC_CTYPE category
is discussed in the "Internationalization: Locales and Character Sets" in
\[z/OS XL C/C++ Programming Guide\]

To provide an ASCII input/output format for applications using these functions,
define the feature test macro __LIBASCII as described [24]

**Returned Value**

If the integer satisfies the test condition, these functions return nonzero.

If the integer does not satisfy the test condition, these functions return 0.

**Example**

**CELEBI02**

/* CELEBI02 */

This example analyzes all characters between code 0x0 and
code UPPER_LIMIT.
The output of this example is a 256-line table showing the
characters from 0 to 255, and a notification of whether they
have the attributes tested.

*/
#include <stdio.h>
#include <ctype.h>

#define UPPER_LIMIT 0xFF

int main(void)
{
    int ch;
isalnum to isxdigit

for ( ch = 0; ch <= UPPER_LIMIT; ++ch )
{
    printf("%3d ", ch);
    printf("%#04x ", ch);
    printf(" %c", isprint(ch) ? ch : ' ');
    printf("%3s ", isalnum(ch) ? "Alphanumeric" : " ");
    printf("%2s " , isalpha(ch) ? "Alphabetic" : " ");
    printf("%2s ", iscntrl(ch) ? "Control" : " ");
    printf("%2s", isdigit(ch) ? "Digit" : " ");
    printf("%2s","Graphic": " ");
    printf("%2s ", isgraph(ch) ? "Graphic" : " ");
    printf("%2s ", islower(ch) ? "Lower" : " ");
    printf("%3s", ispunct(ch) ? "Punctuation" : " ");
    printf("%2s", isspace(ch) ? "Space" : " ");
    printf("%3s", isprint(ch) ? "Printable" : " ");
    printf("%2s ", isupper(ch) ? "Upper" : " ");
    printf("%2s ", isxdigit(ch) ? "Hex" : " ");

    putchar(\n');
}

_XOPEN_SOURCE
#define _XOPEN_SOURCE
#include <ctype.h>

int isascii(int c);

_ALL_SOURCE
#define _ALL_SOURCE
#include <ctype.h>

int isascii(int c);

General Description

Special Behavior for _XOPEN_SOURCE

The isascii() function tests whether c is a 7-bit US-ASCII character code. The isascii() function is defined on all integer values.

Special Behavior for _ALL_SOURCE

The isascii() function tests whether the character with EBCDIC encoding c in the current locale is a member of the set of POSIX Portable Characters and POSIX Control Characters shown below.

Returned Value

Special Behavior for _XOPEN_SOURCE

isascii() returns nonzero if c is a 7-bit US-ASCII character code between 0 and hexadecimal 007F inclusive; otherwise it returns 0.

Special Behavior for _ALL_SOURCE

isascii() returns nonzero if c is the EBCDIC encoding in the current locale for a character in the set of POSIX Portable Characters and Control Characters; otherwise it returns 0.

Following is a list of the symbolic names, IBM-1047 EBCDIC code page encodings, and ISO8859-1 ASCII encodings for the set of POSIX Portable Characters and POSIX Control Characters. Cases where EBCDIC character encodings vary across EBCDIC Country Extended Code Pages (CECPs) are noted.

isastream

isastream() — Test a File Descriptor

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int isastream(int fildes);
```

General Description

The isastream() function tests whether `fildes`, an open file descriptor, is associated with a STREAMS-based file.

Returned Value

If successful, isastream() returns 1 if `fildes` refers to a STREAMS-based file and 0 if not.

If unsuccessful, isastream() returns -1 and sets errno to one of the following values.

**Note:** z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for isastream() to return 1 since there are no STREAMS-based file descriptors. It will return 0 unless `fildes` is not a valid open file descriptor, in which case it will return -1 with errno set to indicate the failure. See "open() — Open a File" on page 1313

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The <code>fildes</code> argument is not a valid open file descriptor.</td>
</tr>
</tbody>
</table>

isatty() — Test if Descriptor Represents a Terminal

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int isatty(int fildes);
```

General Description

Determines if a file descriptor, *fildes*, is associated with a terminal.

isatty() only works in an environment where either a controlling terminal exists, or stdin and stderr refer to tty devices. Specifically, it does not work in a TSO environment.

Returned Value

isatty() returns 1 if the given file descriptor is a terminal, or 0 otherwise.

Special Behavior for XPG4

isatty() returns 1 if the given file descriptor is a terminal, or 0 otherwise and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The <em>fildes</em> argument is not a valid open file descriptor.</td>
</tr>
<tr>
<td>ENOTTY</td>
<td>The <em>fildes</em> argument is not associated with a terminal.</td>
</tr>
</tbody>
</table>

Example

```
CELEBI03
/* CELEBI03 */

This example determines if a file descriptor is associated with a terminal.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>

void check_fd(int fd) {
    printf("fd \%d is ", fd);
    if (!isatty(fd))
        printf("NOT ");
    puts("a tty");
}
```
isatty

main() {
  int p[2], fd;
  char fn[]="temp.file";

  if (pipe(p) != 0)
    perror("pipe() error");
  else {
    if ((fd = creat(fn, S_IWUSR)) < 0)
      perror("creat() error");
    else {
      check_fd(0);
      check_fd(fileno(stderr));
      check_fd(p[1]);
      close(fd);
      unlink(fn);
    }
    close(p[0]);
    close(p[1]);
  }
}

Output
fd 0 is a tty
fd 2 is a tty
fd 4 is NOT a tty
fd 5 is NOT a tty

__isBFP() — Determine Application Floating-Point Format

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>both</td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

```
#include <_Ieee754.h>

int __isBFP(void);
```

General Description

The __isBFP() function determines the application floating-point mode.

Returned Value

__isBFP() returns 1 if the floating-point mode of the caller is IEEE, and returns 0 if the floating-point mode of the caller is hexadecimal.

Related Information

- "_Ieee754.h" on page 49
- "fp_read_rnd() — Determine Rounding Mode" on page 647
- "fp_swap_rnd() — Swap Rounding Mode" on page 660
isblank

isblank() — Test for Blank Character Classification

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <ctype.h>

int isblank(int c);
```

General Description

Tests whether the current LC_CTYPE locale category assigns \(c\) the blank character attribute. The \textit{tab} and \textit{space} characters have the blank attribute in the POSIX locale (with name “POSIX” or “C”).

To avoid infringing on the user’s name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (for example, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

\textbf{Note}: The isblank() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII Support” on page 2495 for details.

Returned Value

\(\text{isblank()}\) returns nonzero if the current LC_CTYPE locale category assigns \(c\) the blank character attribute.

Otherwise, \(\text{isblank()}\) returns 0.

Example

```c
/* This example tests if \(c\) is a blank type. */
#include <stdio.h>
#include <ctype.h>
#include <locale.h>

void check(char c) {
    if ((c != ' ') && (isprint(c)))
        printf(" %c is ", c);
    else
        printf("x%02x is ", c);
    if (!isblank(c))
        printf("not ");
    puts("a blank type character");
}

main() {
    printf("\nIn LC_CTYPE category of locale \\
with name \"%s\":\n",",
```
setlocale(LC_CTYPE, NULL);
check('a');
check(' ');
check(0x00);
check('\n');
check('\t');
}

Output
In LC_CTYPE category of locale with name "......";
a is not a blank type character
x40 is a blank type character
x00 is not a blank type character
x15 is not a blank type character
x05 is a blank type character

iscics

iscics() — Verify Whether CICS is Running

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <cics.h>

int iscics(void);
```

General Description

Determines whether the program is running under CICS.

Returned Value

If your program is currently running under CICS, iscics() returns nonzero.

If not running under CICS, iscics() returns 0.

Example

```
CELEBI04
/* CELEBI04

This example tests to see if the program is running under CICS. If not, it calls
a subroutine ABCPJM; otherwise, it uses a CICS EXEC statement to invoke
ABCPGM.
*/

#define _POSIX_SOURCE
#ifdef __cplusplus
extern "OS" void ABCPJM(char *);
#else
#pragma linkage(ABCPJM, 05)
void ABCPJM(char *);
#endif

#include <stdio.h>
#include <cics.h>
#include <string.h>
#include <sys/wait.h>
#include <sys/types.h>
#include <unistd.h>

int main(void)
{
    char mydata[123];
    
    if (iscics() == 0)
    {
        /* not a CICS environment */
        ABCPJM(mydata);
    }
    else {
```
EXEC CICS, LINK PROGRAM,("ABCPGM "), COMMAREA(mydata);
iscntrl

isdigit() — Test for decimal-digit classification

The information for this function is included in isalnum() to isxdigit() — Test Integer Value on page 1004.
isfinite() — Determines if its argument has a finite value

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R9</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C/C++ DFP</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int isfinite(real-floating x);
```

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

int isfinite(real-floating x);
int isfinite(decimal-floating x);
```

General Description

The isfinite() macro determines if its argument has a finite value.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>isfinite</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Note:
- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- This function works in IEEE decimal floating-point format. See “IEEE Decimal Floating-Point” for more information.

Returned Value

The isfinite() macro returns 1 if and only if its argument value is finite, else returns 0.

Special behavior in Hex

The isfinite() macro always returns 1.

Related Information
- "math.h" on page 60
isgraph() — Test for Graphic Classification

The information for this function is included in "isalnum() to isxdigit() — Test Integer Value" on page 1004.
isgreater() — Determines if X is greater than Y

Standards

<table>
<thead>
<tr>

```

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

int isgreater(real-floating x, real-floating y);
int isgreater(decimal-floating x, decimal-floating y);
```

General Description

The isgreater() macro determines whether the argument x is greater than y. It is equivalent to \((x) > (y)\), but no exception is raised if \(x\) or \(y\) are NaN.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>isgreater</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- This function works in IEEE decimal floating-point format. See “IEEE Decimal Floating-Point” for more information.

Returned Value

The isgreater() macro returns 1 if the value of \(x\) is greater than \(y\), else returns 0.

islower() — Test for Lowercase

The information for this function is included in "isalnum() to isxdigit() — Test Integer Value" on page 1004.
ismccollel

ismccollel() — Identify a Multicharacter Collating Element

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <collate.h>

int ismccollel(collel_t c);
```

General Description

Determines whether a character is a multicharacter collating element. A collating element is a glyph, usually a character, that has a value used to define its order in a collating sequence. A multicharacter collating element is a sequence of two or more characters that are to be collated as one entity.

Returned Value

ismccollel() returns:

- 1 if collel_t represents a multicharacter collating element
- 0 if collel_t represents a single-character collating element
- -1 if collel_t is out of range, or otherwise not valid

Example

**CELEBI05**

```c
/* CELEBI05

This example prints all of the collating elements in the collating sequence, by using the ismccollel function to determine if the collating element is a multi-character collating element.

*/
#include <collate.h>
#include <locale.h>
#include <stdio.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
    collel_t e, *rp;
    int i;

    setlocale(LC_ALL, "");
    i = collorder(&rp);
    for (; i-- > 0; rp++) {
        if (ismccollel(*rp))
            printf("%s", colltostr(*rp));
        else if (iswprint(*rp))
            printf("%lc", *rp);
        else
            printf("%x", *rp);
    }
}

<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C/C++ DFP</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define __XOPEN_SOURCE
#include <math.h>

int isnan(double x);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int isnan(real-floating x);
int isnan(decimal-floating x);
```

General Description

The isnan() function tests whether x is NaN (not a number).

isnan() is available as a macro. For better performance, the macro form is recommended over the functional form. To use the functional form, do one of the following:

- Do not include math.h.
- Specify `#undef isnan` after the inclusion of math.h.
- Enclose the call statement in parentheses.

Note:

1. This function works in both IEEE binary floating-point and hexadecimal floating-point formats. For hexadecimal floating-point isnan() always returns 0, but for IEEE Binary Floating-Point, this function returns nonzero if x is a NaN. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.
2. The functional form is not available for IEEE decimal floating-point.

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

For hexadecimal floating point numbers, isnan() always returns 0. For IEEE Decimal Floating Point numbers and Binary Floating Point numbers, a non-zero value is returned if x is a NaN.

There are no errno values defined.

isnormal

isnormal() — Determines if X is normal

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R9</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C/C++ DFP</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <math.h>

int isnormal(real-floating x);
```

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

int isnormal(real-floating x);
int isnormal(decimal-floating x);
```

General Description

The isnormal() macro determines if its argument value is normal, that is, not zero, infinity, subnormal or a NaN.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>isnormal</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

The isnormal() macro returns 1 if the argument value is normal, else returns 0.

Special behavior in Hex

For normalized numbers, isnormal() returns one. For zero or an unnormalized number, isnormal() returns zero.

Related Information

- "math.h" on page 60
__isPosixOn() — Test for Posix Run-time Option

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

int __isPosixOn(void);
```

General Description

The __isPosixOn() function returns 1 if the kernel is active and the POSIX run-time option is in effect for the calling process.

Returned Value

The __isPosixOn() function returns 1 if the POSIX run-time option is in effect for the calling process and returns 0 otherwise.

If POSIX is in effect, then the kernel is active, although the kernel may be active without POSIX being in effect.

There are no errno values defined.

int iswalpha(wint_t wc);
int iswcntrl(wint_t wc);
int iswdigit(wint_t wc);
int iswgraph(wint_t wc);
int iswlower(wint_t wc);
int iswprint(wint_t wc);
int iswpunct(wint_t wc);
int iswspace(wint_t wc);
int iswupper(wint_t wc);
int iswxdigit(wint_t wc);
```

General Description

The functions listed above, which are all declared in wctype.h, test a given wide integer value. These functions are sensitive to locale. For locale descriptions, see “Internationalization: Locales and Character Sets” in z/OS XL C/C++ Programming Guide. Here are descriptions of each function in this group.

- **iswalnum()** Test for a wide alphanumeric character, as defined in the alnum locale source file and in the alnum class of the LC_CTYPE category of the current locale.
- **iswalpha()** Test for a wide alphabetic character, as defined in the alpha locale source file and in the alpha class of the LC_CTYPE category of the current locale.
- **iswcntrl()** Test for a wide control character, as defined in the cntrl locale source file and in the cntrl class of the LC_CTYPE category of the current locale.
- **iswdigit()** Test for a wide decimal-digit character: 0 through 9, as defined in the digit locale source file and in the digit class of the LC_CTYPE category of the current locale.
- **iswgraph()** Test for a wide printing character, not a space, as defined in the graph locale source file and in the graph class of the LC_CTYPE category of the current locale.
- **iswlower()** Test for a wide lowercase letter, as defined in the lower locale source file and in the lower class of the LC_CTYPE category of the current locale.
- **iswprint()** Test for any wide printing character, as defined in the print locale source file and in the print class of the LC_CTYPE category of the current locale.
iswalnum to iswxdigit

iswpunct() Test for a wide nonalphanumeric, nonspace character, as defined in the punct locale source file and in the punct class of the LC_CTYPE category of the current locale.

iswspace() Test for a wide white space character, as defined in the space locale source file and in the space class of the LC_CTYPE category of the current locale.

iswupper() Test for a wide uppercase letter, as defined in the upper locale source file and in the upper class of the LC_CTYPE category of the current locale.

iswxdigit() Test for a wide hexadecimal digit 0 through 9, a through f, or A through F, as defined in the xdigit locale source file and in the xdigit class of the LC_CTYPE category of the current locale.

The behavior of these wide-character function are affected by the LC_CTYPE category of the current locale. The space, uppercase, and lowercase characters can be redefined by their respective class of the LC_CTYPE in the current locale. If you change the category, undefined results can occur.

Returned Value

If the wide integer satisfies the test value, these functions return nonzero.

If the wide integer does not satisfy the test value, these functions return 0.

The value for wc must be representable as a wide unsigned character. WEOF is a valid input value.

Example

CELEBI06

/* CELEBI06

This example tests for various wide integer values and prints a result.

*/
#include <stdio.h>
#include <wctype.h>

int main(void)
{
    wint_t wc;

    for (wc=0; wc <= 0xFF; wc++) {
        printf("%3d", wc);
        printf(" %4x", wc);
        printf("%3c", iswalnum(wc) ? "AN" : "");
        printf("%3s", iswalpha(wc) ? "A" : "");
        printf("%3s", iswcontrol(wc) ? "C" : "");
        printf("%3s", iswdigit(wc) ? "D" : "");
        printf("%3s", iswgraph(wc) ? "G" : "");
        printf("%3s", iswlower(wc) ? "L" : "");
        printf("%3s", iswprint(wc) ? "P" : "");
        printf("%3s", iswpunct(wc) ? "U" : "");
        printf("%3s", iswspace(wc) ? "S" : "");
        printf("%3s", iswxdigit(wc) ? "X" : "");
    }
}

iswblank

iswblank() — Test for Blank Character Classification

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include<wctype.h>

int iswblank(wint_t wc);
```

C99

```
#define _ISOC99_SOURCE
#include<wctype.h>

int iswblank(wint_t wc);
```

General Description

Tests for a wide blank character.

The space, uppercase, and lowercase characters can be redefined by their respective classes of the LC_CTYPE in the current locale.

For Use as a C Library Function

To avoid infringing on the user’s name space, this nonstandard function has two names. One name, __iswblk(), and the other as shown above. The name shown above is exposed only when you use the compiler option LANGLEVEL(EXTENDED) or define the _EXT feature test macro.

For Use as a z/OS UNIX Function

Define the _OPEN_SYS feature test macro.

Note: The iswblank() function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII Support” on page 2495 for details.

Returned Value

If the wide integer satisfies the test value, iswblank() returns nonzero.

If the wide integer does not satisfy the test value, iswblank() returns 0.

The value for wc must be representable as a wide unsigned char. WEOF is a valid input value.

The behavior of iswblank() is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.
Related Information

iswcntrl

iswcntrl() — Test for Control Classification

The information for this function is included in "iswalnum() to iswxdigit() — Test Wide Integer Value" on page 1039.
iswctype() — Test for Character Property

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wctype.h>

int iswctype(wint_t wc, wctype_t wc_prop);
```

General Description

Determines whether the wide character `wc` has the property `wc_prop`. If the value of `wc` is neither WEOF nor any value of the wide character that corresponds to a multibyte character, the behavior is undefined. If the value of `wc_prop` is not valid (that is, not obtained by a previous call to wctype(), or `wc_prop` has been invalidated by a subsequent call to setlocale() that has affected category LC_CTYPE), the behavior is undefined.

These twelve strings are reserved for the standard (basic) character classes: alnum, alpha, blank, cntrl, digit, graph, lower, print, punct, space, upper, and xdigit.

The functions are shown below with their equivalent isw*() function:

```c
iswctype(wc, wctype("alnum")); - iswalnum(wc);
iswctype(wc, wctype("alpha")); - iswalpha(wc);
iswctype(wc, wctype("blank")); - iswblank(wc);
iswctype(wc, wctype("cntrl")); - iswcntrl(wc);
iswctype(wc, wctype("digit")); - iswdigit(wc);
iswctype(wc, wctype("graph")); - iswgraph(wc);
iswctype(wc, wctype("lower")); - iswlower(wc);
iswctype(wc, wctype("print")); - iswprint(wc);
iswctype(wc, wctype("punct")); - iswpunct(wc);
iswctype(wc, wctype("space")); - iswspace(wc);
iswctype(wc, wctype("upper")); - iswupper(wc);
iswctype(wc, wctype("xdigit")); - iswxdigit(wc);
```

Returned Value

`iswctype()` returns nonzero (true) if the wide character `wc` has the property `wc_prop`.

Example

```c
CELEBI07
/* CELEBI07
 * This example test various wide characters for certain properties and
 * prints the result.
 */
#include <stdio.h>
#include <wchar.h>
#include <wctype.h>
```
int main(void)
{
    int wc;

    for (wc=0; wc <= 0xFF; wc++) {
        printf("%3d", wc);
        printf(" %4x", wc);
        printf("%3s", iswctype(wc, wctype("alnum")) ? "AN" : " ");
        printf("%3s", iswctype(wc, wctype("alpha")) ? "A" : " ");
        printf("%3s", iswctype(wc, wctype("cntrl")) ? "C" : " ");
        printf("%3s", iswctype(wc, wctype("digit")) ? "D" : " ");
        printf("%3s", iswctype(wc, wctype("graph")) ? "G" : " ");
        printf("%3s", iswctype(wc, wctype("lower")) ? "L" : " ");
        printf(" %c", iswctype(wc, wctype("print")) ? wc : ' ');
        printf("%3s", iswctype(wc, wctype("punct")) ? "PU" : " ");
        printf("%3s", iswctype(wc, wctype("space")) ? "S" : " ");
        printf("%3s", iswctype(wc, wctype("print")) ? "PR" : " ");
        printf("%3s", iswctype(wc, wctype("upper")) ? "U" : " ");
        printf("%3s", iswctype(wc, wctype("xdigit")) ? "X" : " ");

        putchar('\n');
    }
}

itoa

itoa() — Convert int into a string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R5</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * itoa(int n, char *buffer, int radix);
```

General Description

The `itoa()` function converts the integer `n` into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, `itoa()` produces the same result as the following statement:

```c
(void) sprintf(buffer, "%d", n);
```

with buffer the returned character string. When the radix is OCTAL, `itoa()` formats integer `n` into an unsigned octal constant. When the radix is HEX, `itoa()` formats integer `n` into an unsigned hexadecimal constant. The hexadecimal value will include lower case abcdef, as necessary.

Returned Value

String pointer (same as buffer) will be returned. When passed a non-valid radix argument, function will return NULL and set errno to EINVAL.

Portability Considerations

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

JoinWorkUnit() — Join a WLM Work Unit

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX System Services</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__wlm.h>

int JoinWorkUnit(wlmetok_t *enclavetoken);
```

General Description

The JoinWorkUnit function provides the ability for an application to join a WLM work unit.

* `enclavetoken` Points to a work unit enclave token that was returned from a call to either CreateWorkUnit() or ContinueWorkUnit().

Returned Value

If successful, JoinWorkUnit() returns 0.

If unsuccessful, JoinWorkUnit() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>

**jrand48( ) — Pseudo-Random Number Generator**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE
#include <stdlib.h>

long int jrand48(unsigned short int x16v[3]);
```

**General Description**

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval \([0.0, 1.0)\).

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval \([0, 2^{31})\).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval \([-2^{31}, 2^{31})\).

The jrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, \(X(i)\), according to the linear congruential formula:

\[
X(n+1) = (ax(n) + c) \mod (2^{48}) \quad n\geq0
\]

The jrand48() function uses storage provided by the argument array, \(x16v[3]\), to save the most recent 48-bit integer value in the sequence, \(X(i)\). The jrand48() function uses \(x16v[0]\) for the low-order (rightmost) 16 bits, \(x16v[1]\) for the middle-order 16 bits, and \(x16v[2]\) for the high-order 16 bits of this value.

The initial values of \(a\), and \(c\) are:

\[
\begin{align*}
a &= 5deece66d \quad (\text{base 16}) \\
c &= b \quad (\text{base 16})
\end{align*}
\]

The values \(a\) and \(c\), may be changed by calling the lcong48() function. The initial values of \(a\) and \(c\) are restored if either the seed48() or srand48() function is called.

**Special Behavior for z/OS UNIX Services**

You can make the jrand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.
If you do not request thread-specific behavior for the \texttt{drand48} family, C/370 serializes access to the storage for \(X(n), a\) and \(c\) by functions in the \texttt{drand48} family when they are called by a multithreaded application.

If thread-specific behavior is requested and the \texttt{jrand48()} function is called from thread \(t\), the \texttt{jrand48()} function generates the next 48-bit integer value in a sequence of 48-bit integer values, \(X(t,i)\), for the thread according to the linear congruential formula:

\[
X(t,n+1) = (a(t)X(t,n) + c(t)) \mod (2^{48}) \quad n \geq 0
\]

The \texttt{jrand48()} function uses storage provided by the argument array, \texttt{x16v[3]}, to save the most recent 48-bit integer value in the sequence, \(X(t,i)\). The \texttt{jrand48()} function uses \texttt{x16v[0]} for the low-order (rightmost) 16 bits, \texttt{x16v[1]} for the middle-order 16 bits, and \texttt{x16v[2]} for the high-order 16 bits of this value.

The initial values of \(a(t)\) and \(c(t)\) on the thread \(t\) are:

\[
a(t) = 5\text{dece66d (base 16)}
c(t) = b \quad \text{(base 16)}
\]

The values \(a(t)\) and \(c(t)\) may be changed by calling the \texttt{lcong48()} function from the thread \(t\). The initial values of \(a(t)\) and \(c(t)\) are restored if either the \texttt{seed48()} or \texttt{srand48()} function is called from the thread.

\textbf{Returned Value}

\texttt{jrand48()} saves the generated 48-bit value, \(X(n+1)\), in storage provided by the argument array, \texttt{x16v[3]}. \texttt{jrand48()} transforms the generated 48-bit value to a signed long integer value on the interval \([-2^{31},2^{31})\) and returns this transformed value.

\textbf{Special Behavior for z/OS UNIX Services}

If thread-specific behavior is requested for the \texttt{drand48} family and the \texttt{jrand48()} function is called on thread \(t\), the \texttt{jrand48()} function saves the generated 48-bit value, \(X(t,n+1)\), in storage provided by the argument array, \texttt{x16v[3]}. The \texttt{jrand48()} function transforms the generated 48-bit value to a signed long integer value on the interval \([-2^{31},2^{31})\) and returns this transformed value.

</tbody>
</table>

Format

```c
#include <math.h>

double j0(double x);

double j1(double x);

double jn(int n, double x);
```

Compiler Option

LANGLVL(SAA), LANGLVL(SAAL2), or LANGLVL(EXTENDED)

General Description

The j0(), j1(), and jn() functions are Bessel functions of the first kind, for orders 0, 1, and n, respectively. Bessel functions are solutions to certain types of differential equations. The argument x must be positive. The argument n should be greater than or equal to 0. If n is less than 0, there will be a negative exponent in the result.

Note: This function works in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE Binary Floating-Point " on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

If successful, the calculated value is returned.

For j0(), j1(), y0(), or y1(), if the absolute value of x is too large, the function sets errno to ERANGE to indicate a value that is out of range, and returns 0.

Special Behavior for IEEE

If x is negative, y0(), y1(), and yn() return the value NaNQ. If x is 0, y0(), y1(), and yn() return the value -HUGE_VAL. In all cases, errno remains unchanged.

Example

CELEBJ01

```c
/* CELEBJ01

   This example computes y to be the order 0 Bessel function of
   the first kind for x, and z to be the order 3 Bessel function
   of the second kind for x.

   */

#include <math.h>
```
Bessel j functions

```c
#include <stdio.h>

int main(void)
{
    double x, y, z;
    x = 4.27;
    y = j0(x);    /* y = -0.3660 is the order 0 bessel */
    /* function of the first kind for x */
    z = yn(3,x);  /* z = -0.0875 is the order 3 bessel */
    /* function of the second kind for x */
    printf("x = %f\n y = %f\n z = %f\n", x, y, z);
}
```

### kill() — Send a Signal to a Process

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td>POSIX(ON)</td>

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#define _POSIX_SOURCE
#include "signal.h"

int kill(pid_t pid, int sig);
```

#### General Description

Sends a signal to a process or process group. A process has permission to send a signal if the real or effective user ID of the sender is the same as the real or effective user ID of the intended recipient. A process can also send signals if it has appropriate privileges. If `_POSIX_SAVED_IDS` is defined in the unistd.h header file, the saved set user ID of the intended recipient is checked instead of its effective user ID.

Regardless of user ID, a process can always send a `SIGCONT` signal to a process that is a member of the same session (same session ID) as the sender.

You can use either `signal()` or `sigaction()` to specify how a signal will be handled when `kill()` is invoked.

A process can use `kill()` to send a signal to itself. If the signal is not blocked or ignored, at least one pending unblocked signal is delivered to the sender before `kill()` returns. If there are no other pending unblocked signals, the delivered signal is `sig`.

*pid* can be used to specify these processes:

- **pid_t pid;** Specifies the processes that the caller wants to send a signal to:
  - If *pid* is greater than 0, `kill()` sends its signal to the process whose ID is equal to *pid*.
  - If *pid* is equal to 0, `kill()` sends its signal to all processes whose process group ID is equal to that of the sender, except for those that the sender does not have appropriate privileges to send a signal to.
  - If *pid* is −1, `kill()` returns −1.
  - **Special Behavior for XPG4.2:** If *pid* is −1, `kill()` sends the signal, *sig*, to all processes, except for those to which the sender does not have appropriate privileges to send a signal.
  - If *pid* is less than −1, `kill()` sends its signal to all processes whose process group ID is equal to the absolute value of *pid*, except for those that the sender does not have appropriate privileges to send a signal to.
The signal that should be sent to the processes specified by \textit{pid}. (For a list of signals, see \autoref{table:signals}.) This must be 0 or one of the signals defined in the \textit{signal.h} header file. If \textit{sig} is 0, \texttt{kill()} performs error checking but does not send a signal. You can code \textit{sig} as 0 to check whether the \textit{pid} argument is valid.

This function is supported only in a POSIX program. See \autoref{z/OS XL C/C++ applications with z/OS UNIX System Services C functions} for more information. You can use it to pass \texttt{SIGIOERR}.

### Usage note

The use of the \texttt{SIGTHSTOP} and \texttt{SIGTHCONT} signal is not supported with this function.

### Returned Value

\texttt{kill()} returns 0 if it has permission to send \textit{sig} to any of the processes specified by \textit{pid}.

If \texttt{kill()} fails to send a signal, it returns \texttt{−1} and sets \texttt{errno} to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of \textit{sig} is incorrect or is not the number of a supported signal.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The caller does not have permission to send the signal to any process specified by \textit{pid}.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>There are no processes or process groups corresponding to \textit{pid}.</td>
</tr>
</tbody>
</table>

### Example

#### CELEBK01

```c
/* CELEBK01 */
#define _POSIX_SOURCE
#include <signal.h>
#include <stdio.h>
#include <sys/types.h>
#include <unistd.h>
#include <sys/wait.h> /*FIX: used to be <wait.h>*/

main()
{
    sigset_t sigset;
    int   p[2], status;
    char  c='z';
    pid_t pid;

    if (pipe(p) != 0)
        perror("pipe() error");
    else {
        if ((pid = fork()) == 0) {
            sigemptyset(&sigset);
            puts("child is letting parent know he's ready for signal");
            write(p[1], &c, 1);
            puts("child is waiting for signal");
            sigsuspend(&sigset);
            exit(0);
        }

        puts("parent is waiting for child to say he's ready for signal");
        read(p[0], &c, 1);
        puts("child has told parent he's ready for signal");
    }
}
```

kill(pid, SIGTERM);

wait(&status);
if (WIFSIGNALED(status))
    if (WTERMSIG(status) == SIGTERM)
        puts("child was ended with a SIGTERM");
    else
        printf("child was ended with a %s signal\n", WTERMSIG(status));
else
    puts("child was not ended with a signal");

    close(p[0]);
    close(p[1]);
}

Output
parent is waiting for child to say he's ready for signal
child is letting parent know he's ready for signal
child is waiting for signal
child has told parent he's ready for signal
child was ended with a SIGTERM

**killpg() — Send a Signal to a Process Group**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int killpg(pid_t pgrp, int sig);
```

**General Description**

The `killpg()` function sends a signal to a process group.

A process has permission to send a signal if the real or effective user ID of the sender is the same as the real or effective user ID of the intended recipient. A process can also send signals if it has appropriate privileges. If `_POSIX_SAVED_IDS` is defined in the `<unistd.h>` include file, the saved set user ID of the intended recipient is checked instead of its effective user ID.

Regardless of user ID, a process can always send a `SIGCONT` signal to a process group that is a member of the same session (same session ID) as the sender.

`pid_t pgrp;` Specifies the process group that the caller wants to send a signal to:

- If `pgrp` is greater than one, `killpg()` sends the signal, `sig`, to the process whose process group ID is equal to `pgrp` and which the sender has appropriate privileges to send a signal.
- If `pgrp` is equal to or less than one, `killpg()` returns a −1 and sets `errno` to `EINVAL`.

`int sig;` The signal that should be sent to the processes specified by `pgrp`. (For a list of signals, see [Table 47 on page 1881](#). This must be zero, or one of the signals defined in the `<signal.h>` include file. If `sig` is zero, `killpg()` performs error checking but doesn’t really send a signal. You can code `sig` as zero to check whether the `pid` argument is valid.

This function is supported only in a POSIX program. See “z/OS XL C/C++ applications with z/OS UNIX System Services C functions” on page 13 for more information.

**Usage note**

The use of the SIGTSTOP and SIGTCONT signal is not supported with this function.

**Returned Value**

If successful, `killpg()` returns 0 if it has permission to send `sig` to any of the processes in the process group ID specified by `pgrp`.

If unsuccessful, `killpg()` returns −1 and sets `errno` to one of the following values:
<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of <code>sig</code> is incorrect or is not the number of a supported signal, or the value of <code>pgrp</code> is less than or equal to one.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The caller does not have permission to send the signal to any process in the process group ID specified by <code>pgrp</code>.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>There are no process groups corresponding to <code>pgrp</code>.</td>

<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

long int labs(long int n);
```

General Description

Calculates the absolute value of its long integer argument `n`. The result is undefined when the argument is equal to `LONG_MIN`, the smallest available long integer (-2 147 483 648). The value `LONG_MIN` is defined in the limits.h header file.

Returned Value

Returns the absolute value of the long integer argument `n`.

Example

```c
CELEBL01

/* CELEBL01

    This example computes y as the absolute value of the long integer -41567.

*/
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    long x, y;
    x = -41567L;
    y = labs(x);
    printf("The absolute value of %ld is %ld\n", x, y);
}
```

Output

The absolute value of -41567 is 41567

__lchattr() — Change the Attributes of a File or Directory when they point to a symbolic or external link.

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R5</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __lchattr (char *pathname, attrib_t *attributes, int attributes_len);
```

General Description

The __lchattr() function modifies the attributes that are associated with a file. The pathname specifies a symbolic or external link (a pointer to another file, directory, or data set).

The __lchattr() service changes the attributes of the symbolic link itself, provided the attributes requested can apply to a symbolic link. Only the owner and security label can be changed for a symbolic link, all other attributes do not apply and will be ignored.

The attributes argument is the address of an attrib_t structure which is used to identify the attributes to be modified and the new values desired. The attrib_t type is an f_attributes structure as defined in <sys/stat.h> for use with the __lchattr() function. For proper behavior, the user should ensure that this structure has been initialized to zeros before it is populated. The f_attributes structure is defined as indicated in Table 23 on page 267.

Returned Value

If successful, __lchattr() returns 0.

If unsuccessful, __lchattr() returns -1 and sets errno to one of the following values:

**EACCES**
The calling process did not have appropriate permissions. Possible reasons include:

- The calling process was attempting to set access time or modification time to current time, and the effective UID of the calling process does not match the owner of the file; the process does not have write permission for the file; or the process does not have appropriate privileges.
- The calling process was attempting to truncate the file, and it does not have write permission for the file.

**EFBIG**
The calling process was attempting to change the size of a file, but the specified length is greater than the maximum file size limit for the process.

**EINVAL**
The attributes structure containing the requested changes is not valid.
__lchattr

ELOOP
A loop exists in symbolic links that were encountered during resolution of the pathname argument. This error is issued if more than 24 symbolic links are detected in the resolution of pathname.

ENAMETOOLONG
pathname is longer than 1023 characters, or a component of the pathname is longer than 255 characters (Filename truncation is not supported).

ENOENT
No file named pathname was found.

ENOTDIR
Some component of pathname is not a directory.

EPERM
The operation is not permitted for one of the following reasons:

- The calling process was attempting to change the mode or the file format, but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the owner, but it does not have appropriate privileges.
- The calling process was attempting to change the general attribute bits, but it does not have write permission for the file.
- The calling process was attempting to set a time value (not current time), but the effective user ID does not match the owner of the file, and it does not have appropriate privileges.
- The calling process was attempting to set the change time or reference time to current time, but it does not have write permission for the file.
- The calling process was attempting to change auditing flags, but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the Security Auditor's auditing flags, but the user does not have auditor authority.
- Attributes indicate that the security label is to be set, and one or more of the following conditions applies:
  - The calling process does not have RACF SPECIAL authorization and appropriate privileges.
  - The security label currently associated with the file is already set.

EROFS
pathname specifies a file that is on a read-only file system.

</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int lchown(const char *path, uid_t owner, gid_t group);
```

General Description

The `lchown()` function has the same effect as `chown()` except in the case where the named file is a symbolic link. In this case `lchown()` changes the ownership of the symbolic link file itself, while `chown()` changes the ownership of the file or directory to which the symbolic link refers.

Returned Value

If successful, `lchown()` returns 0.

If unsuccessful, `lchown()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied on a component of the path prefix of <code>path</code>.</td>

<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdlib.h>

void lcong48(unsigned short int param[7]);
```

General Description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The lcong48(), seed48(), and srand48() functions are initialization functions, one of which should be invoked before either the drand48(), lrand48() or mrand48() function is called.

The drand48(), lrand48() and mrand48() functions generate a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

\[ X(n+1) = (aX(n) + c) \mod(2^{48}) \quad n \geq 0 \]

The initial values of X, a, and c are:

\[ X(0) = 1 \]
\[ a = 5deece66d \quad \text{(base 16)} \]
\[ c = b \quad \text{(base 16)} \]

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The lcong48() function is used to reinitialize the most recent 48-bit value in this storage. The lcong48() function replaces the low-order (rightmost) 16 bits of this storage with `param[0]`, the middle-order 16 bits with `param[1]`, and the high-order 16 bits with `param[2]`.

Special Behavior for z/OS UNIX Services

You can make the lcong48() function and other functions in the drand48 family thread-specific by setting the environment variable `_RAND48` to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.
If thread-specific behavior is requested, calls to the drand48(), lrand48() and mrand48() functions from thread \( t \) generate a sequence of 48-bit integer values, \( X(t,i) \), according to the linear congruential formula:
\[
X(t,n+1) = (a(t)X(t,n) + c(t)) \mod (2^{48}) \quad n \geq 0
\]

C/370 provides thread-specific storage to save the most recent 48-bit integer value of the sequence, \( X(t,i) \). When the lcong48() function is called from thread \( t \), it reinitializes the most recent 48-bit value in this storage. The lcong48() function replaces the low-order (rightmost) 16 bits of this storage with \( \text{param}[0] \), the middle-order 16 bits with \( \text{param}[1] \), and the high-order 16 bits with \( \text{param}[2] \).

The lcong48() function may also be used to change values of \( a(t) \) and \( c(t) \) for the thread \( t \). The lcong48() function replaces the low-order (rightmost) 16 bits of \( a(t) \) with \( \text{param}[3] \), the middle-order 16 bits with \( \text{param}[4] \), and the high-order 16 bits with \( \text{param}[5] \). The lcong48() function replaces \( c(t) \) with \( \text{param}[6] \).

**Returned Value**

After lcong48() has used values from the argument array, \( \text{param}[7] \), to change the values of \( a \) and \( c \) and to reinitialized storage for the most recent 48-bit integer value in the sequence, \( X(i) \), it returns.

**Special Behavior for z/OS UNIX Services**

If thread-specific behavior is requested for the drand48 family and lcong48() is called on thread \( t \), it uses the argument array, \( \text{param}[7] \), to change the values of \( a(t) \) and \( c(t) \) and to reinitialize storage for the most recent 48-bit integer value in the sequence, \( X(t,i) \), for the thread. Then it returns.

</tr>
</tbody>
</table>

Format

```c
#include <math.h>

double ldexp(double x, int exp);
float ldexpf(float x, int exp); /* C++ only */
long double ldexpl(long double x, int exp); /* C++ only */
long double ldexp(long double x, int exp);
```

General Description

Calculates the value of \( x \times (2^{\text{exp}}) \).

Returned Value

Returns the calculated value.

Otherwise, if the correct calculated value is outside the range of representable values, ±HUGE_VAL is returned, according to the sign of the value. The value ERANGE is stored in errno to indicate that the result was out of range.

Special Behavior for XPG4.2

Error Code Description
ERANGE The result underflowed. ldexp() returns 0.0.

Example

**CELEBL02**

```c
/* CELEBL02
   This example computes y = 1.5*\( 2^{5} \).
*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y;
    int p;
    x = 1.5;
    p = 5;
```
ldexp, ldexpf, ldexpl

```c
y = ldexp(x, p);
printf("%lf times 2 to the power of %d is %Lf\n", x, p, y);
}
```

Output
1.500000 times 2 to the power of 5 is 48.000000

_Decimal32 ldexpd32(_Decimal32 x, int exp);
_Decimal64 ldexpd64(_Decimal64 x, int exp);
_Decimal128 ldexpd128(_Decimal128 x, int exp);
_Decimal32 ldexp(_Decimal32 x, int exp); /* C++ only */
_Decimal64 ldexp(_Decimal64 x, int exp); /* C++ only */
_Decimal128 ldexp(_Decimal128 x, int exp); /* C++ only */
```

General Description

Calculates the value of \( x \times 10^{\text{exp}} \).

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

Returns the calculated value.

Otherwise, if the correct calculated value is outside the range of representable values, ±HUGE_VAL_D32, ±HUGE_VAL_D64, or ±HUGE_VAL_D128 is returned, according to the sign of the value. The value ERANGE is stored in errno to indicate that the result was out of range.

Example

```c
/* CELEBL19 */

This example illustrates the ldexpd32() function.

This example computes \( y = 1.5 \times 10^{5} \)

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal32 x, y;
    int p;
    x = 1.5DF;
    p = 5;
    ```
ldexpd32, ldexpd64, ldexpd128

    y = ldexpd32(x, p);
    printf("%Hf times 10 to the power of %d is %Hf\n", x, p, y);
}

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>
ldiv_t ldiv(long int numerator, long int denominator);
```

General Description

Calculates the quotient and remainder of the division of `numerator` by `denominator`.

Returned Value

Returns a structure of type `ldiv_t`, containing both the quotient `long int quot` and the remainder `long int rem`.

If the value cannot be represented, the returned value is undefined. If `denominator` is 0, a divide by 0 exception is raised.

Example

```c
CELEBL03

/* CELEBL03

This example uses the &ldiv. function to calculate the
quotients and remainders for a set of two dividends and two
divisors.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    long int num[2] = {45, -45};
    long int den[2] = {7, -7};
    ldiv_t ans; /* ldiv_t is a struct type containing two long ints:
    'quot' stores quotient; 'rem' stores remainder */
    short i, j;

    printf("Results of long division:\n");
    for (i = 0; i < 2; i++)
        for (j = 0; j < 2; j++)
            { ans = ldiv(num[i], den[j]);
              printf("Dividend: %6ld  Divisor: %6ld", num[i], den[j]);
              printf("  Quotient: %6ld  Remainder: %6ld\n", ans.quot, ans.rem);
            }
}
```
Output

Results of long division:
Dividend: 45  Divisor:  7  Quotient:  6  Remainder:  3
Dividend: 45  Divisor: -7  Quotient: -6  Remainder:  3
Dividend: -45  Divisor:  7  Quotient: -6  Remainder:  3
Dividend: -45  Divisor: -7  Quotient:  6  Remainder: -3

<td>z/OS UNIX System Services</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__wlm.h>

int LeaveWorkUnit(wlmetok_t *enclavetoken);
```

General Description

The LeaveWorkUnit() function provides the ability for an application to leave a WLM work unit.

* `enclavetoken` Points to a work unit enclave token that was returned from a call to CreateWorkUnit() or ContinueWorkUnit().

Returned Value

If successful, LeaveWorkUnit() returns 0.

If unsuccessful, LeaveWorkUnit() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>

Get Condition Information Block

General Description
Returns the Condition Information Block (CIB) structure associated with the current signal.

Notes:
1. This function is valid when called while a Language Environment exception handler is running.
2. This function is valid when called while a POSIX(OFF) signal catcher is running.
3. This function is valid when called while a POSIX(ON) signal catcher is running, if the signal is generated and caught immediately to the same thread. __le_cib_get() will fail if called from POSIX(ON) signal catchers that are driven as a result of signals generated by another thread or process. It may also fail when called from a catcher, if the caught signal is from the same thread but was delayed by blocking or by other signals being delivered at the same time.

Returned Value
If there is an active condition the returned value is a pointer to the currently active CIB. If there is more than one active condition, the returned CIB will be for the most recent (most deeply nested) condition.

NULL is returned there is no active CIB, and the errno will be set to EMVSERR.

Error Code     Description
EMVSERR         No active CIB is available.
__le_condition_token_build

__le_condition_token_build() — Build a Language Environment Condition Token

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>AMODE 64</td>
</tr>
</tbody>
</table>

Format

```
#include <__le_api.h>

void *__le_condition_token_build(_.INT2*c_1, _INT2*c_2,
  _INT2*format, _INT2*severity,
  _INT2*control, _CHAR3facility_ID,
  _INT4*i_s_info,
  _FEEDBACK*cond_token,
  _FEEDBACK*fc);
```

General Description

Dynamically constructs a 16-byte Language Environment condition token. The condition token is only to be used to retrieve messages from a Language Environment message file.

Parameter Description

- **c_1**
  - `c_1` is a 2-byte binary integer representing the value of the first 2 bytes of the 4-byte condition_ID. `c_1` and `c_2` make up the condition_ID portion of the condition token.

- **c_2**
  - `c_2` is a 2-byte binary integer representing the value of the second 2 bytes of the 4-byte condition_ID.
  - For format 1, this is the `Msg_No`; for format 2, the `cause_code`.

- **format**
  - A 2-byte binary integer defining the format of the condition_ID portion of the token.

- **severity**
  - A 2-byte binary integer indicating the condition’s severity. In both format 1 and 2 conditions, this field is used to test the condition’s severity. For format 1 conditions, the value of this field is the same as the severity value specified in the condition_ID.

  **Possible severity Values:**
  
  - 0 = Information only, if entire token is 0 there is no information.
  - 1 = Warning
  - 2 = Error
  - 3 = Severe Error
  - 4 = Critical Error

- **control**
  - A 2-byte binary integer containing flags describing or controlling various aspects of condition handling. Valid values for the control field are 1 and 0. 1 indicates the `facility_ID` assigned by IBM, 0 indicates the `facility_ID` assigned by the user.

- **facility_ID**
  - A 3 character field containing three alphanumeric characters (A-Z,
a-z, and 0-9) identifying the product or component of a product
generating this condition or feedback information, for example,
CEE.

The \textit{facility\_ID} is associated with the repository of the run-time
messages. If a unique ID is required (for IBM and non-IBM
products), an ID can be obtained by contacting an IBM project
office.

If you create a new \textit{facility\_ID} to use with a message table, created
using the CEEBLDTX utility, be aware that the \textit{facility\_ID} must be
part of the Language Environment message table name. For more
information about the CEEBLDTX utility, see \textit{z/OS Language
Environment Programming Guide}. It is important to follow the
naming guidelines below in order to have a module name that does
not cause your application to abend.

First, begin a non-IBM assigned product \textit{facility\_ID} with letters J
through Z. (See the \textit{control} parameter above to indicate whether
the \textit{facility\_ID} has been assigned by IBM.) Secondly, special
characters, including blank spaces, cannot be used in a
\textit{facility\_ID}. Lastly, there are no other constraints (besides the alphanumeric
requirement) on a non-IBM assigned \textit{facility\_ID}.

\begin{itemize}
\item \textit{i\_s\_info} A fullword binary integer identifying the ISI, that contains insert
data.
\item \textit{cond\_token} A 16–byte representation of the constructed condition token.
\item \textit{fc} A 16–byte Feedback Code indicating the results of this function.
\end{itemize}

\begin{tabular}{|c|c|c|l|}
\hline
\textbf{Code} & \textbf{Severity} & \textbf{Message Number} & \textbf{Message Text} \\
\hline
CEE000 & 0 & - - & The function completed successfully. \\
CEE0CH & 3 & 401 & A non-valid case code \textit{case-code} was passed to routine \textit{routine-name}. \\
CEE0CI & 3 & 402 & A non-valid control code \textit{control-code} was passed to routine \textit{routine-name}. \\
CEE0CJ & 3 & 403 & A non-valid severity code \textit{severity-code} was passed to routine \textit{routine-name}. \\
CEE0CK & 3 & 404 & Facility ID, \textit{facility-id}, with non-alphanumeric characters was passed to routine \textit{routine-name}. \\
CEE0E4 & 1 & 452 & An invalid facility ID \textit{facility-id} was passed to routine \textit{routine-name}. \\
\hline
\end{tabular}

\textbf{Application Usage}

1. The structure of the condition token (type \_FEEDBACK) is described in the
"\_le\_api.h" header file shipped with Language Environment. You can assign
values directly to the fields of the token in the header file without using the
\_le\_condition\_token\_build() function.

2. This condition token is \textbf{only} to be used to retrieve messages from a Language
Environment message table.

__le_msg_add_insert() — Add Insert to a Language Environment Message

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>AMODE 64</td>
</tr>
</tbody>
</table>

Format

```c
#include <__le_api.h>

void *__le_msg_add_insert( _FEEDBACK * cond_token,
                          _INT4 * insert_seq_num,
                          _VSTRING * insert_data,
                          _FEEDBACK * fc );
```

General Description

Copies message insert data and loads the address of that data into the Instance Specific Information (ISI) associated with the condition being processed. The number of ISIs per thread is limited to 15.

Parameter Description

- **cond_token**: A 16-byte condition token that defines the condition for which the q_data_token is retrieved.

- **insert_seq_num**: A 4-byte integer that contains the insert sequence number (such as insert 1 insert 2). It corresponds to an insert number specified with an :ins. tag in the message source file created by the CEEBLDTEX utility. For more information about the CEEBLDTEX utility see [z/OS Language Environment Programming Guide](https://www.ibm.com/support/manuals/language-environment-programming-guide).

- **insert_data**: A halfword-prefixed length string, used without truncation, that represents the insert data. DBCS strings must be enclosed within shift-out (0x0E) and shift-in (0x0F) characters.

  **Note**: The maximum size for an individual insert item is 254 bytes.

- **fc**: A 16-byte Feedback Code indicating the results of this function.

__le_msg_get() — Get a Language Environment Message

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>AMODE 64</td>
</tr>
</tbody>
</table>

Format

```c
#include <__le_api.h>

void *__le_msg_get(_FEEDBACK * cond_token,
                    _CHAR80 message_area,
                    _INT4 * msg_index,
                    _FEEDBACK * fc);
```

General Description

Retrieves, formats, and stores, in a passed message area, a Language Environment message corresponding to a user supplied condition token. The caller can later retrieve the message to modify or to write as output.

Parameter Description

- **cond_token** A 16-byte condition token supplied by the invoker.
- **message_area** A fixed-length 80 character string, where the message is placed.
  
  **Note:** The message is left-justified and padded on the right with blanks.

- **msg_index** A 4-byte binary integer returned to the invoker.
  
  The **msg_index** should be set to zero on the first invocation of __le_msg_get(). If a message is too large to be contained in the message_area, **msg_index** is returned as an index into the message. This index is used on subsequent invocations to retrieve the remaining portion of the message. Feedback Code is also returned, indicating the message has been truncated. When the entire message is returned, **msg_index** is zero.

**msg_index** contains different results based on the length of the message.

- If a message contains fewer than 80 characters, the entire message is returned on the first invocation. **msg_index** contains 0.
- If a message contains exactly 80 characters, the entire message is returned on the first invocation. **msg_index** contains 0.
- If the message is more than 80 characters it is split into segments. The **msg_index** does not contain the cumulative index for the entire message returned, but contains only the index of the segment that was just returned. It is up to the user to maintain the cumulative count if needed. When a message is too long, the following can occur:
  - If a message contains more than 80 characters and at least one blank is contained in the first 80 characters, the string up to and including the last blank is returned on the first invocation.
__le_msg_get

- If the 80th character is non-blank (even if the 81st character is a blank), `msg_index` contains the index of the last blank (something less than 80), and the next invocation starts with the next character.
- If the 80th character is a blank, `msg_index` contains 80 and the next invocation starts with the 81st character, blank or non-blank.
- If a message contains more than 80 characters and at least the first 80 are all non-blank, the first 80 are returned. The next invocation does not add any blanks and starts with the 81st character. `msg_index` contains 80.

fc A 16-byte Feedback Code indicating the results of this function.

Table 38. Resulting Feedback Codes:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>

</tr>
<tr>
<td>CEE0EA</td>
<td>1</td>
<td>458</td>
<td>The message repository repository-name could not be located.</td>
</tr>
</tbody>
</table>

Application Usage

z/OS UNIX System Services consideration – In multithreaded applications, __le_msg_get() affects only the invoking thread. However, __le_msg_get() uses the NATLANG value of the enclave. Any subsequent calls to __le_msg_get(), for a given condition, use the NATLANG value in effect at the time of the first invocation.

Table 39. Resulting Feedback Codes: (continued)

| CEE3CV | 3 | 3,487 | An internal message service error occurred while locating a message number within the ranges specified in the repository. |

Application Usage

z/OS UNIX System Services consideration – In multithreaded applications, __le_msg_get_and_write() affects only the invoking thread. When multiple threads write to ‘stderr’ the output is interwoven by line. To group lines of output, serialize ‘stderr’ access (for example, by using a mutex).

Format

```c
#include <__le_api.h>

void *__le_msg_write(_VSTRING *message_string,
                        _INT4 *destination_code,
                        _FEEDBACK *fc);
```

General Description

Writes a user-defined Language Environment message string to 'stderr'.

Parameter Description

- `message_string`:
  A halfword-prefixed printable character string containing a message. DBCS characters must be enclosed within shift-out (0x0F) and shift-in (0x0E) characters.

  Insert data cannot be placed in the message with __le_msg_write(). The halfword-prefixed message string must contain only printable characters and be a length greater than zero. Unpredictable results will occur if the byte following the halfword prefix is 0x00.

- `destination_code`:
  A 4–byte binary integer written to 'stderr'. The only acceptable value is 2.

- `fc`:
  A 16–byte Feedback Code indicating the results of this function.

__le_traceback

__le_traceback() – call chain traceback service

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
<tr>
<td></td>
<td></td>
<td>AMODE 64</td>
</tr>
</tbody>
</table>

Format

#include <__le_api.h>

void __le_traceback(int cmd, void* cmd_parms, _FEEDBACK *fc);

General Description

The __le_traceback() function assists in tracing the call chain. It identifies the language, program unit, entry point, current location, caller’s DSA, and other information from the address of a DSA for a program unit. This is essential for creating meaningful traceback messages.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>

</table>
The `__tf_parms_s` structure is defined as follows:

```c
typedef struct __tf_string_s {
    size_t __tf_bufflen;
    char* __tf_buff;
} __tf_string_t;

typedef struct __tf_parms_s {
    /****************************************************************
    /* Input */
    /****************************************************************
    void* __tf_dsa_addr;
    void* __tf_caa_addr;
    void* __tf_call_instruction;
    /****************************************************************
    /* Output related to input DSA */
    /****************************************************************
    void* __tf_pu_addr;
    void* __tf_entry_addr;
    struct __cib* __tf_cib_addr;
    uint8_t __tf_member_id;
    int __tf_is_main:1;
    int :23;
    int :32;
    __tf_string_t __tf_pu_name;
    __tf_string_t __tf_entry_name;
    __tf_string_t __tf_statement_id;
    /****************************************************************
    /* Output related to caller's DSA */
    /****************************************************************
    void* __tf_caller_dsa_addr;
    void* __tf_caller_call_instruction;
} __tf_parms_t;
```

The following are members of the structure:

<table>
<thead>
<tr>
<th>Void* __tf_dsa_addr</th>
<th>The address of the DSA for the current routine in the traceback. When this field is zero on input, the address of the DSA for the caller of <code>__le_traceback()</code> will be used and the address will be returned. No attempt is made to verify that the input is a DSA. Incorrect input can lead to unpredictable results.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Void* __tf_caa_addr</td>
<td>The address of the CAA associated with the DSA. When this field is zero on input, the address of the CAA for the current thread will be used and the address will be returned. No attempt is made to verify that the input is a CAA. Incorrect input can lead to unpredictable results.</td>
</tr>
</tbody>
</table>
### void* __tf_call_instruction
The address of the instruction that caused transfer out of the routine. This is either the address of a BASR, BRAS or BRASL instruction if transfer was made by subroutine call, or the address of the interrupted statement if transfer was caused by an exception. When multiple calls are made to __le_traceback() to scan the call chain, the callers_call_instruction (described below) returned from the previous call can be used here. If the address is not known, this field should be set to zero. When this field is zero on input and the address can be determined, it will be returned.

### void* __tf_pu_addr
The address of the start of the program unit for the routine associated with the DSA is returned in this field. If the program unit address cannot be determined, this field is set to zero.

### void* __tf_entry_addr
The address of the entry point into the routine associated with the DSA is returned in this field. If the entry point address cannot be determined, this parameter is set to zero.

### struct __cib* __tf_cib_addr
The address of the CIB (struct __cib) associated with the DSA, if an exception occurred, is returned in this field. If no exception occurred, this field is set to zero. Note that if an exception caused transfer out of the routine, the state of the registers after the last instruction ran in the routine is saved in the CIB, rather than in the DSA.

### uint8_t __tf_member_id
The member identifier for the routine associated with the DSA will be returned in this field. If the member ID cannot be determined, this field is set to negative one.

### int __tf_is_main:1
In this field, one of the following values is returned:
- 0 The routine associated with the DSA is not the main program.
- 1 The routine associated with the DSA is the main program.
**__tf_string_t __tf_pu_name**

A structure that will be used to return the name of the program unit containing the routine associated with the DSA. The structure has the following fields:

- **char* __tf_buff**
  - The address of a buffer in which the entry point name will be returned. The name will be returned in the buffer as a null terminated string.

- **size_t __tf_bufflen**
  - The size of the buffer

If the program unit name cannot be determined, the buffer is set to a null string. If the program unit name cannot fit within the supplied string, it is truncated. (Truncation of DBCS preserves even byte count and SI/SO pairing.) If __tf_buff is NULL or __tf_bufflen is zero, the program unit name is not returned.

**__tf_string_t __tf_entry_name**

A structure that will be used to return the name of the entry point into the routine associated with the DSA. The structure has the following fields:

- **char* __tf_buff**
  - The address of a buffer in which the entry point name will be returned. The name will be returned in the buffer as a null terminated string.

- **size_t __tf_bufflen**
  - The size of the buffer

If the entry point name cannot be determined, the buffer is set to a null string. If the entry point name cannot fit within the supplied string, it is truncated. (Truncation of DBCS preserves even byte count and SI/SO pairing.) If __tf_buff is NULL or __tf_bufflen is zero, the entry point name is not returned.
__tf_string_t __tf_statement_id

A structure that will be used to return the identifier of the statement containing the instruction which caused transfer out of the routine associated with the DSA. The structure has the following fields:

char* __tf_buff

The address of a buffer in which the entry point name will be returned. The name will be returned in the buffer as a null terminated string.

size_t __tf_bufflen

The size of the buffer

If the statement id cannot be determined, the buffer is set to a null string. If the statement id cannot fit within the supplied string, it is truncated. (Truncation of DBCS preserves even byte count and SI/SO pairing.) If __tf_buff is NULL or __tf_bufflen is zero, the statement id is not returned.

void* __tf_callers_dsa_addr

The address of the DSA for the caller is returned in this field. If the address of the caller’s DSA cannot be determined or is not valid (points to inaccessible storage), then this field is set to zero.

void* __tf_callers_call_instruction

The address of the instruction that caused transfer out of the caller is returned in this field. This is either the address of a BASR, BRAS or BRASL instruction if transfer was made by subroutine call, or the address of the interrupted statement if transfer was caused by an exception. If the address cannot be determined, this parameter is set to zero.

Example

#include <__le_api.h>
#include <stdlib.h>

int main() {
    __tfParms_t tbck_parms;
    char pu_name[256];
    char entry_name[256];
    char statement_id[256];
    _FEEDBACK fc;
    int rc;

    tbck_parms.__tf_pu_name.__tf_bufflen = sizeof(pu_name);
    tbck_parms.__tf_entry_name.__tf_bufflen = sizeof(entry_name);
    tbck_parms.__tf_statement_id.__tf_bufflen = sizeof(statement_id);

    tbck_parms.__tf_pu_name.__tf_buff = pu_name;
    tbck_parms.__tf_entry_name.__tf_buff = entry_name;
    tbck_parms.__tf_statement_id.__tf_buff = statement_id;

    tbck_parms.__tf_dsa_addr = 0;
    tbck_parms.__tf_caa_addr = 0;
    tbck_parms.__tf_call_instruction = 0;
}
# _le_traceback

```c
  do {
     _le_traceback(__TRACEBACK_FIELDS, &tbck_parms, &fc);
     if ( fc.tok_sev >= 2 ) {
        printf("Error: __le_traceback() failed.\n");
        break;
    }
    printf("Entry=%s Offset=%c%x Line=%s\n",
        tbck_parms.__tf_entry_name.__tf_buff,
        tbck_parms.__tf_call_instruction
        < tbck_parms.__tf_entry_addr ? '-' : '+',
        abs((int)((long)tbck_parms.__tf_call_instruction
        - (long)tbck_parms.__tf_entry_addr)),
        tbck_parms.__tf_statement_id.__tf_buff
    );
    tbck_parms.__tf_dsa_addr = tbck_parms.__tf_caller_dsa_addr;
    tbck_parms.__tf_call_instruction =
        tbck_parms.__tf_caller_call_instruction;
  } while (!tbck_parms.__tf_is_main);
  return 0;
}
```

</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <search.h>

void *lfind(const void *key, const void *base, size_t *nelp,
             size_t width, int (*compar)(const void *, const void *));
```

General Description

The lfind() function is the same as a lsearch() except that if the entry is not found, it is not added to the table. Instead, a NULL pointer is returned.

Special Behavior for C++

Because C and C++ linkage conventions are incompatible, lfind() cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to lfind(), the compiler will flag it as an error. You can pass a C or C++ function to lfind() by declaring it as extern "C".

Returned Value

If the searched-for entry is found, lfind() returns a pointer to it.

If not found, lfind() returns a NULL pointer.

No errors are defined.

Igamma

Igamma(), Igammaf(), Igammal() — Log Gamma Function

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <math.h>

double lgamma(double x);
extern int signgam;
int *__signgam(void);
```

```c
#define _ISOC99_SOURCE
#include <math.h>

double lgamma(double x);
float lgammaf(float x);
long double lgammal(long double x);
```

General Description

The lgamma() function computes the

\[ \log_e |\Gamma(x)| \]

where

\[ \Gamma(x) \]

is defined as

\[ \int_{0}^{\infty} e^{-t} t^{(x-1)} \, dt \]

The sign of \[ \Gamma(x) \]

is returned in the external integer \textit{signgam}. The argument \( x \) may not be a non-positive integer.

In a multithreaded process, each thread has its own instance of the \textit{signgam} variable. Threads access their instances of the variable by calling the \texttt{__signgam()} function. See \texttt{__signgam()} — Return signgam Reference” on page 1923. The
math.h header (see “math.h” on page 60) redefines the string “signgam” to an invocation of the __signham function. The actual signgam external variable is used to store the signgam value for the IPT.

**Note:** The following table shows the viable formats for these functions. See “IEEE Binary Floating-Point” on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>lgamma</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>lgammaf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>lgammal</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

**Returned Value**

If successful, lgamma() returns the above function of its argument.

lgamma() will fail under the following conditions:

- If the result overflows, the function will return HUGE_VAL and set errno to ERANGE.
- If x is a non-positive integer and _XOPEN_SOURCE is defined, lgamma() returns HUGE_VAL and sets errno to EDOM.
- If x is a non-positive integer and _ISOC99_SOURCE is defined, lgamma() returns HUGE_VAL and sets errno to ERANGE.

**Note:** If both _XOPEN_SOURCE and _ISOC99_SOURCE are defined, the _ISOC99_SOURCE behavior will take precedence.

**Example**

```c
/* This example uses lgamma() to calculate ln(|G(x)|), where x = 42.
 */
#include <math.h>
#include <stdio.h>

int main(void)
{
  double x=42, g_at_x;

  g_at_x = exp(lgamma(x)); /* g_at_x = 3.345253e+49 */
  printf("The value of G(\%4.2f) is \%7.2e\n", x, g_at_x);
}
```

**Output**
The value of G(42.00) is 3.35e+49

__librel

__librel() — Query Release Level

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <stdlib.h>

int __librel(void);

General Description

Provides the release level of the z/OS XL C/C++ library. To use this function, you must compile with LANGLVL(EXTENDED).

Returned Value

Returns the z/OS XL C/C++ Specific Library release level that your z/OS XL C or z/OS XL C++ program is using. The value is meant to be printed in a hexadecimal format. The first byte of the value returned contains the product and version, second byte the release, and the third and fourth bytes contain the modification level. For C programs running under the C/370 Specific Library (the common library version), the product designation is 0.

The following diagram shows the formats of the 32-bit int returned by the versions of __librel().

The C/370 V2R2 version of __librel() returns 0x02020000

```
+--- Mod level
+----- Release
+------- Version
```

In this case, the high-order 8 bits are used to return the version number.

The OS/390 R8 version of __librel() returns 0x22080000

```
+--- Mod level
+----- Release level
+------- Version level
+--------- Product 2 (OS/390)
```

The OS/390 R9 version of __librel() returns 0x22090000

```
+--- Mod level
+----- Release level
+------- Version level
+--------- Product 2 (OS/390)
```

The OS/390 R10 version of __librel() returns 0x220A0000

```
+--- Mod level
+----- Release level
+------- Version level
+--------- Product 2 (OS/390)
```
**Note:** When running under z/OS 1.1, \( \_\text{librel}() \) returns the same value as for OS/390 R10.

The z/OS 1.2 version of \( \_\text{librel}() \) returns 0x41020000

<table>
<thead>
<tr>
<th>Mod level</th>
<th>Release level</th>
<th>Version level</th>
<th>Product 4 (z/OS)</th>
</tr>
</thead>
</table>

The z/OS 1.3 version of \( \_\text{librel}() \) returns 0x41030000

<table>
<thead>
<tr>
<th>Mod level</th>
<th>Release level</th>
<th>Version level</th>
<th>Product 4 (z/OS)</th>
</tr>
</thead>
</table>

The z/OS 1.4 version of \( \_\text{librel}() \) returns 0x41040000

<table>
<thead>
<tr>
<th>Mod level</th>
<th>Release level</th>
<th>Version level</th>
<th>Product 4 (z/OS)</th>
</tr>
</thead>
</table>

The z/OS 1.5 version of \( \_\text{librel}() \) returns 0x41050000

<table>
<thead>
<tr>
<th>Mod level</th>
<th>Release level</th>
<th>Version level</th>
<th>Product 4 (z/OS)</th>
</tr>
</thead>
</table>

The z/OS 1.6 version of \( \_\text{librel}() \) returns 0x41060000

<table>
<thead>
<tr>
<th>Mod level</th>
<th>Release level</th>
<th>Version level</th>
<th>Product 4 (z/OS)</th>
</tr>
</thead>
</table>

The z/OS 1.7 version of \( \_\text{librel}() \) returns 0x41070000

<table>
<thead>
<tr>
<th>Mod level</th>
<th>Release level</th>
<th>Version level</th>
<th>Product 4 (z/OS)</th>
</tr>
</thead>
</table>

The z/OS 1.8 version of \( \_\text{librel}() \) returns 0x41080000

<table>
<thead>
<tr>
<th>Mod level</th>
<th>Release level</th>
<th>Version level</th>
<th>Product 4 (z/OS)</th>
</tr>
</thead>
</table>

The z/OS 1.9 version of \( \_\text{librel}() \) returns 0x41090000

<table>
<thead>
<tr>
<th>Mod level</th>
<th>Release level</th>
<th>Version level</th>
<th>Product 4 (z/OS)</th>
</tr>
</thead>
</table>

In these cases, these 8 bits are divided into two fields. The first 4 bits contain the product number and the second 4 bits contain the version number.

**Note:** When running under z/OS.e, \( \_\text{librel}() \) returns the same value as for z/OS.
Example

CELEBL04

/* CELEBL04

This example calls the __librel() function that returns the library release level your program is currently using in the following hexadecimal format 0xPVRMMMM.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    printf("The current release of the library is: \%X\n", __librel());
}

Output
The current release of the library is: 41090000

**link() — Create a Link to a File**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _POSIX_SOURCE
#include <unistd.h>

int link(const char *oldfile, const char *newname);
```

**General Description**

Provides an alternative pathname for the existing file, so that the file can be accessed by either the old or the new name. **link() creates a link from the pathname newname to an existing file, with the pathname oldfile.** The link can be stored in the same directory as the original file or in a completely different one.

Links are allowed to files only, not to directories.

This is a hard link, which ensures the existence of a file even after its original name has been removed.

If **link()** successfully creates the link, it increments the **link count** of the file. The link count tells how many links there are to the file. At the same time, **link()** updates the change time of the file, and the change time and modification time of the directory that contains newname (that is, the directory that holds the link). If **link()** fails, the link count is not incremented.

If oldfile names a symbolic link, **link()** creates a link that refers to the file that results from resolving the pathname contained in the symbolic link. If newname names a symbolic link, **link()** fails and sets errno to EEXIST.

**Returned Value**

If successful, **link()** returns 0.

If unsuccessful, **link()** returns −1 and sets errno to one of the following values:

**Error Code** | **Description**
---|---
EACCES | The process did not have appropriate permissions to create the link. Possible reasons include no search permission on a pathname component of oldfile or newname, no write permission on the directory intended to contain the link, or no permission to access oldfile.
EEXIST | Either newname refers to a symbolic link, or a file or directory with the name newname already exists.
EINVAL | Either oldfile or newname is incorrect, because it contains a NULL.
ELOOP | A loop exists in symbolic links. This error is issued if the number of
symbolic links encountered during resolution of `oldfile` or `newname` is greater than POSIX_SYMLOOP.

EMLINK `oldfile` already has its maximum number of links. The maximum number of links to a file is given by `LINK_MAX`, which you can determine by using `pathconf()` or `fpathconf()`.

ENAMETOOLONG `oldfile` or `newname` is longer than `PATH_MAX`, or a component of one of the pathnames is longer than `NAME_MAX` while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link in `oldfile` or `newname` exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined using `pathconf()`.

ENOENT A pathname component of `oldfile` or `newname` does not exist, or `oldfile` itself does not exist, or one of the two arguments is an empty string.

ENOSPC The directory intended to contain the link cannot be extended to contain another entry.

ENOTDIR A pathname component of one of the arguments is not a directory.

EPERM `oldfile` is the name of a directory, and links to directories are not supported.

EROFS Creating the link would require writing on a read-only file system.

EXDEV `oldfile` and `newname` are on different file systems.

Example

```c
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#include <stdlib.h>
#include <stdio.h>

main() {
    char fn[]="link.example.file";
    char ln[]="link.example.link";
    int fd;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        if (link(fn, ln) != 0) {
            perror("link() error");
            unlink(fn);
        } else {
            unlink(fn);
            unlink(ln);
        }
    }
}
```

</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int listen(int socket, int backlog);
```

Berkeley Sockets

```c
#define _OE_SOCKETS
#include <sys/socket.h>

int listen(int socket, int backlog);
```

General Description

The listen() function applies only to stream sockets. It indicates a readiness to accept client connection requests, and creates a connection request queue of length `backlog` to queue incoming connection requests. Once full, additional connection requests are rejected.

Parameter Description

- `socket`  The socket descriptor.
- `backlog` Defines the maximum length for the queue of pending connections.

The listen() call indicates a readiness to accept client connection requests. It transforms an active socket into a passive socket. Once called, `socket` can never be used as an active socket to initiate connection requests. Calling listen() is the third of four steps that a server performs to accept a connection. It is called after allocating a stream socket with `socket()`, and after binding a name to `socket` with `bind()`. It must be called before calling `accept()`.

If the backlog is less than 0, `backlog` is set to 0. If the backlog is greater than SOMAXCONN, as defined in `sys/socket.h`, `backlog` is set to SOMAXCONN.

For AF_UNIX sockets, this value is variable and can be set in the application. For AF_INET and AF_INET6 sockets, the value cannot exceed the maximum number of connections allowed by the installed TCP/IP.

Special Behavior for C++

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.
Returned Value

If successful, listen() returns 0.

If unsuccessful, listen() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The socket parameter is not a valid socket descriptor.</td>
</tr>

</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>
long long llabs(long long int n);
```

Compile Requirement

Use of this function requires the long long data type. See z/OS XL C/C++ Language Reference for information on how to make long long available.

General Description

Calculates the absolute value of its long long integer argument \( n \). The result is undefined when the argument is equal to `LONGLONG_MIN`, the smallest available long long integer (-9,223,372,036,854,775,808). The value `LONGLONG_MIN` is defined in the `limits.h` header file.

Returned Value

Returns the absolute value of the long long integer argument \( n \).

Related Information

<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>
long long lldiv(long long numer, long long denom);
```

Compile Requirement

Use of this function requires the long long data type. See z/OS XL C/C++ Language Reference for information on how to make long long available.

General Description

Calculates the quotient and remainder of the division of numerator by denominator.

Returned Value

Returns a structure of type `lldiv_t`, containing both the quotient `long long quot` and the remainder `long long rem`.

If the value cannot be represented, the returned value is undefined. If `denominator` is 0, a divide by 0 exception is raised.

Example

```c
/*
 * This example uses the lldiv() function to calculate the quotients and remainders for a set of two dividends and two divisors.
 */
#define _LONG_LONG 1
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    long long num[2] = {45,-45};
    long long den[2] = {7,-7};
    lldiv_t ans; /* lldiv_t is a struct type containing two long long int fields:
                   'quot' stores quotient; 'rem' stores remainder */
    short i,j;

    printf("Results of long division:\n");
    for (i = 0; i < 2; i++)
        for (j = 0; j < 2; j++)
        {
            ans = lldiv(num[i], den[j]);
            printf("Dividend: %6lld Divisor: %6lld", num[i], den[j]);
            printf("Quotient: %6lld Remainder: %6lld", ans.quot, ans.rem);
        }
    return 0;
}
```
printf(" Quotient: %lld Remainder: %lld\n", ans.quot, ans.rem);
}
}

**Output**

Results of long division:
Dividend: 45 Divisor: 7 Quotient: 6 Remainder: 3
Dividend: 45 Divisor: -7 Quotient: -6 Remainder: 3
Dividend: -45 Divisor: 7 Quotient: -6 Remainder: -3
Dividend: -45 Divisor: -7 Quotient: 6 Remainder: -3

Ilround(), Ilroundf(), Ilroundl() — Round to the Nearest Integer

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <math.h>

long long int ilround(double x);
long long int ilroundf(float x);
long long int ilroundl(long double x);
```

Compile Requirement

Use of this function requires the long long data type. See 
["z/OS XL C/C++ Language Reference"] for information on how to make long long available.

General Description

The Ilround() family of functions round `x` to the nearest integer, rounding halfway cases away from zero, regardless of the current rounding mode.

Note: The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ilround</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>ilroundf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>ilroundl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

If successful, they return the rounded integer. If the correct value is positive or negative and too large to represent as a `long long`, a domain error will occur and an unspecified value is returned.

Example

```c
/*
 * This program illustrates the use of ilround() function
 *
*/
#define _ISOC99_SOURCE
#include <math.h>
#include <_Ieee754.h> /* fpc functions */
#include <stdio.h>

void main() {

    _FP_fpcreg_t save_rmode;
```
Ilround, Ilroundf, Ilroundl

```c
long long int rnd2nearest;
double number;

printf("Illustrates the llround() function\n\n");

save_rmode.rmode = _RMODE_RZ;
__fpc_sm(save_rmode.rmode); /* set rounding mode to round to zero */

number=501.1;
rnd2nearest = llround(number);
printf ("llround(%.1f) = %lli\n",number, rnd2nearest);

number=1.5;
rnd2nearest = llround(number);
printf ("llround(%.1f) = %lli\n",number, rnd2nearest);

number=-2.5;
rnd2nearest = llround(number);
printf ("llround(%.1f) = %lli\n",number, rnd2nearest);
}
```

Output

Illustrates the llround() function

```
llround(501.1) = 501
llround(1.5) = 2
llround(-2.5) = -3
```

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>
long long int llroundd32(_Decimal32 x);
long long int llroundd64(_Decimal64 x);
long long int llroundd128(_Decimal128 x);
long long int llroundd32(_Decimal32 x); /* C++ only */
long long int llroundd64(_Decimal64 x); /* C++ only */
long long int llroundd128(_Decimal128 x); /* C++ only */
```

Note:

Use of this function requires the long long data type. See Z/OS XL C/C++ Language Reference for information on how to make long long available.

General Description

The Ilround() family of functions round x to the nearest integer, rounding halfway cases away from zero, regardless of the current rounding mode.

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

If successful, they return the rounded integer. If the correct value is positive or negative and too large to represent as a long long, a domain error will occur and an unspecified value is returned.

Example

```c
/* CELEBL21

   This example illustrates the llroundd32() function.
*/

#pragma strings(readonly)

Iltoa

Iltoa() — Convert long long into a string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R5</td>
</tr>
</tbody>
</table>

Format

```
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * lltoa(int64_t ll, char * buffer, int radix);
```

Compile Requirement

Use of this function requires the long long data type. See z/OS XL C/C++ Language Reference for information on how to make long long available.

General Description

The lltoa() function converts the int64_t ll into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, lltoa() produces the same result as the following statement:

```
(void) sprintf(buffer, "%lld", ll);
```

with buffer the returned character string. When the radix is OCTAL, lltoa() formats int64_t ll into an unsigned octal constant. When the radix is HEX, lltoa() formats int64_t ll into an unsigned hexadecimal constant. The hexadecimal value will include lower case abcdfe, as necessary.

Returned Value

String pointer (same as buffer) will be returned. When passed an invalid radix argument, function will return NULL and set errno to EINVAL.

Portability Considerations

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

localdtconv() — Date/Time Formatting Convention Inquiry

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td></td>
<td>both</td>
</tr>
</tbody>
</table>

Format

```c
#include <locale.h>

struct dtconv *localdtconv(void);
```

General Description

Determines the date/time format information of the current locale.

To avoid infringing on the user’s name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Returned Value

Returns the address of the dtconv structure:

```c
struct dtconv {
    char *abbrev_month_names[12]; /* Abbreviated month names */
    char *month_names[12]; /* Full month names */
    char *abbrev_day_names[7]; /* Abbreviated day names */
    char *day_names[7]; /* Full day names */
    char *date_time_format; /* Date and time format */
    char *date_format; /* Date format */
    char *time_format; /* Time format */
    char *am_string; /* AM string */
    char *pm_string; /* PM string */
    char *time_format_ampm; /* Long date format */
    char *iso_std8601_2000; /* ISO 8601:2000 std date format */
};
```

The dtconv structure is an IBM extension that stores values from the LC_TIME category of the current locale. It is initialized by the setlocale() function and copied to the user-supplied dtconv when localdtconv() is called.

The dtconv structure can be overwritten by subsequent calls to localdtconv() and setlocale() with LC_ALL or LC_TIME.

</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <locale.h>

struct lconv *localeconv(void);
```

General Description

Sets the components of a structure having type `struct lconv` to values appropriate for the current locale. The structure may be overwritten by another call to `localeconv()` or by calling `setlocale()` and passing `LC_ALL`, `LC_MONETARY`, or `LC_NUMERIC`.

For a list of the elements in the `lconv` structure, see Table 9 on page 57.

Pointers to strings with a value of "" indicate that the value is not available in the C locale or is of 0 length. `char` types with a value of `UCHAR_MAX` indicate that the value is not available in the current locale.

Returned Value

Returns a pointer to the structure.

Example

```
CELEBL06

/* CELEBL06

  This example prints out the default decimal point for your locale and then the decimal point for the Fr_CA locale.

  */
#include <stdio.h>
#include <locale.h>

int main(void)
{
  char * string;
  struct lconv * mylocale;
  mylocale = localeconv();
  /* Display default decimal point */
  printf( "Default decimal point is a %s\n",
             mylocale->decimal_point );

  if (NULL != (string = setlocale(LC_ALL, "Fr_CA.IBM-1047" )))
  {
    mylocale = localeconv();
    /* A comma is set to be the decimal point when the locale is Fr_CA.IBM-1047 */
```
localeconv

    printf("French-speaking Canadian decimal point is a %.\n", 
           mylocale->decimal_point);
    }
else {
    printf("setlocale(LC_ALL, Fr_CA.IBM-1047) returned <NULL>\n");
    } 
    return 0;
}

Output
Default decimal-point is a .
French-speaking Canadian decimal-point is a ,

<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <time.h>

struct tm *localtime(const time_t *timeval);
```

General Description

Converts the calendar time pointed to by `timeval` to a broken-down time expressed in local time. Calendar time is usually obtained by a call to the `time()` function.

Returned Value

Returns a pointer to a `tm` structure containing the broken-down time, expressed as a local time, and corresponding to the calendar time pointed to by `timeval`. If the calendar time cannot be converted, `localtime()` returns a NULL pointer. See `time.h` on page 93 for a description of the fields of the `tm` structure.

Error Code

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EOVERFLOW</td>
</tr>
</tbody>
</table>

The result cannot be represented.

Notes:

- This function is sensitive to time zone information which is provided by:
  - The TZ environmental variable when POSIX(ON) and TZ is correctly defined, or by the _TZ environmental variable when POSIX(OFF) and _TZ is correctly defined.
  - The LC_TOD category of the current locale if POSIX(OFF) or TZ is not defined.

The time zone external variables `tzname`, `timezone`, and `daylight` declarations remain feature test protected in `time.h`.

- The `ctime()`, `localtime()`, and `mktime()` functions now return Coordinated Universal Time (UTC) unless customized locale information is made available, which includes setting the `timezone_name` variable.
- In POSIX you can supply the necessary information by using environment variables.
- In non-POSIX applications, you can supply customized locale information by setting time zone and daylight information in LC_TOD.
- By customizing the locale, you allow the time functions to preserve both time and date, correctly adjusting for daylight time on a given date.
The `gmtime()` and `localtime()` functions may use a common, statically allocated structure for the conversion. Each call to one of these functions will alter the result of the previous call.

Calendar time returned by the `time()` function begins at the epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.

The `localtime()` function converts calendar time (that is, seconds elapsed since the epoch) to broken-down time, expressed as local time, using time zone information. Such information is provided as follows:

- For a POSIX program, time zone information is provided by the `TZ` environment variable or the current LC_TOD locale category. The `localtime()` function calls the `tzset()` function to parse the `TZ` environment variable. If `tzset()` cannot find the `TZ` environment variable or cannot parse it, `tzset()` obtains time zone information for the `localtime()` function from the current LC_TOD locale category. See "z/OS XL C/C++ applications with z/OS UNIX System Services C functions" on page 13 for more information about using POSIX support.

- For all other C and C++ applications, time zone information is provided by the current LC_TOD locale category.

See "Internationalization: Locales and Character Sets" in z/OS XL C/C++ Programming Guide for a description of LC_TOD, which is a nonstandard, z/OS XL C/C++ proprietary locale category.

Example

CELEBL07

```c
#include <time.h>
#include <stdio.h>

int main(void)
{
    struct tm *newtime;
    time_t ltime;
    time(&ltime);
    newtime = localtime(&ltime);
    printf("The date and time is %s", asctime(newtime));
}
```

Output

This output would occur if the local time is 3:00 p.m. June 16, 2001:

The date and time is Fri Jun 16 15:00:00 2001

localtime_r() — Convert Time Value to Broken-Down Local Time

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <time.h>

struct tm *localtime_r(const time_t *__restrict__ clock,
                        struct tm *__restrict__ result);
```

General Description

The localtime_r() function converts the calendar time pointed to by `clock` into a broken-down time stored in the structure to which `result` points. The localtime_r() function also returns a pointer to that same structure.

Unlike localtime(), the reentrant version is not required to set tzname.

Returned Value

If successful, localtime_r() returns a pointer to the structure pointed to by the argument `result`.

If an error is detected, localtime() returns a null pointer and set errno to indicate the error.

Error Code

**EOVERFLOW**

The result cannot be represented.

The lockf() function allows sections of a file to be locked with advisory-mode locks. Calls to lockf() from other processes which attempt to lock the locked file section will either return an error value or block until the section becomes unlocked. All the locks for a process are removed when the process terminates. Record locking with lockf() is supported for regular files.

The filedes argument is an open file descriptor. The file descriptor must have been opened with a write-only permission (O_WRONLY) or with read/write permission (O_RDWR) to establish a lock with this function.

The function argument is a control value which specifies the action to be taken. The permissible values for function are defined in <unistd.h> as follows:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_ULOCK</td>
<td>unlock locked sections</td>
</tr>
<tr>
<td>F_LOCK</td>
<td>lock a section for exclusive use</td>
</tr>
<tr>
<td>F_TLOCK</td>
<td>test and lock a section for exclusive use</td>
</tr>
<tr>
<td>F_TEST</td>
<td>test a section for locks by other processes</td>
</tr>
</tbody>
</table>

F_TEST detects if a lock by another process is present on the specified section; F_LOCK and F_TLOCK both lock a section of a file if the section is available; F_ULOCK removes locks from a section of the file.

The size argument is the number of contiguous bytes to be locked or unlocked. The section to be locked or unlocked starts at the current offset in the file and extends forward for a positive size or backward for a negative size (the preceding bytes up to but not including the current offset). If size is 0, the section from the current offset through the largest possible file offset is locked (that is, from the current offset through the present or any future End Of File (EOF)). An area need not be allocated to the file to be locked because locks may exist past the End Of File.

The sections locked with F_LOCK or F_TLOCK may, in whole or in part, contain or be contained by a previously locked section for the same process. When this occurs, or if adjacent locked sections would occur, the sections are combined into a single locked section. If the request would cause the number of locks to exceed a system-imposed limit, the request will fail.
F_LOCK and F_TLOCK requests differ only by the action taken if the section is not available. F_LOCK blocks the calling process until the section is available. F_TLOCK makes the function fail if the section is already locked by another process.

File locks are released on first close by the locking process of any file descriptor for the file.

F_UNLOCK requests may release (wholly or in part) one or more locked sections controlled by the process. Locked sections will be unlocked starting at the current file offset through size bytes or to the End Of File (EOF) if size is (off_t)0. When all of a locked section is not released (that is, when the beginning or end of the area to be unlocked falls within a locked section), the remaining portions of that section are still locked by the process. Releasing the center portion of a locked section will cause the remaining locked beginning and end portions to become two separate locked sections. If the request would cause the number of locks in the system to exceed a system-imposed limit, the request will fail.

A potential for deadlock occurs if a process controlling a locked section is blocked by accessing another process’s locked section. If the system detects that a deadlock would occur, lockf() will fail with an EDEADLK error.

Locks obtained by lockf() are controlled by the same facility controlling locks obtained by fcntl().

The interaction between fcntl() and lockf() locks is unspecified.

Blocking on a section is interrupted by any signal.

Large Files for HFS

Note: Large Files for HFS behavior is automatic for AMODE 64 applications. Applications that are compiled with the option LANGLVL(LONGLONG) and also define the Feature Test Macro (FTM) _LARGE_FILES before any headers are included will enable this function to operate on HFS files that are larger than 2 gig-1 in size. File size and offset fields will be enlarged to 63 bits in width so any other function operating on this file will have to be enabled with the same FTM.

Returned Value

If successful, lockf() returns 0.

If unsuccessful, existing locks are not changed, lockf() returns –1, and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>

</tr>
</tbody>
</table>

Format

```
#include <math.h>

double log(double x);
float log(float x);            /* C++ only */
long double log(long double x); /* C++ only */
float logf(float x);
long double logl(long double x);
```

General Description

Calculates the natural logarithm (base e) of x, for x greater than 0.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [IEEE Binary Floating-Point](#) for more information about IEEE Binary Floating-Point.

Returned Value

Returns the computed value.

If x is negative, the function sets errno to EDOM and returns −HUGE_VAL. If x is 0.0, the function returns −HUGE_VAL and sets errno to ERANGE. If the correct value would cause an underflow, 0 is returned and the value ERANGE is stored in errno.

Special Behavior for IEEE

If x is greater than 0, the function returns the natural logarithm (base e) of x.

If x is negative, the function sets errno to EDOM and returns NaNQ. If x is 0.0, the function returns −HUGE_VAL and errno remains unchanged.

Example

```
CELEBL08
/* CELEBL08 */

This example calculates the natural logarithm of 1000.0.

*/
#include <math.h>
#include <stdio.h>

int main(void)
```
{  
double x = 1000.0, y;
  
y = log(x);
  
printf("The natural logarithm of %lf is %lf\n", x, y);
}

Output
The natural logarithm of 1000.000000 is 6.907755

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double logb(double x);

C99
#define _ISOC99_SOURCE
#include <math.h>

float logbf(float x);
long double logbl(long double x);
```

General Description

Returns the exponent of its argument `x`, as a signed integer value in floating-point mode. If `x` is subnormal, it is treated as a normalized number.

**Note:** The following table shows the viable formats for these functions. See “IEEE Binary Floating-Point” on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>

<td>logb</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>logbf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>logbl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

If successful, `logb()` returns the exponent of `x`.

`logb()` will fail under the following condition: If `x` is equal to 0.0, `logb()` will return −HUGE_VAL and set `errno` to EDOM.

Example

```c
/*
 * This program illustrates the use of logb() function
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <math.h>  /* Needed for FLT_RADIX */
#include <stdio.h>

void main() {
```
int i;
union {
    double number;
    unsigned char uchars [sizeof(double)];
} dblval;
double logbx;
printf("Illustrates the logb() function");

#ifdef __BFP__
    printf(" (IEEE version)\n\n");
#else
    printf(" (HFP version)\n\n");
#endif

/* generate the smallest possible double number */
for (i=0; i<sizeof(double); i++)
    dblval.uchars[i] = 0;
dblval.uchars[1] = 0x10;
logbx = logb(dblval.number);
printf("x = %g\n", dblval.number);
printf("logb(x) = %f\n", logbx);
printf("pow(FLT_RADIX, logb(x) ) should equal x\n");
printf("pow(%d,%f) = %g\n",FLT_RADIX, logbx, pow(FLT_RADIX, logbx));
}

Output
Illustrates the logb() function (IEEE version)

x = 2.22507e-308
logb(x) = -1022.000000
pow(FLT_RADIX, logb(x) ) should equal x
pow(2, -1022.000000) = 2.22507e-308

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 logbd32(_Decimal32 x);
_Decimal64 logbd64(_Decimal64 x);
_Decimal128 logbd128(_Decimal128 x);

_Decimal32 logb(_Decimal32 x); /* C++ only */
_Decimal64 logb(_Decimal64 x); /* C++ only */
_Decimal128 logb(_Decimal128 x); /* C++ only */
```

General Description

Returns the unbiased exponent of its argument x as a signed integer value in decimal floating-point mode. For typical numbers, the value returned is the logarithm of |x| rounded down (toward -INF) to the nearest integer value.

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See “IEEE Decimal Floating-Point” for more information.

Returned Value

If successful, these functions return the unbiased exponent of x as a signed integer value in decimal floating-point mode.

These functions will fail under the following condition: If x is equal to 0.0, -HUGE_VAL_D32, -HUGE_VAL_D64, or -HUGE_VAL_D128 is returned and errno is set to EDOM.

Example

```c
/* CELEBL24

This program illustrates the use of logbd32() function
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
#include <stdlib.h>

void main()
{
    _Decimal32 x, logbx;

    printf("Illustrates the logbd32() function\n");
```
/* Generate the smallest possible positive _Decimal32 number    */

x = strtod32("0000001.E-101", NULL);

logbx = logbd32(x);

printf("x = %Hg\n", x);
printf("logb(x) = %Hf\n", logbx);

printf("powd32(10.0, logb32(x)) should equal x\n");
printf("powd32(%Hf, %Hf) = %Hg",
      10.0DF, logbx, powd32(10.0DF, logbx));

__login

__login() — Create a New Security Environment for Process

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS
#include <unistd.h>

int __login(int function_code,
            int identity_type,
            int identity_length,
            void *identity,
            int pass_length,
            char *pass,
            int certificate_length,
            char *certificate,
            int option_flags);
```

General Description

The __login() function provides a way for a process to change its identity so as to be different than the address space identity and create a new security environment for the process. Once changed the process should not revert back to a previous identity and security environment. The following rules apply:

- Any single-threaded process can issue a __login to change its security environment.
- If the process is in a multiproc/multiuser environment and there is no task level security associated with the process, then the new security environment will be associated with the process.
- If the process is in a multiproc/multiuser environment and there is task level security associated with the process, then the old security environment will be replaced by the new security environment.

The function has the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>function_code</td>
<td>Specifies the function. Specify __LOGIN_CREATE, as defined in the unistd.h header file, to create a process level security environment for the caller’s process.</td>
</tr>
<tr>
<td>identity_type</td>
<td>Specifies the format of the the user identity being provided in *identity. Specify __LOGIN_USERID, as defined in the unistd.h header file. The user ID identity is in the format of a 1-to-8-character userid and is passed as input.</td>
</tr>
<tr>
<td>identity_length</td>
<td>Specifies the length of the identity as defined by identity_type.</td>
</tr>
<tr>
<td>identity</td>
<td>Specifies the user identity as defined by identity_type.</td>
</tr>
<tr>
<td>pass_length</td>
<td>Specifies the length of the password defined by pass.</td>
</tr>
<tr>
<td>pass</td>
<td>Specifies a user password or pass ticket.</td>
</tr>
<tr>

</tr>
<tr>
<td>certificate</td>
<td>Is not used presently and must be set to zero.</td>
</tr>
</tbody>
</table>
certificate  Is not used presently and must point to void.

option_flags  Specifies options used to tailor request. Must be set to 0.

Usage Notes:
1. The intent of the __login() service is to provide a way for a process to change its identity so as to be different than the address space identity. The process should either terminate or select a new user ID, but should not try to revert back to the original identity. The user could issue the __login() again with the original user identity, but the task would retain its own security environment and not share the the security environment at the address space level.

2. A security manager supporting multiproc/multiuser environment must be installed and operational.

Returned Value

If successful, __login() returns 0.

If unsuccessful, __login() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Permission is denied.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>A parameter is invalid.</td>

</table>
+-----------------+----------------+----------------+

Format

```c
#include <math.h>

double log1p(double x);
```

C99

```c
#define _ISOC99_SOURCE
#include <math.h>

float log1pf(float x);
long double log1pl(long double x);
```

General Description

Computes

\[ \log_e (1.0 + x) \]

The value of x must be greater than -1.0.

**Note:** The following table shows the viable formats for these functions. See "IEEE Binary Floating-Point" on page 108 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>log1p</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>log1pf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>log1pl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned Value

If successful, log1p() returns the value of the above function of x.

log1p() will fail under the following conditions:

- If x is less than -1.0, log1p() will return -HUGE_VAL and set errno to EDOM.
- If x is equal to -1.0, log1p() will return -HUGE_VAL and set errno to ERANGE.

**Special Behavior for IEEE**

If successful, log1p() returns the
Log$_e (1.0 + x)$

The value of $x$ must be greater than -1.0.

log1p() will fail under the following conditions:

- If $x$ is less than −1.0, log1p() will return NaN and set errno to EDOM.
- If $x$ is equal to −1.0, log1p() will return −HUGE_VAL and errno remains unchanged.

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <math.h>

double log10(double x);
float log10f(float x);  /* C++ only */
long double log10l(long double x); /* C++ only */
float log10(float x);
long double log10l(long double x);
```

General Description

Calculates the base 10 logarithm of the positive value of x.

**Note:** These functions work in both [IEEE Binary Floating-Point](#) and hexadecimal floating-point formats. See [IEEE Binary Floating-Point](#) on page 108 for more information about IEEE Binary Floating-Point.

Returned Value

Returns the computed value.

If x is negative, the function sets errno to EDOM and returns -HUGE_VAL. If x is 0, the function returns -HUGE_VAL, and sets errno to ERANGE. If the correct value would cause an underflow, 0 is returned and the value ERANGE is stored in errno.

Special Behavior for IEEE

If successful, the function returns the base 10 logarithm of the positive value of x.

If x is negative, the function sets errno to EDOM and returns NaN. If x is 0, the function returns -HUGE_VAL and errno remains unchanged.

Example

```c
/* CELEBL09 */

/* CELEBL09 */

This example calculates the base 10 logarithm of 1000.0.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
```
double x = 1000.0, y;
y = log10(x);
printf("The base 10 logarithm of %lf is %lf\n", x, y);
}

Output
The base 10 logarithm of 1000.000000 is 3.000000

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 log10d32(_Decimal32 x);
_Decimal64 log10d64(_Decimal64 x);
_Decimal128 log10d128(_Decimal128 x);
_Decimal32 log10(_Decimal32 x); /* C++ only */
_Decimal64 log10(_Decimal64 x); /* C++ only */
_Decimal128 log10(_Decimal128 x); /* C++ only */
```

General Description

Calculates the base 10 logarithm of the positive value of `x`.

Note:
- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned Value

If successful, the function returns the base 10 logarithm of the positive value of `x`.

If `x` is negative, the function sets `errno` to `EDOM` and returns `NaNQ`. If `x` is 0, the function returns `-HUGE_VAL_D32`, `-HUGE_VAL_D64`, or `-HUGE_VAL_D128` and `errno` remains unchanged.

Example

```c
/* CELEBL23

This example illustrates the log10d128() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x = 1000.0DL, y;
    y = log10d128(x);
    printf("The base 10 logarithm of %DDf is %DDf\n", x, y);
}
```
