</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double logb(double x);

C99:
#define _ISOC99_SOURCE
#include <math.h>

float logbf(float x);
long double logbl(long double x);

C++ TR1 C99:
#define _TR1_C99
#include <math.h>

float logb(float x);
long double logb(long double x);
```

General description

Returns the exponent of its argument `x`, as a signed integer value in floating-point mode. If `x` is subnormal, it is treated as a normalized number.

**Note:** The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>logb</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>logbf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>logbl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned value

If successful, logb() returns the exponent of `x`.

logb() will fail under the following condition: If `x` is equal to 0.0, logb() will return -HUGE_VAL and set errno to EDOM.
Example

/*
 * This program illustrates the use of logb() function
 *
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <float.h> /* Needed for FLT_RADIX */
#include <stdio.h>

void main() {
    int i;
    union {
        double number;
        unsigned char uchars [sizeof(double)];
    } dblval;
    double logbx;

    printf("Illustrates the logb() function");

    #ifdef __BFP__
        printf(" (IEEE version)\n\n");
    #else
        printf(" (HFP version)\n\n");
    #endif

    /* generate the smallest possible double number */
    for (i=0; i<sizeof(double); i++)
        dblval.uchars[i] = 0;
    dblval.uchars[1] = 0x10;

    logbx = logb(dblval.number);

    printf("x = \%.g",dblval.number);
    printf("logb(x) = \%.f", logbx);

    printf("pow(FLT_RADIX, logb(x) ) should equal x\n");
    printf("pow(\%.d,\%.f) = \%.g",FLT_RADIX, logbx, pow(FLT_RADIX, logbx));
}

Output
Illustrates the logb() function (IEEE version)

x = 2.22507e-308
logb(x) = -1022.000000

pow(FLT_RADIX, logb(x) ) should equal x
pow(2,-1022.000000) = 2.22507e-308

</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 logbd32(_Decimal32 x);  
_Decimal64 logbd64(_Decimal64 x);  
_Decimal128 logbd128(_Decimal128 x);  

_Decimal32 logb(_Decimal32 x);      /* C++ only */
_Decimal64 logb(_Decimal64 x);      /* C++ only */
_Decimal128 logb(_Decimal128 x);    /* C++ only */
```

General description

Returns the unbiased exponent of its argument as a signed integer value in decimal floating-point mode. For typical numbers, the value returned is the logarithm of |x| rounded down (toward -INF) to the nearest integer value.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, these functions return the unbiased exponent of as a signed integer value in decimal floating-point mode.

These functions will fail under the following condition: If is equal to 0.0, -HUGE_VAL_D32, -HUGE_VAL_D64, or -HUGE_VAL_D128 is returned and errno is set to EDOM.

Example

```c
/* CELEBL24

   This program illustrates the use of logbd32() function

*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
#include <stdlib.h>

void main()
{
   _Decimal32 x, logbx;
   printf("Illustrates the logbd32() function\n");
}```
/* Generate the smallest possible positive _Decimal32 number */
x = strtod32("0000001.E−101", NULL);
logbx = logbd32(x);
printf("x = %Hg\n", x);
printf("logb(x) = %Hf\n", logbx);
printf("powd32(10.0, logb32(x)) should equal x\n");
printf("powd32(%Hf, %Hf) = %Hg\n",
       10.0DF, logbx, powd32(10.0DF, logbx));
}

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.8</td>
</tr>
</tbody>
</table>

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

.Decimal32 logd32(_Decimal32 x);
.Decimal64 logd64(_Decimal64 x);
.Decimal128 logd128(_Decimal128 x);

.Decimal32 log(_Decimal32 x); /* C++ only */
.Decimal64 log(_Decimal64 x); /* C++ only */
.Decimal128 log(_Decimal128 x); /* C++ only */
```

General description

Calculates the natural logarithm (base e) of x, for x greater than 0.

Notes:
1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If x greater than 0, the function returns the natural logarithm (base e) of x.

If x is negative, the function sets errno to EDOM and returns NaNQ.

If x is 0.0, the function returns -HUGE_VAL_D32, -HUGE_VAL_D64, or -HUGE_VAL_D128 and errno remains unchanged.

Example

```
/* CELEBL22
   This example illustrates the logd64() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 x = 1000.0DD, y;
    y = logd64(x);
    printf("The natural logarithm of %.10f is %.10f\n", x, y);
}
```

__login, login_applid

__login(), __login_applid() — Create a new security environment for process

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS
#include <unistd.h>

int __login(int function_code,
            int identity_type,
            int identity_length,
            void *identity,
            int pass_length,
            char *pass,
            int certificate_length,
            char *certificate,
            int option_flags);

int __login_applid(int function_code,
                    int identity_type,
                    int identity_length,
                    void *identity,
                    int pass_length,
                    char *pass,
                    int certificate_length,
                    char *certificate,
                    int option_flags,
                    const char *applid);
```

General description

The __login() function provides a way for a process to change its identity so as to be different than the address space identity and create a new security environment for the process. Once changed the process should not revert back to a previous identity and security environment. The following rules apply:

- Any single-threaded process can issue a __login to change its security environment.
- If the process is in a multiprocessing or multiple user environment and there is no task level security associated with the process, then the new security environment will be associated with the process.
- If the process is in a multiprocessing or multiple user environment and there is task level security associated with the process, then the old security environment will be replaced by the new security environment.

The __login_applid() function is equivalent to __login() with the added feature that it also allows the application identifier (APPLID) to be supplied that will be passed on to the security product to assist with authentication. This is useful, for example, in situations where a pass ticket is provided and the pass ticket was created with a USERID/APPLID combination. When applid is NULL or a pointer to NULL, no application identifier will be passed on to the security product.

The function has the following parameters:
## __login, login_applid

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>function_code</td>
<td>Specifies the function. Specify __LOGIN_CREATE, as defined in the unistd.h header file, to create a process level security environment for the caller's process.</td>
</tr>
<tr>
<td>identity_type</td>
<td>Specifies the format of the the user identity being provided in *identity. Specify __LOGIN_USERID, as defined in the unistd.h header file. The user ID identity is in the format of a 1-to-8-character userid and is passed as input.</td>
</tr>
<tr>
<td>identity_length</td>
<td>Specifies the length of the identity as defined by identity_type.</td>
</tr>
<tr>
<td>*identity</td>
<td>Specifies the user identity as defined by identity_type.</td>
</tr>
<tr>
<td>pass_length</td>
<td>Specifies the length of the password or PassTicket, or the password phrase defined by pass.</td>
</tr>
<tr>
<td>*pass</td>
<td>Specifies a user password or PassTicket, or a password phrase.</td>
</tr>
<tr>
<td>certificate_length</td>
<td>Is not used presently and must be set to zero.</td>
</tr>
<tr>
<td>certificate</td>
<td>Is not used presently and must point to void.</td>
</tr>
<tr>
<td>option_flags</td>
<td>Specifies options used to tailor request. Must be set to 0.</td>
</tr>
<tr>
<td>applid</td>
<td>Specifies the application identifier that will be used for authentication with the security product.</td>
</tr>
</tbody>
</table>

### Usage notes

1. The intent of the __login() service is to provide a way for a process to change its identity so as to be different than the address space identity. The process should either terminate or select a new user ID, but should not try to revert back to the original identity. The user could issue the __login() again with the original user identity, but the task would retain its own security environment and not share the the security environment at the address space level.
2. A security product supporting multiprocessing or multiple user environment must be installed and operational.

### Returned value

If successful, __login() returns 0.

If unsuccessful, __login() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Permission is denied.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>A parameter is not valid. For example, length of applid exceeds 8 bytes.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>An MVS environmental error or internal occurred.</td>
</tr>
<tr>
<td>EMVSEXPIRE</td>
<td>The password or PassTicket, or a password phrase for the specified resource has expired.</td>
</tr>
<tr>
<td>EMVSSAF2ERR</td>
<td>An error occurred in the security product. The userid has been revoked or is unable to use the application.</td>
</tr>
<tr>
<td>ENOSYS</td>
<td>The function is not implemented.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The operation is not permitted. Calling process may not be</td>
</tr>
</tbody>
</table>
authorized in BPX.DAEMON facility class. The function is not supported in an address space where a load was done from an uncontrolled library. A required password or PassTicket, or a password phrase was not specified.

ESRCH The USERID cannot become an OMVS process. The userid provided is not defined to the security product or doesn't have an OMVS segment defined.

#define _ISOC99_SOURCE
#include <math.h>

float log1pf(float x);
long double log1pl(long double x);

C++ TR1 C99:
#define _TR1_C99
#include <math.h>

float log1p(float x);
long double log1p(long double x);
```

General description

Computes

\[ \log_e (1.0 + x) \]

The value of \( x \) must be greater than -1.0.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>

<td>X</td>
<td>X</td>
</tr>
<tr>
<td>log1pf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>log1pl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned value

If successful, log1p() returns the value of the above function of \( x \).

log1p() will fail under the following conditions:

- If \( x \) is less than -1.0, log1p() will return \(-\text{HUGE\_VAL}\) and set errno to EDOM.
**log1p**

- If $x$ is equal to $-1.0$, `log1p()` will return −HUGE_VAL and set `errno` to ERANGE.

**Special behavior for IEEE:** If successful, `log1p()` returns the

$$ \log_e (1.0 + x) $$

The value of $x$ must be greater than -1.0.

`log1p()` will fail under the following conditions:
- If $x$ is less than $-1.0$, `log1p()` will return NaNQ and set `errno` to EDOM.
- If $x$ is equal to $-1.0$, `log1p()` will return −HUGE_VAL and `errno` remains unchanged.

double log10(double x);
float log10(float x); /* C++ only */
long double log10(long double x); /* C++ only */
float log10f(float x);
long double log10l(long double x);
```

General description

Calculates the base 10 logarithm of the positive value of x.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See the IEEE binary floating-point on page 94 for more information about IEEE Binary Floating-Point.

Returned value

Returns the computed value.

If x is negative, the function sets errno to EDOM and returns -HUGE_VAL. If x is 0, the function returns -HUGE_VAL, and sets errno to ERANGE. If the correct value would cause an underflow, 0 is returned and the value ERANGE is stored in errno.

Special behavior for IEEE: If successful, the function returns the base 10 logarithm of the positive value of x.

If x is negative, the function sets errno to EDOM and returns NaNQ. If x is 0, the function returns -HUGE_VAL and errno remains unchanged.

Example

```c
CELEBL09
/* CELEBL09
   This example calculates the base 10 logarithm of 1000.0.
*/
#include <math.h>
#include <stdio.h>

int main(void)
{
```
double x = 1000.0, y;
y = log10(x);
printf("The base 10 logarithm of %lf is %lf\n", x, y);
}

Output
The base 10 logarithm of 1000.000000 is 3.000000

_DECIMAL128 log2d128(_DECIMAL128 x);

_DECIMAL32 log2(_DECIMAL32 x); /* C++ only */
_DECIMAL64 log2(_DECIMAL64 x); /* C++ only */
_DECIMAL128 log2(_DECIMAL128 x); /* C++ only */
```

General description

The log2() functions compute the base-2 logarithm of \( x \).

Notes:
1. These functions work in IEEE decimal floating-point format. See [IEEE decimal floating-point](#) on page 95 for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

The log2 functions return \( \log_2 x \).

A domain error occurs if \( x \) is less than zero.

A range error may occur if \( x \) is zero.

Example

/* CELEBL28

  This example illustrates the log2d32() function.
  */

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
void main(void)
{
  _DECIMAL32 x, y;
  x = 85.7DF;
  y = log2d32(x);
  printf("log2d32( %Hf ) = %Hf\n", x, y);
}```

</tr>
</tbody>
</table>

Format

```c
#include <setjmp.h>

void longjmp(jmp_buf env, int value);
```

General description

Restores a stack environment previously saved in `env` by `setjmp()`. The `setjmp()` and `longjmp()` functions provide a way to perform a nonlocal `goto`. They are often used in signal handlers.

A call to `setjmp()` causes the current stack environment to be saved in `env`. A subsequent call to `longjmp()` restores the saved environment, and returns control to a point in the program corresponding to the `setjmp()` call. Execution resumes as if the `setjmp()` call had just returned the given `value` of the value argument. All variables that are accessible to the function that receives control contain the values they had when `longjmp()` was called. The values of register variables are unpredictable. Nonvolatile `auto` variables that are changed between calls to `setjmp()` and `longjmp()` are also unpredictable.

**Note:** Ensure that the function that calls `setjmp()` does not return before you call the corresponding `longjmp()` function. Calling `longjmp()` after the function calling `setjmp()` returns causes unpredictable program behavior.

The `value` argument passed to `longjmp()` must be nonzero. If you give a 0 argument for `value`, `longjmp()` substitutes a 1 in its place.

**Notes:**
1. If `longjmp()` is used to jump back into an XPLink routine, any `alloca()` requests issued by the XPLink routine after the earlier `setjmp()` (or `_setjmp()`, `sigsetjmp()`, `getcontext()`, etc.) was called and before `longjmp()` is called are backed out. All storage obtained by these `alloca()` requests is freed before the XPLink routine is resumed.
2. If `longjmp()` is used to jump back into a non-XPLink routine, `alloca()` requests made after `setjmp()` (and so on) and before `longjmp()` are not backed out.

**Special behavior for POSIX:** In a POSIX program, the signal mask is not saved. Thus, to save and restore a stack environment that includes the current signal mask, use `sigsetjmp()` and `siglongjmp()` instead of `setjmp()` and `longjmp()`. The `sigsetjmp()—siglongjmp()` pair, the `setjmp()—longjmp()` pair, the `_setjmp()—_longjmp()` pair, and the `getcontext()—setcontext()` pair cannot be intermixed. A stack environment saved by `setjmp()` can be restored only by `longjmp()`.
Special behavior for C++: If setjmp() and longjmp() are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic objects is undefined. Additionally, if any automatic objects would be destroyed by a thrown exception transferring control to another (destination) point in the program, then a call to longjmp() at the throw point that transfers control to the same (destination) point has undefined behavior. This applies to both z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of setjmp() and longjmp() in conjunction with try(), catch(), and throw() is also undefined.

Special behavior for XPG4.2: In a program that was compiled with the feature test macro, _XOPEN_SOURCE_EXTENDED, defined, another pair of functions, _setjmp()—_longjmp() are available. These functions are, on this implementation, functionally identical to setjmp()—longjmp(). Therefore it is possible, but not recommended, to intermix the setjmp()—longjmp() pair with the _setjmp()—_longjmp() pair.

Special behavior for XPLINK-compiled C++: Restrictions concerning setjmp.h and ucontext.h:

Notes:
1. All XPLINK programs compiled with the Release 10 or later C compilers that are to run with Language Environment Release 10 or later libraries and use the jmp_buf, sigjmp_buf or ucontext_t types must not be compiled with C headers from Language Environment 2.9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define jmp_buf, sigjmp_buf or ucontext_t data items and pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(), setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.
3. When __XPLINK__ is defined, the Release 10 and later headers define a larger jmp_buf, sigjmp_buf or ucontext_t area that is required by setjmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Release 10 and later headers define a shorter jmp_buf, sigjmp_buf or ucontext_t area. The Language Environment headers before Release 10 also define the shorter version of these data areas. If an XPLINK function calls setjmp(), getcontext() or similar functions with a short jmp_buf, sigjmp_buf or ucontext_t area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

longjmp() does not use the normal function call and return mechanisms; it returns no values.

Example

This example provides for saving the stack environment at this statement:
if(setjmp(mark) != 0) ...

When the system first performs the if statement, it saves the environment in mark and sets the condition to FALSE because setjmp() returns a 0 when it saves the environment. The program prints the message: setjmp has been called

The subsequent call to function p tests for a local error condition, which can cause it to perform the longjmp() function. Then, control returns to the original setjmp() function using the environment saved in mark. This time the condition is TRUE
longjmp

because -1 is the returned value from the longjmp() function. The example then performs the statements in the block and prints: longjmp has been called

It then performs the recover function and leaves the program.

/* Illustration of longjmp(). */
#include <stdio.h>
#include <setjmp.h>
jmp_buf mark;
void p(void);
void recover(void);

int main(void)
{
    if (setjmp(mark) != 0)
    {
        printf("longjmp has been called\n");
        recover();
        exit(1);
    }
    printf("setjmp has been called\n");
    ...
    p();
    ...
}

void p(void)
{
    int error = 0;
    ...
    error = 9;
    ...
    if (error != 0)
        longjmp(mark, -1);
    ...
}

void recover(void)
{
    ...
}

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <setjmp.h>

void _longjmp(jmp_buf env, int value);
```

General description

The `_longjmp()` function restores a stack environment previously saved in `env` by `_setjmp()`. The `_setjmp()` and `_longjmp()` functions provide a way to perform a nonlocal `goto`. They are often used in signal handlers.

A call to `_setjmp()` causes the current stack environment to be saved in `env`.

A subsequent call to `_longjmp()` restores the saved environment and returns control to a point in the program corresponding to the `_setjmp()` call. Execution resumes as if the `_setjmp()` call had just returned the given `value` of the value argument. All variables that are accessible to the function that receives control contain the values they had when `_longjmp()` was called. The values of register variables are unpredictable. Nonvolatile `auto` variables that are changed between calls to `_setjmp()` and `_longjmp()` are also unpredictable.

The X/Open standard states that `_longjmp()` and `_setjmp()` are functionally identical to `longjmp()` and `setjmp()`, respectively, with the addition restriction that `_longjmp()` and `_setjmp()` do not manipulate the signal mask. However, on this implementation `longjmp()` and `setjmp()` do not manipulate the signal mask. So on this implementation `_longjmp()` and `_setjmp()` are literally identical to `longjmp()` and `setjmp()`, respectively.

To save and restore a stack environment, including the current signal mask, use `sigsetjmp()` and `siglongjmp()` instead of `_setjmp()` and `_longjmp()`, or `setjmp()` and `longjmp()`.

The `_setjmp()`—`_longjmp()` pair, the `setjmp()`—`longjmp()` pair, the `sigsetjmp()`—`siglongjmp()` pair, and the `getcontext()`—`setcontext()` pair cannot be intermixed. A stack environment saved by `_setjmp()` can be restored only by `_longjmp()`.

Notes:

1. However, on this implementation, since the `_setjmp()`—`_longjmp()` pair are functionally identical to the `setjmp()`—`longjmp()` pair it is possible to intermix them, but it is not recommended.

2. Ensure that the function that calls `_setjmp()` does not return before you call the corresponding `_longjmp()` function. Calling `_longjmp()` after the function calling `_setjmp()` returns causes unpredictable program behavior.
_longjmp

3. If longjmp() is used to jump back into an XPLink routine, any alloca() requests issued by the XPLink routine after the earlier setjmp() (or _setjmp(), sigsetjmp(), getcontext() and so on.) was called and before _longjmp() is called are backed out. All storage obtained by these alloca() requests is freed before the XPLink routine is resumed.

4. If longjmp() is used to jump back into a non-XPLink routine, alloca() requests made after setjmp() (etc.) and before _longjmp() are not backed out.

The value argument passed to _longjmp() must be nonzero. If you give a zero argument for value, _longjmp() substitutes a 1 in its place.

env An address for a jmp_buf structure

value The return value from _setjmp()

Special behavior for C++: If _setjmp() and _longjmp() are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic objects is undefined. Additionally, if any automatic objects would be destroyed by a thrown exception transferring control to another (destination) point in the program, then a call to _longjmp() at the throw point that transfers control to the same (destination) point has undefined behavior. This applies both to z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of _setjmp() and _longjmp() in conjunction with try(), catch(), and throw() is also undefined.

Special behavior for XPLINK-compiled C++: Restrictions concerning setjmp.h and ucontext.h:

Notes:
1. All XPLINK programs compiled with the Release 10 or later C compilers that are to run with Language Environment Release 10 or later libraries and use the jmp_buf, sigjmp_buf or ucontext_t types must not be compiled with C headers from Language Environment 2.9 or earlier.

2. Non-XPLINK functions compiled with any level of Language Environment headers must not define jmp_buf, sigjmp_buf or ucontext_t data items and pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(), setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.

3. When __XPLINK__ is defined, the Release 10 and later headers define a larger jmp_buf, sigjmp_buf or ucontext_t area that is required by setjmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Release 10 and later headers define a shorter jmp_buf, sigjmp_buf or ucontext_t area. The Language Environment headers before Release 10 also define the shorter version of these data areas. If an XPLINK function calls setjmp(), getcontext() or similar functions with a short jmp_buf, sigjmp_buf or ucontext_t area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

_longjmp() does not use the normal function call and return mechanisms; it returns no values. When _longjmp() completes, program execution continues as if the corresponding invocation of _setjmp() had just returned the value specified by value.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdlib.h>
long int irand48(void);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0).

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The irand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

\[ X(n+1) = (aX(n) + c) \text{mod}(2^{48}) \quad n \geq 0 \]

The initial values of X, a, and c are:

\[ X(0) = 1 \]

\[ a = 5deece66d \text{ (base 16)} \]

\[ c = b \text{ (base 16)} \]

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The value, X(n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function. Likewise, the values of a and c, may be changed by calling the lcong48() function. Thereafter, whenever the seed48() or srand48() function is called to change X(n), the initial values of a and c are also reestablished.

Special behavior for z/OS UNIX Services: You can make the Irand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.
If thread-specific behavior is requested, and the lrand48() function is called from thread \( t \), the lrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, \( X(t,i) \), for the thread \( t \). The sequence of values for a thread is generated according to the linear congruential formula:

\[
X(t,n+1) = (a(t)X(t,n) + c(t)) \mod (2^{48}) \quad n \geq 0
\]

The initial values of \( X(t) \), \( a(t) \) and \( c(t) \) for the thread \( t \) are:

\[
\begin{align*}
X(t,0) &= 1 \\
a(t) &= \text{5deece66d (base 16)} \\
c(t) &= \text{b (base 16)}
\end{align*}
\]

C/370 provides storage which is specific to the thread \( t \) to save the most recent 48-bit integer value of the sequence, \( X(t,i) \), generated by the drand48(), lrand48() or mrand48() function. The value, \( X(t,n) \), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function from the thread \( t \). Likewise, the values of \( a(t) \) and \( c(t) \) for thread \( t \) may be changed by calling the lcong48() function from the thread. Thereafter, whenever the seed48() or srand48() function is called from the thread to change \( X(t,n) \), the initial values of \( a(t) \) and \( c(t) \) are also reestablished.

**Returned value**

lrand48() transforms the generated 48-bit value, \( X(n+1) \), to a nonnegative, long integer value on the interval \([0,2^{31})\) and returns this transformed value.

**Special behavior for z/OS UNIX Services:** If thread-specific behavior is requested for the drand48 family and lrand48() is called on thread \( t \), lrand48() transforms the generated 48-bit value, \( X(t,n+1) \), to a nonnegative, long integer value on the interval \([0,2^{31})\) and returns this transformed value.

<tr>
<td>llrintl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>
Returned value

If successful, they return the rounded integer value. If the correct value is positive or negative and too large to represent as a long (lrint() family) or long long (llrint() family), a domain error will occur and an unspecified value is returned.

Example

```c
/*
 * This program illustrates the use of lrint() function
 * Note: To get the output shown in this book, this program
 * should be compiled using FLOAT(IEEE)
 */

#define _ISOC99_SOURCE
#include <math.h>
#include <stdio.h>
#include <_Ieee754.h> /* save/get fpc functions */

char *RoundStr (_FP_rmode_t rm_type) {
    char *RndStr="undetermined";
    switch (rm_type) {
    case (_RMODE_RN):
        RndStr="round to nearest";
        break;
    case (_RMODE_RZ):
        RndStr="round toward zero";
        break;
    case (_RMODE_RP):
        RndStr="round toward +infinity ";
        break;
    case (_RMODE_RM):
        RndStr="round toward -infinity ";
        break;
    }
    return (RndStr);
}

void main() {
    _FP_fpcreg_t save_rmode, current_rmode;
    long int rnd2nearest;
    double number=500.99;
    printf("Illustrates the lrint() function\n");
    __fpc_rd(&current_rmode); /* get current rounding mode */
    rnd2nearest = lrint(number);
    printf ("When rounding direction is %s:
        lrint(%.2f) = %li\n",RoundStr(current_rmode.rmode), number, rnd2nearest);
    save_rmode.mode = _RMODE_RZ;
    __fpc_sm(save_rmode.mode); /* set rounding mode to round to zero */
    rnd2nearest = lrint(number);
    printf ("When rounding direction is %s:
        lrint(%.2f) = %li\n",RoundStr(save_rmode.mode), number, rnd2nearest);
}

Output
Illustrates the lrint() function
When rounding direction is round to nearest:
lrint(500.99) = 501
When rounding direction is round toward zero:
lrint(500.99) = 501
```

</tr>
<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <math.h>

long int lround(double x);
long int lroundf(float x);
long int lroundl(long double x);

C++ TR1 C99:
#define _TR1_C99
#include <math.h>

long lround(float x);
long lround(long double x);
```

General description

The Iround functions round x to the nearest integer value, rounding halfway cases away from zero, regardless of the current rounding mode.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Iround</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>Iroundf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>Iroundl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned value

The Iround functions return the rounded integer value of x.

If the rounded value is outside the range of the return type, the numeric result is unspecified. A range error may occur if the magnitude of x is too large.

<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.8</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

long int lroundd32(_Decimal32 x);
long int lroundd64(_Decimal64 x);
long int lroundd128(_Decimal128 x);

long int lround(_Decimal32 x); /* C++ only */
long int lround(_Decimal64 x); /* C++ only */
long int lround(_Decimal128 x); /* C++ only */
```

General description

The lround functions round x to the nearest integer value, rounding halfway cases away from zero, regardless of the current rounding mode.

Notes:
1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The lround functions return the rounded integer value of x.

If the rounded value is outside the range of the return type, the numeric result is unspecified. A range error may occur if the magnitude of x is too large.

Example

```c
/* CELEBL21

Isearch

Isearch() — Linear search and update

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <search.h>

void *lsearch(const void *key, void *base, size_t *nelp,
               size_t width,
               int (*compar)(const void *, const void *));
```

General description

The lsearch() function is a linear search routine. It returns a pointer into a table indicating where an entry may be found. If the entry does not occur, it is added at the end of the table. The key argument points to the entry to be sought in the table. The base argument points to the first element in the table. The width argument is the size of an element in bytes. The nelp argument points to an integer containing the current number of elements in the table. The integer to which nelp points is incremented if the entry is added to the table. The compar argument points to a comparison function which the user must supply (strcmp(), for example). It is called with two arguments that point to the elements being compared. The function must return 0 if the elements are equal and nonzero otherwise.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, lsearch() cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to lsearch(), the compiler will flag it as an error. You can pass a C or C++ function to lsearch() by declaring it as extern "C".

Returned value

If the searched for entry is found, lsearch() returns a pointer to it.

If not found, lsearch() returns a pointer to the newly added element. A NULL pointer is returned in case of error.

No errors are defined.

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

#define _POSIX_SOURCE
#include <unistd.h>

off_t lseek(int fildes, off_t offset, int pos);

General description

Changes the current file offset to a new position in a z/OS UNIX file. The new position is the given byte offset from the position specified by pos. After you have used lseek() to seek to a new location, the next I/O operation on the file begins at that location.

lseek() lets you specify new file offsets past the current end of the file. If data is written at such a point, read operations in the gap between this data and the old end of the file will return bytes containing zeros. (In other words, the gap is assumed to be filled with zeros.)

Seeking past the end of a file, however, does not automatically extend the length of the file. There must be a write operation before the file is actually extended.

Special behavior for POSIX C: For character special files, lseek() sets the file offset to the specified value. z/OS UNIX services ignore the file offset value during the read/write processing to character special files.

int fildes; The file whose current file offset you want to change.

off_t offset; The amount (positive or negative) the byte offset is to be changed.
The sign indicates whether the offset is to be moved forward (positive) or backward (negative).

int pos; One of the following symbols (defined in the unistd.h header file):

SEEK_SET The start of the file
SEEK_CUR The current file offset in the file
SEEK_END The end of the file

Large file support for z/OS UNIX files:

Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANG_LVL(longlong) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.
Iseek

Returned value

If successful, lseek() returns the new file offset, measured in bytes from the beginning of the file.

If unsuccessful, lseek() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>fildes is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>pos contained something other than one of the three options, or the combination of the pos values would have placed the file offset before the beginning of the file.</td>
</tr>
<tr>
<td>EOVERFLOW</td>
<td>The resulting file offset would be a value which cannot be represented correctly in an object of type off_t.</td>
</tr>
<tr>
<td>ESPIPE</td>
<td>fildes is associated with a pipe or FIFO special file.</td>
</tr>
</tbody>
</table>

Example

This fragment positions a file (that has at least 10 bytes) to an offset of 10 bytes before the end of the file.

```c
lseek(fildes,-10,SEEK_END);
```

Istat() — Get status of file or symbolic link

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX1_SOURCE 2
#include <sys/stat.h>

int lstat(const char *__restrict__ pathname, struct stat *__restrict__ buf);
```

General description

Gets status information about a specified file and places it in the area of memory pointed to by the `buf` argument. You do not need permissions on the file itself, but you must have search permission on all directory components of the `pathname`.

If the named file is a symbolic link, `lstat()` returns information about the symbolic link itself.

The information is returned in the following `stat` structure, defined in the `sys/stat.h` header file.

`Table 41. Elements of stat Structure`

<table>
<thead>
<tr>
<th>Structure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode_t st_mode</td>
<td>A bit string indicating the permissions and privileges of the file.</td>
</tr>
<tr>
<td></td>
<td>Symbols are defined in the <code>sys/stat.h</code> header file to refer to bits in a</td>
</tr>
<tr>
<td></td>
<td><code>mode_t</code> value; these symbols are listed in [<code>chmod()</code> — Change the</td>
</tr>
<tr>
<td></td>
<td>mode of a file or directory](page 284).</td>
</tr>
<tr>
<td>ino_t st_ino</td>
<td>The serial number of the file.</td>
</tr>
<tr>
<td>dev_t st_dev</td>
<td>The numeric ID of the device containing the file.</td>
</tr>
<tr>
<td>nlink_t st_nlink</td>
<td>The number of links to the file.</td>
</tr>
<tr>
<td>uid_t st_uid</td>
<td>The numeric user ID of the file's owner.</td>
</tr>
<tr>
<td>gid_t st_gid</td>
<td>The numeric group ID of the file's group.</td>
</tr>
<tr>
<td>off_t st_size</td>
<td>For regular files, the file's size in bytes. For symbolic links, the length</td>
</tr>
<tr>
<td></td>
<td>of the pathname contained therein not counting the trailing NULL. For</td>
</tr>
<tr>
<td></td>
<td>other kinds of files, the value of this field is unspecified.</td>
</tr>
<tr>
<td>time_t st_atime</td>
<td>The most recent time the file was accessed.</td>
</tr>
<tr>
<td>time_t st_ctime</td>
<td>The most recent time the status of the file was changed.</td>
</tr>
<tr>
<td>time_t st_mtime</td>
<td>The most recent time the contents of the file were changed.</td>
</tr>
</tbody>
</table>

Values for `time_t` are given in terms of seconds that have elapsed since epoch.

If the named file is a symbolic link, `lstat()` updates the time-related fields before putting information in the `stat` structure.
You can examine properties of a `mode_t` value from the `st_mode` field by using a collection of macros defined in the `sys/modes.h` header file. If `mode` is a `mode_t` value, and `genvalue` is an `unsigned int` value from the stat structure, then:

- `S_ISBLK(mode)` is nonzero for block special files.
- `S_ISCHR(mode)` is nonzero for character special files.
- `S_ISDIR(mode)` is nonzero for directories.
- `S_ISEXTL(mode,genvalue)` is nonzero for external links.
- `S_ISFIFO(mode)` is nonzero for pipes and FIFO special files.
- `S_ISLNK(mode)` is nonzero for symbolic links.
- `S_ISREG(mode)` is nonzero for regular files.
- `S_ISSOCK(mode)` is nonzero for sockets.

If `lstat()` successfully determines all this information, it stores it in the area indicated by the `buf` argument.

### Large file support for z/OS UNIX files:

Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option `LANGLEVEL(LLONGLONG)` and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

### Returned value

If successful, `lstat()` returns 0.

If unsuccessful, `lstat()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The process does not have search permission on some component of the <code>pathname</code> prefix.</td>
</tr>
<tr>
<td>EINVAL</td>
<td><code>buf</code> contains a NULL.</td>
</tr>
<tr>
<td>EIO</td>
<td>Added for XPG4.2: An I/O error occurred while reading from the file system.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error is issued if the number of symbolic links encountered during resolution of the <code>pathname</code> argument is greater than POSIX_SYMLOOP.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td><code>pathname</code> is longer than <code>PATH_MAX</code> characters or some...</td>
</tr>
</tbody>
</table>
component of pathname is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined through pathconf().

ENOENT There is no file named pathname, or pathname is an empty string.
ENOTDIR A component of the pathname prefix is not a directory.
EOVERFLOW The file size in bytes or the number of blocks allocated to the file or the file serial number cannot be represented correctly in the structure pointed to by buf.

Note: Starting with z/OS V1.9, environment variable _EDC_EOVERFLOW can be used to control behavior of lstat() with respect to detecting an EOVERFLOW condition for z/OS UNIX files. By default, lstat() will not set EOVERFLOW when the file size can not be represented correctly in structure pointed to by buf. When _EDC_EOVERFLOW is set to YES, lstat() will check for an overflow condition.

Example

CELEBL12
/* CELEBL12 */

This example provides status information for a file.

*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <time.h>

main() {
char fn[]="temp.file", ln[]="temp.link";
struct stat info;
int fd;
if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
else {
    close(fd);
    if (link(fn, ln) != 0)
        perror("link() error");
    else {
        if (lstat(ln, &info) != 0)
            perror("lstat() error");
        else {
            puts("lstat() returned:");
            printf( " inode: %d\n", (int) info.st_ino);
            printf( " dev id: %d\n", (int) info.st_dev);
            printf( " mode: %08x\n", info.st_mode);
            printf( " links: %d\n", info.st_nlink);
            printf( " uid: %d\n", (int) info.st_uid);
            printf( " gid: %d\n", (int) info.st_gid);
            printf("created: %s", ctime(&info.st_createtime));
        }
    }
}
Istat

    unlink(ln);
    }
    unlink(fn);
    }

Output

lstat() returned:
    ino: 3022
    dev id: 1
    mode: 03000080
    links: 2
    uid: 25
    gid: 500
    created: Fri Jun 16 15:00:00 2001

I64a() — Convert long to base 64 string representation

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *l64a(long value);
```

General description

The l64a() function converts a long integer into its corresponding base 64 character representation. In this notation, long integers are represented by up to 6 characters, each character representing a digit in base 64 notation. The following characters are used to represent digits:

<table>
<thead>
<tr>
<th>Character</th>
<th>Digit represented</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>0</td>
</tr>
<tr>
<td>/</td>
<td>1</td>
</tr>
<tr>
<td>0-9</td>
<td>2-11</td>
</tr>
<tr>
<td>A-Z</td>
<td>12-37</td>
</tr>
<tr>
<td>a-z</td>
<td>38-63</td>
</tr>
</tbody>
</table>

Returned value

l64a() returns a pointer to the base 64 representation of value. If value is zero, l64a() returns a pointer to a NULL string.

l64a() returns a pointer to a static buffer, which will be overwritten by subsequent calls. Buffers are allocated on a per-thread basis.

There are no errno values defined.

Itoa

Itoa() — Convert long into a string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R5</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * ltoa(long l, char * buffer, int radix);
```

General description

The ltoa() function converts the long l into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, ltoa() produces the same result as the following statement:

```c
(void) sprintf(buffer, "%ld", l);
```

with buffer the returned character string. When the radix is OCTAL, ltoa() formats long l into an unsigned octal constant. When the radix is HEX, ltoa() formats long l into an unsigned hexadecimal constant. The hexadecimal value will include lowercase abcdef, as necessary

Usage notes

1. This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

Returned value

String pointer (same as buffer) will be returned. When passed an invalid radix argument, function will return NULL and set errno to EINVAL.

makecontext() — Modify user context

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2 Single UNIX Specification, Version 3</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ucontext.h>

void makecontext(ucontext_t *ucp, void (*)(void), int argc, ...);
```

General description

The makecontext() function modifies the context specified by `ucp`, which has been initialized using `getcontext()`. When this context is resumed using `setcontext()` or `swapcontext()`, program execution continues by calling `func()`, passing it the arguments that follow `argc` in the makecontext() call.

The value of `argc` must match the number of integer arguments passed to `func()`, otherwise the behavior is undefined.

The `uc_link` member of `ucontext_t` is used to determine the context that will be resumed when the context being modified by makecontext() returns. If the `uc_link` member is not equal to 0, the process continues as if after a call to `setcontext()` with the context pointed to by the `uc_link` member. If the `uc_link` member is equal to 0, the process exits as if `exit()` were called. The `uc_link` member should be initialized before the call to makecontext().

This function is supported only in a POSIX program.

This function is not supported in an AMODE 31 XPLINK environment (for example, one which is in AMODE 31 and in which either the main() function was compiled with the XPLINK option, or the XPLINK(ON) run-time option was specified).

The `<ucontext.h>` header file defines the `ucontext_t` type as a structure that includes the following members:

- `mcontext_t uc_mcontext` A machine-specific representation of the saved context.
- `ucontext_t *uc_link` Pointer to the context that will be resumed when this context returns.
- `sigset_t uc_sigmask` The set of signals that are blocked when this context is active.
- `stack_t uc_stack` The stack used by this context.

Special behavior for C++

Because C and C++ linkage conventions are incompatible, makecontext() cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to makecontext(), the compiler will flag it as an error. To use the C++ makecontext() function, you must ensure that all functions registered for makecontext() have C linkage by declaring them as extern "C". For example:
makecontext

C:   void func(int, int);
    :makecontext(&context, func, 2, arg1, arg2);

C++: extern "C" void func();
    :makecontext(&context, func, 2, arg1, arg2);

AMODE 64 considerations

Storage for the stack must be above the 2GB bar. It may not be storage acquired
with the __malloc24() or __malloc31() functions. The stack must be big enough to
allow for the creation of a 1M guard page (aligned on a 1M boundary).

The environment variable _EDC_CONTEXT_GUARD can be used to control when
the stack is guarded and unguarded. For details on the _EDC_CONTEXT_GUARD
environment variable, see the "Using Environment Variables" chapter in
z/OS XL C/C++ Programming Guide

Returned value

makecontext() returns no values.

If unsuccessful, makecontext() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>
| EINVAL     | The context being modified is using an alternate stack, and the
target function entry point is not a valid Language Environment or C
targetfunction entry point.
    
The argc argument specifies a value less than 0.
| ENOMEM     | The ucp argument does not have enough stack left to complete the
operation. Or more than 15 arguments are passed to the target
function, and there is not enough storage to hold all of the
arguments.

Note: If the target function is in a DLL that has not yet been
loaded, then makecontext() cannot determine the size
requirement and assumes that the size required is
MINSIGSTKSZ. Therefore, in this case, the stack must be at
least the size indicated by MINSIGSTKSZ. If the size
required by the target function is more than MINSIGSTKSZ,
then you must load the DLL before invoking makecontext().

Example

This example creates a context in main with the getcontext() statement, then
modifies the context to have its own stack and to invoke the function func. It
invokes the function with the setcontext() statement. Since the uc_link member is
set to 0, the process exits when the function returns.

/* This example shows the usage of makecontext(). */
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>
#include <stdio.h>
#include <ucontext.h>
#include <errno.h>

#ifdef _LP64

#endif

ifdef _LP64
#define STACK_SIZE 2097152+16384 /* large enough value for AMODE 64 */
#else
#define STACK_SIZE 16384 /* AMODE 31 addressing */
#endif

void func(int);

ucontext_t context, *cp = &context;

int main(void) {

    int value = 1;
    getcontext(cp);
    context.uc_link = 0;
    if ((context.uc_stack.ss_sp = (char *) malloc(STACK_SIZE)) != NULL) {
        context.uc_stack.ss_size = STACK_SIZE;
        context.uc_stack.ss_flags = 0;
        errno = 0;
        makecontext(cp,func,1,value);
        if(errno != 0){
            perror("Error reported by makecontext()");
            return -1; /* Error occurred exit */
        }
    } else {
        perror("not enough storage for stack");
        abort();
    }
    printf("context has been built\n");
    setcontext(cp);
    perror("returned from setcontext");
    abort();

    }
void func(int arg) {

    printf("function called with value %d\n",arg);
    printf("process will exit when function returns\n");
    return;

}

Output
context has been built
function called with value 1
process will exit when function returns

</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <stdlib.h>

void *malloc(size_t size);
```

**General description**

Reserves a block of storage of size bytes. Unlike the calloc() function, the content of the storage allocated is indeterminate. The storage to which the returned value points is always aligned for storage of any type of object. Under z/OS XL C only, if 4K alignment is required, use the __4kmalc() function. (This function is available to C applications in stand-alone System Productivity Facility (SPF) applications.) The library functions specific to the System Programming C (SPC) environment are described in [z/OS XL C/C++ Programming Guide](https://www.ibm.com/support/knowledgecenter/SSEQ0G_11.2.0/zos_cxx/zos_cxx.html).

**Special behavior for C++**

The C++ keywords new and delete are not interoperable with calloc(), free(), malloc(), or realloc().

**Returned value**

If successful, malloc() returns a pointer to the reserved space. The storage space to which the returned value points is always suitably aligned for storage of any type of object.

If not enough storage is available, or if size was specified as 0, malloc() returns NULL. If malloc() returns NULL because there is not enough storage, it sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>Insufficient memory is available</td>
</tr>
</tbody>
</table>

**Example**

```c
CELEBM01

/* CELEBM01

This example prompts you for the number of array entries you want and then reserves enough space in storage for the entries. If &malloc. was successful, the example assigns values to the entries and prints out each entry; otherwise, it prints out an error.

*/
```
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    long * array; /* start of the array */
    long * index; /* index variable */
    int i; /* index variable */
    int num; /* number of entries of the array */

    printf( "Enter the size of the array\n" );
    scanf( "%i", &num );

    /* allocate num entries */
    if ( (index = array = (long *)malloc( num * sizeof( long ))) != NULL )
    {
        for ( i=0 ; i< num; ++i ) /* put values in array */
            *index++ = i; /* using pointer notation */
        for ( i=0 ; i< num; ++i ) /* print the array out */
            printf( "array\[ %i \] = %i\n", i, array[i] );
    }
    else /* malloc error */
    {
        printf( "Out of storage\n" );
        abort();
    }
}

Output
Enter the size of the array
array[ 0 ] = 0
array[ 1 ] = 1
array[ 2 ] = 2
array[ 3 ] = 3
array[ 4 ] = 4

__map_init

__map_init() — Designate a storage area for mapping blocks

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>both</td>
<td></td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>OS/390 V2R9</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_MAP_EXTENSION
#include <sys/mman.h>

int __map_init(struct _Mmg_init *parmlist);
```

General description

The __map_init() function allocates a map area in the private area of the calling address space. This map area is propagated to child address spaces on fork, which is the only way that multiple processes can share a map area. The application can connect and disconnect blocks of storage in the map area, providing a very fast way to connect up to persistent memory. The __map_init() function is meant to be used by applications which need more shared memory or mmap storage than will fit in the address space.

The application should set the following values in the _Mmg_init structure:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_Mmg_numbblks</td>
<td>Set to the number of blocks to be contained in the map area.</td>
</tr>
<tr>
<td>_Mmg_megsperblk</td>
<td>Set to the size in megabytes of each block in the map area.</td>
</tr>
<tr>
<td>_Mmg_token</td>
<td>Set to an 8 character map token when successful. This map token should be saved and must be used as a parameter on calls to the __map_service() function calls.</td>
</tr>
<tr>
<td>_Mmg_res01a</td>
<td>Reserved, set to 0.</td>
</tr>
<tr>
<td>_Mmg_res01b</td>
<td>Reserved, set to 0.</td>
</tr>
<tr>
<td>_Mmg_areaaddr</td>
<td>As input, set to 0 if you want the address assigned or set to the address of storage where you want the map to begin. As output, this field contains the actual address of the map area.</td>
</tr>
</tbody>
</table>

Usage notes

- It is intended that the application call the __map_init() service once to create the map area.
- The application then issues fork to create child processes which will inherit a map area initialized to the hidden state.
- The initial process or the child (and grandchildren) process can then use the __map_service to connect and disconnect blocks of storage which are persistent until explicitly deleted.
- When the process which created the initial map area terminates, all further activity against the map blocks is terminated. The map blocks are then deleted when the last child process with an active map area terminates.
- There is no explicit call to delete the map area. This is unlike shared memory or other IPC constructs.
__map_init

Returned value

If successful, __map_init() returns NULL.

If unsuccessful, __map_init() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EEXIST</td>
<td>An attempt was made to create more than one map for the process.</td>

<td>OS/390 V2R9</td>
</tr>
</tbody>
</table>

### Format

```c
#define _OPEN_SYS_MAP_EXTENSION
#include <sys/mman.h>

int __map_service(struct _Mmg_service *parmlist, int count, *Map_token_t);
```

### General description

The __map_service() function is used to manipulate the map area created by the __map_init() function. The supported functions are defined under _Mmg_servicetype below.

Before calling the __map_service() service, the application should set values in the _Mmg_service structure as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_Mmg_servicetype</td>
<td>Set the type of service being requested for each memory block defined in the array.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Request</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_Mmg_newblock</td>
<td>Set for an allocation of a new data block in the mapped area.</td>
</tr>
<tr>
<td>_Mmg_conn</td>
<td>Set to request that a data block be connected at the requested location in the map area.</td>
</tr>
<tr>
<td>_Mmg_disconn</td>
<td>Set to disconnect a data block from the map area.</td>
</tr>
<tr>
<td>_Mmg_free</td>
<td>Set to free the storage backing a data block.</td>
</tr>
<tr>
<td>_Mmg_cntl</td>
<td>Set to change the read or write permission settings for a data block.</td>
</tr>
</tbody>
</table>

| _Mmg_servicetflag | Used for _Mmg_cntl to indicate read or write and all other bits set to zero. For _Mmg_disconn to indicate if the backing storage is to be freed after disconnect. For _Mmg_newblock the option of _Mmg_NoConn can be set on to bypass the connect to the map area block. The token returned will have to be saved and used for connect services on a later call to make the block accessible. For all other _Mmg_servicetype requests, set all the bits to zero. |

| _Mmg_serviceOflag | Used for status of the request. When the request has been successfully processed all the bits are set to zero. When processing an list of requests and a failure occurs in _Mmg_Reqfail is set on and further processing on the list is aborted. _Mmg_servicetype requests, set all the bits to zero. |

| _Mmg_token       | This is returned as output for a _Mmg_newblock request and is used as input for _Mmg_conn, and _Mmg_free. It is ignored for _Mmg_disconn and _Mmg_cntl. |
Usage notes

- The _map_init and the _map_service functions are intended to be used in the following manner:
  - The initial process calls _map_init to create a map area large enough for the biggest expected usage.
  - The initial process forks worker processes which inherit the map area at the same virtual address. By having the map area at the same virtual address, storage blocks can be connected to the same block in map areas of different worker processes and pointers can be used to point to data in this or other blocks. This assumes they are always connected at the same location in the map area.
  - As worker processes perform their tasks, they can request new blocks of storage to be created in the map area. Each block has a token associated with it. This token allows other worker processes to connect to the same block. In this respect, the map area acts like shared memory.
  - The worker processes can connect as many blocks to their map area as will fit.
  - When the worker process has no further need for a data block, it can disconnect it from the map area. After a delete request for a block, this block is actually freed when the last worker process disconnects for this block.
  - When a worker process is completely done with a data block, the storage can be freed. This data is actually freed when the last worker process disconnects from that block.
  - Using these services, the application could create multiple gigabytes of storage, of which only certain blocks are mapped into the worker processes at a given time.
  - This service is designed to perform the storage connects and disconnects very fast. No data movement occurs.
  - Storage blocks are initially connected in write mode. When a block is in write mode, all worker processes which have the block connected, have the block in write mode. If the block access is changed to read-only, then all worker processes which have the block connected, have the block in read-only mode.
  - If the initial process or a worker process forks, then the child process inherits a map area initialized to the hidden state.
  - Any areas within the map area which do not have a block connected are in the hidden state. Any reference to storage in the hidden state will trigger a SIGSEGV signal.
Returned value

If successful, __map_service() returns 0.

If unsuccessful, __map_service() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EEXIST</td>
<td>A request was made to perform a service on a block but a map is not currently active in the process.</td>
</tr>
<tr>

</tr>
</tbody>
</table>

### Format

```c
#include <stdlib.h>

int mblen(const char *string, size_t n);
```

### General description

Determines the length in bytes of the multibyte character pointed to by `string`. A maximum of `n` bytes is examined.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. Changing the LC_CTYPE category invalidates the internal shift state: undefined results can occur.

If the current locale supports EBCDIC DBCS characters, then the shift state is updated where applicable. (See “Conforming to ANSI Standards” in [z/OS XL C/C++ Language Reference](link)) The length returned may be up to 4 (for the shift-out character, 2-byte code, and the shift-in character). If `string` is a NULL pointer, this function resets itself to the initial state.

The function maintains the internal shift state that is altered by subsequent calls.

### Returned value

If `string` is NULL, `mblen()` returns:
- Nonzero when DBCS-host code (EBCDIC systems) is used
- Nonzero if multibyte encodings are state-dependent
- Zero otherwise

If `string` is not NULL, `mblen()` returns:
- Zero if `string` points to the NULL character
- The number of bytes comprising the multibyte character
- The value −1 if `string` does not point to a valid multibyte character

### Example

```c
#include <locale.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    char *mbs = "a"
    "\x0E"  /* shift out */
    "\x44\x66" /* <j0158> */
    "\x44\x76" /* <j0159> */
    return 0;
}
```
char *loc = setlocale(LC_ALL, "JA_JP.IBM-939");
int n;
if (!loc) /* setlocale() failure */
{
    exit(8);
}
printf("We’re in the %s locale.\n", loc);

n = mblen(NULL, MB_CUR_MAX);
/***************************************************************************/
/* n is nonzero, indicating state-dependent encoding; mblen() has */
/* forced the internal shift state to "initial". */
/***************************************************************************/
printf("n = mblen(NULL, MB_CUR_MAX); ===> n = %s\n",
        n ? "NONZERO" : "ZERO");

n = mblen(mbs, MB_CUR_MAX);
/***************************************************************************/
/* n is 1, 'a' is a multibyte character of length 1, internal */
/* shift state remains at "initial". */
/***************************************************************************/
printf("n = mblen(mbs, MB_CUR_MAX); ===> n = %d\n", n);

n = mblen(mbs + 1, MB_CUR_MAX);
/***************************************************************************/
/* n is 3, 'shift out' plus two byte character '<j0158>'. The */
/* internal state changes to "shift out". */
/***************************************************************************/
printf("n = mblen(mbs + 1, MB_CUR_MAX); ===> n = %d\n", n);

n = mblen(mbs + 4, MB_CUR_MAX);
/***************************************************************************/
/* n is 2, two byte character '<j0159>'. The internal shift */
/* state remains "shift out" */
/***************************************************************************/
printf("n = mblen(mbs + 4, MB_CUR_MAX); ===> n = %d\n", n);

n = mblen(mbs + 6, MB_CUR_MAX);
/***************************************************************************/
/* n is 3, two byte character '<j0160>' plus 'shift in'. The */
/* internal shift state returns to "initial" */
/***************************************************************************/
printf("n = mblen(mbs + 6, MB_CUR_MAX); ===> n = %d\n", n);

n = mblen(mbs + 9, MB_CUR_MAX);
/***************************************************************************/
/* n is 1, 'b' is a multibyte character of length 1, internal */
/* shift state remains at "initial". */
/***************************************************************************/
printf("n = mblen(mbs + 9, MB_CUR_MAX); ===> n = %d\n", n);

n = mblen(mbs + 10, MB_CUR_MAX);
/***************************************************************************/
/* n is 0 (end of multibyte character string). */
/***************************************************************************/
printf("n = mblen(mbs + 10, MB_CUR_MAX); ===> n = %d\n", n);
return 0;

Output
We're in the JA_JP.IBM-939 locale.

n = mblen(NULL, MB_CUR_MAX); \implies n = NONZERO
n = mblen(mbs, MB_CUR_MAX); \implies n = 1
n = mblen(mbs + 1, MB_CUR_MAX); \implies n = 3
n = mblen(mbs + 4, MB_CUR_MAX); \implies n = 2
n = mblen(mbs + 6, MB_CUR_MAX); \implies n = 3
n = mblen(mbs + 9, MB_CUR_MAX); \implies n = 1
n = mblen(mbs + 10, MB_CUR_MAX); \implies n = 0

Format

Non-XPG4

```c
#include <wchar.h>

size_t mbrlen(const char * __restrict__ s, size_t n, mbstate_t * __restrict__ ps);
```

XPG4

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t mbrlen(const char *s, size_t n, mbstate_t *ps);
```

General description

Calculates the number of bytes required to return to the initial shift state. This is equivalent to

```
mbrtowc((wchar_t *)0, s, n, ps != NULL ? ps : &internal);
```

where &internal is the address of the internal mbstate_t object for the mbrlen() function.

mbrlen() is a restartable version of mblen(). That is, shift state information is passed as one of the arguments, and is updated on exit. With mbrlen(), you can switch from one multibyte string to another, provided that you have kept the shift-state information.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the mbrlen() function in the wchar header available when you compile your program. Please see Table 2 on page 14 for a list of XPG4 and other feature test macros.

Returned value

If s is a NULL pointer, mbrlen() resets the shift state to the initial shift state and returns 0.

If s is not a NULL pointer, mbrlen() returns the first of the following that applies.

0 If the next n or fewer bytes complete the valid multibyte character that corresponds to the NULL wide character.
If the next \( n \) or fewer bytes complete the valid multibyte character; the value returned is the number of bytes that complete the multibyte character.

-2 If the next \( n \) bytes form an incomplete (but potentially valid) multibyte character, and all \( n \) bytes have been processed; it is unspecified whether this can occur when the value of \( n \) is less than that of the MB_CUR_MAX macro.

**Note:** When a -2 value is returned, and \( n \) is at least MB_CUR_MAX, the string would contain redundant shift-out and shift-in characters. To continue processing the multibyte string, increment the pointer by the value \( n \), and call the mbrtowc() function.

-1 If an encoding error occurs (when the next \( n \) or fewer bytes do not contribute to the complete and valid multibyte character), the value of the macro EILSEQ is stored in errno, but the conversion state remains unchanged.

**Example**

```c
CELEBM03
/* CELEBM03 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
    char mbs[5] = "a";  /* string containing the multibyte char */
    mbstate_t ss = 0;   /* set shift state to the initial state */
    int length;

    /* Determine the length in bytes of a multibyte character pointed */
    /* to by mbs. */
    length = mbrlen(mbs, MB_CUR_MAX, &ss);

    printf(" length: %d \n", length);
    printf(" mbs:"%s\n", mbs);
    printf("MB_CUR_MAX: %d \n", MB_CUR_MAX);
    printf(" ss: %d \n", ss);
}
```

**Output**

```
length: 1
mbs:"a"
MB_CUR_MAX: 4
ss: 0
```

Format

Non-XPG4

```c
#include <wchar.h>

size_t mbtowc(wchar_t *__restrict pwc, const char *__restrict s, size_t n, mbstate_t *__restrict ps);
```

XPG4

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t mbtowc(wchar_t *pwc, const char *s, size_t n, mbstate_t *ps);
```

General description

The mbtowc() function is equivalent to mbtowc(NULL,",",1,ps).

If s is a NULL pointer, the mbtowc() function ignores the n and the pwc, and resets the shift state, pointed to by ps, to the initial shift state.

If s is not a NULL pointer, mbtowc() inspects at most n bytes, beginning with the byte pointed to by s, and the shift state pointed to by ps, and determines the number of bytes that is needed to complete the valid multibyte character.

When the multibyte character is completed, mbtowc() determines the value of the corresponding wide character and stores it in the object pointed to by pwc, so long as pwc is not a NULL pointer. Finally, mbtowc() stores the actual shift state in the object pointed to by ps. If ps is a NULL pointer, mbtowc() uses its own internal object to track the shift state.

mbtowc() is a restartable version of mbtowc(). That is, shift-state information is passed as one of the arguments and is updated on exit. With mbtowc(), you can switch from one multibyte string to another, provided that you have kept the shift-state information.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results may occur.

Special behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the mbtowc() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.
**mbtowc**

**Returned value**

If `s` is a NULL pointer, `mbtowc()` resets the shift state to the initial shift state and returns 0.

If `s` is not a NULL pointer, `mbtowc()` returns one of the following, in the order shown:

- **0** If the next `n` or fewer bytes complete the valid multibyte character that corresponds to the NULL wide character.

- **positive integer** If the next `n` or fewer bytes complete the valid multibyte character; the value returned is the number of bytes that complete the multibyte character.

- **−2** If the next `n` bytes form an incomplete (but potentially valid) multibyte character, and all `n` bytes have been processed. It is unspecified whether this can occur when the value of `n` is less than that of the MB_CUR_MAX macro.

**Note:** When a −2 value is returned, and `n` is at least MB_CUR_MAX, the string would contain redundant shift-out and shift-in characters. To continue processing the multibyte string, increment the pointer by the value `n`, and call the `mbtowc()` function.

- **−1** If an encoding error occurs (when the next `n` or fewer bytes do not contribute to the complete and valid multibyte character). The value of the macro EILSEQ is stored in errno, but the conversion state is unchanged.

**Example**

CELEBM04

```c
/* CELEBM04 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
    wchar_t wc;
    char mbs[5] = "a"; /* string containing the multibyte char */
    mbstate_t ss = 0; /* set shift state to the initial state */
    int length;

    /* Determine the length of the multibyte character pointed to by mbs. Store the multibyte character in the wchar_t object wcs. */

    length = mbtowc(&wc, mbs, MB_CUR_MAX, &ss);

    printf(" length: %d \n", length);
    printf("wc:'%lc'\n", wc);
    printf("mbs:'%s'\n", mbs);
    printf("MB_CUR_MAX: %d \n", MB_CUR_MAX);
    printf(" ss: %d \n", ss);
}
```

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

**Non-XPG4**

```c
#include <wchar.h>

int mbsinit(const mbstate_t *ps);
```

**XPG4**

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int mbsinit(const mbstate_t *ps);
```

General description

If `ps` is not a NULL pointer the mbsinit() function determines whether the pointer to mbstate_t object describes an initial conversion state.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

**Special behavior for XPG4**

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the mbsinit() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

If `ps` is a NULL pointer or if the pointed-to object describes an initial conversion state, mbsinit() returns nonzero.

Otherwise, mbsinit() returns 0.

Example

**CELEBM05**

```c
/* CELEBM05

This example checks the conversion state to see if it is in the initial state.

*/
#include "stdio.h"
#include "wchar.h"
#include "stdlib.h"
```
main() {
    char *string = "ABC";
    mbstate_t state = 0;
    wchar_t wc;
    int rc;
    rc = mbrtowc(&wc, string, MB_CUR_MAX, &state);
    if (mbsinit(&state))
        printf("In initial conversion state\n");
}

mbsrtowcs

mbsrtowcs() — Convert a multibyte string to a wide-character string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

Non-XPG4

```c
#include <wchar.h>

size_t mbsrtowcs(wchar_t *dst, const char **src, size_t len, mbstate_t *ps);
```

XPG4

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t mbsrtowcs(wchar_t *dst, const char **src, size_t len, mbstate_t *ps);
```

General description

Converts a sequence of multibyte characters that begins in the conversion state described by `ps` from the array indirectly pointed to by `src`. It converts this sequence into a sequence of corresponding wide characters, that, if `dst` is not a NULL pointer, are then stored into the array pointed to by `dst`. Conversion continues up to and including a terminating NULL character, and the terminating NULL wide character is also stored. Conversion stops earlier in two cases: (1) when a sequence of bytes is reached that does not form a valid multibyte character, or (2) if `dst` is not a NULL pointer, when `len` codes have been stored into the array pointed to by `dst`. Each conversion takes place as if by a call to the mbtowc() function.

If `dst` is not a NULL pointer, the pointer object pointed to by `src` is assigned either a NULL pointer (if conversion stopped because a terminating NULL character was reached) or the address just past the last multibyte character converted. If conversion stopped because a terminating NULL character was reached, the resulting state is the initial state.

mbsrtowcs() is a restartable version of mbstowcs(). That is, shift-state information is passed as an of the arguments and is updated on exit. With mbsrtowcs(), you can switch from one multibyte string to another, provided that you have kept the shift-state information.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the mbsrtowcs() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.
mbsrtowcs

Returned value

If successful, mbsrtowcs() returns the number of multibyte characters converted, not including the terminating NULL character, if any.

If the input string contains an invalid multibyte character, mbsrtowcs() returns (size_t)−1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EILSEQ</td>
<td>Encoding error (the conversion state is undefined).</td>
</tr>
</tbody>
</table>

Example

CELEBM06

/* CELEBM06 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#define SIZE 10

int main(void)
{
    wchar_t wcs[SIZE];
    char  mbs[SIZE]="abcd"; /* string containing the multibyte char */
    char  *ptr = mbs;     /* pointer to the mbs string */
    int   length;

    /* Determine the length of the multibyte string pointed to by mbs. Store the multibyte characters in the wchar_t array. */
    length = mbsrtowcs(wcs, (const char**)&ptr, SIZE, NULL);
    wcs[length] = L'\0';

    printf(" length: %d \
", length);
    printf(" wcs:"%ls\n",wcs);
    printf(" mbs:"%ls\n",mbs);
    printf(" &mbs: %p \n", mbs);
    printf(" &ptr: %p \n", ptr);
}

mbstowcs

mbstowcs() — Convert multibyte characters to wide characters

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <stdlib.h>

size_t mbstowcs(wchar_t * __restrict__ pwc, const char* __restrict__ string, size_t n);
```

General description

Determines the length of the sequence of the multibyte characters that start in the initial shift state and that are pointed to by `string`. It then converts each of the multibyte characters to a `wchar_t`, and stores no more than `n` codes in the array pointed to by `pwc`. The conversion stops if either an invalid multibyte sequence is encountered or if `n` codes have been converted.

Processing continues up to and including the terminating NULL character, and characters that follow it are not processed. The terminating NULL character is converted into a code with the value 0.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

If `pwc` is a null pointer, `mbstowcs()` will return the length required to convert the entire array regardless of the value of `n`, but no values are stored.

Returned value

If successful, `mbstowcs()` returns the number of `pwc` array elements modified (or required if `pwc` is null), not counting the terminating 0 code (the wchar_t 0 code). Note that, if the return value is `n`, the resulting wchar_t array will not be NULL-terminated.

If an invalid multibyte character is encountered, `mbstowcs()` returns `(size_t) -1`.

Example

```
CELEBM07
/* CELEBM07

This example uses mbstowcs. to convert a multibyte character string to a wide character string.

*/
#include <stdio.h>
#include <stdlib.h>

int main()
{
```

```
mbstowcs

```c
char mbsin[8] = "\x50\x0e\x42\xf1\x0f\x50\x00";
wchar_t wcsout[5];
size_t wcssize;

printf("mbsin is 0x%.2x 0x%.2x 0x%.2x 0x%.2x 0x%.2x 0x%.2x 0x%.2x\n",
    mbsin[0], mbsin[1], mbsin[2],
    mbsin[3], mbsin[4], mbsin[5],
    mbsin[6]);

wcssize = mbstowcs(wcsout, mbsin, 5);
printf("mbstowcs(wcsout, mbsin, 5); returned %d\n", wcssize);
printf("wcsout is 0x%.4x 0x%.4x 0x%.4x 0x%.4x\n",
    wcsout[0], wcsout[1],
    wcsout[2], wcsout[3]);
```

**Output**
mbsin is 0x50 0x0e 0x42 0xf1 0x0f 0x50 0x00
mbstowcs(wcsout, mbsin, 5); returned 3
wcsout is 0x0050 0x42f1 0x0050 0x0000

Format

```c
#include <stdlib.h>

int mbtowc(wchar_t * __restrict__ pwc, const char* __restrict__ string, size_t n);
```

General description

Converts a multibyte character to a wide character and returns the number of bytes of the multibyte character. It first determines the length of the multibyte character pointed to by `string`. It then converts the multibyte character to the corresponding wide character and places the wide character in the location pointed to by `pwc`, if `pwc` is not a NULL pointer. A maximum of `n` bytes is examined.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If `string` is NULL, `mbtowc()` returns:
- Nonzero if the multibyte encoding in the current locale (LC_CTYPE) is shift-dependent.
- 0 otherwise.
- The current shift state is set to the initial state.

Otherwise if `string` is not NULL, `mbtowc()` returns:
- The number of bytes comprising the converted multibyte character, if `n` or fewer bytes form a valid multibyte character.
- 0 if `string` points to the NULL character.
- –1 if `string` does not point to a valid multibyte character, and the next `n` bytes do not form a valid multibyte character.

If the current locale supports EBCDIC DBCS characters, the shift state is updated where applicable. The length returned may be up to 4 characters long (for the shift-out character, 2-byte code, and the shift-in character).

After the function is placed into its initial state, it interprets multibyte characters—pointed to by `string`—accordingly. During the processing of shift-dependent encoded characters, you cannot stop processing one string, then move temporarily to processing another string, and return to the first, because the state would be valid for the second string, not the place where you stopped in the first string.
Example

/* This example uses mbtowc() to convert a multibyte character into a wide character.
 */
#include <stdio.h>
#include <stdlib.h>

int temp;
char string[6];
wchar_t arr[6];

int main(void)
{ /* Set string to point to a multibyte character. */

    temp = mbtowc(arr, string, MB_CUR_MAX);
    printf("wide-character string: %ls",arr);
}

<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <sys/layout.h>

LayoutObject m_create_layout(const AttrObject attrobj, const char *modifier);

General description

The m_create_layout() function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The m_create_layout() function creates a LayoutObject associated with the locale identified by attrobj. The LayoutObject is an opaque object containing all the data and methods necessary to perform the layout operations on context-dependent or directional characters of the locale identified by the attrobj.

The memory for the LayoutObject is allocated by m_create_layout(). The LayoutObject created has default layout values. If the modifier argument is not NULL, the layout values specified by the modifier will overwrite the default layout values associated with the locale. Also, internal states maintained by the layout transformation function across transformations are set to their initial values.

The attrobj argument is or may be an amalgam of many opaque objects. A locale object is just one example of the type of object that can be attached to an attribute object. The attrobj argument specifies a name that is usually associated with a locale category. If attrobj is NULL, the LayoutObject created is associated with the current locale as set by the setlocale() function.

The modifier argument can be used to announce a set of layout values when the LayoutObject is created.

A LayoutObject created by m_create_layout() is deleted by calling the m_destroy_layout() function.

For a detailed description of bidirectional layout transformation, see Bidirectional Language Support in z/OS XL C/C++ Programming Guide.

Returned value

If successful, m_create_layout() returns a LayoutObject for use in subsequent calls to m_*_layout() functions.

If unsuccessful, m_create_layout() returns (LayoutObject)0 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>

EBADF  The attribute object is invalid or the locale associated with the attribute object is not available.

EINVAL  The modifier string has a syntax error or it contains unknown layout values.

ENOMEM  Insufficient storage space is available.

Format

```c
#include <sys/layout.h>

int m_destroy_layout(const LayoutObject *layoutobject);
```

General description

The m_destroy_layout() function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The m_destroy_layout() function destroys a LayoutObject by deallocating the layout object and all the associated resources previously allocated by the m_create_layout( ) function.

Returned value

If successful, m_destroy_layout() returns 0.

If unsuccessful, m_destroy_layout() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>Errors occurred while processing the request.</td>

<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <string.h>

void *memccpy(void *__restrict__ s1, const void *__restrict__ s2, int c, size_t n);
```

General description

The memccpy() function copies bytes from memory area s2 into memory area s1, stopping after the first occurrence of byte c (converted to an unsigned char) is copied, or after n bytes are copied, whichever comes first.

Returned value

If successful, memccpy() returns a pointer to the byte after the copy of c in s1.

If c was not found in the first n bytes of s2, memccpy() returns a NULL pointer.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>

void *memchr(const void *buf, int c, size_t count);
```

General description

The `memchr()` built-in function searches the first `count` bytes pointed to by `buf` for the first occurrence of `c` converted to an unsigned character. The search continues until it finds `c` or examines `count` bytes.

Returned value

If successful, `memchr()` returns a pointer to the location of `c` in `buf`.

If `c` is not within the first `count` bytes of `buf`, `memchr()` returns `NULL`.

Example

```c
CELEBM11

/* CELEBM11

   This example finds the first occurrence of "x" in
   the string that you provide.
   If it is found, the string that starts with that character is
   printed.
   If you compile this code as MYPROG, then it could be invoked
   like this, with exactly one parameter:
   MYPROG skixing

   */
#include <stdio.h>
#include <string.h>

int main(int argc, char ** argv)
{
    char * result;
    if ( argc != 2 )
        printf( "Usage: %s string\n", argv[0] );
    else
    {
        if ((result = (char *)memchr( argv[1], 'x', strlen(argv[1])) ) != NULL)
            printf( "The string starting with x is %s\n", result );
        else
            printf( "The letter x cannot be found in the string\n" );
    }
}
```
Output
The string starting with x is xing

Related information

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <string.h>

int memcmp(const void *buf1, const void *buf2, size_t count);
```

**General description**

The `memcmp()` built-in function compares the first `count` bytes of `buf1` and `buf2`. The relation is determined by the sign of the difference between the values of the leftmost first pair of bytes that differ. The values depend on EBCDIC encoding. This function is not locale sensitive.

**Returned value**

Indicates the relationship between `buf1` and `buf2` as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td>The contents of the buffer pointed to by <code>buf1</code> less than the contents of the buffer pointed to by `buf2</td>
</tr>
<tr>
<td>= 0</td>
<td>The contents of the buffer pointed to by <code>buf1</code> identical to the contents of the buffer pointed to by `buf2</td>
</tr>
<tr>
<td>&gt; 0</td>
<td>The contents of the buffer pointed to by <code>buf1</code> greater than the contents of the buffer pointed to by `buf2</td>
</tr>
</tbody>
</table>

**Example**

```c
CELEBM12

/* CELEBM12
   This example compares first and second arguments passed to main to determine which, if either, is greater.

   */
#include <stdio.h>
#include <string.h>

int main(int argc, char ** argv)
{
    int len;
    int result;

    if ( argc != 3 )
    {
        printf( "Usage: %s string1 string2\n", argv[0] );
    }
```

```
else
{
    /* Determine the length to be used for comparison */
        len = strlen( argv[1] );
    else
        len = strlen( argv[2] );

    result = memcmp( argv[1], argv[2], len );

    printf( "When the first %i characters are compared,\n", len );
    if ( result == 0 )
        printf( "%s" is identical to "%s", argv[1], argv[2] );
    else if ( result < 0 )
        printf( "%s" is less than "%s", argv[1], argv[2] );
    else
        printf( "%s" is greater than "%s", argv[1], argv[2] );
}

Output

If the program is passed the arguments firststring and secondstring, you would obtain following:

When the first 11 characters are compared,
"firststring" is less than "secondstring"

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>

void *memcpy(void * __restrict__ dest, const void * __restrict__ src, size_t count);
```

General description

The memcpy() built-in function copies `count` bytes from the object pointed to by `src` to the object pointed to by `dest`. See "Built-in functions" on page 93 for information about the use of built-in functions. For memcpy(), the source characters may be overlaid if copying takes place between objects that overlap. Use the memmove() function to allow copying between objects that overlap.

Returned value

memcpy() returns the value of `dest`.

Example

```c
CELEBM13

/* CELEBM13 */

This example copies the contents of source to target.

*/
#include <string.h>
#include <stdio.h>

#define MAX_LEN 80

char source[ MAX_LEN ] = "This is the source string";
char target[ MAX_LEN ] = "This is the target string";

int main(void)
{
    printf( "Before memcpy, target is \"%s\"\n", target );
    memcpy( target, source, sizeof(source) );
    printf( "After memcpy, target becomes \"%s\"\n", target );
}
```

Output

Before memcpy, target is "This is the target string"
After memcpy, target becomes "This is the source string"

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>

void *memmove(void *dest, const void *src, size_t count);
```

General description

Copies `count` bytes from the object pointed to by `src` to the object pointed to by `dest`. The `memmove()` function allows copying between possibly overlapping objects as if the `count` bytes of the object pointed to by `src` must first copied into a temporary array before being copied to the object pointed to by `dest`.

Returned value

`memmove()` returns the value of `dest`.

Example

```c
CELEBM14
/* CELEBM14

   This example copies the word shiny from position target + 2
to position target + 8.

*/
#include <string.h>
#include <stdio.h>
#define SIZE 21

char target[SIZE] = "a shiny white sphere";

int main( void )
{
   char *p = target + 8; /* p points at the starting character
   of the word we want to replace */
   char *source = target + 2; /* start of "shiny" */

   printf("Before memmove, target is \"%s\"\n", target);
   memmove( p, source, 5 );
   printf("After memmove, target becomes \"%s\"\n", target);
}
```

Output

Before memmove, target is "a shiny white sphere"
After memmove, target becomes "a shiny shiny sphere"

</table>

Format

```c
#include <string.h>

void *memset(void *dest, int c, size_t count);
```

General description

The memset() built-in function sets the first `count` bytes of `dest` to the value `c` converted to an unsigned int.

Returned value

memset() returns the value of `dest`.

Example

```c
CELEBM15

/* CELEBM15

This example sets 10 bytes of the buffer to "A" and the next 10 bytes to "B".

*/
#include <string.h>
#include <stdio.h>
#define BUF_SIZE 20
#define HALF_BUF_SIZE BUF_SIZE/2

int main(void)
{
    char buffer[BUF_SIZE + 1];
    char *string;
    memset(buffer, 0, sizeof(buffer));
    string = (char *)memset(buffer,'A', HALF_BUF_SIZE);
    printf("\nBuffer contents: \%s\n", string);
    memset(buffer+HALF_BUF_SIZE, 'B', HALF_BUF_SIZE);
    printf("\nBuffer contents: \%s\n", buffer);
}
```

Output

```
Buffer contents: AAAAAAAAA

Buffer contents: AAAAAAAAAABBBBBBBBB
```

m_getvalues_layout

m_getvalues_layout() — Query layout values of a layout object (bidi data)

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <sys/layout.h>

int m_getvalues_layout(const LayoutObject layout_object, LayoutValues values,
        int *index_returned);

General description

The m_getvalues_layout() function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The m_getvalues_layout() function is used to query the current setting of layout values within a LayoutObject. The layout_object argument specifies a LayoutObject returned by the m_create_layout() function. The values argument specifies the list of layout values which are to be queried.

Each value element of a LayoutValueRec must point to a location where the layout value is stored. For example, if a layout value is of type T, the argument must be of type T*. The values are queried from the LayoutObject and represent its current state.

If the layout value name has QueryValueSize OR-ed to it, instead of the value of the layout value, only its size is returned. This option can be used by the caller to determine the amount of memory needed to be allocated for the layout values queried.

It is the user's responsibility to manage the space allocation for the layout values queried.

For a detailed description of bidirectional layout transformation, see Bidirectional Language Support in z/OS XL C/C++ Programming Guide.

Returned value

If successful, m_getvalues_layout() returns 0.

If any value cannot be queried, m_getvalues_layout() stores into index_returned the (zero-based) index of the value causing the error. It returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The layout value specified by index_returned is unknown or its value is invalid or the argument layout_object is invalid.</td>
</tr>

<td>S_IWGRP</td>
<td>Write permission for the file's group.</td>
</tr>
</tbody>
</table>
S_IWOTH  Write permission for users other than the file owner.
S_IWUSR  Write permission for the file owner.
S_IXGRP  Search permission (for a directory) or execute permission (for a file) for the file’s group.
S_IXOTH  Search permission for a directory, or execute permission for a file, for users other than the file owner.
S_IXUSR  Search permission (for a directory) or execute permission (for a file) for the file owner.

The owner ID of the new directory is set to the effective user ID of the process. The group ID of the new directory is set to the group ID of the owning directory.

mkdir() sets the access, change, and modification times for the new directory. It also sets the change and modification times for the directory that contains the new directory.

If pathname names a symbolic link, mkdir() fails.

Returned value

If successful, mkdir() returns 0.

If unsuccessful, mkdir() does not create a directory, returns −1, and sets errno to one of the following values:

<table>
<thead>
<tr>

Example

CELEBM16

/* CELEBM16

   The following example creates a new directory.

   */
#define _POSIX_SOURCE
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char new_dir[]="new_dir"

    if (mkdir(new_dir, S_IRWXU|S_IRGRP|S_IXGRP) != 0)
        perror("mkdir() error");
    else if (chdir(new_dir) != 0)
        perror("first chdir() error");
    else if (chdir("..") != 0)
        perror("second chdir() error");
    else if (rmdir(new_dir) != 0)
        perror("rmdir() error");
    else
        puts("success!");
}

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <sys/stat.h>

int mkfifo(const char *pathname, mode_t mode);
```

General description

Sets the access, change, and modification times for the new file. It also sets the change and modification times for the directory that contains the new file.

`mkfifo()` creates a new FIFO special file, `pathname`. The file permission bits in `mode` are changed by the file creation mask of the process, and then used to set the file permission bits of the FIFO file being created. If `pathname` contains a symbolic link, `mkfifo()` fails. For more information on the file creation mask, see "umask() — Set and retrieve file creation mask" on page 2330 for information about the file permission bits, see "chmod() — Change the mode of a file or directory" on page 284.

The owner ID of the FIFO file is set to the effective user ID of the process. The group ID of the FIFO file is set to the group ID of the owning directory. `pathname` cannot end in a symbolic link.

Returned value

If successful, `mkfifo()` returns 0.

If unsuccessful, `mkfifo()` does not create a FIFO file, returns –1, and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The process does not have search permission on some component of <code>pathname</code>, or does not have write permission on the parent directory of the file to be created.</td>

<td>Either the named file refers to a symbolic link, or there is already a file or directory with the given <code>pathname</code>.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal is received while this open is blocked waiting for an open() for read (if O_WRONLY was specified) or for an open() for write (if O_RDONLY was specified).</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP (defined in the limits.h header file) symbolic links are detected in the resolution of <code>pathname</code>.</td>
</tr>
</tbody>
</table>
EMLINK  The link count of the parent directory has already reached the maximum defined for the system.

ENAMETOOLONG  

pathname is longer than PATH_MAX characters or some component of pathname is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined using pathconf().

ENOENT  Some component of pathname does not exist, or pathname is an empty string.

ENOSPC  The file system does not have enough space to contain a new file, or the parent directory cannot be extended.

ENOTDIR  A component of the pathname prefix is not a directory.

ERofs  The parent directory of the FIFO file is on a read-only file system.

Example

CELEBM17

/* CELEBM17

This example uses mkfifo() to create a FIFO special file named temp.fifo and then writes and reads from the file before closing it.

*/
#define _POSIX_SOURCE
#include <sys/stat.h>
#include <unistd.h>
#include <fcntl.h>
#include <stdio.h>

main() {
    char fn[]="temp.fifo";
    char out[20]="FIFO's are fun!", in[20];
    int rfd, wfd;

    if (mkfifo(fn, S_IRWXU) != 0)
        perror("mkfifo() error");
    else {
        if ((rfd = open(fn, O_RDONLY|O_NONBLOCK)) < 0)
            perror("open() error for read end");
        else {
            if ((wfd = open(fn, O_WRONLY)) < 0)
                perror("open() error for write end");
            else {
                if (write(wfd, out, strlen(out)+1) == -1)
                    perror("write() error");
                else if (read(rfd, in, sizeof(in)) == -1)
                    perror("read() error");
                else printf("read 's  from the FIFO\n", in);
                close(wfd);
            }
        }
    }
    close(rfd);
    unlink(fn);
}

Output

read 'FIFO's are fun!' from the FIFO

Format

```c
_OPEN_SYS
#define _OPEN_SYS
#include <sys/stat.h>

int mknod(const char *path, mode_t mode, rdev_t dev_identifier);

_XOPEN_SOURCE_EXTENDED 1
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/stat.h>

int mknod(const char *path, mode_t mode, dev_t dev_identifier);
```

General description

Creates a new directory, regular file, character special file, or FIFO special file (named pipe), with the pathname specified in the `path` argument.

The first byte of the `mode` argument determines the file type of the file:

- S_IFCHR: Character special file
- S_IFIFO: FIFO special file
- S_IFREG: Regular file
- S_IFDIR: Directory file

The file permission bits of the new file are initialized with the remaining bits in `mode` and changed by the file creation mask of the process. For more information on these symbols, refer to "chown() — Change the owner of a file or directory" on page 284.

`dev_identifier` applies only to a character special file. It is ignored for the other file types. `dev_identifier` contains a value representing the device major and device minor numbers. The major number is contained in the high-order 16 bits; it identifies a device driver supporting a class of devices, such as interactive terminals. The minor number is contained in the low-order 16 bits of `dev_identifier`; it identifies a specific device within the class referred to by the device major number. With z/OS UNIX services, the device major numbers are:

1 Master pseudoterminal
2 Slave pseudoterminal
3 /dev/tty
4 /dev/null
5 /dev/fdn
Device major numbers 1, 2 and 7: The device minor numbers range between 0 and one less than the maximum number of pseudoterminal pairs defined by the installation.

Device major numbers 3, 4, 6, 8 and 9: The device minor number is ignored.

Device major number 5: The device minor number value represents the file descriptor to be referred to. For example, device minor 0 refers to file descriptor 0.

When it completes successfully, mknod() marks for update the following fields of the file: st_atime, st_ctime, and st_mtime. It also marks for update the st_ctime and st_mtime fields of the directory that contains the new file.

Returned value

If successful, mknod() returns 0.

If unsuccessful, mknod() returns −1 and sets errno to one of the following values:

<table>

**mkstemp() — Make a unique filename**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int mkstemp(char *template);
```

**General description**

The `mkstemp()` function replaces the contents of the string pointed to by `template` with a unique file name, and returns a file descriptor for the file open for reading and writing. The function thus prevents any possible race condition between testing whether the file exists and opening it for use. The string in `template` should look like a file name with six trailing 'X's; `mkstemp()` replaces each 'X' with a character from the portable file name character set. The characters are chosen such that the resulting name does not duplicate the name of an existing file. This function is supported only in a POSIX program.

**Returned value**

If successful, `mkstemp()` returns an open file descriptor.

If no suitable file could be created, `mkstemp()` returns -1.

There are no errno values defined.

**Related information**

- "stdlib.h" on page 69

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *mktemp(char *template);
```

General description

The `mktemp()` function replaces the contents of the string pointed by `template` by a unique file name and returns `template`. The application must initialize `template` to be a file name with six trailing 'X's; `mktemp()` replaces each 'X' with a single-byte character from the portable file name character set.

This function is supported only in a POSIX program.

**Note:** The `mktemp()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `mkstemp()` function is preferred for portability and greater reliability.

Returned value

If successful, `mktemp()` returns a pointer to `template`.

If a unique name cannot be created, `mktemp()` sets `template` to a NULL string.

There are no `errno` values defined.

</tr>
</tbody>
</table>

#### Format

```
#include <time.h>

time_t mktime(struct tm *tmptr);
```

```
#define _LARGE_TIME_API
#include <time.h>

long long mktime64 (struct tm *tmptr);
```

**Compile requirement:** Use of mktime64() function requires the long long data type. For more information on how to make long long data type available, see [Z/OS XL C/C++ Language Reference](#).

#### General description

The `mktime()` function converts broken-down time, expressed as a local time, in the `tm` structure (described in Table 16 on page 79) pointed to by `tmptr`, to calendar time. Calendar time is the number of seconds since epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.

The values of the structure members passed to the `mktime()` function are not restricted to the ranges described in `time.h`. For values that are outside the specified range, the `mktime()` function will use date arithmetic to adjust the values to produce a valid date and time (see “Example” on page 1257). The values of `tm_wday` and `tm_yday` are ignored and are assigned their correct values on return.

On the successful completion of the function, all the members of the structure pointed to by `time` are set to represent the specified time since the Epoch with their values forced into the ranges described in `time.h`. The value of `tm_wday` is set after the values of `tm_mon` and `tm_year` are determined. The output value of `tm_isdst` is determined by the `mktime()` function, independent of the value presented as input to the `mktime()` function.

If an application uses the `localtime()` function to determine local time, the `localtime()` function will determine if daylight savings applies (assuming DST information is available) and will correctly set the `tm_isdst` flag. If the application wants to determine seconds from Epoch corresponding to a `tm` structure returned by the `localtime()` function, it should not modify the `tm_isdst` flag set by the `localtime()` function.

If an application sets `tm_isdst` to 0 before calling the `mktime()` function, it is asserting that daylight savings does not apply to the input values of the `tm`
structure, regardless of the system DST start and end dates. Likewise, if the application has set a value for tm_isdst to be greater than 0, it is asserting that the time represented by the tm structure has been shifted for daylight savings. Therefore, the mktime() function unshifts the time in determining seconds since Epoch.

Setting tm_isdst to -1 indicates the mktime() function will determine whether daylight savings time applies. If yes, the mktime() function returns tm_isdst greater than 0. If not, it returns tm_isdst of 0 unless DST information is not available on the system, in which case tm_isdst of -1 is returned.

Your time zone might not be using DST, perhaps because the TZ environment variable does not specify a daylight savings time name or perhaps because DSTNAME is unspecified in the current LC_TOD locale category. In such a case, if you code tm_isdst=1 and call the mktime() function, (time-t)-1 is returned to indicate an error.

The mktime64() function behaves exactly like the mktime() function except it will support a structured date beyond 00:00:00 UTC January 1, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

**Returned value**

If successful, the mktime() function returns a time_t representing seconds since the Epoch. The number of seconds corresponds to the broken-down time, expressed as local time, based on the user-supplied tm structure pointed to by tmptr.

If the mktime() function cannot convert the broken-down time to a calendar time, it returns (time_t)-1 to indicate an error, such as time before January 1, 1970 (UTC).

**Error Code**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EOVERFLOW</td>
</tr>
<tr>
<td>The result cannot be represented.</td>
</tr>
</tbody>
</table>

**Usage notes**

1. The ctime(), localtime(), and mktime() functions now return Coordinated Universal Time (UTC) unless customized locale information is made available, which includes setting the timezone_name variable.
2. Applications working with local time may define time zone information by using the TZ (POSIX) or _TZ (non-POSIX) environment variable or by customizing the LC_TOD category of the locale in use.
3. When neither TZ nor _TZ is defined, the current locale is interrogated for time zone information. If neither TZ nor _TZ is defined and LC_TOD time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock. For more information about customizing a time zone to work with local time, see Customizing a time zone in z/OS XL C/C++ Programming Guide.
4. The mktime() functions fail when a result overflows the time_t object used to return the number of seconds elapsed from the time in tmptr back to the start of the standard epoch. In 31-bit, the last year that mktime() supports is 2037. In
64-bit, the time_t grows from 4 bytes to 8 bytes in length, so that mktime() can accommodate dates further into the future. The upper bound in 64-bit is set to the year 9999.

Example

CELEBM19
/
/* CELEBM19
   This example prints the day of the week that is 40 days and
   16 hours from the current date.
*/
#include <stdio.h>
#include <time.h>
char *wday[] = { "Sunday", "Monday", "Tuesday", "Wednesday",
                "Thursday", "Friday", "Saturday" };

int main(void)
{
  time_t t1, t3;
  struct tm *t2;
  t1 = time(NULL);
  t2 = localtime(&t1);
  t2 -> tm_mday += 40;
  t2 -> tm_hour += 16;
  t3 = mktime(t2);

  printf("40 days and 16 hours from now, it will be a %s \n",
         wday[t2 -> tm_wday]);
}

Output
40 days and 16 hours from now, it will be a Sunday

<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SOURCE_EXTENDED 2
#include <sys/mman.h>

int __mlockall(int flags);
```

General description

The function __mlockall() causes all of the pages mapped by the address space of a process to be memory resident until unlocked or until the process exits or execs another process image. The flags argument determines whether the pages are to be locked or unlocked.

<table>
<thead>
<tr>
<th>Flags</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>_BPX_NONSWAP</td>
<td>Lock the current pages mapped for this address space.</td>
</tr>
<tr>
<td>_BPX_SWAP</td>
<td>Unlock the current pages previously locked.</td>
</tr>
</tbody>
</table>

Returned value

If successful, __mlockall() returns 0.

If unsuccessful, __mlockall() returns -1 and no change is made to the memory state of the address space.

Note: This function will return a EINVAL with an errno2() of 09300be if the kernel is not available.

<td></td>
<td></td>
</tr>
<tr>
<td>z/OS UNIX</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/mman.h>

void *mmap(void *addr, size_t len, int prot, int flags, int fildes, off_t off);
```

General description

The mmap() function establishes a mapping between an address space of a process (for `len` bytes) and a file associated with the file descriptor `fildes` at offset `off` for `len` bytes. The format of the call is as follows:

```c
pa = mmap(addr, len, prot, flags, fildes, off);
```

The value of `pa` is an unspecified function of the argument `addr` and values of `flags`, further described below. A successful `mmap()` call returns `pa` as its results. The address ranges covered by `[pa, pa + len]` and `[off, off + len]` must be legitimate for the possible (not necessarily current) address space of a process and the file, respectively.

If the size of the mapped file changes after the call to `mmap()`, the effect of references to portions of the mapped region that correspond to added or removed portions of the file is unspecified.

The `prot` argument determines whether read, write, execute, or some combination of accesses are permitted to the pages being mapped. The protection options are defined in `<sys/mman.h>`:

- `PROT_READ` Page can be read
- `PROT_WRITE` Page can be written
- `PROT_EXEC` Page can be executed
- `PROT_NONE` Page can be accessed

Implementations need not enforce all combinations of access permissions. However, write shall only be permitted when `PROT_WRITE` has been set.

The `flags` argument provides other information about the handling of the mapped pages. The options are defined in `<sys/mman.h>`:

- `MAP_SHARED` Share changes
- `MAP_PRIVATE` Changes are private
- `MAP_FIXED` Interpret `addr` exactly
The MAP_PRIVATE and MAP_SHARED flags control the visibility of write references to the memory region. Exactly one of these flags must be specified. The mapping type is retained across a fork.

If MAP_SHARED is set in flags, write references to the memory region by the calling process may change the file and are visible in all MAP_SHARED mappings of the same portion of the file by any process.

If MAP_PRIVATE is set in flags, write references to the memory region by the calling process do not change the file and are not visible to any process in other mappings of the same portion of the file.

All changes to the mapped data made by processes that have mapped the memory region using MAP_SHARED are shared and are visible to all other processes that have mapped the same file-offset range.

When MAP_FIXED is set in the flags argument, the implementation is informed that the value of pa must be addr, exactly. If MAP_FIXED is set, mmap() may return (void*)-1 and set errno to EINVAL. If a MAP_FIXED request is successful, the mapping established by mmap() replaces any previous mappings for the process's pages in the range [pa, pa + len].

When MAP_FIXED is not set, the implementation uses addr in an unspecified manner to arrive to pa. The pa so chosen will be an area of the address space which the implementation deems suitable for a mapping of len bytes to the file. All implementation interpret an addr value of 0 as granting the implementation complete freedom in selecting pa, subject to constraints described below. A nonzero value of addr is taken to be a suggestion of a process address near which the mapping should be placed. When the implementation selects a value for pa, it never places a mapping at address 0, nor does it replace any extant mapping, nor map into dynamic memory allocation areas.

The off argument is constrained to be aligned and sized according to the value returned by sysconf() when passed_SC_PAGESIZE or_SC_PAGE_SIZE. When MAP_FIXED is specified, the argument addr must also meet these constraints. The implementation performs mapping operations over whole pages. Thus, while the argument len need not meet a size or alignment constraint, the implementation will include, in any mapping operation, any partial page specified by the range [pa, pa + len].

The implementation always zero-fills any partial page at the end of a memory region. Further, the implementation never writes out any modified portions of the last page of a file that are beyond the end of the mapped portion of the file. If the mapping established by mmap() extends into pages beyond the page containing the last byte of the file, an application references to any of the pages in the mapping that are beyond the last page results in the delivery of a SIGBUS or SIGSEGV signal.

The mmap() function adds an extra reference to the file associated with the file descriptor fildes which is not removed by a subsequent close() on that file descriptor. This reference is removed when there are not more mappings to the file.
The st_atime field of the mapped file may be marked for update at any time between the mmap() call and the corresponding munmap() call. The initial read or write reference to a mapped region will cause the file's set_atime field to be marked for update if it has not already been marked for update.

The st_ctime and st_mtime fields of a file that is mapped with MAP_SHARED and PROT_WRITE, will be marked for update at stime point in the interval between a write reference to the mapped region and the next call to msync() with MS_ASYNC or MS_SYNC for that portion of the file by any process. If there is no such call, these fields may be marked for update at any time after a write reference if the underlying file is modified as a result.

If a memory mapped region is not unmapped before the process terminates, process termination will not automatically write out to disk any modified data in the mapped region. Modified private data in a MAP_PRIVATE region will be discarded. If the map region is MAP_SHARED, the modified data will continue to reside in the cache (if the same file-offset range is being shared) and may ultimately be written out to disk by another process using the msync() service. However, if no other processes map the same file-offset range as MAP_SHARED, the modified data is discarded.

There may be implementation-dependent limits on the number of memory regions that can be mapped (per process or per system). If such a limit is imposed, whether the number of memory regions that can be mapped by a process is decreased by the use of shmat() is implementation-dependent.

Specification of the __MAP_MEGA option results in the system allocating storage to map the file in megabyte increments. This option should only be used for large files. Any file over half a megabyte in size will likely achieve better performance by using this option. When using this option, mmaps and munmaps are in megabyte ranges on megabyte boundaries.

When __MAP_MEGA is specified, all changes to the mapped data are shared. Modifications to the mapped data are visible to all other processes that map the same file-offset range. That is, __MAP_MEGA behaves much like MAP_SHARED. __MAP_MEGA is mutually exclusive with MAP_PRIVATE and MAP_SHARED. Specification of __MAP_MEGA with either MAP_PRIVATE or MAP_SHARED will result in the request failing with errno set to EINVAL.

The __MAP_MEGA option may be specified with MAP_FIXED.

Map_address parameter: If the map address is not zero and __MAP_MEGA has been specified, then for non MAP_FIXED requests, the kernel will attempt to create the mapping at the map_address, truncated to the nearest megabyte boundary. If unsuccessful, it will proceed as if a map_address of zero were specified. For MAP_FIXED requests, the value of map_address must be multiples of the segment size (megabyte multiples). If not, the mmap request fails with errno set to EINVAL.

Map_length parameter: When __MAP_MEGA is specified, mapping operations are performed over whole segments (megabyte chunks). If the length is not a multiple of the segment size, the entire trailing portion of the last segment will also be mapped into the user storage.

File_descriptor: The file descriptor identifies the file being mapped. If an attempt is made to map a file that is already mapped but was mapped with a different specification of __MAP_MEGA, then the current request fails with errno set to
EINVAL-MMapTypeMismatch. That is, at any point in time a file may be mapped with the __MAP_MEGA option or without the __MAP_MEGA option but not both ways at the same time.

For a __MAP_MEGA mapping, if this is the first map to the file represented by the specified file descriptor then whether the file was opened for read or for write will determine what protection options may be specified for the file by this mmap and any future mmaps and mprotects, by this or any other process mapping to the same file. If the file was opened for read but not write then only PROT_READ, PROT_EXEC or PROT_NONE will be allowed. If the file was opened for write, then any of the protection options will be allowed. Only regular files may be mapped. Note also that remote files accessed through NFS or DFS may not be mapped.

**Protect options:** The specification made for Protect options has a global effect when the file is mapped with the __MAP_MEGA option. The Protect option specified immediately effects all processes currently mapped to the same file-offset range.

**Large file support for z/OS UNIX files:**

Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLEVEL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

**Usage notes**

1. The mmap() function does not support shared memory objects or typed memory objects.

**Returned value**

If successful, mmap() returns the address at which the mapping was placed.

If unsuccessful, mmap() returns MAP_FAILED and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The fildes argument is not open for read, regardless of the protection specified, or fildes is not open for write and PROT_WRITE was specified for a MAP_SHARED type mapping.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The fildes argument is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The addr argument (if MAP_FIXED was specified) or off is not a multiple of the page size as returned by sysconf(), or are considered invalid by the implementation. The value of flags is invalid (neither MAP_PRIVATE nor MAP_SHARED is set).</td>
</tr>
<tr>
<td>EMFILE</td>
<td>The number of mapped regions would exceed an implementation-dependent limit (per process or per system).</td>
</tr>
<tr>
<td>ENODEV</td>
<td>The fildes argument refers to a file whose type is not supported by mmap().</td>
</tr>
</tbody>
</table>
ENOMEM  MAP_FIXED was specified, and the range \([addr, addr + range\) [addr, addr + len], rounding len] exceeds that allowed for the address space for a process; or if MAP_FIXED was not specified and there is insufficient room in the address space to effect the mapping.

ENXIO  Address in the range \([off, off + len\] are invalid for fildes

EOVERFLOW  The file is a regular file and the value of off plus len exceeds the offset maximum established in the open file.

**Note:** Starting with z/OS V1.9, environment variable _EDC_EOVERFLOW can be used to control behavior of mmap() with respect to detecting an EOVERFLOW condition for z/OS UNIX files. By default, mmap() will not set EOVERFLOW when the offset maximum is exceeded associated with fildes. When _EDC_EOVERFLOW is set to YES, mmap() will check for an overflow condition.

<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <math.h>

double modf(double x, double *intptr);
float modf(float x, int *intptr); /* C++ only */
long double modf(long double x, int *intptr); /* C++ only */
float modff(float x, int *intptr);
long double modfl(long double x, int *intptr);
```

General description

Breaks down the floating-point value `x` into fractional and integral parts. The integral part is stored as double, in the object pointed to by `intptr`. Both the fractional and integral parts are given the same sign as `x`.

Restriction

The `modff()` function does not support the `_FP_MODE_VARIABLE` feature test macro.

Returned value

Returns the signed fractional portion of `x`.

Example

**CELEBM20**

```c
/* CELEBM20

    This example breaks the floating-point number -14.876 into
    its fractional and integral components.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y, d;
    x = -14.876;
    y = modf(x, &d);
```
modf, modff, modfl

```c
    printf("x = \%lf\n", x);
    printf("Integral part = \%lf\n", d);
    printf("Fractional part = \%lf\n", y);
}
```

Output

```
x = -14.876000
Integral part = -14.000000
Fractional part = -0.876000
```

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.8</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 modfd32(_Decimal32 x, _Decimal32 *p);
_Decimal64 modfd64(_Decimal64 x, _Decimal64 *x);
_Decimal128 modfd128(_Decimal128 x, _Decimal128 *x);
_Decimal32 modf(_Decimal32 x, _Decimal32 *x); /* C++ only */
_Decimal64 modf(_Decimal64 x, _Decimal64 *x); /* C++ only */
_Decimal128 modf(_Decimal128 x, _Decimal128 *x); /* C++ only */
```

General description

Breaks down the decimal floating-point value x into fractional and integral parts. The integral part is stored in the object point to by p. Both the fractional and integral parts are given the same sign as x.

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The lround functions return the signed fractional portion of x.

If the rounded value is outside the range of the return type, the numeric result is unspecified. A range error may occur if the magnitude of x is too large.

Example

```c
/* CELEBM24

This example illustrates the modfd128() function.

This example breaks the floating-point number -14.876 into its fractional and integral components.

*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x, y, d;
    x = -14.876DL;
```
modfd32, modfd64, modfd128

```c
y = modfd128(x, &d);
printf("Number = %Df\n", x);
printf("Integral part = %Df\n", d);
printf("Fractional part = %Df\n", y);
```
__moservices() - Memory object services

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMODE 64 Language Environment</td>
<td>both</td>
<td>z/OS V1.10</td>
</tr>
</tbody>
</table>

Format

```
#include <stdlib.h>

int __moservices(int reqtype, size_t mopllen,
                 struct __mopl_s *mopl, void **moorigin);
```

General description

The __moservices() function allows the caller to perform the following memory object services:
- Create a memory object that will be associated with the current Language Environment enclave;
- Free a memory object that was created using a previous __moservices() call;
- Specify a shared memory dump priority to be used when allocating shared memory.

Argument Description

- **reqtype**
  - The request type. Valid values are
    - __MO_GETSTOR
      - Use IARV64 REQUEST(GETSTOR) to create a memory object that is associated with the current Language Environment enclave.
    - __MO_DETACH
      - Use IARV64 REQUEST(DETACH) to free a memory object that was created using __moservices().
    - __MO_SHMDUMPPRIORITY
      - Set a shared memory dump priority, to be associated with shared memory segments on subsequent shmget() calls.

- **mopllen**
  - The length of the passed mopl structure. If a mopl is not passed, this length should be set to zero.

- **mopl**
  - Points to a structure describing additional characteristics for the request.
    - For __MO_GETSTOR and __MO_SHMDUMPPRIORITY requests, this structure is required.
    - For __MO_DETACH requests, this structure is optional.

- **moorigin**
moservices

On __MO_GETSTOR calls, morigin contains the origin address of the memory object upon return.

On __MO_DETACH calls, morigin contains the origin address of the memory object to be detached.

The __mopl_s structure is defined in stdlib.h and has the following format:

```
struct __mopl_s {
  unsigned long __moplrequestsize;
  int __mopldumppriority;
  unsigned int __moplgetstorflags;
  long __moplreserved;
  int __mopl_iarv64_rc;
  int __mopl_iarv64_rsn;
};
```

The entire __mopl_s structure must be set to binary zeroes prior to use. The fields are used as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>__mopldumppriority</td>
<td>For __MO_GETSTOR, the desired memory object dump priority (1-99). For __MO_SHMDUMPPRIORITY, the desired shared memory dump priority (1-99).</td>
</tr>
<tr>
<td>__moplsize</td>
<td>For __MO_GETSTOR, the size of the memory object to be created, in MB.</td>
</tr>
<tr>
<td>__moplgetstorflags</td>
<td>For __MO_GETSTOR, flags identifying additional characteristics for the memory object to be created. The following flags are defined:</td>
</tr>
<tr>
<td></td>
<td>• __MOPL_PAGEFRAMESIZE1MEG - the memory object will be backed by 1 Megabyte page frames.</td>
</tr>
<tr>
<td></td>
<td>• __MOPL_PAGEFRAMESIZE64 - the memory object will be backed by the largest page frame size supported, and backed by 4K page frames if the current hardware does not have Large Page support or if large page frames are unavailable on the system.</td>
</tr>
<tr>
<td></td>
<td>• __MOPL_PAGEFRAMESIZE64 - the memory object will be backed by the largest page frame size supported, and backed by 4K page frames if the current hardware does not have Large Page support or if large page frames are unavailable on the system.</td>
</tr>
<tr>
<td></td>
<td>When 4K page frames are used, the request will be successful, but __mopl_iarv64_rc and __mopl_iarv64_rsn will contain values to indicate the memory object is not backed by large page frames.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If none of the above flags are set, then the memory object will be backed by 4K page frames. Also, the above flags are mutually exclusive.</td>
</tr>
<tr>
<td>__mopl_iarv64rc</td>
<td>The return code from the call to IARV64</td>
</tr>
<tr>
<td>__mopl_iarv64rsn</td>
<td>The reason code from the call to IARV64</td>
</tr>
</tbody>
</table>

Constants are available which identify the dump priorities of memory objects obtained by Language Environment:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>__MO_DUMP_PRIORITY_STACK</td>
<td>Dump priority of memory objects to be used as Language Environment stacks. Value is 5.</td>
</tr>
<tr>
<td>__MO_DUMP_PRIORITY_HEAP</td>
<td>Dump priority of memory objects to be used as Language Environment heaps. Value is 15.</td>
</tr>
</tbody>
</table>
moservices

For the dump priority of memory objects obtained by other programs (such as Java), refer to the corresponding documentation for those programs.

All memory objects obtained by __moservices() are unguarded and count towards the address space memlimit. For more information on memory objects and the IARV64 service, see z/OS MVS Programming: Assembler Services Guide and the z/OS MVS Programming: Assembler Services Reference ABE-HSP.

Returned value

If successful, __moservices() returns 0.

If unsuccessful, __moservices() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>An argument to this function contained an incorrect value. Use __errno2() to obtain more detailed information on the error.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>A z/OS environmental or internal error occurred. Use __errno2() to obtain more detailed information on the error.</td>
</tr>
</tbody>
</table>

If the underlying IARV64 call is unsuccessful, and the mopl argument has been specified, then __mopl_iarv64_rc and __mopl_iarv64_rsn will contain the return and reason codes returned by IARV64.

Example

```c
#include <stdlib.h>
#include <stdio.h>
#include <errno.h>
#include <string.h>

int main(void) {
  __mopl_t mymopl;
  int mos_rv;
  void *mymoptr;
  memset(&mymopl, 0, sizeof(__mopl_t));
  /* Set a shared memory dump priority for subsequent shmget() */
  mymopl.__mopldumppriority = 8;
  mos_rv = __moservices(__MO_SHMDUMPPRIORITY, sizeof(mymopl),
                         &mymopl, &mymoptr);
  if (mos_rv != 0) {
    perror("moservices(SHMDUMPPRIORITY) call failed");
  }
  /* Obtain a 100MB memory object whose dump priority falls */
  /* between the dump priorities of the Language Environment */
  /* stacks and heaps. */
  mymopl.__mopldumppriority = __MO_DUMP_PRIORITY_STACK + 5;
  mymopl.__moplroutinesize = 100;
  mos_rv = __moservices(__MO_GETSTOR, sizeof(mymopl),
                         &mymopl, &mymoptr);
  if (mos_rv == 0) {
    /* ... */
  }
}
```
moservices

printf("moservices(GETSTOR) successful, MO addr: %p\n", mymoptr);
/* Free the 100MB memory object.                       */
mos_rv = __moservices(__MO_DETACH, 0, NULL, &mymoptr);
if (mos_rv != 0) {
    perror("moservices(DETACH) call failed");
    }
else {
    perror("moservices(GETSTOR) call failed");
    }
    return 0;
}

mount

mount() — Make a file system available

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <sys/stat.h>

int mount(const char *path, char *filesystem,
           char *filesystype, mtm_t mtm,
           int parmlen, char *parm);
```

General description

Adds a file system to the hierarchical file system (HFS). The same file system cannot be mounted at more than one place in the hierarchical file system.

In order to mount a file system, the caller must be an authorized program, or must be running for a user with appropriate privileges.

- `path` The mount point directory that the file system is to be mounted to.
- `filesystem` The name of the file system to be mounted; it must be unique within the system. For a hierarchical file system (HFS) data set, this is a 1-to-44-character MVS data set name specified as all uppercase letters.
  This name is terminated with NULL characters.
- `filesystype` The name for the file system that will perform the mount. This 8-character name must match the TYPE operand on a FILESYSTYPE statement in the BPXPRMxx parmlib member for the file system.
- `mtm` A flag field that specifies the mount mode and additional mount options:
  - MTM_RDONLY Mount the file system as a read-only file system.
  - MTM_RDWR Mount the file system as a read/write file system.
  - MTM_NOSUID The SETUID and SETGID mode flags will be ignored for programs that reside in this file system.
  - MTM_SYNCHONLY The mount must be completed synchronously or fail if it cannot.
- `parmlen` Length of the `parm` argument. The maximum length is 500 characters. For a hierarchical file system (HFS) data set, this is not specified.
- `parm` A parameter passed to the physical file system that performs the mount. This parameter may not be required. The form and content of the `parm` are determined by the physical file system. A hierarchical file system (HFS) data set does not require a `parm`. 
Returned value

If successful, mount() returns 0.

If the mount() is proceeding asynchronously, it returns 1.

If unsuccessful, mount() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBUSY</td>
<td>The specified file system is unavailable.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>A parameter was incorrectly specified. Verify filesystype and mtm. Another possible reason for this error is that the mount point is the root of a file system or that the file system is already mounted.</td>
</tr>
<tr>
<td>EIO</td>
<td>An I/O error occurred.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP (defined in the limits.h header file) symbolic links are detected in the resolution of pathname.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>The mount point does not exist.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>There is not enough storage available to save the information required for this file system.</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>The mount point is not a directory.</td>
</tr>
<tr>
<td>EPERM</td>
<td>Superuser authority is required to issue a mount.</td>
</tr>
</tbody>
</table>

Example

CELEBM21

/* CELEBM21

This example adds a file system to the hierarchical file system.

*/
#define _OPEN_SYS
#include <sys/stat.h>
#include <stdio.h>
#include <unistd.h>
main() {
    char mount_point[]="/new_fs";
    char HFS[]="POSIX.NEW.HFS";
    char filesystype[9]="HFS  ";
    setvbuf(stdout, NULL, _IOLBF, 0);
    puts("before mount()");
    system("df −Pk");
    if (mount(mount_point, HFS, filesystype, MTM_RDWR, 0, NULL) != 0)
        perror("mount() error");
    else {
        puts("After mount()");
        system("df −Pk");
        if (umount(HFS, MTM_UMOUNT) != 0)
            perror("umount() error");
    }
}

Output
mount

before mount()
Filesystem  1024-blocks Used Available Capacity Mounted on
POSIX.ROOT.FS  9600  8660  940  90%  /

After mount()
Filesystem  1024-blocks Used Available Capacity Mounted on
POSIX.NEW.HFS  200  20  180  10%  /new_fs
POSIX.ROOT.FS  9600  8660  940  90%  /

Format

```c
#define _OPEN_SYS
#include <sys/stat.h>
#include <sys/mntent.h>

int __mount(struct mnte *mnte, char *sysname);
```

General description

Adds a file system to the hierarchical file system. The same file system cannot be mounted at more than one place in the hierarchical file system.

In order to mount a file system, the caller must be an authorized program or must be running for a user with appropriate privileges.

Element descriptions

To mount or change the mount of an HFS file in a sysplex, the application should set values in `mnte` as follows:

- `mnt2h_cbid` The mnte2 control block ID. Initialize it to "MNT2".
- `mnt2h_cblen` The mnte2 size. Initialize it to the size of struct mnte2.
- `mh2_cursor` Contains the internal cursor. This should be set to 0 initially, and must be left unchanged for subsequent calls.
- `mnt2_devno` This element contains the device number, if needed.
- `mh_bodylen` The mnte2 size of w_mntent2. Must be initialized to the sizeof the w_mntent2 body.
- `rsrd` This field must be set to all zeros.
- `mnt2_fstype` The file system type.
- `mnt2_mode` File system mount mode. A flag field that specifies the mount mode and additional mount options:
  - `mntentfsaunmount` If it is 1 after the file system is mounted, the file system will be unmounted when a system leaves the sysplex. If it is 0, then the setting of `mntentfsnoautomove` will be used. See `mntentfsnoautomove` below. This option can be changed after the file is mounted by changing this bit and setting the request bit, `mntentnewauto`, to 1 before calling `__mount()`. If changed to 0, also set `mntentfsnoautomove` to indicate automove or no move.
  - `mntentfsclient` If it is 0, then the file system is a sysplex client. If it is 1, then the file system is not a sysplex client.
**Note:** Note that `mntentfsclient` is not an input parameter.

`mntentfsnoautomove`

If it is 0 after the file system is mounted, it can be moved automatically. If it is 1 after the file system is mounted, it will not be moved automatically. The mode can be reversed after the file is mounted (when `mntentfsaunmount` is 0) by changing this bit and setting the request bit, `mnte2ntnewauto`, to 1 before calling `__mount()`.

**Note:** The setting of this bit only applies if `mntentfsaunmount` is 0.

`mntentfsmodenosec`

If it is 1, then the file system will not enforce security checks. If it is 0, then the file system will enforce security checks.

`mntentfsmodeexport`

If it is 0, then the file system has not been exported by DFS. If it is 1, then the file system has been exported by DFS.

`mntentfsmoderonly`

If it is 0, then the file system is mounted as read/write. If it is 1, then the file system is mounted as read-only.

`mntentfsmodenosuid`

If it is 1, then the SETUID and SETGID mode flags will be ignored for programs that reside in this file system. If it is 0, then the SETUID and SETGID mode flags will be enforced for programs that reside in this file system. This information is returned by the function but should not be changed.

`mnt2_dev`

Device # which `stat` will return for all files in this file system. Not set on input to `__mount()`.

`mnt2_parentdev`

`st_dev` of parent file system. Not set on input to `__mount()`.

`mnt2_rootino`

The ino of the mount point. Not set on input to `__mount()`.

`mnt2_status`

Status of the file system. The field is not an input parameter. It can be tested on output after a successful request.

`mnt2_ddname`

The ddname specified on mount. 1 to 8 characters are allowed.

`mnt2_fstname`

The name of the file system type specified by the `FILESYS` statement. The name for the file system that will perform the mount. This 8-character name must match the TYPE operand on a `FILESYSTYPE` statement in the `BPXPRMxx` parmlib member for the file system. 1 to 8 characters are allowed.

`mnt2_fsname`

The name of the file system to be mounted; it must be unique within the system. For a hierarchical file system (HFS) data set, this is a 1-to-44-character MVS data set name specified as all uppercase letters. This name is terminated with NULL characters.
mnt2_pathlen  The length of mount point path.

mnt2_mountpoint  
The name of the directory where the file system is mounted. 1 to 1023 characters are allowed. Also refers to the mount point directory where the file system will be mounted.

mnt2_parmoffset  
Offset of mount parameter mnt2_parmreturn from mnt2_fstype. Also refers to a parameter passed to the physical file system that performs the mount. This parameter may not be required. The form and content of the parameter are determined by the physical file system. A hierarchical file system (HFS) data set does not require a parameter.

mnt2_parmlen  
The length of the mount parameter with size mnt2_parmreturn. Also refers to the length of the parameter argument. The maximum length is 1024 characters. A hierarchical file system data set does not require a parameter.

mnt2_sysname  
The name of the target system. 1 to 8 characters are allowed. Changing the target system is always supplied as sysname. For all other calls, sysname must be supplied as NULL or the target name will be changed. When sysname is supplied, the mnte2ntchange flag must be set off for a mount function call, or the mnte2ntchange flag must be set on for a change mount function call. When you specify system on a mount it means mount this file on this system or when you specify system on a change mount it means move the file system from where it is currently mounted to this system.

mnt2_qsystem  
The name of the quiesce system. 1 to 8 characters are allowed but the character(s) are padded with blanks and do not contain a NULL terminator. This field is an output only field from getmntent().

mnt2_fromsys  
The name of the system from which the file system has moved.

mnt2_flags  
The field containing the request flags. A flag field that specifies the change for existing mounted file system:

mnt2ntnewauto  
This flag instigates a change of mode which will effect the automove state depending on the value that is set for mnte2ntfsnoautomove. See the explanation under mnte2ntfsnoautomove.

mnt2ntchange  
The request in this w_mntent is a change to existing status or mode. This flag must be set on for all change mount requests. The w_mntent structure needs to modify either the mnte2ntfsname field or the mnte2ntmountpoint and mnte2ndpathlen fields. When the request is to mount a directory, then this flag must be set to off.

mnt2_status2  
The file system status extensions.

mnt2_success  
This field is used to return the number of successfully moved file systems when moving a collection of file systems. It is not used in other cases.

parm_point  
This field contains the mountpoint parameters to be used when
mounting a file system. It is a separate field in the mnte2 structure
but contiguously allocated following the w_mnte2 body. The
mnte2_parmoffset field contains the offset to the start of parm_point.

mnt2_syslistlength
Length of system list.

mnt2_syslistoffset
Offset of system list.

mnt2_aggnamelen
Length of the aggregate name in mnt2_aggnamel. The length does
not include the null terminating character, and is only valid if
mnt2_aggnamelo has a non-zero value.

mnt2_aggnamelo
The offset of mnt2_aggnam from w_mntent. If the value is zero,
then no aggregate name is returned.

The mnte3 structure can also be used in place of the mnte2 structure. The following
mnt3 fields are equivalent to their mnte2 counterparts, with appropriate changes to
the header fields to specify the usage of the mnte3 structure:

mnt3h_cbid
The mnte3 control block ID. Initialize it to "MNT3".

mnt3h_cblen
The mnte size. Initialize to the size of struct mnt3.

mh3_cursor

mh3_devno

mh_bodylen
The mnte size of w_mntent3. Must be initialized to the size of the
w_mntent3 body.

**Returned value**

If successful, `__mount()` returns 0.

If the `__mount()` is proceeding asynchronously, it returns 1.

If unsuccessful, `__mount()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBUSY</td>
<td>The specified file system is unavailable.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>A parameter was incorrectly specified. Verify <code>filesystype</code> and <code>mtm</code>. Another possible reason for this error is that the mount point is the root of a file system or that the file system is already mounted.</td>
</tr>
<tr>
<td>EIO</td>
<td>An I/O error occurred.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error is issued if more than <code>POSIX_SYMLOOP</code> (defined in the <code>limits.h</code> header file) symbolic links are detected in the resolution of <code>pathname</code>.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>The mount point does not exist.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>There is not enough storage available to save the information required for this file system.</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>The mount point is not a directory.</td>
</tr>
<tr>
<td>EPERM</td>
<td>Appropriate authority is required to issue a mount.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
<tr>
<td>z/OS UNIX</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/mman.h>

int mprotect(void *addr, size_t len, int prot);
```

General description

The mprotect() function changes the access protections on the mappings specified by the `len` up to the next multiple of the page size as returned by `sysconf()`, to be that specified by `prot`. Legitimate values for `prot` are the same as those permitted for `mprotect()` and are defined in `<sys/mman.h>`:

- PROT_READ  page can be read
- PROT_WRITE page can be written
- PROT_EXEC  page can be executed
- PROT_NONE  page cannot be accessed

The range provided by the `Map_address` and `Map_length` may span regular maps as well as __MAP_MEGA maps. Mprotect affects __MAP_MEGA maps very differently than regular maps. The difference is in the scope of the change. When a change is made to a __MAP_MEGA map, the change affects all processes which are currently mapped to the same file-offset range represented by the pages within the provided range. For example, changing a file-offset range (storage pages) that is currently in use with a protection of write to a protection of read, makes the file-offset range read for all processes, not just the current one. In other words, the changes are global. On the other hand, changes to regular maps affect only the process that issues mprotect.

When mprotect() fails for reasons other than EINVAL, the protection on some of the pages in the range `[addr, addr + len)` may have been changed.

Returned value

If successful, mprotect() returns 0.

If unsuccessful, mprotect() returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The <code>prot</code> argument specifies a protection that violates the access permission the process has to the underlying memory object.</td>
</tr>
<tr>
<td>EAGAIN</td>
<td>The <code>prot</code> argument specifies PROT_WRITE over a MAP_PRIVATE mapping and there are insufficient memory resources to reserve for locking the private page.</td>
</tr>
</tbody>
</table>
EINVAL

The `addr` argument is not a multiple of the page size as returned by `sysconf()`.

ENOMEM

Addresses in the range `[addr, addr + len)` are invalid for the address space of a process, or specify one or more pages

</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdlib.h>

long int mrand48(void);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval \([0.0,1.0)\).

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval \([0,2^{31})\).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval \([-2^{31},2^{31})\).

The mrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, \(X(i)\), according to the linear congruential formula:

\[
X(n+1) = (aX(n) + c) \mod (2^{48}) \quad n\geq0
\]

The initial values of \(X\), \(a\), and \(c\) are:

\[
X(0) = 1 \\
a = \text{5deece66d (base 16)} \\
c = \text{b (base 16)}
\]

C/370 provides storage to save the most recent 48-bit integer value of the sequence, \(X(i)\). This storage is shared by the drand48(), lrand48() and mrand48() functions. The value, \(X(n)\), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function. Likewise, the values of \(a\) and \(c\), may be changed by calling the lcong48() function. Thereafter, whenever the seed48() or srand48() function is called to change \(X(n)\), the initial values of \(a\) and \(c\) are also reestablished.

Special behavior for z/OS UNIX services

You can make the mrand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.
If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for \( X(n) \), \( a \) and \( c \) by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, and the \texttt{mrand48()} function is called from thread \( t \), the \texttt{mrand48()} function generates the next 48-bit integer value in a sequence of 48-bit integer values, \( X(t,i) \), for the thread \( t \). The sequence of values for a thread is generated according to the linear congruential formula:

\[
X(t,n+1) = (a(t)X(t,n) + c(t)) \mod 2^{48} \quad n \geq 0
\]

The initial values of \( X(t) \), \( a(t) \) and \( c(t) \) for the thread \( t \) are:

\[
\begin{align*}
X(t,0) &= 1 \\
a(t) &= \text{5deece66d (base 16)} \\
c(t) &= \text{b (base 16)}
\end{align*}
\]

C/370 provides storage which is specific to the thread \( t \) to save the most recent 48-bit integer value of the sequence, \( X(t,i) \), generated by the \texttt{drand48()}, \texttt{lrand48()} or \texttt{mrand48()} function. The value, \( X(t,n) \), in this storage may be reinitialized by calling the \texttt{lcong48()}, \texttt{seed48()} or \texttt{srand48()} function from the thread \( t \). Likewise, the values of \( a(t) \) and \( c(t) \) for thread \( t \) may be changed by calling the \texttt{lcong48()} function from the thread. Thereafter, whenever the \texttt{seed48()} or \texttt{srand48()} function is called from the thread \( t \) to change \( X(t,n) \), the initial values of \( a(t) \) and \( c(t) \) are also reestablished.

**Returned value**

\texttt{mrand48()} transforms the generated 48-bit value, \( X(n+1) \), to a signed long integer value on the interval \([-2^{31},2^{31})\) and returns this transformed value.

**Special behavior for z/OS UNIX Services**

If thread-specific behavior is requested for the drand48 family and the \texttt{mrand48()} function is called on thread \( t \), the \texttt{mrand48()} function transforms the generated 48-bit value, \( X(t,n+1) \), to a signed long integer value on the interval \([-2^{31},2^{31})\) and returns this transformed value.

m_setvalues_layout

m_setvalues_layout() — Set layout values of a layout object (bidi data)

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td>z/OS V1R2</td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <sys/layout.h>

int m_setvalues_layout(LayoutObject layout_object, const LayoutValues values,
                        int *index_returned);
```

General description

The m_setvalues_layout() function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The m_setvalues_layout() function is used to change the layout values of a LayoutObject. The layout_object argument specifies a LayoutObject returned by the m_create_layout() function. The values argument specifies the list of layout values which are to be changed. The values are written into the LayoutObject and may affect the behavior of subsequent layout functions.

**Note:** Some layout values do alter internal states maintained by a LayoutObject.

The m_setvalues_layout() function can be implemented as a macro that evaluates the first argument twice.

Returned value

If successful, m_setvalues_layout() sets the requested layout values and returns 0.

If any value cannot be set, m_setvalues_layout() does not change any of the layout values. It stores into index_returned the (zero-based) index of the value causing the error. It returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The layout value specified by index_returned is unknown or its value is invalid or the argument layout_object is invalid.</td>
</tr>
</tbody>
</table>

msgctl() — Message control operations

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <sys/msg.h>

int msgctl(int msgid, int cmd, struct msqid_ds *buf);
```

General description

The msgctl() function provides message control operations as specified by `cmd`. The following values for `cmd`, and the message control operations they specify, are (These symbolic constants are defined by the `<sys/ipc.h>` header):

- **IPC_STAT** Place the current value of each member of the `msqid_ds` data structure associated with `msgid` into the structure pointed to by `buf`. The contents of this structure are defined in `<sys/msg.h>`. This command requires read permission.

- **IPC_SET** Set the value of the following members of the `msqid_ds` data structure associated with `msgid` to the corresponding value found in the structure pointed to by `buf`:
  - `msg_perm.uid`
  - `msg_perm.gid`
  - `msg_perm.mode`
  - `msg_qbytes`

  IPC_SET can only be executed by a process with the appropriate privileges or that has an effective user ID equal to the value of `msg_perm.cuid` or `msg_perm.uid` in the `msqid_ds` data structure associated with `msgid`. Only a process with appropriate privileges can raise the value of `msg_qbytes`.

- **IPC_RMID** Remove the message queue identifier specified by `msgid` from the system and destroy the message queue and `msqid_ds` data structure associated with it. IPC_RMID can only be executed by a process with appropriate privileges or one that has an effective user ID equal to the value of `msg_perm.cuid` or `msg_perm.uid` in the `msqid_ds` data structure associated with `msgid`.

Returned value

If successful, `msgctl()` returns 0.

If unsuccessful, `msgctl()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The argument <code>cmd</code> is IPC_STAT and the calling process does not have read permission.</td>
</tr>
</tbody>
</table>
EINVAL  The value of msgid is not a valid message queue identifier, or the value of cmd is not a valid command.

EPERM  The argument cmd is IPC_RMID or IPC_SET and the effective user ID of the calling process is not equal to that of a process with appropriate privileges and it is not equal to the value of msg_perm.cuid or msg_perm.uid in the data structure associated with msgid.

Or the argument cmd is IPC_SET, an attempt is being made to increase the value of msg_qbytes, and the effective user ID of the calling process does not have appropriate privileges.

msgget() — Get message queue

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <sys/msg.h>

int msgget(key_t key, int msgflg);
```

General description

The msgget() function returns the message queue identifier associated with the argument `key`.

A message queue identifier, associated message queue and data structure (see `<sys/msg.h>`) are created for the argument `key` if one of the following is true:

- The argument `key` is equal to `IPC_PRIVATE`
- The argument `key` does not already have a message queue identifier associated with it, and the flag `IPC_CREAT` is on in `msgflg`.

Valid values for the argument `msgflg` include any combination of the following constants defined in `<sys/ipc.h>` and `<sys/modes.h>`:

- **IPC_CREAT** Create a message queue if the `key` specified does not already have an associated ID. `IPC_CREAT` is ignored when `IPC_PRIVATE` is specified
- **IPC_EXCL** Causes the msgget() function to fail if the `key` specified has an associated ID. `IPC_EXCL` is ignored when `IPC_CREAT` is not specified or `IPC_PRIVATE` is specified
- **IPC_RCVTYPEPID** Creates a message queue that can only be read from msgrcv() when Message_Type is the process ID of the invoker. This restriction does not apply if the msgrcv() invoker has the same effective UID as the message queue creator.
- **IPC_SNDTYPEPID** Creates a message queue that can only be written to msgsnd() when MSG_TYPE is the process ID of the invoker. This restriction does not apply if the msgsnd() invoker has the same effective UID as the message queue creator.
- **S_IRUSR** Permits read access when the effective user ID of the caller matches either `msg_perm.cuid` or `msg_perm.uid`
- **S_IWUSR** Permits write access when the effective user ID of the caller matches either `msg_perm.cuid` or `msg_perm.uid`
- **S_IRGRP** Permits read access when the effective group ID of the caller matches either `msg_perm.cgid` or `msg_perm.gid`
msgget

S_IWGRP Permits write access when the effective group ID of the caller matches either msg_perm.cgid or msg_perm.gid

S_IROTH Permits other read access

S_IWOTH Permits other write access

When a message set associated with argument key already exists, setting IPC_EXCL and IPC_CREAT in argument msgflg will force msgget() to fail.

Upon creation, the msg_ds data structure associated with the new message queue identifier is initialized as follows:

- The fields msg_perm.cuid, msg_perm.uid, msg_perm.cgid, and msg_perm.gid are set equal to the effective user ID and effective group ID, respectively, of the calling process.
- The low-order 9 bits of msg_perm.mode are set equal to the low-order 9 bits of msgflg.
- The fields msg_qnum, msg_lspid, msg_lrpid, msg_stime, and msg_rtime are set to zero.
- The field msg_ctime is set equal to the current time.
- The field msg_qbytes is set equal to the system limit.

Usage notes

1. In a client/server environment, two message queues can be used. One inbound to the server created with IPC_SNDTYPEPID and the other outbound from the server created with IPC_RCVTYPEPID. This arrangement guarantees that the server knows the process ID of the client and the client is the only process that receives the server's returned message. The server may invoke msgrcv() with PID=0 to see if any messages belong to process IDs that have gone away.

2. Important terms and their descriptions are explained:

<table>
<thead>
<tr>
<th>Term</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLO</td>
<td>Perform Lock Operation.</td>
</tr>
<tr>
<td>IPC_PLO1</td>
<td>Use PLO serialization (if available) until a select() involving this message queue is detected.</td>
</tr>
<tr>
<td>IPC_PLO2</td>
<td>Allow the kernel to use its best judgment with serialization (IPC_PLO1 ignored).</td>
</tr>
</tbody>
</table>

- Message Flags IPC_PLO1 and IPC_PLO2 are ignored if the PLO instruction is not present on the hardware.
- Performance of the PLO instruction for serialization will vary with the msgrcv type, number of messages on the queue and the number of tasks doing msgsnd() and msgrcv(). Msgrcv() with type<0 and long message queues is expected to be a worse performer. Msgrcv() with type>0 is expected to be an equivalent or good performer. Msgrcv() with type=0 is expected to be a very good performer.
- Message queues created with Ipc_RcvTypePID, Ipc_SndTypePID, IPC_PLO1 and IPC_PLO2 will show these bits and may show the IPC_PLOINUSE bit in the S_MODE byte returned with w_getipc.
- Message queue PLO serialization is not compatible with select() using message queues. When msgrcv() detects a select() for a message queue, serialization will be changed to use traditional latches.
- Performance runs should be made with IPC_PLO1 since IPC_PLO2 may switch to latch serialization and the user would not know when.
Returned value

If successful, msgget() returns a nonnegative integer, namely a message queue identifier.

If unsuccessful, msgget() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>A message queue identifier exists for the argument key, but access permission as specified by the low-order 9 bits of msgflg could not be granted</td>
</tr>
<tr>
<td>EEXIST</td>
<td>A message queue identifier exists for the argument key, but both IPC_CREAT and IPC_EXCL are specified in msgflg</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of argument msgflg is not currently supported</td>
</tr>
<tr>
<td>ENOENT</td>
<td>A message queue identifier does not exist for the argument key and IPC_CREAT is not specified.</td>
</tr>
<tr>
<td>ENOSPC</td>
<td>A message queue identifier is to be created but the system-imposed limit on the maximum number of allowed message queue identifiers system-wide would be exceeded.</td>
</tr>
</tbody>
</table>

When msgflg equals 0, the following applies:

- If a message queue identifier has already been created with key earlier, and the calling process of this msgget() has read and/or write permissions to it, then msgget() returns the associated message queue identifier.
- If a message queue identifier has already been created with key earlier, and the calling process of this msgget() does not have read and/or write permissions to it, then msgget() returns -1 and sets errno to EACCES.
- If a message queue identifier has not been created with key earlier, then msgget() returns -1 and sets errno to ENOENT.

msgrcv

**msgrcv() — Message receive operation**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

**Non-Single UNIX Specification, Version 2**

```c
#define _XOPEN_SOURCE
#include <sys/msg.h>

int msgrcv(int msgid, void *msgp, size_t msgsz, long int msgtyp, int msgflg);
```

**Single UNIX Specification, Version 2**

```c
#define _XOPEN_SOURCE 500
#include <sys/msg.h>

ssize_t msgrcv(int msgid, void *msgp, size_t msgsz, long int msgtyp, int msgflg);
```

**General description**

The `msgrcv()` function reads a message from the queue associated with the message queue identifier specified by `msgid` and places it in the user-defined buffer pointed to by `msgp`.

The argument `msgp` points to a user-defined buffer that must contain first a field of type `long int` that will specify the type of the message, and then a data portion that will hold the data bytes of the message. The structure below is an example of what this user-defined buffer should look like:

```c
struct message
{
    long int mtype;  // Message type
    int mtext[n];    // Message text
}
```

The structure member, `mtype`, is the received message's type as specified by the sending process. The structure member, `mtext`, is the text of the message.

The argument `msgsz` specifies the size in bytes of `mtext`. The received message is truncated to `msgsz` bytes if it is larger than `msgsz` and the `MSG_NOERROR` flag was specified in the argument `msgflg`. The truncated portion of the message is lost and no indication of the truncation is given to the calling process.

The argument `msgtyp` specifies the type of message requested, as follows:

- If `msgtyp` is equal to zero, the first message on the queue is received.
- If `msgtyp` is greater than 0, the first message of type, `msgtyp`, is received.
- If `msgtyp` is less than 0, the first message of the lowest type that is less than or equal to the absolute value of `msgtyp` is received.

The argument `msgflg` specifies the action to be taken if a message of the desired type is not on the queue. These are as follows:
If the **IPC_NOWAIT** flag is on in `msgflg`, the calling process will return immediately with a return value of −1 and `errno` set to **ENOMSG**.

If the **IPC_NOWAIT** flag is off in `msgflg` the calling process will suspend execution until one of the following occurs:

- A message of the desired type is placed on the queue.
- The message queue identifier, `msgid`, is removed from the system; when this occurs, `errno` is set to **EIDRM** and a value of −1 is returned.
- The calling process receives a signal that is to be caught; in this case a message is not received and the calling process resumes execution. A value of −1 is returned and `errno` is set to **EINTR**.

If successful, the following actions are taken with respect to the data structure, `msgq_ds`, associated with `msgid`:

1. `msg_qnum` is decremented by 1.
2. `msg_lrpids` is set equal to the process ID of the calling process.
3. `msg_rtime` is set equal to the current time.

## Returned value

If successful, `msgrcv()` returns a value equal to the number of bytes actually placed into the `mtext` field of the user-defined buffer pointed to by `msgp`. A value of zero indicates that only the `mtype` field was received from the message queue.

If unsuccessful, `msgrcv()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2BIG</td>
<td>The value of <code>mtext</code> is greater than <code>msgsz</code> and the flag <strong>MSG_NOERROR</strong> was not specified.</td>
</tr>
<tr>
<td>EACCES</td>
<td>The calling process does not have read permission to the message queue associated with the message queue identifier <code>msgid</code> or the message queue was built with <code>IPC_RCVTYPEPID</code> and the Message_Type was other than the invoker's process ID (JRTYPENotPID).</td>
</tr>
<tr>
<td>EIDRM</td>
<td>The message queue identifier, <code>msgid</code>, has been removed from the system while the caller of <code>msgrcv()</code> was waiting.</td>
</tr>
<tr>
<td>EINTR</td>
<td>The function <code>msgrcv()</code> was interrupted by a signal before a message could be received.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of argument <code>msgid</code> is not a valid message queue identifier or the value of <code>msgsz</code> is less than zero.</td>
</tr>
<tr>
<td>ENOMSG</td>
<td>The flag <strong>IPC_NOWAIT</strong> was specified and the message queue does not contain a message of the desired type.</td>
</tr>
</tbody>
</table>

__msgrcv_timed

__msgrcv_timed() — Message receive operation with timeout

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R10</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_TIMED_EXT 1
#include <time.h>
#include <sys/msg.h>

int __msgrcv_timed(int msgid, void *msgp, size_t msgsz,
                   long int msgtyp, int msgflg, struct timespec *set);
```

General description

Reads a message from the queue associated with the message queue identifier specified by `msgid` and places it in the user-defined buffer pointed to by `msgp`.

The argument `msgp` points to a user-defined buffer that must contain first a field of type long int that will specify the type of the message, and then a data portion that will hold the data bytes of the message. The structure below is an example of what this user-defined buffer should look like:

```c
struct message {
    long int mtype; Message type
    int mtext[n]; Message text
}
```

The structure member, `mtype`, is the received message's type as specified by the sending process. The structure member, `mtext`, is the text of the message.

The argument `msgsz` specifies the size in bytes of `mtext`. The received message is truncated to `msgsz` bytes if it is larger than `msgsz` bytes and the `MSG_NOERROR` flag was specified in the argument `msgflg`. The truncated portion of the message is lost and no indication of the truncation is given to the calling process.

The argument `msgtyp` specifies the type of message requested, as follows:

- If `msgtyp` is equal to zero, the first message on the queue is received.
- If `msgtyp` is greater than 0, the first message of type, `msgtyp`, is received.
- If `msgtyp` is less than 0, the first message of the lowest type that is less than or equal to the absolute value of `msgtyp` is received.

The argument `msgflg` specifies the action to be taken if a message of the desired type is not on the queue. These are as follows:

The argument `set` is the timespec structure which contains the timeout value.

- If the `IPC_NOWAIT` flag is on in `msgflg`, the calling process will return immediately with a return value of -1 and `errno` set to ENOMSG.
- If the `IPC_NOWAIT` flag is off in `msgflg` the calling process will suspend execution until one of the following occurs:
  - A message of the desired type is placed on the queue.
__msgrcv_timed

- The message queue identifier, msgid, is removed from the system; when this occurs, errno is set to EIDRM and a value of −1 is returned.
- The calling process receives a signal that is to be caught; in this case a message is not received and the calling process resumes execution. A value of −1 is returned and errno is set to EINTR.

If successful, the following actions are taken with respect to the data structure, msqid_ds, associated with msgid:
1. msg_qnum is decremented by 1.
2. msg_lrpid is set equal to the process ID of the calling process.
3. msg_rtime is set equal to the current time.

The variable set gives the timeout specification.
- If the __msgrcv_timed() function finds that none of the messages specified by msgid are received, it waits for the time interval specified in the timespec structure referenced by set. If the timespec structure pointed to by set is zero-valued and if none of the messages specified by msgid are received, then __msgrcv_timed() returns immediately with EAGAIN. A timespec with the tv_sec field set with INT_MAX, as defined in <limits.h>, will cause the __msgrcv_timed() service to wait until a message is received. If set is the NULL pointer, it will be treated the same as when timespec structure was supplied with the tv_sec field set with INT_MAX.

Returned value

If successful, __msgrcv_timed() returns a value equal to the number of bytes actually placed into the mtext field of the user-defined buffer pointed to by msgp. A value of zero indicates that only the mtype field was received from the message queue.

If unsuccessful, __msgrcv_timed() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2BIG</td>
<td>The value of mtext is greater than msgsz and the flag MSG_NOERROR was not specified.</td>
</tr>
<tr>
<td>EACCES</td>
<td>The calling process does not have read permission to the message queue associated with the message queue identifier msgid.</td>
</tr>
<tr>
<td>EAGAIN</td>
<td>The operation would result in time requested expired before any messages were received. This would result if the timeout specified expires before a message is posted.</td>
</tr>
<tr>
<td>EIDRM</td>
<td>The message queue identifier, msgid, has been removed from the system while the caller of __msgrcv_timed() was waiting.</td>
</tr>
<tr>
<td>EINTR</td>

**msgsnd() — Message send operations**

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++ Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
</tr>
</tbody>
</table>

### Format

```c
#define _XOPEN_SOURCE
#include <sys/msg.h>

int msgsnd(int msgid, const void *msgp, size_t msgsz, int msgflg);
```

### General description

The `msgsnd()` function is used to send a message to the queue associated with the message queue identifier specified by `msgid`.

The argument `msgp` points to a user-defined buffer that must contain first a field of type `long int` that will specify the type of the message, and then a data portion that will hold the data bytes of the message. The structure below is an example of what this user-defined buffer should look like:

```c
struct message
{
    long int mtype;  // Message type
    int mtext[n];   // Message text
}
```

The structure member, `mtype`, must be a nonzero positive value that can be used by the receiving process for message selection. The structure member, `mtext`, is any text of length, `msgsz`, bytes.

The argument `msgsz` specifies the size in bytes of `mtext`. When only `mtype` is to be sent with no `mtext`, `msgsz` is set to zero. The argument can range from zero to a system-imposed maximum or the maximum number of bytes allowed in the message queue.

The argument `msgflg` specifies the action to be taken if one or more of the following are true:

- Placing the message on the message queue would cause the current number of bytes on the message queue (`msg_cbytes`) to exceed the maximum number of bytes allowed on this queue, as specified in `msg_qbytes`.
- The total number of messages on the queue is equal to the system-imposed limit.

These actions are as follows:

- If the **IPC_NOWAIT** flag is on in `msgflg`, the message not be sent and the calling process will return immediately. `msgsnd()` will return -1 and set `errno` to EAGAIN.
- If the **IPC_NOWAIT** flag is off in `msgflg`, the calling process will suspend execution until one of the following occurs:
  1. The condition responsible for the suspension no longer exists, in which case the message is sent.
2. The message queue identifier, *msgid*, is removed from the system; when this occurs, errno is set to EIDRM and a value of -1 is returned.

3. The calling process receives a signal that is to be caught; in this case a message is not sent and the calling process resumes execution. A value of -1 is returned and error is set to EINTR.

If successful, the following actions are taken with respect to the data structure, *msqid_ds*, associated with *msgid*:

1. msg_qnum is incremented by 1.
2. msg_lspid is set equal to the process ID of the calling process.
3. msg_stime is set equal to the current time.

**Returned value**

If successful, msgsnd() returns 0.

If unsuccessful, no message is sent, msgsnd() returns -1, and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The calling process does not have write permission to the message queue associated with the message queue identifier <em>msgid</em> or the message queue was built with IPC_SNDTYPEPID and the MSG_TYPE was other than the invoker's process ID (JRTypeNotPID).</td>
</tr>
<tr>
<td>EAGAIN</td>
<td>The message cannot be sent for one of the reasons cited above and IPC_NOWAIT was specified.</td>
</tr>
<tr>
<td>EIDRM</td>
<td>The message queue identifier, <em>msgid</em>, has been removed from the system while the caller of msgsnd() was waiting.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The function msgsnd() was interrupted by a signal before a message could be sent.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of argument <em>msgid</em> is not a valid message queue identifier, or the value of mtype is less than 1; or the value of msgsz is less than zero or greater than the system-imposed limit.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Not enough system storage exists to complete the msgsnd() function.</td>
</tr>
</tbody>
</table>

msgxrcv() — Extended message receive operation

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_IPC_EXTENSIONS
#include <sys/msg.h>

int msgxrcv(int msgid, void *msgp, size_t msgsz, long int msgtyp, int msgflg);
```

Note: To expose the msgxrcv() name, the feature test macro _OPEN_SYS_IPC_EXTENSIONS should be defined. Otherwise, the function's name is __msgxrcv().

General description

The msgxrcv() function reads an extended message from the queue associated with the message queue identifier specified by `msgid` and places it in the user-defined buffer pointed to by `msgp`.

The argument `msgp` points to a user-defined buffer where the extended message will be received. This buffer must be defined by a data structure of the following format:

```c
typedef struct msgxbuf {
    time_t mtime;   // Time and date message was sent
    uid_t muid;     // Sender's effective user ID
    gid_t mgid;     // Sender's effective group ID
    pid_t mpid;     // Sender's process ID
    long int mtype; // Message type
    int mtext[n];  // Message text
} msgxbuf;
```

The structure member, `mtype`, is the received message's type as specified by the sending process. The structure member, `mtext`, is the text of the message.

The argument `msgsz` specifies the size in bytes of `mtext`. The received message is truncated to `msgsz` bytes if it is larger than `msgsz` and the MSG_NOERROR flag was specified in the argument `msgflg`. The truncated portion of the message is lost and no indication of the truncation is given to the calling process.

The argument `msgtyp` specifies the type of message requested, as follows:

- If `msgtyp` is equal to zero, the first message on the queue is received.
- If `msgtyp` is greater than 0, the first message of type, `msgtyp`, is received.
- If `msgtyp` is less than 0, the first message of the lowest type that is less than or equal to the absolute value of `msgtyp` is received.

The argument `msgflg` specifies the action to be taken if a message of the desired type is not on the queue. These are as follows:

- If the IPC_NOWAIT flag is on in `msgflg`, the calling process will return immediately with a return value of −1 and errno set to ENOMSG.
msgxrcv

- If the **IPC_NOWAIT** flag is off in **msgflg** the calling process will suspend execution until one of the following occurs:
  - A message of the desired type is placed on the queue.
  - The message queue identifier, **msgid**, is removed from the system; when this occurs, **errno** is set to EIDRM and a value of −1 is returned.
  - The calling process receives a signal that is to be caught; in this case a message is not received and the calling process resumes execution. A value of −1 is returned and **errno** is set to EINTR.

If successful, the following actions are taken with respect to the data structure, **msgid_ds**, associated with **msgid**:
1. **msg_qnum** is decremented by 1.
2. **msg_lrpid** is set equal to the process ID of the calling process.
3. **msg_rtime** is set equal to the current time.

**Returned value**

If successful, **msgxrcv()** returns a value equal to the number of bytes actually placed into the **mtext** field of the user-defined buffer pointed to by **msgp**. A value of zero indicates that only the **mtype** field was received from the message queue.

If unsuccessful, **msgxrcv()** returns −1 and sets **errno** to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>

msync() — Synchronize memory with physical storage

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2 Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/mman.h>

int msync(void *addr, size_t len, int flags);
```

General description

The msync() function writes all modified copies of pages over the range `[addr, addr + len)` to the underlying hardware, or invalidates any copies so that further references to the pages will be obtained by the system from their permanent storage locations.

The `flags` argument is:

- **MS_ASYNC** Perform asynchronous writes
- **MS_INVALIDATE** Invalidate mappings
- **MS_SYNC** Perform synchronous writes

The function synchronizes the file contents to match the current contents to the memory region.

- All write references to the memory region made before the call are visible by subsequent read operations on the file.
- It is unspecified whether writes to the same portion of the file before the call are visible by read references to the memory region.
- It is unspecified whether unmodified pages in the specified range are also written to the underlying hardware.

If `flags` is **MS_ASYNC**, the function may return immediately once all write operations are schedule; if `flags` is **MS_SYNC**, the function does not return until all write operations are completed.

**MS_INVALIDATE** synchronizes the contents of the memory region to match the current file contents.

- All writes to the mapped portion of the file made before the call are visible by subsequent read references to the mapped memory region.
- It is unspecified whether write references before the call, by any process, to memory regions mapped to the same portion of the file using MAP_SHARED, are visible by read references to the region.

If msync() causes any write to the file, then the file's `st_ctime` and `st_mtime` fields are marked for update.
msync

Returned value

If successful, msync() returns 0.

If unsuccessful, msync() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The <code>addr</code> argument is not a multiple of the page size as returned by <code>sysconf</code>.</td>
</tr>
<tr>
<td>EIO</td>
<td>An I/O error occurred while reading from or writing to the file system.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Some or all the addresses in the range <code>[addr, addr + range [addr, addr + len)]</code> are invalid for the address space of the process or pages not mapped are specified.</td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/layout.h>

int m_transform_layout(LayoutObject layout_object,
                        const char *InpBuf,
                        const size_t InpSize,
                        void *OutBuf,
                        size_t *Outsize,
                        size_t *InpToOut,
                        size_t *OutToInp,
                        unsigned char *Property,
                        size_t *InpBufIndex);
```

General description

The `m_transform_layout()` function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The `m_transform_layout()` function performs layout transformations (reordering, shaping, cell determination). Alternatively, it may provide additional information needed for layout transformation, such as:

- The expected size of the transformed layout
- The nesting level of different segments in the text
- Cross references between the locations of the corresponding elements before and after the layout transformation.

Both the input text and output text are character strings. The `m_transform_layout()` function transforms the input text in `InpBuf` according to the current layout values in `layout_object`.

Any layout value whose value type is `LayoutTextDescriptor` describes the attributes of the `InpBuf` and `OutBuf` arguments. If the attributes are the same for both `InpBuf` and `OutBuf`, a null transformation is performed with respect to that specific layout value.

The `InpBuf` argument specifies the source text to be processed. The `InpBuf` may not be NULL, except when there is a need to reset the internal state.

The `InpSize` argument is the number of bytes within `InpBuf` to be processed by the transformation. Its value will not have changed at the return from the transformation. `InpSize` set to -1 indicates that the text in `InpBuf` is delimited by a NULL code element. If `InpSize` is not set to -1, it is possible to have some NULL elements in the input buffer. This might be used, for example, for a one shot transformation of several strings, separated by NULLs.
Outputs of this function may be one or more of the following, depending on the setting of the arguments:

<table>
<thead>
<tr>
<th>Output</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OutBuf</td>
<td>Any transformed data is stored in OutBuf, converted to ShapeCharset.</td>
</tr>
<tr>
<td>Outsize</td>
<td>The number of bytes in OutBuf.</td>
</tr>
<tr>
<td>InpToOut</td>
<td>A cross reference from each InpBuf code element to the transformed data.</td>

</tr>
</tbody>
</table>
m_transform_layout

transformed. If the entire substring has been transformed successfully, `InpBufIndex` will be incremented by the amount defined by `InpSize`.

Each of these output arguments may be NULL to specify that no output is desired for the specific argument, but at least one of them should be set to non-NULL to perform any significant work.

The `layout_object` maintains a directional state that keeps track of directional changes, based on the last segment transformed. The directional state is maintained across calls to the layout transformation functions and allows stream data to be processed with the layout functions. The directional state is reset to its initial state whenever any of the layout values `TypeOfText`, `Orientation` or `ImplicitAlg` is modified by means of a call to `m_setvalues_layout()`.

The `layout_object` argument specifies a LayoutObject returned by the `m_create_layout()` function.

The `OutBuf` argument contains the transformed data. This argument can be specified as a NULL pointer to indicate that no transformed data is required. The encoding of the `OutBuf` argument depends on the `ShapeCharset` layout value defined in `layout_object`. If the `ActiveShapeEditing` layout value is not set (False), the encoding of `OutBuf` is guaranteed to be the same as the codeset of the locale associated with the LayoutObject defined by `layout_object`.

On input, the `OutSize` argument specifies the size of the output buffer in number of bytes. The output buffer should be large enough to contain the transformed result; otherwise, only a partial transformation is performed. If the `ActiveShapeEditing` layout value is set (True), the `OutBuf` should be allocated to contain at least the `InpSize` multiplied by `ShapeCharsetSize`.

Upon return, the `OutSize` argument is updated to be the actual number of bytes placed in `OutBuf`.

When the `OutSize` argument is specified as zero, the function calculates the size of an output buffer large enough to contain the transformed text, and the result is returned in this field. The content of the buffers specified by `InpBuf` and `OutBuf`, and the value of `InpBufIndex`, remain unchanged.

If `OutSize` = NULL, the EINVAL error condition is returned.

If the `InpToOut` argument is not a NULL pointer, it points to an array of values with the same number of bytes as `InpBuf`, starting with the one pointed by `InpBufIndex` and up to the end of the substring in the buffer.

On output, the nth value in `InpToOut` corresponds to the nth byte in `InpBuf`. This value is the index (in units of bytes) in `OutBuf` that identifies the transformed `ShapeCharset` element of the nth byte in `InpBuf`.

In the case of multibyte encoding, for each of the bytes of a code element in the `InpBuf`, the index points to the first byte of the transformed code element in the `OutBuf`. `InpToOut` may be specified as NULL if no index array from `InpBuf` to `OutBuf` is desired.
m_transform_layout

If the OutToInp argument is not a NULL pointer, it points to an array of values with the same number of bytes as contained in OutBuf. On output, the nth value in OutToInp corresponds to the nth byte in OutBuf. This value is the index in InpBuf, starting with the byte pointed to by InpBufIndex, that identifies the logical code element of the nth byte in OutBuf.

In the case of multibyte encoding, the index will point, for each of the bytes of a transformed code element in the OutBuf, to the first byte of the code element in the InpBuf.

OutToInp may be specified as NULL if no index array from OutBuf to InpBuf is desired.

To perform shaping of a text string without reordering of code elements, the layout object should be set with input and output layout value TypeOfText set to TEXT_VISUAL, and both in and out of Orientation set to the same value.

Returned value

If successful, m_transform_layout() returns 0.

If unsuccessful, m_transform_layout() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2BIG</td>
<td>The size of OutBuf is not large enough to contain the entire transformed text. The input text state at the end of the uncompleted transformation is saved internally.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The layout values are set to a meaningless combination or the layout object is not valid.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Transformation stopped due to an incomplete composite sequence at the end of the input buffer, or OutSize contains NULL.</td>
</tr>
</tbody>
</table>

munmap() — Unmap pages of memory

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>z/OS UNIX</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/mman.h>

int munmap(void *addr, size_t len);
```

General description

The munmap() function removes the mappings for pages in the range `[addr, addr + len)` rounding the `len` argument up to the next multiple of the page size as returned by `sysconf()`. If `addr` is not the address of a mapping established by a prior call to `mmap()`, the behavior is undefined. After a successful call to `munmap()` and before any subsequent mapping of the unmapped pages, further references to these pages will result in the delivery of a SIGBUS or SIGSEGV signal to the process.

__MAP_MEGA mapping:__ The munmap service removes the mapping for pages in the requested range. The requested range may span multiple maps, and the maps may represent the same or different files. The pages in the range may be part of a regular mapping or may be part of a __MAP_MEGA mapping. When unmapping a regular mapping, entire pages are unmapped; when unmapping a __MAP_MEGA mapping, entire segments are unmapped.

__Map_address:__ The value of map address must be a multiple of the page size. The specified value does not have to be the start of a mapping. However, if the value specified for Map_address falls within a __MAP_MEGA map, then the address is rounded down to a megabyte multiple so that an entire segment is included in the unmap operation. It is not possible to unmap a part of a segment when processing a __MAP_MEGA map.

__Map_length:__ The length can be the size of the whole mapping, or a part of it. If the specified length is not in multiples of the page size, it will be rounded up to a page boundary. If the Map_address plus the Map_length falls within a __MAP_MEGA map, then the length is rounded up to a segment boundary, thus including the entire segment (not necessarily the entire __MAP_MEGA mapping).

Returned value

If successful, `munmap()` returns 0.

If unsuccessful, `munmap()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>One of the following error conditions exists:</td>
</tr>
<tr>
<td></td>
<td>• The <code>addr</code> argument is not a multiple of the page size as returned by <code>sysconf</code>.</td>
</tr>
</tbody>
</table>
munmap

- Addresses outside the valid range for the address space of a process.
- The len argument is 0.

__must_stay_clean() — Enable or query clean

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>Z/OS V1R8</td>
</tr>
</tbody>
</table>

Format

```c
#define __OPEN_SYS
#include <unistd.h>

int __must_stay_clean(int request);
```

General description

The __must_stay_clean() function queries or enables the "must stay clean" state for a process. A process that must stay clean is prohibited from doing an exec(), spawn(), or other load of a non-program controlled executable. Only a program controlled executable can enable the must stay clean state. The must stay clean state of a process is propagated to its children created using fork or spawn. Once the must stay clean state is enabled, it cannot be changed. All processes in the address space will be forced to stay clean until they have all terminated. The query support allows a process to determine if it was created in a trusted environment. The BPX.DAEMON class profile must be defined to use the enable function.

Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>Specify the value _MSC_QUERY to query the state. Specify the value _MSC_ENABLE to enable &quot;must stay clean&quot; for the process.</td>
</tr>
</tbody>
</table>

Returned value

If successful, __must_stay_clean() returns the current "must stay clean" state of the process. The following state values are possible:

- **_MSC_NOT_ENABLED**
  - The "must stay clean" state is not enabled.

- **_MSC_ENABLED**
  - The "must stay clean" state is enabled, meaning that it was set using this function, and that it will continue to be enabled even after an exec() that causes job step termination.

- **_MSC_ENABLED_COND**
  - The "must stay clean" state is enabled conditionally, meaning that a prior call to a security service, such as __passwd(), implicitly enabled the must stay clean state, and that the state will be reset to "not enabled" at the next exec() that causes job step termination. This state value can only be returned using the query request.

If unsuccessful, __must_stay_clean() returns _MSC_FAILED(-1) and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>A parameter was not valid.</td>
</tr>
</tbody>
</table>
| EMVSERR    | An MVS environmental error occurred. One possible cause is that a
must_stay_clean

'dirty' process attempted to enable the must stay clean attribute. Another cause could be that the BPX.DAEMON class profile is not defined.

EMVSSAF2ERR
An error occurred in the security product.

Example

/* celebm22.c */
/* This example shows how to use __must_stay_clean() to request */
/* the environment is to "stay clean" until all processes in the */
/* address space are terminated. */
/* Requirements: */
/* 1. The environment must already be clean, noting that the */
/* program issuing the request must be program-controlled */
/* 2. BPX.DAEMON must be defined */

#define _OPEN_SYS
#include <unistd.h>
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>

int main(void){
    int rc;
    rc = __must_stay_clean(_MSC_ENABLE); /* Stay Clean! */
    if (rc == __MSC_FAILED){
        perror("could not enable must stay clean");
        printf("errno=%d errno2=%08x\n",errno,__errno2());
        exit(1);
    }
    return 0;
}

                        size_t *InpToOut,
                        unsigned char *Property,
                        size_t *InpBufIndex);
```

General description

The `m_wtransform_layout()` function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The `m_wtransform_layout()` function performs layout transformations (reordering, shaping, cell determination). Alternatively, it may provide additional information needed for layout transformation, such as:

- The expected size of the transformed layout
- The nesting level of different segments in the text
- Cross references between the locations of the corresponding elements before and after the layout transformation.

Both the input text and output text are wide-character strings. The `m_wtransform_layout()` function transforms the input text in `InpBuf` according to the current layout values in `layout_object`.

Any layout value whose value type is `LayoutTextDescriptor` describes the attributes of the `InpBuf` and `OutBuf` arguments. If the attributes are the same for both `InpBuf` and `OutBuf`, a null transformation is performed with respect to that specific layout value.

The `InpBuf` argument specifies the source text to be processed. The `InpBuf` may not be NULL, except when there is a need to reset the internal state.

The `InpSize` argument is the number of characters within `InpBuf` to be processed by the transformation. Its value will not have changed at the return from the transformation. `InpSize` set to -1 indicates that the text in `InpBuf` is delimited by a NULL code element. If `InpSize` is not set to -1, it is possible to have some NULL elements in the input buffer. This might be used, for example, for a one shot transformation of several strings, separated by NULLs.
### Outputs of this function may be one or more of the following, depending on the setting of the arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>OutBuf</strong></td>
<td>Any transformed data is stored in <code>OutBuf</code>, converted to <code>ShapeCharset</code>.</td>
</tr>
<tr>
<td><strong>Outsize</strong></td>
<td>The number of wide characters in <code>OutBuf</code>.</td>
</tr>
<tr>
<td><strong>InpToOut</strong></td>
<td>A cross reference from each <code>InpBuf</code> code element to the transformed data. The cross reference relates to the data in <code>InpBuf</code>, starting with the first element that <code>InpBufIndex</code> points to (and not necessarily starting from the beginning of the <code>InpBuf</code>.)</td>
</tr>
<tr>
<td><strong>OutToInp</strong></td>
<td>A cross reference to each <code>InpBuf</code> code element from the transformed data. The cross reference relates to the data in <code>InpBuf</code>, starting with the first element that <code>InpBufIndex</code> points to (and not necessarily starting from the beginning of the <code>InpBuf</code>.)</td>
</tr>
<tr>
<td><strong>Property</strong></td>
<td>A weighted value that represents specific input string transformation properties with different connotations as explained below. If this argument is not a NULL pointer, it represents an array of values with the same number of elements as the source substring text before the transformation. Each byte will contain relevant property information of the corresponding element in <code>InpBuf</code>, starting from the element pointed by <code>InpBufIndex</code>. The four rightmost bits of each property byte will contain information for bidirectional environments (when <code>ActiveDirectional</code> is True) and they will mean NestingLevels. The possible value from 0 to 15 represents the nesting level of the corresponding element in the <code>InpBuf</code>, starting from the element pointed by <code>InpBufIndex</code>. If <code>ActiveDirectional</code> is False, the content of NestingLevels bits will be ignored. The leftmost bit of each property byte will contain a new cell indicator for composed character environments. It will be a value of either 1, for an element in <code>InpBuf</code> that is transformed to the beginning of a new cell, or 0, for the zero-length composing character elements, when these are grouped into the same presentation cell with a non-composing character. Here again, each element of property pertains to the elements in the <code>InpBuf</code>, starting from the element pointed by <code>InpBufIndex</code>. (Remember that this is not necessarily the beginning of InpBuf.)</td>
</tr>
<tr>
<td><strong>InpBufIndex</strong></td>
<td>An offset value to the location of the transformed text. When m_wtransform_layout() is called, <code>InpBufIndex</code> contains the offset to the element in <code>InpBuf</code> that will be transformed first. (Note that this is not necessarily the first element in <code>InpBuf</code>.) At the return from the transformation, <code>InpBufIndex</code> contains the offset to the first element in the <code>InpBuf</code> that has not been...</td>
</tr>
</tbody>
</table>
transformed. If the entire substring has been transformed successfully, InpBufIndex will be incremented by the amount defined by InpSize.

Each of these output arguments may be NULL to specify that no output is desired for the specific argument, but at least one of them should be set to non-NULL to perform any significant work.

In addition to the possible outputs above, the layout_object maintains a directional state across calls to the transform functions. The directional state is reset to its initial state whenever any of the layout values *OfTypeText*, Orientation or ImplicitAlg is modified by means of a call to m_setvalues_layout().

The layout_object argument specifies a LayoutObject returned by the m_create_layout() function.

The OutBuf argument contains the transformed data. This argument can be specified as a NULL pointer to indicate that no transformed data is required. The encoding of the OutBuf argument depends on the ShapeCharset layout value defined in layout_object. If the ActiveShapeEditing layout value is not set (False), the encoding of OutBuf is guaranteed to be the same as the codeset of the locale associated with the LayoutObject defined by layout_object.

On input, the OutSize argument specifies the size of the output buffer in number of wide characters. The output buffer should be large enough to contain the transformed result; otherwise, only a partial transformation is performed. If the ActiveShapeEditing layout value is set (True), the OutBuf should be allocated to contain at least the InpSize multiplied by ShapeCharsetSize.

Upon return, the OutSize argument is updated to be the actual number of code elements placed in OutBuf.

When the OutSize argument is specified as zero, the function calculates the size of an output buffer large enough to contain the transformed text, and the result is returned in this field. The content of the buffers specified by InpBuf and OutBuf, and the value of InpBufIndex, remain unchanged.

If OutSize = NULL, the EINVAL error condition is returned.

If the InpToOut argument is not a NULL pointer, it points to an array of values with the same number of wide characters as InpBuf, starting with the one pointed by InpBufIndex and up to the end of the substring in the buffer.

On output, the nth value in InpToOut corresponds to the nth wide character in InpBuf. This value is the index (in units of wide characters) in OutBuf that identifies the transformed ShapeCharset element of the nth wide character in InpBuf.

InpToOut may be specified as NULL if no index array from InpBuf to OutBuf is desired.

If the OutToInp argument is not a NULL pointer, it points to an array of values with the same number of wide characters as contained in OutBuf. On output, the nth value in OutToInp corresponds to the nth wide character in OutBuf. This value is the index in InpBuf, starting with the wide character pointed to by InpBufIndex, that identifies the logical code element of the nth byte in OutBuf.
m_wtransform_layout

*OutToInp* may be specified as NULL if no index array from *OutBuf* to *InpBuf* is desired.

To perform shaping of a text string without reordering of code elements, the *layout_object* should be set with input and output layout value *TypeOfText* set to TEXT_VISUAL, and both in and out of Orientation set to the same value.

**Returned value**

If successful, m_wtransform_layout() returns 0.

If unsuccessful, m_wtransform_layout() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2BIG</td>
<td>The size of <em>OutBuf</em> is not large enough to contain the entire transformed text. The input text state at the end of the uncompleted transformation is saved internally.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The layout values are set to a meaningless combination or the layout object is not valid.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Transformation stopped due to an incomplete composite sequence at the end of the input buffer, or <em>OutSize</em> contains NULL.</td>
</tr>
</tbody>
</table>

<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <math.h>

double nan(const char *tagp);
float nanf(const char *tagp);
long double nanl(const char *tagp);
```

General description

In the nan() family of functions, the call `nan("n-char-sequence")` is equivalent to `strtod("NAN(n-charsequence)", (char**)NULL)` and the call `nan("")` is equivalent to `strtod("NAN", (char**)NULL)`. If `tagp` does not point to an n-char sequence or an empty string, the call is equivalent to `strtod("NAN", (char**)NULL)`. Calls to `nanf()` and `nanl()` are equivalent to the corresponding calls `strtof()` and `strtold()`.

**Note:** The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>nan</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>nanf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>nanl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned value

If successful, they return a quiet NaN with content indicated by `tagp`.

**Special behavior in hex:** The nan() family of functions always return 0.

Example

```c
/*
 * This program illustrates the use of the nan() function
 * It calls both nan and strtod with equivalent arguments
 * and displays output of both. Output should be identical.
 */
#define _ISOC99_SOURCE
#include <stdio.h>
#include <stdlib.h> /* needed of strtod */
#include <math.h> /* needed of strtod */

#define TESTVALS 5
struct {
```
nan, nanf, nanl

const char * str;
} nan_vals[] = {
/*0*/ { "0" },
/*1*/ { "1" },
/*2*/ { "something" }, /* invalid n-char seq. */
/*3*/ { "2147483647" }, /* int max */
/*4*/ { "2147483648" } /* int max +1 */
},

strod_vals[] = {
/*0*/ { "NAN(0)" },
/*1*/ { "NAN(1)" },
/*2*/ { "NAN" },
/*3*/ { "NAN(2147483647)" },
/*4*/ { "NAN(2147483648)" }
};

void main()
{
    double outnan,
    outstrtod;
    int i;
    char *tagp = (char *)NULL;
    printf("Illustrates the nan() function\n");
    printf("Output for both nan() and strtod() should be identical.\n\n");
    for (i=0; i<TESTVALS; i++) {
        outnan = nan(nan_vals[i].str);
        outstrtod = strtod(strod_vals[i].str, &tagp);
        printf("nan(%) returned = %g\n",nan_vals[i].str, outnan);
        printf("strtod(%) returned = %g\n",strod_vals[i].str, outstrtod);
    }
}

Output

Illustrates the nan() function
Output for both nan() and strtod() should be identical.
nan(0) returned = 0
strtod(NAN(0)) returned = 0

nan(1) returned = NaNQ(1)
strtod(NAN(1)) returned = NaNQ(1)

nan(something) returned = NaNQ(1)
strtod(NAN) returned = NaNQ(1)

nan(2147483647) returned = NaNQ(2147483647)
strtod(NAN(2147483647)) returned = NaNQ(2147483647)

nan(2147483648) returned = 0
strtod(NAN(2147483648)) returned = 0

nand32(), nand64(), nand128() — Return quiet NaN

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.8</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 nand32(const char *tagp);
_Decimal64 nand64(const char *tagp);
_Decimal128 nand128(const char *tagp);
```

General description

In the nan() family of functions, the call nand32("n-char-sequence") is equivalent to
strtod32("NAN(n-char-sequence)", (char**) NULL) and the call nand32("") is
equivalent to strtod32("NAN()", (char**) NULL). If tagp does not point to an n-char
sequence or an empty string, the call is equivalent to strtod32("NAN", (char**) NULL). Calls to nand64() and nand128() are equivalent to the corresponding calls
strtod64() and strtod128().

Notes:
1. To use IEEE decimal floating-point, the hardware must have the Decimal
   Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal
   Floating-Point" for more information.

Returned value

If successful, they return a quiet NaN with content indicated by tagp.

Example

```c
/* CELEBN05

This program illustrates the use of the nand32() function.

It calls both nand32() and strtod32() with equivalent arguments
and displays output of both. Output should be identical.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
#include <stdlib.h> /* needed for strtod32() */

#define TESTVALS 5

struct {
    const char * str;
} nan_vals[] =
{ /*0*/ { "0" },
```
nand32, nand64, nand128

```c
/*1*/ { "1" },
/*2*/ { "something" }, /* invalid n-char seq. */
/*3*/ { "999999" }, /* max nancode */
/*4*/ { "1000000" } /* max nancode + 1 */
}

strod_vals[] =
{
/*0*/ { "NAN(0)" },
/*1*/ { "NAN(1)" },
/*2*/ { "NAN" },
/*3*/ { "NAN(999999)" },
/*4*/ { "NAN(1000000)" }
};

int main(void)
{
  _Decimal32 outnan,
  outstrtod;
  int i;

  printf("Illustrates the nand32() function\n\n");
  printf("Output for both nand32() and strtod32()";
        "should be identical.\n\n");

  for (i = 0; i < TESTVALS; i++)
  {
    outnan = nand32( nan_vals[i].str );
    outstrtod = strtod32(strod_vals[i].str, NULL);

    printf("nand32(\%s) returned = %Hg\n", nan_vals[i].str, outnan);
    printf("strtod32(\%s) returned = %Hg\n", strod_vals[i].str, outstrtod);
  }

  return 0;
}
```

</tr>
<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <math.h>

double nearbyint(double x);
float nearbyintf(float x);
long double nearbyintl(long double x);
```

```c
#define _TR1_C99
#include <math.h>

float nearbyint(float x);
long double nearbyintl(long double x);
```

General description

The nearbyint() family of functions round \(x\) to an integer value, in floating-point format, using the current rounding mode without raising the inexact floating-point exception.

Note: The following table shows the viable formats for these functions. See [IEEE binary floating-point “on page 94](#) for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>nearbyint</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>nearbyintf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>nearbyintl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned value

If successful, they return the rounded integer value. If the correct value causes an overflow, a range error occurs and the value, respectively, of the macro: +/-HUGE_VAL, +/-HUGE_VALF, or +/-HUGE_VALL (with the same sign as \(x\)) is returned.

Example

```c
/*
 * This program illustrates the use of nearbyint() function
 * 
 * Note: to get the results shown in this book, this program
 * should be compiled using FLOAT(IEEE)
 */
#define _ISOC99_SOURCE
#include <math.h>
```
nearbyint, nearbyintf, nearbyintl

```c
#include <stdio.h>
#include <_Ieee754.h> /* save/get fpc functions */
char *RoundStr (_FP_rmode_t rm_type) {
    char *RndStr="undetermined";
    switch (rm_type) {
        case (_RMODE_RN):
            RndStr="round to nearest";
            break;
        case (_RMODE_RZ):
            RndStr="round toward zero";
            break;
        case (_RMODE_RP):
            RndStr="round toward +infinity";
            break;
        case (_RMODE_RM):
            RndStr="round toward -infinity";
            break;
    }
    return (RndStr);
}

void main() {
    _FP_fpcreg_t save_rmode, current_rmode;
    double rnd2nearest;
    double number1=1.5,
    number2=-3.92;

    printf("Illustrates the nearbyint() function\n");
    __fpc_rd(&current_rmode); /* get current rounding mode */
    rnd2nearest = nearbyint(number1);
    printf("When rounding direction is %s:
    nearbyint(%.2f) = %f
", RoundStr(current_rmode.rmode),number1, rnd2nearest);
    save_rmode.rmode = _RMODE_RZ;
    __fpc_sm(save_rmode.rmode); /* set rounding mode to round to zero */
    rnd2nearest = nearbyint(number2);
    printf("When rounding direction is %s:
    nearbyint(%.2f) = %f
", RoundStr(save_rmode.rmode),number2, rnd2nearest);
}
```

Output
Illustrates the nearbyint() function
When rounding direction is round to nearest:
nearbyint(1.50) = 2.000000
When rounding direction is round toward zero:
nearbyint(-3.91) = -3.000000

#include <math.h>
float nextafterf(float x, float y);
long double nextafterl(long double x, long double y);

C++ TR1 C99:
#define _TR1_C99
#include <math.h>
float nextafter(float x, float y);
long double nextafterl(long double x, long double y);
```

General description

The nextafter() function computes the next representable double-precision floating-point value following x in the direction of y. Thus, if y is less than x, nextafter() returns the largest representable floating-point number less than x.

**Note:** The following table shows the viable formats for these functions. See [IEEE binary floating-point](https://en.wikipedia.org/wiki/IEEE_floating_point) for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>

<td>X</td>
</tr>
<tr>
<td>nextafterf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>nextafterl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

**Restriction:** The nextafterf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

The nextafter() functions return the next representable value following x in the direction of y. They always succeed.
nextafter, nextafterf, nextafterl

If x is finite and the correct function value overflows, a range error occurs and ±HUGE_VAL, ±HUGE_VALF, and ±HUGE_VALL (with the same sign as x) are returned as appropriate for the return type of the function.

Errno  Description
ERANGE  The correct value overflows.

<tr>
<td>( x ) does not equal ( y ) and the correct subroutine value is subnormal, 0, or underflows</td>
<td>a range error occurs and either the correct function value (if representable) or 0.0 is returned.</td>
</tr>
<tr>
<td>( x ) or ( y ) is a NaN</td>
<td>a NaN is returned.</td>
</tr>
</tbody>
</table>
Example

```c
/* CELEBN08

   This example illustrates the nexttoward32() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

static void try_nt(_Decimal32 x, _Decimal128 y)
{
    _Decimal32 r = nexttoward32(x, y);
    printf("nexttoward32(%12.12HG, %12.12DDG) = % 12.12HG\n", x, y, r);
    return;
}

int main(void)
{
    try_nt( 2.000000DF , 2.00000001DL );
    try_nt(-2.000000DF , -2.00000001DL );
    try_nt( 2.000000DF , 2.00000000DL );
    try_nt( 2.000000DF , 1.99999990DL );
    try_nt(-2.000000DF , -1.99999990DL );
    try_nt( 9.999999E+96DF, 9.999999E+96DL);
    try_nt( 1.000000E-95DF, 0.9999999E-95DL);

    return 0;
}
```

nftw() — Traverse a file tree

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ftw.h>

int nftw(const char *path,
          int (*fn)(const char *, const struct stat *, int, struct FTW *),
          int fd_limit, int flags);
```

General description

The nftw() function recursively descends the directory hierarchy rooted in *path*. It is similar to ftw() except that it takes an additional argument *flags*, which is a bitwise inclusive-OR of zero or more of the following flags:

- **FTW_CHDIR** If set, nftw() will change the current working directory to each directory as it reports files in that directory. If clear, nftw() will not change the current working directory.
- **FTW_DEPTH** If set, nftw() will report all files in a directory before reporting the directory itself. If clear, nftw() will report any directory before reporting the files in that directory.
- **FTW_MOUNT** If set, nftw() will only report files in the same file system as *path*. If clear, nftw() will report all files encountered during the walk.
- **FTW_PHYS** If set, nftw() performs a physical walk and does not follow symbolic links. If clear, nftw() will follow links instead of reporting them, and will not report the same file twice.

At each file it encounters, nftw() calls the user-supplied function *fn* with four arguments:

- the first argument is the pathname of the object.
- the second argument is a pointer to a stat buffer containing information on the object.
- the third argument is an integer giving additional information. Its value is one of the following:
  - **FTW_D** for a directory
  - **FTW_DNR** for a directory that cannot be read
  - **FTW_DP** for a directory whose subdirectories have been visited. (This condition will only occur if FTW_DEPTH is included in *flags*.)
  - **FTW_F** for a file
  - **FTW_NS** for an object other than a symbolic link on which stat() could not be successfully executed. If the object is a symbolic link, and stat() failed, it is unspecified whether nftw() passes FTW_SL or FTW_NS to the user-supplied function.
FTW_SL for a symbolic link
FTW_SLN for a symbolic link that does not name an existing file. (This condition will only occur if FTW_PHYS is not included in flags.)

- the fourth argument is a pointer to an FTW structure. The value of base is the offset of the object's filename in the pathname passed as the first argument to fn(). The value of level indicates depth relative to the root of the walk, where the root level is 0.

The argument fd_limit limits the directory depth for the search. At most one file descriptor will be used for each directory level.

Large file support for z/OS UNIX files:

Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, nftw() cannot receive a C++ function pointer as the argument. If you attempt to pass a C++ function pointer to nftw(), the compiler will flag it as an error. You can pass a C or C++ function to nftw() by declaring it as extern “C”.

Returned value

nftw() continues until the first of the following conditions occurs:
- An invocation of fn() returns a nonzero value, in which case nftw() returns that value.
- The nftw() function detects an error other than EACCES (see FTW_DNR and FTW_NS above), in which case nftw() returns −1 and sets errno to indicate the error.
- The tree is exhausted, in which case nftw() returns 0.

If unsuccessful, nftw() sets errno to one of the following values. All other errnos returned by nftw() are unchanged.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for any component of path or read permission is denied for path, or fn() returns −1 and does not reset errno.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>Too many symbolic links were encountered.</td>
</tr>
<tr>
<td>EMFILE</td>
<td>OPEN_MAX file descriptors are currently open in the calling process.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>One of the following error conditions exists: Pathname resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX. The length of path exceeds PATH_MAX, or a pathname component is longer than PATH_MAX.</td>
</tr>
<tr>
<td>ENFILE</td>
<td>Too many files are currently open in the system.</td>
</tr>
</tbody>
</table>
ENOENT  A component of path does not name an existing file or path is an empty string.

ENOTDIR A component of path is not a directory.

The errno value might also be set if the function fn causes it to be set.

nice() — Change priority of a process

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <unistd.h>

int nice(int increment);
```

General description

nice() adds the value of `increment` to the nice value of the calling process. A process's nice value is a nonnegative number for which a more positive value results in a lower CPU priority.

A maximum nice value of 2*(NZERO)-1 and a minimum value of zero are imposed by the system. Requests for values above or below these limits result in the nice value being set to the corresponding limit. Only a process with appropriate privileges can lower the nice value.

The changing of a process's nice value has the equivalent effect on a process's scheduling priority value, since they both represent the process's relative CPU priority. For example, increasing one's nice value to its maximum value of (2*NZERO)-1 has the equivalent effect of setting one's scheduling priority value to its maximum value (19), and will be reflected on the nice(), getpriority(), and setpriority() functions.

Returned value

If successful, nice() return the new nice value minus (NZERO).

If unsuccessful, nice() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOSYS</td>
<td>The system does not support this function.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The value of <code>increment</code> was negative and the calling process does not have the appropriate privileges.</td>
</tr>
</tbody>
</table>

Because nice() can return the value -1 on successful completion, it is necessary to set the external variable errno to 0 before a call to nice(). If nice() returns -1, then errno can be checked to see if an error occurred or if the value is a legitimate nice value.

Related information

nlist() — Get entries from a name list

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <nlist.h>

int nlist(const char *loadname, struct nlist *np);
```

General description

The nlist() function allows a program to examine the name list in the executable file named by the `loadname` parameter. It selectively extracts a list of values and places them in the array of nlist structures pointed to by the `np` parameter.

The name list specified by the `np` parameter consists of an array of structures containing names of variables, types and values. The list is terminated with an element that has a NULL string in the name structure member. Each variable name is looked up in the name list of the executable file. If the name is found, the type and the value of the name is copied into the nlist structure field. If the name is not found, both the type and value entry will be set to zero.

All entries are set to zero if the specified executable file cannot be read or it does not contain a valid name list.

Notes:
1. The only variable type that will be supported by this version of nlist() is external function.
2. nlist() will extract the offset of the external functions from `loadname`.
3. The type returned in nlist structure will always be 2 to indicate function if the function name is found in `loadname`.
4. `loadname` must be a HFS linear format load module containing main().
5. `loadname` cannot be a dll (dynamic link library) or a fetchable load module.

Returned value

If successful, nlist() returns 0. The offset and type of functions if found will be returned in the nlist structure.

If unsuccessful, nlist() returns −1.

nl_langinfo

nl_langinfo() — Retrieve locale information

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <langinfo.h>

char *nl_langinfo(nl_item item);
```

General description

Retrieves from the current locale the string that describes the requested information specified by `item`. For a list of macros that define the constants used to identify the information queried in the current locale, see Table 4 on page 36.

Returned value

If successful, `nl_langinfo()` returns a pointer to a NULL-terminated string containing information concerning the active language or cultural area. The active language or cultural area is determined by the most recent `setlocale()` call. The array pointed to by the returned value is modified by subsequent calls to the function. The array shall not be modified by the user's program.

If the item is not valid, `nl_langinfo()` returns a pointer to an empty string.

Example

```c
CELEBN01

/* CELEBN01

   This example retrieves the current codeset name using the
   &nll. function.

   */

#include "langinfo.h"
#include "locale.h"
#include "stdio.h"

main() {
    char *codeset;
    setlocale(LC_ALL, "");
    codeset = nl_langinfo(CODESET);
    printf("codeset is %s
", codeset);
}
```

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdlib.h>

long int nrnd48(unsigned short int x16v[3]);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), nrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval \([0.0,1.0)\).

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval \([0,2^{31})\).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval \([-2^{31},2^{31})\).

The nrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, \(X(n)\), according to the linear congruential formula:

\[
X(n+1) = (ax(n) + c) \mod (2^{48}) \quad n \geq 0
\]

The nrand48() function uses storage provided by the argument array, \(x16v[3]\), to save the most recent 48-bit integer value in the sequence, \(X(n)\). The nrand48() function uses \(x16v[0]\) for the low-order (rightmost) 16 bits, \(x16v[1]\) for the middle-order 16 bits, and \(x16v[2]\) for the high-order 16 bits of this value.

The initial values of \(a\) and \(c\) are:

\[
a = 5deece66d \quad \text{(base 16)} \\
c = b \quad \text{(base 16)}
\]

The values \(a\) and \(c\), may be changed by calling the lcong48() function. The initial values of \(a\) and \(c\) are restored if either the seed48() or srand48() function is called.

Special behavior for z/OS UNIX Services: You can make the nrand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for \(X(n)\), \(a\) and \(c\) by functions in the drand48 family when they are called by a multithreaded application.
nrand48

If thread-specific behavior is requested and the nrand48() function is called from thread t, the nrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread according to the linear congruential formula:

\[ X(t,n+1) = (a(t)X(t,n) + c(t)) \mod(2^{48}) \quad n \geq 0 \]

The nrand48() function uses storage provided by the argument array, x16v[3], to save the most recent 48-bit integer value in the sequence, X(t,i). The nrand48() function uses x16v[0] for the low-order (rightmost) 16 bits, x16v[1] for the middle-order 16 bits, and x16v[2] for the high-order 16 bits of this value.

The initial values of a(t) and c(t) on the thread t are:

- \( a(t) = 5dece66d \) (base 16)
- \( c(t) = b \) (base 16)

The values a(t) and c(t) may be changed by calling the lcong48() function from the thread t. The initial values of a(t) and c(t) are restored if either the seed48() or srand48() function is called from the thread.

Returned value

nrand48() saves the generated 48-bit value, X(n+1), in storage provided by the argument array, x16v[3]. nrand48() transforms the generated 48-bit value to a nonnegative, long integer value on the interval \([0,2^{31})\) and returns this transformed value.

**Special behavior for z/OS UNIX Services:** If thread-specific behavior is requested for the drand48 family and nrand48() is called on thread t, nrand48() saves the generated 48-bit value, X(t,n+1), in storage provided by the argument array, x16v[3]. nrand48() transforms the generated 48-bit value to a nonnegative, long integer value on the interval \([0,2^{31})\) and returns this transformed value.

</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <fcntl.h>

int open(const char *pathname, int options, ...);
```

General description

Opens a file and returns a number called a file descriptor.

The `pathname` argument must be a z/OS UNIX file file name. You can use this file descriptor to refer to the file in subsequent I/O operations, for example, read() or write(). Each file opened by a process gets a new file descriptor.

Restriction: Using this function with FIFOs, POSIX terminals, and character special files requires z/OS XL C programs running POSIX(ON).

The argument `pathname` is a string giving the name of the file you want to open. The integer `options` specifies options for the open operation by taking the bitwise inclusive-OR of symbols defined in the `fcntl.h` header file. The options indicate whether the file should be accessed for reading, writing, reading and writing, and so on.

An additional argument (…) is required if the O_CREAT option is specified in `options`. This argument may be called the `mode` and has the `mode_t` type. It specifies file permission bits to be used when a file is created. All the file permission bits are set to the bits of `mode`, except for those set in the file-mode creation mask of the process. Here is a list of symbols that can be used for a mode.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>

</tr>
<tr>
<td>S_ISGID</td>
<td>Privilege to set group ID (GID) for execution. When this file is run through an exec function, the effective group ID of the process is</td>
</tr>
</tbody>
</table>

Chapter 3. Library functions 1343
**open**

set to the group ID of the file, so that the process has the same authority as the file owner rather than the authority of the actual invoker.

S_ISUID Privilege to set the user ID (UID) for execution. When this file is run through an exec function, the effective user ID of the process is set to the owner of the file, so that the process has the same authority as the file owner rather than the authority of the actual invoker.

S_ISVTX Indicates shared text. Keep loaded as an executable file in storage.

S_IWGRP Write permission for the file's group.

S_IWOTH Write permission for users other than the file owner.

S_IWUSR Write permission for the file owner.

S_IXGRP Search permission (for a directory) or execute permission (for a file) for the file's group.

S_IXOTH Search permission for a directory, or execute permission for a file, for users other than the file owner.

S_IXUSR Search permission (for a directory) or execute permission (for a file) for the file owner.

Most open operations position a file offset (an indicator showing where the next read or write will take place in the file) at the beginning of the file; however, there are options that can change this position. One of the following must be specified in the options argument of the open() operation:

- O_RDONLY Open for reading only
- O_WRONLY Open for writing only
- O_RDWR Open for both reading and writing

One or more of the following can also be specified in options:

- O_APPEND Positions the file offset at the end of the file before each write operation.
- O_CREAT Indicates that the call to open() has a mode argument. If the file being opened already exists O_CREAT has no effect except when O_EXCL is also specified; see O_EXCL following.

If the file being opened does not exist it is created. The user ID is set to the effective ID of the process, and its group ID is set to the group ID of its directory. File permission bits are set according to mode.

If O_CREAT is specified and the file did not previously exist a successful open() sets the access time, change time, and modification time for the file. It also updates the change time and modification time fields in the parent directory.

- O_EXCL

If both O_EXCL and O_CREAT are specified open() fails if the file already exists. If both O_EXCL and O_CREAT are specified and pathname names a symbolic link open() fails regardless of the contents of the symbolic link.
open

The check for the existence of the file and the creation of the file if it does not exist is atomic with respect to other threads executing open() naming the same filename in the same directory with O_EXCL and O_CREAT set.

O_NOCTTY If pathname specifies a terminal open() does not make the terminal the controlling terminal of the process (and the session). If O_NOCTTY is not specified the terminal becomes the controlling terminal if the following conditions are true:
- The process is a session leader.
- There is no controlling terminal for the session.
- The terminal is not already a controlling terminal for another session.

O_NONBLOCK Has different meanings depending on the situation.
- When you are opening a FIFO special file with O_RDONLY or O_WRONLY:
  - If O_NONBLOCK is specified a read-only open() returns immediately. A write-only open() returns with an error if no other process has the FIFO open for reading.
  - If O_NONBLOCK is not specified a read-only open() blocks until another process opens the FIFO for writing. A write-only open() blocks until another process opens the FIFO for reading.
- When you are opening a character special file that supports a nonblocking open(), O_NONBLOCK controls whether subsequent reads and writes can block.

O_TRUNC If the file is successfully opened with O_RDWR or O_WRONLY, this will truncate the file to zero length if the file exists and is a regular file. The mode and owner of the file are unchanged. This option should not be used with O_RDONLY. O_TRUNC has no effect on FIFO special files or directories.
- If O_TRUNC is specified and the file previously existed a successful open() updates the change time and modification time for the file.

O_SYNC Force synchronous update. If this flag is 1 every write() operation on the file is written to permanent storage. That is, the file system buffers are forced to permanent storage. See fsync() also.
- The program is assured that all data for the file has been written to permanent storage on return from a function which performs a synchronous update,

If pathname refers to a STREAM file, oflag may be constructed from O_NONBLOCK OR-ed with either O_RDONLY, O_WRONLY or O_RDWR. Other flag values are not applicable to STREAMS devices and have no effect on them. The value O_NONBLOCK affects the operation of STREAMS drivers and certain functions applied to file descriptors associated with STREAMS files. For STREAMS drivers, the implementation of O_NONBLOCK is device-specific.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for open() to return a valid STREAMS file descriptor.
The largest value that can be represented correctly in an object of type off_t is established as the offset maximum in the open file description.

**Large file support for z/OS UNIX files:**

Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLEVEL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

**Returned value**

If successful, open() returns a file descriptor.

If unsuccessful, open() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Access is denied. Possible reasons include:</td>
</tr>
<tr>
<td></td>
<td>• The process does not have search permission on a component in <code>pathname</code>.</td>
</tr>
<tr>
<td></td>
<td>• The file exists, but the process does not have permission to open the file in the way specified by the flags.</td>
</tr>
<tr>
<td></td>
<td>• The file does not exist, and the process does not have write permission on the directory where the file is to be created.</td>
</tr>
<tr>
<td></td>
<td>• O_TRUNC was specified, but the process does not have write permission on the file.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>The process attempted to open a file that is in use.</td>
</tr>
<tr>
<td>EEXIST</td>

</tr>
<tr>
<td>EINTR</td>
<td>open() was interrupted by a signal.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The <code>options</code> parameter does not specify a valid combination of the O_RDONLY, O_WRONLY and O_TRUNC bits.</td>
</tr>
<tr>
<td>EIO</td>
<td>The <code>pathname</code> argument names a STREAMS file and a hang-up or error occurred during the open().</td>
</tr>
<tr>
<td>EISDIR</td>
<td><code>pathname</code> is a directory, and <code>options</code> specifies write or read/write access.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of <code>pathname</code> is greater than POSIX_SYMLINK.</td>
</tr>
<tr>
<td>EMFILE</td>
<td>The process has reached the maximum number of file descriptors it can have open.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td><code>pathname</code> is longer than PATH_MAX characters, or some component of <code>pathname</code> is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined using pathconf().</td>
</tr>
</tbody>
</table>
ENFILE The system has reached the maximum number of file descriptors it can have open.

ENOENT Typical causes:

- O_CREAT is not specified, and the named file does not exist.
- O_CREAT is specified, and either the prefix of \texttt{pathname} does not exist or the \texttt{pathname} argument is an empty string.

ENOMEM The \texttt{pathname} argument names a STREAMS file and the system is unable to allocate resources.

ENOSPC The directory or file system intended to hold a new file has insufficient space.

ENOSR The \texttt{pathname} argument names a STREAMS-based file and the system is unable to allocate a STREAM.

ENOSYS For master pseudoterminals, slave initialization did not complete.

ENOTDIR A component of \texttt{pathname} is not a directory.

ENXIO O_NONBLOCK and O_WRONLY were specified and the named file is a FIFO, but no process has the file open for reading. For a pseudoterminal, the requested minor number exceeds the maximum number supported by the installation.

EPERM For slave pseudoterminals, permission to open is denied for one of these reasons:

- It is the first open of the slave after the master pseudoterminal was opened, and the user ID associated with the two opening processes is not the same.
- There was an internal error in the security system after the master pseudoterminal was opened.
- The attempt to open the slave used a different pathname than earlier opens used.

EROFS \texttt{pathname} is on a read-only file system, and one or more of the options O_WRONLY, O_RDWR, O_TRUNC, or O_CREAT (if the file does not exist) was specified.

Example

The following opens an output file for appending:

```c
int fd;
fd = open("outfile",O_WRONLY | O_APPEND);
```

The following statement creates a new file with read/write/execute permissions for the creating user. If the file already exists, open() fails.

```c
fd = open("newfile",O_WRONLY|O_CREAT|O_EXCL,S_IRWXU);
```

Format

```c
#define _POSIX_SOURCE
#include <dirent.h>

DIR *opendir(const char *dirname);
```

General description

Opens a directory so that it can be read with readdir() or __readdir2(). `dirname` is a string giving the name of the directory you want to open. The first readdir() or __readdir2() call reads the first entry in the directory.

Returned value

If successful, opendir() returns a pointer to a DIR object. This object describes the directory and is used in subsequent operations on the directory, in the same way that FILE objects are used in file I/O operations.

If unsuccessful, opendir() returns a NULL pointer and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>

</tbody>
</table>

Format

```c
#define _OPEN_SYS_DIR_EXT
#include <dirent.h>

DIR *__opendir2(const char *dirname, size_t bufsize);
```

General description

Opens a directory so that it can be read with readdir() or __readdir2(). The first readdir() or __readdir2() call reads the first entry in the directory.

*dirname* is a string giving the name of the directory you want to open. *bufsize* is the size (in bytes) of the internal work buffer used by readdir() or __readdir2() to hold directory entries. The larger the buffer, the less overhead there will be when reading through large numbers of directory entries. This buffer will exist until the directory is closed. If the specified buffer size is too small, it is ignored. A minimum-size buffer is used instead.

__opendir2() is the same as opendir(), except that the buffer size can be specified as a parameter.

Returned value

If successful, __opendir2() returns a pointer to a DIR object. This object describes the directory and is used in subsequent operations on the directory, in the same way that FILE objects are used in file I/O operations.

If unsuccessful, __opendir2() returns a NULL pointer and sets errno to one of the following values:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <syslog.h>

void openlog(const char *ident, int logopt, int facility);
```

General description

The openlog() function optionally opens a connection to the logging facility, and sets process attributes that affect subsequent calls to the syslog() function. The argument `ident` is a string that is prefixed to every message. `logopt` is a bit field indicating logging options. Current values of `logopt` are:

- **LOG_CONS** Write messages to the system console if they cannot be sent to the logging facility. This option is safe to use in processes that have no controlling terminal, since the syslog() function forks before opening the console.

- **LOG_NDELAY** Open the connection to the logging facility immediately. Normally the open is delayed until the first message is logged. This is useful for programs that need to manage the order in which file descriptors are allocated.

- **LOG_NOWAIT** Do not wait for child processes that have been forked to log messages onto the console. This option should be used by processes that enable notification of child termination using `SIGCHLD`, since the syslog() function may otherwise block waiting for a child whose exit status has already been collected.

- **LOG_ODELAY** Delay open until syslog() is called.

- **LOG_PID** Log the processID with each message. This is useful for identifying specific processes. In the message header, the processID is surrounded by square brackets. The code point values for the square brackets are taken from code page IBM-1047. The value for the left square bracket is 0xAD. The value for the right square bracket is 0xBD.

The `facility` argument encodes a default facility to be assigned to all messages that do not have an explicit facility already encoded. The initial default facility is as follows:

- **LOG_USER** Message generated by random processes. This is the default facility identifier if none is specified.
openlog

**Returned value**

`openlog()` returns no values.

No errors are defined.

__open_stat

__open_stat() — Open a file and get file status information

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>

int __open_stat(const char *pathname, int options, mode_t mode,
                 struct stat *info);
```

General description

Opens a file and returns a number called a file descriptor. __open_stat() also returns information about the opened file. __open_stat() is a combination of open() and fstat().

The parameters are:

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
</table>
| pathname   | This parameter is a NULL-terminated character string containing the hierarchical file system (HFS) pathname of the file to be opened. pathname can begin with or without a slash.  
  - A pathname beginning with a slash is an absolute pathname. The slash refers to the root directory, and the search for the file starts at the root directory.  
  - A pathname not beginning with a slash is a relative pathname. The search for the file begins at the working directory.  
  See [“open() — Open a file” on page 1343](https://www.ibm.com) for more information about the pathname parameter and the types of files that can be opened. |
| options    | An integer containing option bits for the open operation. These options are the same as those in the options parameter passed to open(). These bits are defined in fcntl.h. For a list of these option bits and their meaning, see [“open() — Open a file” on page 1343](https://www.ibm.com). |
| mode       | mode is the same as the optional third parameter for open(), which is used when a new file is being created. For __open_stat(), the mode parameter is always required. If a new file is not being created, mode is ignored, and may be set to 0. When __open_stat() creates a file, the flag bits in mode specify the file permissions and other characteristics for the new file. The flag bits in mode are defined in sys/modes.h. For more information about the mode parameter, see [“open() — Open a file” on page 1343](https://www.ibm.com). |
| info       | The info parameter points to an area of memory where the system will store information about the file that is opened. This parameter is the same as the info parameter in fstat() or stat(). If the file is successfully opened, the system returns file status information in a |
stat structure, as defined in sys/stat.h. The elements of this structure are described in "stat() — Get file information" on page 2039.

Returned value

If successful, __open_stat() returns a file descriptor.

If unsuccessful, __open_stat() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCESS</td>
<td>Access to the file was denied. One of the following errors occurred:</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td>• The calling process does not have permission to open the file in the way specified by the options parameter.</td>
</tr>
<tr>
<td></td>
<td>• The file does not exist, and the calling process does not have permission to write into files in the directory the file would have been created in.</td>
</tr>
<tr>
<td></td>
<td>• The truncate option was specified, but the process does not have write permission for the file.</td>
</tr>
<tr>
<td>EAGAIN</td>
<td>Resources were temporarily unavailable.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>pathname specifies a master pseudoterminal that is either already in use or for which the corresponding slave is open.</td>
</tr>
<tr>
<td>EEXIST</td>
<td>The exclusive create option was specified, but the file already exists.</td>
</tr>
<tr>
<td></td>
<td>Use __errno2() to determine the exact reason the error occurred.</td>
</tr>
<tr>
<td>EFBIG</td>
<td>A request to create a new file is prohibited because the file size limit for the process is set to 0.</td>
</tr>
<tr>
<td>EINTR</td>
<td>The __open_stat() operation was interrupted by a signal.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The options parameter does not specify a valid combination of the 0_RDONLY, 0_WRONLY and 0_TRUNC bits, or the file type specified in the mode parameter is not valid.</td>
</tr>
<tr>
<td></td>
<td>Use __errno2() to determine the exact reason the error occurred.</td>
</tr>
<tr>
<td>EISDIR</td>
<td>The file specified by pathname is a directory and the options parameter specifies write or read/write access.</td>
</tr>
<tr>
<td></td>
<td>Use __errno2() to determine the exact reason the error occurred.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links encountered during resolution of the pathname parameter. This error is issued if more than 8 symbolic links are detected in the resolution of pathname.</td>
</tr>
<tr>
<td>EMFILE</td>
<td>The process has reached the maximum number of file descriptors it can have open.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>pathname is longer than 1023 characters, or a component of pathname is longer than 255 characters. (The system does not support filename truncation.)</td>
</tr>
<tr>
<td>ENODEV</td>
<td>Typical causes of this error are:</td>
</tr>
</tbody>
</table>
An attempt was made to open a character special file for a device not supported by the system.

An attempt was made to open a character special file for a device that is not yet initialized.

Use __errno2() to determine the exact reason the error occurred.

**ENOENT**

Typical causes of this error are:

- The request did not specify that the file was to be created, but the file named by *pathname* was not found.
- The request asked for the file to be created, but some component of *pathname* was not found, or the *pathname* parameter was blank.

Use __errno2() to determine the exact reason the error occurred.

**ENOSPC**

The directory or file system intended to hold a new file has insufficient space.

**ENOTDIR**

A component of *pathname* is not a directory.

**ENXIO**

The __open_stat() request specified write-only and nonblock for a FIFO special file, but no process has the file open for reading. For pseudoterminals, this errno can mean that the minor number associated with *pathname* is too big.

**EPERM**

The caller is not permitted to open the specified slave pseudoterminal or the corresponding master is not yet open. EPERM is also returned if the slave is closed with HUPCL set and an attempt is made to reopen it.

**EROFS**

The *pathname* parameter names a file on a read-only file system, but options that would allow the file to be altered were specified: write-only, read/write, truncate, or -- for a new file -- create.

Use __errno2() to determine the exact reason the error occurred.

__osname — Get true operating system name

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>OS/390 V2R10</td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <sys/utsname.h>

int __osname(struct utsname *name);
```

General description

The __osname() function retrieves information identifying the true operating system you are running on. The argument `name` points to a memory area where a structure describing the true operating system the process is running on can be stored.

The information about the true operating system is returned in a `utsname` structure, which has the following elements:

- `char *sysname;` The true name of the implementation of the operating system.
- `char *nodename;` The node name of this particular machine. The node name is set by the SYSNAME sysparm (specified at IPL), and usually differentiates machines running at a single location.
- `char *release;` The true current release level of the implementation.
- `char *version;` The true current version level of the release.
- `char *machine;` The name of the hardware type the system is running on.

Each of the `utsname` structure elements is a normal C string, terminated with a NULL character.

The values returned by the __osname() function are not intended to be used for comparison purposes in order to determine a level of functionality provided by the operating system. This is because the version and release values are not guaranteed to be equal to or greater than the previous implementation.

Table 42 on page 1360 lists the true operating system information returned by the __osname() function.

</table>

#### Returned value

If successful, the __osname() function returns a nonnegative value.

If unsuccessful, the __osname() function returns −1 and an errno might be set to indicate the reason for the failure.

#### Example

**CELEBO02**

```c
/*
 * This example gets information about the system you are running on.
 */
#define _POSIX_SOURCE
#include <sys/utsname.h>
#include <stdio.h>
main() {
    struct utsname uts;
    if (__osname(&uts) < 0)
        perror("__osname() error");
    else {
        printf("Sysname: %s\n", uts.sysname);
        printf("Nodename: %s\n", uts.nodename);
        printf("Release: %s\n", uts.release);
        printf("Version: %s\n", uts.version);
        printf("Machine: %s\n", uts.machine);
    }
}
```

**Output**

Sysname: z/OS
Nodename: SY1
Release: 13.00
Version: 01
Machine: 2097

#### Related information

__passwd(), __passwd_applid() — Verify or change user password

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <pwd.h>

int __passwd(const char *username, const char *oldpass, const char *newpass);
int __passwd_applid(const char *username, const char *oldpass, const char *newpass, const char *applid);
```

General description

The `__passwd()` function verifies or changes the `username` password or the password phrase. The `username` is a NULL-terminated character string of 1 to 8 bytes. The `oldpass` is the current password or password phrase for user `username`, and is a NULL-terminated character string of a password or a password phrase. When `newpass` is NULL, then `oldpass` represents the password or password phrase to be verified, and no password or password phrase change is performed. Otherwise, `newpass` is a NULL-terminated character string of a password or a password phrase. Other installation-dependent restrictions on passwords or password phrases may apply, both in terms of length and content. Length restrictions may be imposed by the security product.

The `__passwd_applid()` function is equivalent to `__passwd()` with the added feature that it also allows the application identifier (APPLID) to be supplied that will be passed on to the security product to assist with authentication. When `applid` is NULL or a pointer to NULL, no application identifier will be passed on to the security product.

The function has the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>applid</code></td>
<td>Specifies the application identifier that will be used for authentication with the security product.</td>
</tr>
</tbody>
</table>

If the BPX.DAEMON facility class profile is defined, then all modules within the address space must be loaded from a controlled library. This includes all modules in the application and run-time libraries. See also "Checking Which Module is not Defined to Program Control" in [z/OS UNIX System Services Planning, GA22-7800](GA22-7800).

Returned value

If successful, `__passwd()` returns 0. When `newpass` is NULL, the password or the password phrase has been verified. When `newpass` is not NULL, the new password or password phrase has been set.

If a user specifies password for `oldpass` and new password phrase for `newpass` or password phrase for `oldpass` and new password for `newpass`, then `__passwd()` returns -1 and sets `errno` to EMVSPASSWORD and the current password or password phrase is not changed.
If unsuccessful, __passwd() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

long pathconf(const char *pathname, int varcode);
```

General description

Lets an application determine the value of a configuration variable, `varcode`, associated with a particular file or directory, `pathname`.

The `varcode` argument may be any one of the following symbols, defined in the `unistd.h` header file, each standing for a configuration variable:

- `_PC_LINK_MAX`
  - Represents LINK_MAX, the maximum number of links the file can have. If `pathname` is a directory, `pathconf()` returns the maximum number of links that can be established to the directory itself.

- `_PC_MAX_CANON`
  - Represents MAX_CANON, the maximum number of bytes in a terminal canonical input line. `pathname` must refer to a character special file for a terminal.

- `_PC_MAX_INPUT`
  - Represents MAX_INPUT, the maximum number of bytes for which space is available in a terminal input queue. That is, it refers to the maximum number of bytes that a portable application can have the user enter before the application actually reads the input. `pathname` must refer to a character special file for a terminal.

- `_PC_NAME_MAX`
  - Represents NAME_MAX, the maximum number of characters in a file name (not including any terminating NULL at the end if the file name is stored as a string). This symbol refers only to the file name itself, that is, the last component of the file's path name. `pathconf()` returns the maximum length of file names.

- `_PC_PATH_MAX`
  - Represents PATH_MAX, the maximum number of characters in a complete path name (not including any terminating NULL at the end if the path name is stored as a string). `pathconf()` returns the maximum length of a relative path name.

- `_PC_PIPE_BUF`
  - Represents PIPE_BUF, the maximum number of bytes that can be written “atomically” to a pipe. If more than this number of bytes is written to a pipe, the operation may take more than one physical
write operation and physical read operation to read the data on the other end of the pipe. If `pathname` is a FIFO special file, `pathconf()` returns the value for the file itself. If `pathname` is a directory, `pathconf()` returns the value for any FIFOs that exist or that can be created under the directory. If `pathname` is any other kind of file, an `errno` of EINVAl will be returned, indicating an invalid path name was specified.

_**PC_CHOWN_RESTRICTED**_

Represents `_POSIX_CHOWN_RESTRICTED` defined in the `unistd.h` header file, and restricts use of `chown()` to a process with appropriate privileges. It also changes the group ID of a file to the effective group ID of the process or to one of its supplementary group IDs. If `pathname` is a directory, `pathconf()` returns the value for any kind of file under the directory, but not for subdirectories of the directory.

_**PC_NO_TRUNC**_

Represents `_POSIX_NO_TRUNC` defined in the `unistd.h` header file, and generates an error if a file name is longer than `NAME_MAX`. If `pathname` refers to a directory, the value returned by `pathconf()` applies to all files under that directory.

_**PC_VDISABLE**_

Represents `_POSIX_VDISABLE` defined in the `unistd.h` header file. This symbol indicates that terminal special characters can be disabled using this character value, if it is defined; see the callable service `tcsetattr()` for details. `pathname` must refer to a character special file for a terminal.

_**PC_ACL**_

Returns 1 if an access control mechanism is supported by the security product.

_**PC_ACL_ENTRIES_MAX**_

Returns the maximum number of ACL entries in an ACL for a file or directory that supports ACLs.

**Returned value**

If successful, `pathconf()` return the value of the variable requested in `varcode`.

If unsuccessful, `pathconf()` returns -1. If a particular variable has no limit, such as `PATH_MAX`, `pathconf()` returns -1 but does not change `errno`.

If `pathconf()` cannot determine an appropriate value, it sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The process does not have search permission on some component of the <code>pathname</code>.</td>
</tr>
<tr>
<td>EINVAL</td>
<td><code>varcode</code> is not a valid variable code, or the given variable cannot be associated with the specified file.</td>
</tr>
<tr>
<td></td>
<td>- If <code>varcode</code> refers to <code>MAX_CANON</code>, <code>MAX_INPUT</code>, or <code>_POSIX_VDISABLE</code>, and <code>pathname</code> does not refer to a character special file, <code>pathconf()</code> returns -1 and sets <code>errno</code> to EINVAL.</td>
</tr>
<tr>
<td></td>
<td>- If <code>varcode</code> refers to <code>NAME_MAX</code>, <code>PATH_MAX</code>, or <code>POSIX_NO_TRUNC</code>, and <code>pathname</code> does not refer to a directory, <code>pathconf()</code> returns the requested information.</td>
</tr>
</tbody>
</table>
If `varcode` refers to `PC_PIPE_BUF` and `pathname` refers to a pipe or a FIFO, the value returned applies to the referenced object itself. If `pathname` refers to a directory, the value returned applies to any FIFOs that exist or can be created within the directory. If `pathname` refers to any other type of file, the function sets `errno` to `EINVAL`.

**ELOOP**
A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLOOPS` symbolic links are detected in the resolution of `pathname`.

**ENAMETOOLONG**

- `pathname` is longer than `PATH_MAX` characters, or some component of `pathname` is longer than `NAME_MAX` while `_POSIX_NO_TRUNC` is in effect.

  For symbolic links, the length of the path name string substituted for a symbolic link exceeds `PATH_MAX`.

**ENOENT**
There is no file named `pathname`, or the `pathname` argument is an empty string.

**ENOTDIR**
Some component of the `pathname` is not a directory.

### Example

**CELEBP01**

/* CELEBP01 */

This example determines the maximum number of characters in a file name.

```c
#define _POSIX_SOURCE
#include <errno.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    long result;

    errno = 0;
    puts("examining NAME_MAX limit for root filesystem");
    if ((result = pathconf("/", _PC_NAME_MAX)) == -1)
        if (errno == 0)
            puts("There is no limit to NAME_MAX.");
        else perror("pathconf() error");
    else
        printf("NAME_MAX is %ld\n", result);
}
```

**Output:**

examining NAME_MAX limit for root file system
NAME_MAX is 255

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

int pause(void);
```

General description

Suspends execution of the calling thread. The thread does not resume execution until a signal is delivered, executing a signal handler or ending the thread. Some signals can be blocked by the process's thread. See "sigprocmask() — Examine or change a thread" on page 1955 for details.

If an incoming unblocked signal ends the thread, pause() never returns to the caller.

If an incoming signal is handled by a signal handler, pause() returns after the signal handler returns.

Returned value

If pause() returns, it always returns −1 and sets errno to EINTR, indicating that a signal was received and handled successfully.

Example

```c
CELEBP02
/* CELEBP02
   This example suspends execution and determines the current time.
*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <signal.h>
#include <stdio.h>
#include <time.h>

void catcher(int signum) {
   puts("inside catcher...");
}

void timestamp() {
   time_t t;
   time(&t);
   printf("the time is \%s", ctime(&t));
}

main() {
```
struct sigaction sigact;

sigemptyset(&sigact.sa_mask);
sigact.sa_flags = 0;
sigact.sa_handler = catcher;
sigaction(SIGALRM, &sigact, NULL);

alarm(10);
printf("before pause... ");
timestamp();
pause();
printf("after pause... ");
timestamp();
}

Output:
before pause... the time is Fri Jun 16 09:42:29 2001
inside catcher...

after pause... the time is Fri Jun 16 09:42:39 2001

pclose

pclose() — Close a pipe stream to or from a process

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdio.h>

int pclose(FILE *stream);
```

General description

The pclose() function closes a stream that was opened by popen(), waits for the command specified as an argument in popen() to terminate, and returns the status of the process that was running the shell command. However, if a call caused the termination status to be unavailable to pclose(), then pclose() returns -1 with errno set to ECHILD to report this situation; this can happen if the application calls one of the following functions:

- `wait()`
- `waitid()`
- `waitpid()` with a `pid` argument less than or equal to the process ID of the shell command
- any other function that could do one of the above

In any case, pclose() will not return before the child process created by popen() has terminated.

If the shell command cannot be executed, the child termination status returned by pclose() will be as if the shell command terminated using `exit(127)` or `_exit(127)`.

The pclose() function will not affect the termination status of any child of the calling process other than the one created by popen() for the associated stream.

If the argument `stream` to pclose() is not a pointer to a stream created by popen(), the termination status returned will be -1.

Threading Behavior: The pclose() function can be executed from any thread within the parent process.

Returned value

If successful, pclose() returns the termination status of the shell command.

If unsuccessful, pclose() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECHILD</td>
<td>The status of the child process could not be obtained.</td>
</tr>
</tbody>
</table>
Related information

<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Language Environment</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <stdio.h>

void perror(const char *string);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

void perror_unlocked(const char *string);

X/Open:
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdio.h>

void perror(const char *string);

Berkeley sockets:
#define _OE_SOCKETS
#include <stdio.h>

void perror(const char *string);
```

**General description**

Prints an error message to stderr. If string is not NULL and it does not point to a NULL character, the string pointed to by string is printed to the standard error stream, followed by a colon and a space. The message associated with the value in errno is then printed followed with the errno2 value in parenthesis and a newline character. The content of the message is the same as the content of a string returned by strerror() with the argument errno.

The perror() string shown as: EDC5121I Invalid argument. (errno2=0x0C0F8402).

To produce accurate results, you should ensure that perror() is called immediately after a library function returns with an error; otherwise, subsequent calls may alter the errno value.

If the error is associated with the stderr file, a call to perror() is not valid.

There is an environment variable EDC_ADD_ERRNO2, which when set to 0, will remove the append of the current errno2 value at the end of the perror() string shown.
The perror() function will not change the orientation of the stderr stream.

perror_unlocked() is functionally equivalent to perror() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

**Returned value**

perror() returns no values.

**Example**

**CELEBP03**

/* CELEBP03
   This example tries to open a stream.
   If the fopen() function fails, the example prints a message and ends the program.
*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *fh;
    if ((fh = fopen("myfile.dat","r")) == NULL)
    {
        perror("Could not open data file");
        abort();
    }
}

The following example tries to open a stream socket. If the socket fails, the example prints a message and ends the program.

```
#include <stdio.h>
#include <stdlib.h>
#include <sys/socket.h>

int main(void)
{
    int s;
    if ((s = socket (AF_INET,SOCK_STREAM,0)) <0)
    {
        perror("Could not open socket");
        exit(-1);
    }
}
```

**Related information**

__pid_affinity

__pid_affinity() — Add or delete process affinity

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS
#include <unistd.h>

int __pid_affinity(int function_code,
                    pid_t target_pid,
                    pid_t signal_pid,
                    int signal);
```

General description

The __pid_affinity() function adds or deletes an entry in a process's affinity list. When a process terminates, each process in its affinity list is notified (sent a signal) of the termination. The __pid_affinity() function provides the ability to dynamically create or break an association between two processes that is similar to the notification mechanism between parent and child processes without the processes being related.

The `function_code` can be set to one of the following symbolics, as defined in the unistd.h header file:

- __PAF_ADD_PID  
  Add the process and signal specified by `signal_pid` and `signal` to the affinity list of the process specified by `target_pid`.

- __PAF_DELETE_PID  
  Delete the process and signal specified by `signal_pid` and `signal` from the affinity list of the process specified by `target_pid`.

The `target_pid` identifies the process whose affinity list will be altered.

The `signal_pid` identifies the process that upon termination of the `target_pid` will be sent `signal` signal.

The `signal` identifies the signal that the `signal_pid` process will receive when the `target_pid` process terminates.

Usage notes

1. Either the `Target_Pid` or `Signal_Pid` must contain the PID of the caller's process.
2. The __pid affinity service is limited to adding and deleting entries in the caller's affinity list, or adding and deleting entries that contain the caller's PID (`Signal_Pid`) in other processes affinity list.
3. When the PAF_DELETE_PID# function is specified the Signal is ignored. It is not validated and may contain any value.
4. An entry is only deleted (PAF_DELETE_PID# specified) when the `Signal_Pid` matches an entry in the `Target_Pid` process's affinity list.
Entries with duplicate PIDs are not allowed in an affinity list. If adding an entry (PAF_ADD_PID# specified) and an entry with a PID that matches the Signal_Pid is found the entry is reused. This may result in the loss of a specific signal.

No permission is required when adding the caller's PID to another process's affinity list. All processes have permission to send a signal to themselves (raise()).

The PIDs specified by the Target_Pid and Signal_Pid parameters must be greater than 1. Specifying a PID equal to or less than 1 will result in an error.

Returned value

If successful, __pid_affinity() returns 0.

If unsuccessful, __pid_affinity() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>One or more of the following conditions were detected:</td>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

int pipe(int fdinfo[2]);
```

General description

Creates a pipe, an I/O channel that a process can use to communicate with another process (in the same process or another process), or in some cases with itself. Data is written into one end of the pipe and read from the other. `fdinfo[2]` points to a memory area where `pipe()` can store two file descriptors. `pipe()` stores a file descriptor for the input end of the pipe in `fdinfo[1]`, and stores a file descriptor for the output end of the pipe in `fdinfo[0]`. Thus, processes can read from `fdinfo[0]` and write to `fdinfo[1]`. Data written to `fdinfo[1]` is read from `fdinfo[0]` on a first-in-first-out (FIFO) basis.

When `pipe()` creates a pipe, the O_NONBLOCK and FD_CLOEXEC flags are turned off on both ends of the pipe. You can turn these flags on with `fcntl()`. See “fcntl() — Control open file descriptors” on page 539 for details.

If `pipe()` successfully creates a pipe, it updates the access, change, and modification times for the pipe.

It is unspecified whether `fdinfo[0]` is also open for writing and whether `fdinfo[1]` is also open for reading. z/OS UNIX pipes are not STREAMS-based.

Returned value

If successful, `pipe()` returns 0.

If unsuccessful, `pipe()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EMFILE</td>
<td>Opening the pipe would exceed the limit on the number of file descriptors the process can have open. This limit is given by OPEN_MAX, defined in the limits.h header file.</td>
</tr>
<tr>
<td>ENFILE</td>
<td>Opening the pipe would exceed the number of files that the system can have open simultaneously.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Opening the pipe requires more space than is available.</td>
</tr>
</tbody>
</table>

Example

CELEBP04
/* CELEB04

This example creates an I/O channel.
The output shows the data written into one end and read from
the other.
*/

#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>

void reverse(char *s) {
    char *first, *last, temp;
    first = s;
    last = s+strlen(s)-1;
    while (first != last) {
        temp = *first;
        *(first++) = *last;
        *(last--) = temp;
    }
}

main() {
    char original[]="This is the original string";
    char buf[80];
    int p1[2], p2[2];
    if (pipe(p1) != 0)
        perror("first pipe() failed");
    else if (pipe(p2) != 0)
        perror("second pipe() failed");
    else if (fork() == 0) {
        close(p1[1]);
        close(p2[0]);
        if (read(p1[0], buf, sizeof(buf)) == -1)
            perror("read() error in parent");
        else {
            reverse(buf);
            if (write(p2[1], buf, strlen(buf)+1) == -1)
                perror("write() error in child");
        }
        exit(0);
    } else {
        close(p1[0]);
        close(p2[1]);
        printf("parent is writing '\"{}\"' to pipe 1\n", original);
        if (write(p1[1], original, strlen(original)+1) == -1)
            perror("write() error in parent");
        else if (read(p2[0], buf, sizeof(buf)) == -1)
            perror("read() error in parent");
        else printf("parent read '\"{}\"' from pipe 2\n", buf);
    }
}

Output:
parent is writing 'This is the original string' to pipe 1
parent read 'gnirts lanigiro eht si sihT' from pipe 2

__poe() — Port of entry information

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R5</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS
#include <sys/socket.h>

int __poe(__poecb_t *poecbp);
```

General description

The __poe() function allows the application to specify what port of entry (POE) information the system should use in determining various levels of permission checking. The attributes for the port of entry are used by services that perform user ID security authorization (examples are: setuid(), __login(), __passwd()).

Argument `poecbp` is the address of a __poecb_t structure which is used to control the port of entry operation. The __poecb_t structure is defined in <sys/socket.h>. For proper behavior the user should ensure that this structure has been initialized to zeros before it is populated. The elements of the __poecb_t structure are as follows:

__poe_options

Port of entry options. There are scope and action options. The combination defines the behavior of the function.

The scope option values are:

- _POE_SCOPE_THREAD
- _POE_SCOPE_PROCESS
- _POE_SCOPE_SOCKET

Scope options _POE_SCOPE_THREAD, _POE_SCOPE_PROCESS, and _POE_SCOPE_SOCKET are mutually exclusive. One must be specified.

**Note:** As of z/OS V1R12, scope options _POE_THREAD and _POE_PROCESS have been deprecated and replaced with new names. The old names remain for compatibility and must be used when TARGET compile option is prior to z/OS V1R12.

The action option values are:

- _POE_ACTION_READ
- _POE_ACTION_WRITE
- _POE_ACTION_SETGET

Action options _POE_ACTION_READ, _POE_ACTION_WRITE, and _POE_ACTION_SETGET are mutually exclusive. These are optional.

__poe_entry_type

Port of entry type. The types are:
__poe

__POE_SOCKET
Entry is a file descriptor for a socket.

__POE_FILE
Entry is a file descriptor for a non-socket file. Supported file types are character special, FIFO, regular, symbolic link, and directory.

__poe_entry_len
Port of entry length. The lengths are:

__POE_SOCKET_LEN
Length of a file descriptor for a socket.

__POE_FILE_LEN
Length of a file descriptor for a non-socket file.

__poe_entry_ptr
Address of port of entry.

__poe_poeattr
Port of entry attributes. This element is an IocPoeAttr structure as defined in <termios.h>.

The following table summarizes the port of entry operation according to scope and action:

<table>
<thead>
<tr>

</table>
**Options** | **POE Data** | **Description**
---|---|---
**Scope** | **Action** | **Source** | **Destination**
Thread | Read | Thread level (OTCB) | POE data in struct __poe_cb_s | Thread level POE data copied from the OTCB is returned to the caller via the struct __poe_cb_s.
Write | POE data in struct __poe_cb_s | Thread level (OTCB) | POE data received from the caller via the struct __poe_cb_s is copied to the thread level POE data in the OTCB.
SetGet | Socket or file descriptor | Thread level (OTCB) | POE data is extracted form the file/socket descriptor supplied by the caller. The data is copied to the thread level POE data data in the OTCB and returned to the caller via the struct __poe_cb_s.
None | Socket or file descriptor | Thread level (OTCB) | POE data is extracted from the file/socket descriptor supplied by the caller and copied to the thread level POE data in the OTCB.

The ability to register port of entry is a privileged operation. An installation has two ways of allowing an application to use this service:

1. For the highest level of security, the installation defines the BPX.POE FACILITY class profile. For an application to use this service the user ID it runs under must be given read access to this profile. See [z/OS UNIX System Services Planning](https://www.ibm.com) for more information on setting up this profile.

2. For a lower security arrangement, you can assign the user ID under which the application is run a UID of 0 so that it operates as a superuser.

For more detailed information on the usage of this function see [z/OS Planning for Multilevel Security and the Common Criteria](https://www.ibm.com) and [z/OS UNIX System Services Programming: Assembler Callable Services Reference](https://www.ibm.com).
Returned value

If successful, __poe() returns 0.

If unsuccessful, __poe() returns -1 and sets errno to one of the following values:

**EINVAL**

The __poe cb_t structure is not correct. Use __errno2() for more details.

**EPERM**

The calling process does not have the appropriate privileges to read or write the POE attributes.

**EFAULT**

A bad address was received. Either the poecbp parameter or the __poe_entry_ptr field in the __poe cb_t structure is not a valid address.

poll

poll() — Monitor activity on file descriptors and message queues

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

**Sockets:**
#define _XOPEN_SOURCE_EXTENDED 1
#include <poll.h>

int poll(struct pollfd fds[], nfds_t nmsgsfds, int timeout);

**Message queues and sockets:**
#define _XOPEN_SOURCE_EXTENDED 1
#define _OPEN_MSGQ_EXT
#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>
#include <poll.h>

int poll(void *listptr, nmsgsfds_t nmsgsfds, int timeout);

_OPEN_MSGQ_EXT must be defined if message queues are to be monitored.

General description

The poll() function provides applications with a mechanism for multiplexing input/output over the following set of file descriptors:
- regular files
- terminal and pseudoterminal devices
- STREAMS-based files
- sockets
- message queues.
- FIFOs
- pipes

For each member of the array(s) pointed to by listptr, poll() examines the given file descriptor or message queue for the event(s) specified in the member. The number of pollmsg structures and the number of pollfd structures in the arrays are specified by nmsgsfds. The poll() function identifies those file descriptors on which an application can read or write data, or on which an error event has occurred.

listptr A pointer to an array of pollfd structures, pollmsg structures, or to a pollist structure. Each structure specifies a file descriptor or message queue identifier and the events of interest for this file or message queue. The type of parameter to pass depends on whether you want to monitor file and socket descriptors, message queue identifiers, or both. To monitor socket descriptors only, set the high-order halfword of nmsgsfds to 0, the low-order halfword to the number of pollfd structures to be provided, and pass a pointer to an array of pollfd structures. To monitor message queues only, set the low-order halfword of nmsgsfds to 0, the high-order halfword to the number of pollmsg structures to be provided, and pass a
pointer to an array of pollmsg structures. To monitor both, set
`nmsgsfds` as described below, and pass a pointer to a pollist
structure. If a pollist structure is to be used, a structure similar to
the following should be defined in a user program. The pollfd
structure must precede the pollmsg structure.

```c
struct pollist {
    struct pollfd fds[3];
    struct pollmsg msgids[2];
} list;
```

`nmsgsfds` The number of pollmsg structures and the number of pollfd
structures pointed to by `listptr`.

This parameter is divided into two parts. The first half (the
high-order 16 bits) gives the number of pollmsg structures
containing message queue identifiers. This number must not
exceed the value 32767. The second half (the low-order 16 bits)
gives the number of pollfd structures containing file descriptors to
check. If either half of the `nmsgsfds` parameter is equal to a value
of 0, the corresponding pollmsg structures or pollfd structures is
assumed not to be present.

`timeout` The amount of time, in milliseconds, to wait for an event to occur.

If none of the defined events have occurred on any selected
descriptor, poll() waits at least `timeout` milliseconds for an event to
occur on any of the selected descriptors. If the value of `timeout` is
0, poll() returns immediately. If the value of `timeout` is -1, poll()
blocks until a requested event occurs or until the call is interrupted.

The above processing also applies to message queues.

Each pollfd or pollmsg structure contains the following fields:
- `fd/msgid` - open file descriptor or message queue identifier
- `events` - requested events
- `revents` - returned events

The events and revents fields are bitmasks constructed by OR-ing a combination
of the following event flags:

**POLLERR** An error or exceptional condition has occurred. This flag is only
valid in the revents bitmask; it is ignored in the events bitmask.

**POLLHUP** The device has been disconnected. This event and POLLOUT are
mutually exclusive, a stream can never be writable if a hang-up has
occurred. However, this event and POLLIN, POLLRDNORM,
POLLRDPRIO or POLLPRI are not mutually exclusive. This flag is
only valid in the revents bitmask. It is ignored in the events
member.

**POLLIN** Same as POLLRDNORM

**POLLNVAL** The specified fd/msgid value is invalid. This flag is only valid in the
revents bitmask; it is ignored in the events bitmask.

**POLLOUT** Same as POLLWRNORM

**POLLPRI** Out-of-band data may be received without blocking.
POLLRDDBAND
  Data from a nonzero priority band may be read without blocking.
  For STREAMS, this flag is set in revents even if the message is of zero length.

POLLRDNORM
  Normal data may be read without blocking.

POLLWRBAND
  Priority data (priority band greater than 0) may be written.

POLLWRNORM
  Normal data may be written without blocking.

Note: Poll bits are supported as follows.
  Regular Files Always poll() true for reading and writing. This means that all
                 poll() read and write bits are supported. They will never
                 return with POLLERR or POLLHUP.
  FIFOs / PIPEs Do not have the concept of out-of-band data or priority band
                 data. They support POLLIN, POLLRDNORM, POLLOUT, and
                 POLLWRNORM. They ignore POLLPRI, POLLRDDBAND, and
                 POLLWRBAND. They never return POLLERR.
  TTYs / OCS Same support as FIFOs and PIPEs, except that TTYs may
                 return POLLERR.
  Sockets Have the concept of out-of-band data. They support POLLIN,
                 POLLRDNORM, POLLOUT, POLLWRNORM, and POLLPRI
                 for out-of-band data. They ignore POLLRDDBAND and
                 POLLWRBAND. They never return POLLHUP or POLLERR.

If the value of fd/msgid is less than 0, events is ignored and revents is set to 0 in
that entry on return from poll().

In each pollfd structure, poll() clears the revents member except that where the
application requested a report on a condition by setting one of the bits of events
listed above, poll() sets the corresponding bit in revents if the requested condition is
true. In addition, poll() sets the POLLERR flag in revents if the condition is true,
even if the application did not set the corresponding bit in events.

The poll() function is not affected by the O_NONBLOCK flag.

A file descriptor for a socket that is listening for connections will indicate that it is
ready for reading, once connections are available. A file descriptor for a socket that
is connecting asynchronously will indicate that it is ready for writing, once a
connection has been established.

The following macros are provided to manipulate the nmsgsfds parameter and the
return value from poll():

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_SET_FDS_MSGS(nmsgsfds, nmsgs, nfds)</td>
<td>Sets the high-order halfword of nmsgsfds to nmsgs, and sets the low-order halfword of nmsgsfds to nfds.</td>
</tr>
<tr>
<td>_NFDS(n)</td>
<td>If the return value n from poll() is nonnegative, returns the number</td>
</tr>
</tbody>
</table>
of socket descriptors that meet the read, write, and exception criteria. A descriptor may be counted multiple times if it meets more than one given criterion.

_NMSGS(n) If the return value n from poll() is nonnegative, returns the number of message queues that meet the read, write, and exception criteria. A message queue may be counted multiple times if it meets more than one given criterion.

Returned value

If successful, poll() returns a nonnegative value.

A positive value indicates the total number of events that were found to be ready among the message queues and the total number of events that were found to be ready among the file descriptors. The return value is similar to nmsgsfds in that the high-order 16 bits of the return value give the number associated with message queues, and the low-order 16 bits give the number associated with file descriptors. Should the number associated with message queues be greater than 32767, only 32767 will be reported. This is to ensure that the return value does not appear to be negative. Should the number associated with file descriptors be greater than 65535, only 65535 will be reported.

If the call timed out and no file descriptors have been selected, poll() returns 0.

If unsuccessful, poll() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The allocation of internal data structures failed, but a subsequent request may succeed.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal was caught during poll().</td>
</tr>
<tr>
<td>EINVAL</td>
<td>One of the parameters specified a value that was not correct. Consult the reason code to determine the exact reason the error occurred. The following reason codes can accompany this return code.</td>
</tr>
<tr>
<td></td>
<td>• JRWAITFOREVER</td>
</tr>
<tr>
<td></td>
<td>• JRUNVALIDNFDS</td>
</tr>
<tr>
<td></td>
<td>• JRNOFDSTOOMANYQIDS</td>
</tr>
<tr>
<td>EIO</td>
<td>One of the descriptors in the select mask has become inoperative and it is being repeatedly included in a select even though other operations against this descriptor have been failing with EIO. A socket descriptor, for example, can become inoperative if TCP/IP is shut down. A failure from select can not tell you which descriptor has failed so generally select will succeed and these descriptors will be reported to you as being ready for whatever event they were being selected for. Subsequently when the descriptor is used on a receive or other operation you will receive the EIO failure and can react to the problem with the individual descriptor. In general you would close() the descriptor and remove it from the next select mask. If the individual descriptor’s failing return code is ignored though and an inoperative descriptor is repeatedly selected on and used, even though each time it is used that call fails with EIO, eventually the select call itself will fail with EIO.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdio.h>

FILE *popen(const char *command, const char *mode);
```

General description

The `popen()` function executes the command specified by the string `command`. It creates a pipe between the calling program and the executed command, and returns a pointer to a stream that can be used to either read from or write to the pipe.

The environment of the executed command will be as if a child process were created within the `popen()` call using `fork()`, and the child invoked the `sh` utility using the call:

```
execl("/bin/sh", "sh", ":");
```

The `popen()` function ensures that any streams from previous `popen()` calls that remain open in the parent process are closed in the child process.

The `mode` argument to `popen()` is a string that specifies I/O mode:

1. If `mode` is `r`, file descriptor `STDOUT_FILENO` will be the writable end of the pipe when the child process is started. The file descriptor `fileno(stream)` in the calling process, where `stream` is the stream pointer returned by `popen()`, will be the readable end of the pipe.

2. If `mode` is `w`, file descriptor `STDIN_FILENO` will be the readable end of the pipe when the child process is started. The file descriptor `fileno(stream)` in the calling process, where `stream` is the stream pointer returned by `popen()`, will be the writable end of the pipe.

3. If `mode` is any other value, a NULL pointer is returned and `errno` is set to EINVAL.

After `popen()`, both the parent and the child process will be capable of executing independently before either terminates.

Because open files are shared, a mode `r` command can be used as an input filter and a mode `w` command as an output filter.

Buffered reading before opening an input filter (that is, before `popen()`) may leave the standard input of that filter mispositioned. Similar problems with an output filter may be prevented by buffer flushing with `fflush()`.

A stream opened with `popen()` should be closed by `pclose()`.
popen

The behavior of popen() is specified for values of mode of r and w. mode values of rb and wb are supported but are not portable.

If the shell command cannot be executed, the child termination status returned by pclose() will be as if the shell command terminated using exit(127) or _exit(127).

If the application calls waitpid() with a pid argument greater than 0, and it still has a stream that was created with popen() open, it must ensure that pid does not refer to the process started by popen()

The stream returned by popen() will be designated as byte-oriented.

Special behavior for file tagging and conversion: When the FILETAG(AUTOTAG) run-time option is specified, the pipe opened for communication between the parent and child process by popen() will be tagged with the writer’s program CCSID upon first I/O. For example, if popen(some_command, "r") were specified, then the stream returned by the popen() would be tagged in the child process’ program CCSID.

Returned value

If successful, popen() returns a pointer to an open stream that can be used to read or write to a pipe.

If unsuccessful, popen() returns a NULL pointer and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The mode argument is invalid.</td>
</tr>
</tbody>
</table>

popen() may also set errno values as described by spawn(), fork(), or pipe().

posix_openpt() — Open a pseudo-terminal device

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 600
#include <stdlib.h>
#include <fcntl.h>

int posix_openpt(int oflag);
```

General description

The `posix_openpt()` function establishes a connection between a master device for a pseudo-terminal and a file descriptor. The file descriptor is used by other I/O functions that refer to that pseudo-terminal.

The file status flags and file access modes of the open file description are set according to the value of `oflag`.

Values for `oflag` are constructed by a bitwise-inclusive OR of flags from the following list, defined in `<fcntl.h>`:

- **O_RDWR**: Open for reading and writing.
- **O_NOCTTY**: If set, `posix_openpt()` will not cause the terminal device to become the controlling terminal for the process.

The behavior of other values for the `oflag` argument is unspecified.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oflag</code></td>
<td>The value of the file status flags and file access modes of the open file description.</td>
</tr>
</tbody>
</table>

Returned value

Upon successful completion, the `posix_openpt()` function opens a master pseudo-terminal device and returns a non-negative integer representing the lowest numbered unused file descriptor. Otherwise, -1 is returned and `errno` set to indicate the error.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EMFILE</td>
<td>(OPEN_MAX) file descriptors are currently open in the calling process.</td>
</tr>
<tr>
<td>ENFILE</td>
<td>The maximum allowable number of files is currently open in the system.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of <code>oflag</code> is not valid.</td>
</tr>
<tr>
<td>EAGAIN</td>
<td>Out of pseudo-terminal resources.</td>
</tr>
</tbody>
</table>
Example

```c
/* CELEBP71

This example demonstrates how to use posix_openpt() to open a
master psuedo-terminal device.

Expected output:
The master psuedo-terminal id is [first available descriptor]

*/

#define _XOPEN_SOURCE 600
#include <stdlib.h>
#include <fcntl.h>
#include <stdio.h>

void main() {
    int fd;

    fd = posix_openpt(O_RDWR | O_NOCTTY);
    if (fd == -1)
        perror("Error opening a terminal.\n");
    else
        printf("The master psuedo-terminal id is %d\n",fd);
}
```

Format

```c
#include <math.h>

double pow(double x, double y);
double pow(double x, int y); /* C++ only */
float pow(float x, int y); /* C++ only */
float pow(float x, float y); /* C++ only */
long double pow(long double x, int y); /* C++ only */
long double pow(long double x, long double y); /* C++ only */
float powf(float x, float y);
long double powl(long double x, long double y);
```

General description

The pow(), powf(), and powl() functions calculate the value of \( x \) to the power of \( y \).

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See IEEE Binary floating-point on page 94 for more information about IEEE Binary Floating-Point.

Restriction: The powl() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

If successful, the pow(), powf(), and powl() functions return the value of \( x \) to the power of \( y \).

If \( y \) is 0, the function returns 1.

If \( x \) is negative and \( y \) is non-integral, the function sets errno to EDOM and returns -HUGE_VAL. If the correct value is outside the range of representable values, ±HUGE_VAL is returned according to the sign of the value, and the value of ERANGE is stored in errno.

Special behavior for IEEE:

If \( x \) is negative or 0, then the \( y \) parameter must be an integer. If \( y \) is 0, the function returns 1.0 for all \( x \) parameters.

If an overflow occurs, the function returns HUGE_VAL and sets errno to ERANGE.

If both \( x \) and \( y \) are negative, the function returns NaNQ and sets errno to EDOM.
If $x$ is 0 and $y$ is negative, the function returns HUGE_VAL but does not modify errno.

Example

CELEBP05
/* CELEBP05

   This example calculates the value of $2^3$.

*/
#include <math.h>
#include <stdio.h>
int main(void)
{
   double x, y, z;
   x = 2.0;
   y = 3.0;
   z = pow(x,y);
   printf("%lf to the power of %lf is %lf\n", x, y, z);
}

Output:
2.000000 to the power of 3.000000 is 8.000000

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 powd32(_Decimal32 x, _Decimal32 y);
_Decimal64 powd64(_Decimal64 x, _Decimal64 y);
_Decimal128 powd128(_Decimal128 x, _Decimal128 y);

_Decimal32 pow(_Decimal32 x, _Decimal32 y); /* C++ only */
_Decimal64 pow(_Decimal64 x, _Decimal64 y); /* C++ only */
_Decimal128 pow(_Decimal128 x, _Decimal128 y); /* C++ only */
```

General description

The powd32(), powd64(), and powd128() functions calculate the value of x to the power of y.

Notes:
1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, the powd32(), powd64(), and powd128() functions return the value of x to the power of y.

If x is negative or 0, then the y parameter must be an integer. If y is 0, the function returns 1.0 for all x parameters.

If an overflow occurs, the function returns HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128 and sets errno to ERANGE.

If x is negative and y is not an integer, the function returns NaNQ and sets errno to EDOM.

If x is 0 and y is negative, the function returns HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128 but does not modify errno.

Example

```c
/* CELEBP59
   This example illustrates the powd64() function
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
```
int main(void)
{
    _Decimal64 x, y, z;
    x = 2.000D;
    y = 3.000D;
    z = powd64(x, y);
    printf("%.f to the power of %.f is %.f\n", x, y, z);
}

<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R10</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <unistd.h>

ssize_t pread(int fildes, void *buf, size_t nbyte, off_t offset);
```

General description

The pread() function performs the same action as read(), except that it reads from a given position in the file without changing the file pointer.

The first three arguments to pread() are the same as read(), with the addition of a fourth argument `offset` for the desired position inside the file.

An error result is returned for any attempt to perform a pread() on a file that is incapable of a seek action.

For regular files, no data transfer will occur past the offset maximum established in the open file description associated with `fildes`.

Returned value

If successful, pread() returns a non-negative integer indicating the number of bytes actually read.

If unsuccessful, pread() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>O_NONBLOCK is set to 1, but data was not available for reading.</td>

<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R9</td>
</tr>
<tr>
<td></td>
<td></td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_atfork(void (*prepare)(void), void (*parent)(void),
                    void (*child)(void));
```

General description

The `pthread_atfork()` function registers fork handlers to be called before and after `fork()`, in the context of the thread that called `fork()`. Fork handler functions may be named for execution at the following three points in thread processing:

- The `prepare` handler is called before `fork()` processing commences.
- The `parent` handler is called after `fork()` processing completes in the parent process.
- The `child` handler is called after `fork()` processing completes in the child process.

If any argument to `pthread_atfork()` is NULL, the call does not register a handler to be invoked at the point corresponding to that argument.

The order of calls to `pthread_atfork()` is significant. The `parent` and `child` fork handlers are called in the order in which they were established by calls to `pthread_atfork()`. The `prepare` fork handlers are called in the opposite order.

The intended purpose of `pthread_atfork()` is to provide a mechanism for maintaining the consistency of mutex locks between parent and child processes. The handlers are expected to be straightforward programs, designed simply to manage the synchronization variables and must return to ensure that all registered handlers are called. Historically, the prepare handler acquired needed mutex locks, and the parent and child handlers released them. Unfortunately, this usage is not practical on the z/OS platform and is not guaranteed to be portable in the current UNIX standards. When the parent process is multi-threaded (invoked `pthread_create()` at least once), the child process can only safely call async-signal-safe functions before it invokes an `exec()` family function. This restriction was added to the POSIX.1 standard in 1996. Because functions such as `pthread_mutex_lock()` and `pthread_mutex_unlock()` are not async-signal-safe, unpredictable results may occur if they are used in a child handler.

Special behavior for z/OS XL C: The C Library `pthread_atfork()` function has the following restrictions:

- Any fork handler registered by a fetched module that has been released is removed from the list at the time of release. See "fetch() — Get a load module" on page 577, "fetchep() — Share writable static" on page 590, and "release() — Delete a load module" on page 1681 for details about fetching and releasing modules.
**Any handler registered in an explicitly loaded DLL (using `dllload()` or `dlopen()`)
that has been freed (using `dllfree()` or `dlclose()`) is removed from the list, except
when the DLL has also been implicitly loaded.**

- Use of non-C subroutines or functions as fork handlers will result in undefined
behavior.

**Special behavior for z/OS XL C++:**
- All of the behaviors listed under “Special Behavior for z/OS XL C.”
- The `pthread_atfork()` function cannot receive C++ function pointers compiled as
31-bit non-XPLINK objects, because C and C++ linkage conventions are
incompatible in that environment. If you attempt to pass a C++ function pointer to
`pthread_atfork()`, the compiler will flag it as an error. In C++, you must ensure
that all handlers registered for use by `pthread_atfork()` have C linkage by
declaring them as extern "C".

**Returned value**

If successful, `pthread_atfork()` returns zero; otherwise, it returns an error number.

**Error Code**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
</tr>
</tbody>
</table>

Insufficient table space exists to record the fork handler addresses.

**Example**

```c
/* Example using SUSv3 pthread_atfork() interface */
#define _UNIX03_THREADS 1

#include <pthread.h>

pthread_attr_destroy

**pthread_attr_destroy() — Destroy the thread attributes object**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_attr_destroy(pthread_attr_t *attr);
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_destroy(pthread_attr_t *attr);
```

**General description**

Removes the definition of the thread attributes object. An error results if a thread attributes object is used after it has been destroyed.

`attr` is a pointer to a thread attribute object initialized by `pthread_attr_init()`.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

If a thread attribute object is shared between threads, the application must provide the necessary synchronization because a thread attribute object is defined in the application's storage.

**Returned value**

If successful, `pthread_attr_destroy()` returns 0.

If unsuccessful, `pthread_attr_destroy()` returns -1.

There are no documented errno values. Use `perror()` or `strerror()` to determine the cause of the error.

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_attr_destroy()` returns an error number to indicate the error.

**Example**

```c
CELEBP06
/* CELEBP06 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>
```
void *thread1(void *arg) {
    pthread_exit(NULL);
}

int main() {
    pthread_t thid;
    pthread_attr_t attr;

    if (pthread_attr_init(&attr) == −1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    if (pthread_create(&thid, &attr, thread1, NULL) == −1) {
        perror("error in pthread_create");
        exit(2);
    }

    if (pthread_detach(&thid) == −1) {
        perror("error in pthread_detach");
        exit(4);
    }

    if (pthread_attr_destroy(&attr) == −1) {
        perror("error in pthread_attr_destroy");
        exit(5);
    }

    exit(0);
}

<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_attr_getdetachstate(pthread_attr_t *attr);
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_getdetachstate(const pthread_attr_t *attr, int *detachstate);
```

**General description**

Returns the current value of the detachstate attribute for the thread attribute object, `attr`, that is created by `pthread_attr_init()`. The detachstate attribute values are:

- 0 Undetached. An undetached thread will keep its resources after termination.
- 1 Detached. A detached thread will have its resources automatically freed by the system at termination. Thus, you cannot get the thread’s termination status (or wait for the thread to terminate) by using `pthread_join()`.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

**Returned value**

If successful, `pthread_attr_getdetachstate()` returns the detachstate (0 or 1).

If unsuccessful, `pthread_attr_getdetachstate()` returns −1.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine the cause of the error.

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_attr_getdetachstate()` returns an error number to indicate the error.

**Example**

```c
CELEBP07
/* CELEBP07 */
#define _OPEN_THREADS
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>

int main()
```
pthreads

```c
pthread_attr_t attr;
char typ[12];

if (pthread_attr_init(&attr) == -1) {
    perror("error in pthread_attr_init");
    exit(1);
}

switch(pthread_attr_getdetachstate(&attr)) {
    default:
        perror("error in pthread_attr_getdetachstate()");
        exit(2);
    case 0:
        strcpy(typ, "undetached");
        break;
    case 1:
        strcpy(typ, "detached");
}
printf("The detach state is %s\n", typ);

if (pthread_attr_destroy(&attr) == -1) {
    perror("error in pthread_attr_destroy");
    exit(2);
}
exit(0);
```
### pthread_attr_getdetachstate

```c
}
printf("Threads created with this attribute object are %s\n",state);
if (pthread_attr_destroy(&attr) == -1) {
    perror("error in pthread_attr_destroy");
    exit(3);
}
exit(0);
```

</table>

### Format

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_getguardsize(const pthread_attr_t *__restrict__ attr,
                                size_t ** __restrict__ guardsize);
```

### General description

`pthread_attr_getguardsize()` gets the guardsize attribute from `attr` and stores it into `guardsize`.

`attr` is a pointer to a thread attribute object initialized by `pthread_attr_init()`.

The retrieved guardsize always matches the size stored by `pthread_attr_setguardsize()`, despite internal adjustments for rounding to multiples of the PAGESIZE system variable.

### Returned value

If successful, `pthread_attr_getguardsize()` returns 0; otherwise it returns an error number.

#### Error Number

<table>

#include <pthread.h>

int pthread_attr_getstack(const pthread_attr_t *__restrict__ attr,
                           void **__restrict__ addr, size_t *__restrict__ size);
```

**General description**

The `pthread_attr_getstack()` function gets both the base (lowest addressable) storage address and size of the initial stack segment from a thread attribute structure and stores them into `addr` and `size` respectively.

- `attr` is a pointer to a thread attribute object initialized by `pthread_attr_init()`.
- `addr` is a pointer to the user-defined location where this function will place the base address of the initial stack segment.
- `size` points to the user-defined location where this function will store the size of the initial stack segment.

**Note:** An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. The "size" argument refers to the size of the downward-growing stack.

**Returned value**

If successful, `pthread_attr_getstack()` returns 0; otherwise it returns an error number.

### pthread_attr_getstackaddr

**pthread_attr_getstackaddr() - Get stackaddr attribute**

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R9 POSIX(ON)</td>
</tr>
</tbody>
</table>

#### Format

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_getstackaddr(const pthread_attr_t *__restrict__ attr,
                               void ** __restrict__ addr);
```

#### General description

The `pthread_attr_getstackaddr()` function gets the stackaddr attribute from `attr` and stores it into `addr`. The stackaddr attribute holds the storage location of the created thread's initial stack segment.

`attr` is a pointer to a thread attribute object initialized by `pthread_attr_init()`.

**Note:** The `pthread_attr_getstackaddr()` function is provided for historical reasons and is marked obsolete in the Single UNIX Specification, Version 3 (SUSv3). New applications should use the newer function `pthread_attr_getstack()`, which provides functionality compatible with the SUSv3 standard.

#### Returned value

If successful, `pthread_attr_getstackaddr()` returns 0; otherwise it returns an error number.

**Error Number**

- **EINVAL**

  The value specified by `attr` does not refer to an initialized thread attribute object.

#### Example

```c
/* CELEBP64 */
/* Example using SUSv3 pthread_attr_getstackaddr() interface */

#define _UNIX03_THREADS 1
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <limits.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int rc;
    void *stackaddr;
    ```
void *mystack;

if (pthread_attr_init(&attr) == -1) {
    perror("error in pthread_attr_init");
    exit(1);
}

/* Get a big enough stack and align it on 4K boundary. */

mystack = malloc(PTHREAD_STACK_MIN * 2);
if (mystack != NULL) {
    printf("Using PTHREAD_STACK_MIN to align stackaddr \%x.n", mystack);
    mystack = (void *)((((long)mystack + (PTHREAD_STACK_MIN - 1)) /
                         PTHREAD_STACK_MIN) * PTHREAD_STACK_MIN);
} else {
    perror("Unable to acquire storage.");
    exit(2);
}

printf("Setting stackaddr to \%x\n", mystack);
rc = pthread_attr_setstackaddr(&attr, mystack);
if (rc != 0) {
    printf("pthread_attr_setstackaddr returned: %d\n", rc);
    printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
    exit(3);
} else {
    printf("Set stackaddr to \%x\n", mystack);
}

rc = pthread_attr_getstackaddr(&attr, &stackaddr);
if (rc != 0) {
    printf("pthread_attr_getstackaddr returned: %d\n", rc);
    printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
    exit(4);
} else {
    printf("Retrieved stackaddr is \%x\n", stackaddr);
}

rc = pthread_attr_destroy(&attr);
if (rc != 0) {
    perror("error in pthread_attr_destroy");
    printf("Returned: %d, Error: %d\n", rc, errno);
    printf("Errno_Jr: %x\n", __errno2());
    exit(5);
}

exit(0);

### pthread_attr_getstacksize

**pthread_attr_getstacksize() — Get the thread attribute stacksize object**

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_attr_getstacksize(pthread_attr_t *attr, size_t *stacksize);
```

**SUSV3**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_getstacksize(const pthread_attr_t *__restrict__attr, size_t *__restrict__stacksize);
```

#### General description

Gets the value, in bytes, of the stacksize attribute for the thread attribute object, `attr`, that is created by `pthread_attr_init()`. This function returns the value in the variable pointed to by `stacksize`.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

**Note:** An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. The “stacksize” refers to the size of the downward-growing stack.

#### Returned value

If successful, `pthread_attr_getstacksize()` returns 0 and stores the stacksize attribute value in `stacksize`.

If unsuccessful, `pthread_attr_getstacksize()` returns -1.

There are no documented errno values. Use `perr()` or `strerror()` to determine the cause of the error.

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_attr_getstacksize()` returns an error number to indicate the error.

#### Example

```c
CELEBP08
/* CELEBP08 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>
```
int main()
{
    pthread_attr_t attr;
    size_t size;

    if (pthread_attr_init(&attr) == −1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    if (pthread_attr_getstacksize(&attr, &size) == −1) {
        perror("error in pthread_attr_getstackstate()");
        exit(2);
    }

    printf("The stack size is %d.\n", (int) size);

    if (pthread_attr_destroy(&attr) == −1) {
        perror("error in pthread_attr_destroy");
        exit(2);
    }

    exit(0);
}

Output:
The stack size is 524288.

<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define __OPEN_SYS
#include <pthread.h>

int pthread_attr_getsynctype_np(pthread_attr_t *attr);
```

General description

The `pthread_attr_getsynctype_np` function returns the current synctype setting of the `attr` thread attribute object.

The `synctype` can be set to one of the following symbolics, as defined in the pthread.h header file:

- `__PTATSYNCHRONOUS` Can only create as many threads as TCBs available (or as many threads are available, depending on which number is smaller).
- `__PTATASYNCHRONOUS` Allows threads to be queued, that is, can create more threads than TCBs are available up to limit of how many threads are available. The queued threads will be released as TCBs become available.

Returned value

If successful, `pthread_attr_getsynctype_np()` returns the synctype value of the thread attribute object.

If unsuccessful, `pthread_attr_getsynctype_np()` returns -1.

There are no documented errno values. Use perror() or strerror() to determine cause of the error.

Related information

- ["pthread.h" on page 57](#)

pthread_attr_getweight_np

**pthread_attr_getweight_np() — Get weight of thread attribute object**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_attr_getweight_np(pthread_attr_t *attr);
```

**General description**

Obtains the current weight of the thread setting of the thread attributes object, `attr`. The symbols for weight are defined in the `pthread.h` include file. The following weights are supported:

- `__MEDIUM_WEIGHT` - The executing task can be reused when the thread exits.
- `__HEAVY_WEIGHT` - When this exits, the associated MVS task can no longer request threads to process.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each and every thread. You can define more than one thread attribute object.

**Returned value**

If successful, `pthread_attr_getweight_np()` returns the value of the weight of the thread attribute.

If unsuccessful, `pthread_attr_getweight_np()` returns −1.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine the cause of the error.

**Example**

```c
#include <stdio.h>
#include <pthread.h>

int main()
{
    pthread_attr_t attr;
    char weight[12];

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
    }
```

pthread_attr_getweight_np

1422 z/OS V1R13.0 XL C/C++ Run-Time Library Reference
exit(1);
}
switch(pthread_attr_getweight_np(&attr)) {
    default:
        perror("error in pthread_attr_getweight_np()");
        exit(2);
    case __HEAVY_WEIGHT:
        strcpy(weight, "heavy");
        break;
    case __MEDIUM_WEIGHT:
        strcpy(weight, "medium");
    }
    printf("The thread weight is %s.\n", weight);
    if (pthread_attr_destroy(&attr) == -1) {
        perror("error in pthread_attr_destroy()");
        exit(2);
    }
    exit(0);
}

Output:
The thread weight is heavy.

**General description**

Initializes `attr` with the default thread attributes, whose defaults are:

- **stacksize**: Inherited from the STACK run-time option
- **detachstate**: Undetached
- **synch**: Synchronous
- **weight**: Heavy

Using a thread attribute object, you can manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object. All threads are of equal priority.

If a thread attribute object is shared between threads, the application must provide the necessary synchronization because a thread attribute object is defined in the application's storage.

**Note:** An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. "stacksize" always refers to the size of the upward-growing stack. The size of the downward-growing stack is inherited from the THREADSTACK run-time option.

**Returned value**

If successful, `pthread_attr_init()` returns 0.

If unsuccessful, `pthread_attr_init()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>

---

1424  z/OS V1R13.0 XL C/C++ Run-Time Library Reference
ENOMEM Not enough memory is available to create the thread attribute object.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_attr_init() returns an error number to indicate the error.

Example

CELEBP10

/* CELEBP10 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>

void *thread1(void *arg)
{
    printf("hello from the thread\n");
    pthread_exit(NULL);
}

int main()
{
    int rc, stat;
    pthread_attr_t attr;
    pthread_t thid;

    rc = pthread_attr_init(&attr);
    if (rc == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    rc = pthread_create(&thid, &attr, thread1, NULL);
    if (rc == -1) {
        perror("error in pthread_create");
        exit(2);
    }

    rc = pthread_join(thid, (void *)&stat);
    exit(0);
}

```

SUSV3:
```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_setdetachstate(pthread_attr_t *attr, int detachstate);
```

General description

Alters the current detachstate setting of a thread attributes object, which can be set to PTHREAD_CREATE_JOINABLE or PTHREAD_CREATE_DETACHED.

0 Causes all the threads created with attr to be in an undetached state. An undetached thread will keep its resources after termination.

1 Causes all the threads created with attr to be in a detached state. A detached thread will have its resources automatically freed by the system at termination. Thus, you cannot get the thread's termination status, or wait for the thread to terminate by using pthread_join().

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

Returned value

If successful, pthread_attr_setdetachstate() returns 0.

If unsuccessful, pthread_attr_setdetachstate() returns −1.

pthread_attr_setguardsize

pthread_attr_setguardsize() - Set guardsize attribute

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R9 POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_setguardsize(pthread_attr_t *attr, size_t guardsize);
```

General description

`pthread_attr_setguardsize()` sets the guardsize attribute in `attr` using the value of `guardsize`.

`attr` is a pointer to a thread attribute object initialized by `pthread_attr_init()`.

This function stores the guardsize attribute in the thread attribute object for subsequent calls to `pthread_attr_getguardsize()`, but no further action is taken. The guardsize attribute is ignored during thread creation.

Note:

The Single UNIX Specification, Version 3 expects a guard area of at least guardsize bytes, but permits the rounding of guardsize to a multiple of the system variable, PAGESIZE. Stack management in z/OS UNIX sets a guard area of PAGESIZE in 31-bit applications and of (PAGESIZE * PAGESIZE) bytes in AMODE64. These values are the default for the guard size attribute. Requests for larger guard areas will fail with EINVAL.

A zero guardsize requests that no guard area be provided. However, z/OS UNIX stack management requires a guard area. Therefore, this request cannot be satisfied, although `pthread_attr_setguardsize()` will tolerate a guardsize of zero.

Returned value

If successful, `pthread_attr_setguardsize()` returns 0; otherwise, it returns an error number.

Error Code

<table>
<thead>
<tr>
<th>Error Code</th>

Example

```c
/* CELEBP66 */
/* Example using SUSv3 pthread_attr_setguardsize() interface */
#define _XOPEN_SOURCE 600
```
```c
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <limits.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int rc;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    printf("Set guardsize to value of PAGESIZE.
");
    rc = pthread_attr_setguardsize(&attr, PAGESIZE);
    if (rc != 0) {
        printf("pthread_attr_setguardsize returned: %d\n", rc);
        printf("Error: %d, Errno Jr: %08x\n", errno, __errno2());
        exit(2);
    } else {
        printf("Set guardsize is %d\n", PAGESIZE);
    }

    rc = pthread_attr_destroy(&attr);
    if (rc != 0) {
        perror("error in pthread_attr_destroy");
        exit(3);
    }

    exit(0);
}
```

**Format**

```c
#define _UNIX03_THREADS
#include <pthread.h>
#include <sched.h>

int pthread_attr_setschedparam(pthread_attr_t *__restrict__ attr,
                                const struct sched_param *__restrict__ param);
```

**General description**

`pthread_attr_setschedparam()` sets the scheduling priority attribute in `attr` using the value from `param`.

`attr` is a pointer to a thread attribute object initialized by `pthread_attr_init()`.

`param` points to a user-defined scheduling parameter object used by `pthread_attr_setschedparam()` as the source of the thread scheduling priority attribute to set in `attr`. The scheduling priority member of a sched_param structure is declared as an int.

If successful, the `sched_priority` from `param` is available for subsequent calls to the `pthread_getschedparam()` function. However, z/OS UNIX takes no other action based on the value of the scheduling priority stored in `attr`.

**Returned value**

If successful, `pthread_attr_setschedparam()` returns 0; otherwise, it returns an error number.

**Error Code**

<table>

The `pthread_attr_setstack()` function sets the `stackaddr` and `stacksize` attributes in `attr` from the values of `addr` and `size` respectively.

When a thread is created, the `stackaddr` attribute locates the base (lowest addressable byte) of the created thread’s initial stack segment. The `stacksize` attribute is the size, in bytes, of the initial stack segment allocated for the thread.

`attr` is a pointer to a thread attribute object initialized by `pthread_attr_init()`.

`addr` is the memory location to use for the initial stack segment and must be aligned appropriately to be used as a stack. For 31-bit applications, stack alignment is on a 4K boundary; in AMODE64, the alignment is on a one megabyte boundary.

`size` must be at least as large as `PTHREAD_STACK_MIN`. This constant is defined in the `<limits.h>` header.

The minimum stacksize in 31-bit is 4096 (4K) and in 64-bit 1048576 (1M). In addition, the system will allocate an equivalent-sized guardpage. There is no specified maximum stacksize. If more storage is requested than the system can satisfy at pthread creation, then `pthread_create()` will fail and return EINVAL.

Usage notes
1. An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. The "size" argument refers to the size of the downward-growing stack.
2. The Language Environment storage report tolerates but does not maintain statistics on application-managed stacks. Also, the run-time storage option, suboption for dsa initialization does not support application-managed stacks.

Returned value
If successful, `pthread_attr_setstack()` returns 0; otherwise, it returns an error number.

**pthread_attr_setstackaddr() - Set stackaddr attribute**

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R9, POSIX(ON)</td>
</tr>
</tbody>
</table>

### Format

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_setstackaddr(pthread_attr_t *attr, void *addr);
```

### General description

The `pthread_attr_setstackaddr()` function sets the stackaddr attribute in `attr` using the value of `addr`.

- `attr` is a pointer to a thread attribute object initialized by `pthread_attr_init()`.
- `addr` is the lowest addressable byte of the memory designated for use as the initial stack segment. It must have at least `PTHREAD_STACK_MIN` storage allocated. The `PTHREAD_STACK_MIN` constant is defined in `<limits.h>`. The `addr` value must also be aligned with the stack frame size, a multiple of 4K in 31-bit applications and one megabyte in AMODE 64.
- The thread must have permission to read and write to all pages within the stack referenced by `addr`.
- A stacksize is required at pthread creation. If the value is not present in the thread attribute object, the stacksize will default to `PTHREAD_STACK_MIN`. Subsequent calls to `pthread_attr_setstacksize()` can overwrite the stacksize prior to pthread creation.

### Usage notes

1. The `pthread_attr_setstackaddr()` function is provided for historical reasons. It is marked obsolescent in the Single UNIX Specification, Version 3 (SUSv3). New applications should use the newer function `pthread_attr_setstack()`, which provides functionality compatible with the SUSv3 standard.
2. An attribute object with the stackaddr attribute set may not be used more than once, unless it is destroyed and reinitialized, or its stackaddr attribute changed. For more details, see "Thread stack attributes" in the z/OS X/L C/C++ Programming Guide.
3. An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. The variable `addr` always refers to lowest addressable byte of the downward-growing stack.
4. The Language Environment storage report tolerates but does not maintain statistics on application-managed stacks. Also, the run-time storage option, suboption for dsa initialization does not support application-managed stacks.
pthread_attr_setstackaddr

Returned value

If successful, pthread_attr_setstackaddr() returns 0; otherwise, it returns an error number.

Error Code

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>

### Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_attr_setstacksize(pthread_attr_t *attr, size_t stacksize);
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_setstacksize(pthread_attr_t *attr, size_t stacksize);
```

### General description

Sets the stacksize, in bytes, for the thread attribute object, `attr`. `stacksize` is the initial stack size. Other stack characteristics, like stack increment size, are inherited from the STACK64/THREADSTACK64 run-time option.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

### Usage notes

1. An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. The "stacksize" refers to the size of the downward-growing stack.

2. When using Single UNIX Specification, Version thread support, the minimum stacksize in 31-bit is 4096 (4K) and in 64-bit 1048576 (1M). In addition, the system will allocate an equivalent-sized guardpage. There is no specified maximum stacksize. If more storage is requested than the system can satisfy at pthread creation, then pthread_create() will fail and return EINVAL.

### Returned value

- If successful, `pthread_attr_setstacksize()` returns 0.
- If unsuccessful, `pthread_attr_setstacksize()` returns -1.

**Error Code**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
</tr>
</tbody>
</table>

- EINVAL: The value of stacksize is less than PTHREAD_STACK_MIN, or the value specified by `attr` does not refer to an initialized thread attribute object.

**Special behavior for Single UNIX Specification, Version 3:**

- The system will allocate an equivalent-sized guardpage. There is no specified maximum stacksize. If more storage is requested than the system can satisfy at pthread creation, then pthread_create() will fail and return EINVAL.
If unsuccessful, pthread_attr_setstacksize() returns an error number to indicate the error.

Example

CELEBP12

/* CELEBP12 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>

void *thread1(void *arg)
{
    printf("hello from the thread\n");
    pthread_exit(NULL);
}

int main()
{
    int rc, stat;
    size_t s1;
    pthread_attr_t attr;
    pthread_t thid;

    rc = pthread_attr_init(&attr);
    if (rc == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    s1 = 4096;
    rc = pthread_attr_setstacksize(&attr, s1);
    if (rc == -1) {
        perror("error in pthread_attr_setstacksize");
        exit(2);
    }

    rc = pthread_create(&thid, &attr, thread1, NULL);
    if (rc == -1) {
        perror("error in pthread_create");
        exit(3);
    }

    rc = pthread_join(thid, (void *)&stat);
    exit(0);
}

#define _OPEN_SYS
#include <pthread.h>

int pthread_attr_setsynctype_np(pthread_attr_t *attr, int synctype);
```

**General description**

The `pthread_attr_setsynctype_np` function allows you to alter the synctype setting of the `attr` thread attribute object.

The synctype can be set to one of the following symbolics, as defined in the `pthread.h` header file:

- **__PTATSYNCHRONOUS**
  - Can only create as many threads as TCBs available (or as many threads are available, depending on which number is smaller).

- **__PTATASYNCHRONOUS**
  - Allows threads to be queued, that is, can create more threads than TCBs are available up to limit of how many threads are available. The queued threads will be released as TCBs become available. While threads are on the queue, they can still be affected by other pthread functions.

**Returned value**

- If successful, `pthread_attr_setsynctype_np()` returns 0.

- If unsuccessful, `pthread_attr_setsynctype_np()` returns -1.

There are no documented errno values. Use `perror()` or `strerror()` to determine cause of the error.

pthread_attr_setweight_np — Set weight of thread attribute object

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>
#include <pthread.h>

int pthread_attr_setweight_np(pthread_attr_t *attr, int threadweight);
```

General description

Alter the current weight of the thread setting of the thread attribute object, attr.

`threadweight` can be set to one of the following two symbols for the weight of the thread, as defined in the pthread.h header file.

- `__LIGHT_WEIGHT` Not supported.
- `__MEDIUM_WEIGHT` Each thread runs on a task. Upon exiting, if another thread is not queued to run, the task waits for some other thread to issue a pthread_create(), and the thread then runs on that task. The thread is assumed to cleanup all resources it used.
- `__HEAVY_WEIGHT` The task is attached on pthread_create() and terminates upon a pthread_exit(). Full MVS EOT resource cleanup occurs when exiting. When this exits, the associated MVS task can no longer request threads to process.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

Returned value

If successful, pthread_attr_setweight_np() returns 0.

If unsuccessful, pthread_attr_setweight_np() returns −1.

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

Example

```c
CELEBP13
/* CELEBP13 */
#define _OPEN_THREADS
#define _OPEN_SYS /* Needed to identify __MEDIUM_WEIGHT */
#include <stdio.h>
#include <pthread.h>
```
void *thread1(void *arg)
{
    printf("hello from the thread\n");
    pthread_exit((void *)(0));
}

int main()
{
    int rc, stat;
    pthread_attr_t attr;
    pthread_t thid;

    rc = pthread_attr_init(&attr);
    if (rc == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    rc = pthread_attr_setweight_np(&attr, __MEDIUM_WEIGHT);
    if (rc == -1) {
        perror("error in pthread_attr_setweight_np");
        exit(2);
    }

    rc = pthread_create(&thid, &attr, thread1, NULL);
    if (rc == -1) {
        perror("error in pthread_create");
        exit(3);
    }

    rc = pthread_join(thid, (void *)&stat);
    exit(0);
}

pthread_cancel() — Cancel a thread

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_cancel(pthread_t thread);
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_cancel(pthread_t thread);
```

General description

Requests that a thread be canceled. The thread to be canceled controls when this cancelation request is acted on through the cancelability state and type.

The cancelability states can be:

- **PTHREAD_INTR_DISABLE** The thread cannot be canceled.
- **PTHREAD_INTR_ENABLE** The thread can be canceled, but it is subject to type.

The cancelability types can be:

- **PTHREAD_INTR_CONTROLLED** The thread can be canceled, but only at specific points of execution:
  - When waiting on a condition variable, which is `pthread_cond_wait()` or `pthread_cond_timedwait()`
  - When waiting for the end of another thread, which is `pthread_join()`
  - While waiting for an asynchronous signal, which is `sigwait()`
  - Testing specifically for a cancel request, which is `pthread_testcancel()`
  - When suspended because of POSIX functions or one of the following C standard functions: `close()`, `fcntl()`, `open()`, `pause()`, `read()`, `tcdrain()`, `tcsetattr()`, `sigsuspend()`, `sigwait()`, `sleep()`, `wait()`, or `write()`

- **PTHREAD_INTRASYNCHRONOUS** The thread can be canceled at any time.

A thread that is joined on a thread that is canceled has a status of −1 returned to it.
For more information, refer to pthread_join() — Wait for a thread to end on page 1495.
pthread_cancel

pthread_t is the data type used to uniquely identify a thread. It is returned by pthread_create() and used by the application in function calls that require a thread identifier.

Note: A thread in mutex wait will not be interrupted by a signal, and therefore not canceled.

Special behavior for C++: Destructors for automatic objects on the stack will be run when a thread is canceled. The stack is unwound and the destructors are run in reverse order.

Special behavior for SUSv3: Single UNIX Standard, Version 3 defines new symbols for cancelability state and type. These are equivalent to the symbols described above and must be used when compiling in the SUSv3 namespace. The symbols for state are PTHREAD_CANCEL_ENABLE and PTHREAD_CANCEL_DISABLE. Symbols for type are PTHREAD_CANCEL_DEFERRED and PTHREAD_CANCEL_ASYNCHRONOUS.

Returned value

If successful, pthread_cancel() returns 0. Success indicates that the pthread_cancel() request has been issued. The thread to be canceled may still execute because of its interruptibility state.

If unsuccessful, pthread_create() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The specified thread is not valid.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>The specified thread does not refer to a currently existing thread.</td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3:

If unsuccessful, pthread_cancel() returns an error number to indicate the error.

Example

CELEBP14

```c
/* CELEBP14 */
#define _OPEN_THREADS
#include <errno.h>
#include <pthread.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>

int thstatus;

void * thread(void *arg)
{
    puts("thread has started. now sleeping");
    while (1)
        sleep(1);
}

main(int argc, char *argv[])
{
    pthread_t thid;
    void *status;
```
if ( pthread_create(&thid, NULL, thread, NULL) != 0) {
    perror("pthread_create failed");
    exit(2);
}

if ( pthread_cancel(thid) == -1 ) {
    perror("pthread_cancel failed");
    exit(3);
}

if ( pthread_join(thid, &status)== -1 ) {
    perror("pthread_join failed");
    exit(4);
}

if ( status == (int *)-1 )
    puts("thread was cancelled");
else
    puts("thread was not cancelled");

exit(0);

Output:
thread has started. now sleeping
thread was canceled

pthread_cleanup_pop

pthread_cleanup_pop() — Remove a cleanup handler

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

void pthread_cleanup_pop(int execute);
```

General description

Removes the specified routine in the last executed pthread_cleanup_push() statement from the top of the calling thread's cleanup stack.

The execute parameter specifies whether the cleanup routine that is popped should be run or just discarded. If the value is nonzero, the cleanup routine is executed.

pthread_cleanup_push() and pthread_cleanup_pop() must appear in pairs in the program within the same lexical scope, or undefined behavior will result.

When the thread ends, all pushed but not yet popped cleanup routines are popped from the cleanup stack and executed in last-in-first-out (LIFO) order. This occurs when the thread:

- Calls pthread_exit()
- Does a return from the start routine (that gets controls as a result of a pthread_create())
- Is canceled because of a pthread_cancel()

Returned value

pthread_cleanup_pop() returns no values.

This function is used as a statement.

If an error occurs while a pthread_cleanup_pop() statement is being processed, a termination condition is raised.

There are no documented errno values. Use perror() or strerror() to determine the cause of an error.

Example

```c
CELEBP15

/* CELEBP15 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

int iteration;

void noise_maker(void *arg) {
```
printf("hello from noise_maker in iteration %d\n", iteration);
}
void *thread(void *arg) {
    pthread_cleanup_push(noise_maker, NULL);
    pthread_cleanup_pop(iteration == 1 ? 0 : 1);
}
main() {
    pthread_t thid;
    void * ret;
    for (iteration=1; iteration<=2; iteration++) {
        if (pthread_create(&thid, NULL, thread, NULL) != 0) {
            perror("pthread_create() error");
            exit(1);
        }
        if (pthread_join(thid, &ret) != 0){
            perror("pthread_join() error");
            exit(2);
        }
        /*
        if (pthread_detach(&thid) != 0) {
            perror("pthread_detach() error");
            exit(3);
        }
        */
    }
    Output:
    hello from noise_maker in iteration 2!

Related information
- "pthread.h" on page 57

pthread_cleanup_push

pthread_cleanup_push() — Establish a cleanup handler

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

void pthread_cleanup_push(void (*routine)(void *arg), void *arg);
```

General description

Pushes the specified `routine` onto the calling thread's cleanup stack. The cleanup handler is executed as a result of a `pthread_cleanup_pop()`, with a nonzero value for the `execute` parameter.

When the thread ends, all pushed but not yet popped cleanup routines are popped from the cleanup stack and executed in last-in-first-out (LIFO) order. This occurs when the thread:

- Calls `pthread_exit()`
- Does a return from the start routine
- Is canceled because of a `pthread_cancel()`

`pthread_cleanup_push()` and `pthread_cleanup_pop()` must appear in pairs and within the same lexical scope, or undefined behavior will result.

**Special behavior for C++:** Because C and C++ linkage conventions are incompatible, `pthread_cleanup_push()` cannot receive a C++ function pointer as the start routine function pointer. If you attempt to pass a C++ function pointer to `pthread_cleanup_push()`, the compiler will flag it as an error. You can pass a C or C++ function to `pthread_cleanup_push()` by declaring it as extern "C".

Returned value

`pthread_cleanup_push()` returns no values.

This function is used as a statement.

If an error occurs while a `pthread_cleanup_push()` statement is being processed, a termination condition is raised.

There are no documented errno values. Use `perror()` or `strerror()` to determine the cause of an error.

Example

```c
CELEBP16
/* CELEBP16 */
#define _OPEN_THREADS

#include <pthread.h>
#include <stdio.h>
```
#include <stdlib.h>
#include <unistd.h>

int footprint=0;

void *thread(void *arg) {
    char *storage;
    if ((storage = (char*) malloc(80)) == NULL) {
        perror("malloc() failed");
        exit(6);
    }
    /* Plan to release storage even if thread doesn't exit normally */
    pthread_cleanup_push(free, storage);
    puts("thread has obtained storage and is waiting to be cancelled");
    footprint++;
    while (1)
        sleep(1);
    pthread_cleanup_pop(1);
}

main() {
    pthread_t thid;
    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create() error");
        exit(1);
    }
    while (footprint == 0)
        sleep(1);
    puts("IPT is cancelling thread");
    if (pthread_cancel(thid) != 0) {
        perror("pthread_cancel() error");
        exit(3);
    }
    if (pthread_join(thid, NULL) != 0) {
        perror("pthread_join() error");
        exit(4);
    }
}

Output:
thread has obtained storage and is waiting to be canceled
IPT is canceling thread

int pthread_cond_broadcast(pthread_cond_t *cond);
```

SUSV3:

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_cond_broadcast(pthread_cond_t *cond);
```

General description

Unblock all threads that are blocked on the specified condition variable, `cond`. If more than one thread is blocked, the order in which the threads are unblocked is unspecified.

`pthread_cond_broadcast()` has no effect if there are no threads currently blocked on `cond`.

Returned value

If successful, `pthread_cond_broadcast()` returns 0.

If unsuccessful, `pthread_cond_broadcast()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>cond</code> does not refer to an initialized condition variable.</td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3:

If unsuccessful, `pthread_cond_broadcast()` returns an error number to indicate the error.

Example

```c
CELEBP17

/* CELEBP17 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_cond_t cond;
    if (pthread_cond_init(&cond, NULL) != 0) {
```
perror("pthread_cond_init() error");
exit(1);
}

if (pthread_cond_broadcast(&cond) != 0) {
    perror("pthread_cond_broadcast() error");
    exit(2);
}

if (pthread_cond_destroy(&cond) != 0) {
    perror("pthread_cond_destroy() error");
    exit(3);
}

#include <pthread.h>

int pthread_cond_destroy(pthread_cond_t *cond);
```

**SUSV3:**

```c
#define __UNIX03_THREADS
#include <pthread.h>

int pthread_cond_destroy(pthread_cond_t *cond);
```

**General description**

Destroys the condition variable object specified by `cond`.

A condition variable object identifies a condition variable. Condition variables are used in conjunction with mutexes to protect shared resources.

**Returned value**

If successful, `pthread_cond_destroy()` returns 0.

If unsuccessful, `pthread_cond_destroy()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBUSY</td>
<td>An attempt was made to destroy the object referenced by <code>cond</code> while it is referenced by another thread.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>cond</code> is not valid.</td>
</tr>
</tbody>
</table>

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_cond_destroy()` returns an error number to indicate the error.

**Example**

```c
CELEBP18
/* CELEBP18 */
#define __OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_cond_t cond;
    if (pthread_cond_init(&cond, NULL) != 0) {
        perror("pthread_cond_init() error");
        exit(1);
    }
```
if (pthread_cond_destroy(&cond) != 0) {
    perror("pthread_cond_destroy() error");
    exit(2);
}

</tbody>
</table>

**Format**

```c
#include <pthread.h>

int pthread_cond_init(pthread_cond_t *cond, pthread_condattr_t *attr);
```

**SUSV3:**

```c
#include <pthread.h>

int pthread_cond_init(pthread_cond_t *__restrict__cond, pthread_condattr_t *__restrict__attr);
```

**General description**

Initializes the condition variable referenced by `cond` with attributes referenced by `attr`. If `attr` is NULL, the default condition variable attributes are used.

**Returned value**

If successful, `pthread_cond_init()` returns 0.

If unsuccessful, `pthread_cond_init()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>There is not enough memory to initialize the condition variable.</td>
</tr>
<tr>
<td>EAGAIN</td>
<td>The system lacked the necessary resources (other than memory) to initialize another condition variable.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>The implementation has detected an attempt to reinitialize the object referenced by <code>cond</code>, a previously initialized, but not yet destroyed, condition variable.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>attr</code> is invalid.</td>
</tr>
</tbody>
</table>

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_cond_init()` returns an error number to indicate the error.

**Usage notes**

The `_OPEN_SYS_MUTEX_EXT` feature switch can be optionally included. If the feature is set, then significantly larger `pthread_cond_t` objects will be defined. The feature is used for the management of mutex and condition variables in shared memory. If the feature switch is set in the define of the condition variables in shared memory, then the same feature switch must be set in the define of the mutex associated with the condition variables.
If the supplied extended pthread_cond_t object is not in shared memory, pthread_cond_init() will treat the object as a non-shared object, since it is not accessible to any other process.

If the _OPEN_SYS_MUTEX_EXT feature switch is set, a shared condition variable is tied to the specified mutex for the life of the condition variable and mutex the very first time a pthread_cond_wait() or pthread_cond_timedwait() is issued. No other mutex can be associated with the specified condition variable or vice versa until the condition variable or mutex is destroyed.

It is recommended that you define and initialize pthread_cond_t objects in the same compile unit. If you pass a pthread_cond_t object around to be initialized, make sure the initialization code has been compiled with the same _OPEN_SYS_MUTEX_EXT feature setting as the code that defines the object.

The following sequence may cause storage overlay with unpredictable results:
1. Declare or define a pthread_cond_t object (in shared storage) without #define of the _OPEN_SYS_MUTEX_EXT feature. The created pthread_cond_t object is standard size (i.e. small) without the _OPEN_SYS_MUTEX_EXT feature defined.
2. Pass the pthread_cond_t object to another code unit, which was compiled with the _OPEN_SYS_MUTEX_EXT feature defined, to be initialized as a shared object. The pthread_cond_t initialization generally involves the following steps:
   a. pthread_condattr_init()
   b. pthread_condattr_setpshared(). This step sets the attribute of the pthread_cond_t as PTHREAD_PROCESS_SHARED and designates the object to be of extended size.
   c. pthread_cond_init(). This step initializes the passed-in (small) pthread_cond_t object as if it is an extended object, causing storage overlay.

Example

CELEBP19
/* CELEBP19 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_cond_t cond;

    if (pthread_cond_init(&cond, NULL) != 0) {
        perror("pthread_cond_init() error");
        exit(1);
    }

    if (pthread_cond_destroy(&cond) != 0) {
        perror("pthread_cond_destroy() error");
        exit(2);
    }
}

</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>cond</code> does not refer to an initialized condition variable.</td>
</tr>
</tbody>
</table>

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_cond_signal()` returns an error number to indicate the error.

**Example**

```c
CELEBP20
/* CELEBP20 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_cond_t cond;

    if (pthread_cond_init(&cond, NULL) != 0) {
        perror("pthread_cond_init() error");
        exit(1);
    }
```
if (pthread_cond_signal(&cond) != 0) {
    perror("pthread_cond_broadcast() error");
    exit(2);
}

if (pthread_cond_destroy(&cond) != 0) {
    perror("pthread_cond_destroy() error");
    exit(3);
}

### pthread_cond_timedwait

#### pthread_cond_timedwait() — Wait on a condition variable

##### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

##### Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_cond_timedwait(pthread_cond_t *cond, pthread_mutex_t *mutex, const struct timespec *abstime);
```

SUSV3:

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_cond_timedwait(pthread_cond_t *__restrict__cond, pthread_mutex_t *__restrict__mutex, const struct timespec *__restrict__abstime);
```

##### General description

Allows a thread to wait on a condition variable until satisfied or until a specified time occurs. `pthread_cond_timedwait()` is the same as `pthread_cond_wait()` except it returns an error if the absolute time, specified by `abstime`, satisfies one of these conditions:

- Passes before `cond` is signaled or broadcasted
- Has already been passed at the time of the call

When such timeouts occur, `pthread_cond_timedwait()` reacquires the mutex, referenced by `mutex` (created by `pthread_mutex_init()`).

The two elements within the struct `timespec` are defined as follows:

- `tv_sec` The time to wait for the condition signal. It is expressed in seconds from midnight, January 1, 1970 UTC. The value specified must be greater than or equal to current calendar time expressed in seconds since midnight, January 1, 1970 UTC and less than 2,147,483,648 seconds.

- `tv_nsec` The time in nanoseconds to be added to `tv_sec` to determine when to stop waiting. The value specified must be greater than or equal to zero (0) and less than 1,000,000,000 (1,000 million).

##### Returned value

If successful, `pthread_cond_timedwait()` returns 0.

If unsuccessful, `pthread_cond_timedwait()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>For a private condition variable, the time specified by <code>abstime</code> has passed.</td>
</tr>
</tbody>
</table>
pthread_cond_timedwait

EINVAL Can be one of the following error conditions:
• The value specified by cond is not valid.
• The value specified by mutex is not valid.
• The value specified by abstime (tv_sec) is not valid.
• The value specified by abstime (tv_nsec) is not valid.
• Different mutexes were specified for concurrent operations on the same condition variable.

ETIMEDOUT

For a shared condition variable, the time specified by abstime has passed.

Note: In SUSV3, pthread_cond_timedwait() also returns ETIMEDOUT for a private condition variable, when the time specified by abstime has passed.

EPERM The mutex was not owned by the current thread at the time of the call.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_cond_timedwait() returns an error number to indicate the error.

Usage notes

If the condition variable is shared (PTHREAD_PROCESS_SHARED), the mutex must also be shared, with the _OPEN_SYS_MUTEX_EXT feature defined when the mutex was created and initialized.

If the condition variable is private (PTHREAD_PROCESS_PRIVATE), the mutex must also be private.

If the condition variable is shared, all calls to pthread_cond_wait() or pthread_cond_timedwait() for a given condition variable must use the same mutex for the life of the process, or until both the condition variable and mutex are destroyed (using pthread_cond_destroy() and pthread_mutex_destroy()).

Example

CELEBP21
/* CELEBP21 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>
#include <time.h>
#include <errno.h>

main() {
    pthread_cond_t cond;
    pthread_mutex_t mutex;
    time_t T;
    struct timespec t;

    if (pthread_mutex_init(&mutex, NULL) != 0) {
        perror("pthread_mutex_init() error");
        exit(1);
    }

    if (pthread_cond_init(&cond, NULL) != 0) {
        perror("pthread_cond_init() error");
        exit(2);
    }

    pthread_mutex_lock(&mutex);
    pthread_cond_signal(&cond);
    pthread_mutex_unlock(&mutex);

    time(&T);
    t.tv_sec = T;
    t.tv_nsec = 0;
    if (pthread_cond_timedwait(&cond, &mutex, &t) == 0) {
        printf("Condition waited.");
    } else {
        perror("pthread_cond_timedwait() error");
        exit(3);
    }

    pthread_mutex_unlock(&mutex);
    pthread_mutex_destroy(&mutex);
    pthread_cond_destroy(&cond);
}
if (pthread_mutex_lock(&mutex) != 0) {
    perror("pthread_mutex_lock() error");
    exit(3);
}

time(&T);
t.tv_sec = T + 2;
printf("starting timedwait at %s", ctime(&T));
if (pthread_cond_timedwait(&cond, &mutex, &t) != 0)
    if (errno == EAGAIN)
        puts("wait timed out");
    else {
        perror("pthread_cond_timedwait() error");
        exit(4);
    }

time(&T);
printf("timedwait over at %s", ctime(&T));
}

Output:
starting timedwait at Fri Jun 16 10:44:00 2001
wait timed out
timedwait over at Fri Jun 16 10:44:02 2001

pthread_cond_wait

pthread_cond_wait() — Wait on a condition variable

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_cond_wait(pthread_cond_t *cond, pthread_mutex_t *mutex);
```

SUSV3:

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_cond_wait(pthread_cond_t * __restrict__cond, 
                       pthread_mutex_t * __restrict__mutex);
```

General description

Blocks on a condition variable. It must be called with `mutex` locked by the calling thread, or undefined behavior will result. A mutex is locked using `pthread_mutex_lock()`.

`cond` is a condition variable that is shared by threads. To change it, a thread must hold the `mutex` associated with the condition variable. The `pthread_cond_wait()` function releases this `mutex` before suspending the thread and obtains it again before returning.

The `pthread_cond_wait()` function waits until a `pthread_cond_broadcast()` or a `pthread_cond_signal()` is received. For more information on these functions, refer to "pthread_cond_broadcast() — Broadcast a condition" on page 1450 and to "pthread_cond_signal() — Signal a condition" on page 1457.

Returned value

If successful, `pthread_cond_wait()` returns 0.

If unsuccessful, `pthread_cond_wait()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Different mutexes were specified for concurrent operations on the same condition variable.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The mutex was not owned by the current thread at the time of the call.</td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_cond_wait()` returns an error number to indicate the error.
Usage notes

If the condition variable is shared (PTHREAD_PROCESS_SHARED), the mutex must also be shared, with the _OPEN_SYS_MUTEX_EXT feature defined when the mutex was created and initialized.

If the condition variable is private (PTHREAD_PROCESS_PRIVATE), the mutex must also be private.

If the condition variable is shared, all calls to pthread_cond_wait() or pthread_cont_timedwait() for a given condition variable must use the same mutex for the life of the process, or until both the condition variable and mutex are destroyed (using pthread_cond_destroy() and pthread_mutex_destroy()).

Example

CELEBP22

/* CELEBP22 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>
#include <time.h>
#include <unistd.h>

pthread_cond_t cond;
pthread_mutex_t mutex;

int footprint = 0;

void *thread(void *arg) {
void *t;

if (pthread_mutex_lock(&mutex) != 0) {
    perror("pthread_mutex_lock() error");
    exit(6);
}

time_t T;
printf("starting wait at \%s", ctime(&T));

footprint++;

if (pthread_cond_wait(&cond, &mutex) != 0) {
    perror("pthread_cond_wait() error");
    exit(7);
}

time_t T;
printf("wait over at \%s", ctime(&T));
}

main() {
    pthread_t thid;
time_t T;
struct timespec t;

if (pthread_mutex_init(&mutex, NULL) != 0) {
    perror("pthread_mutex_init() error");
    exit(1);
}

if (pthread_cond_init(&cond, NULL) != 0) {
    perror("pthread_cond_init() error");
    exit(2);
}

if (pthread_create(&thid, NULL, thread, NULL) != 0) {
    perror("pthread_create() error");
}
pthread_cond_wait

    exit(3);
}

while (footprint == 0)
    sleep(1);
puts("IPT is about ready to release the thread");
sleep(2);
if (pthread_cond_signal(&cond) != 0) {
    perror("pthread_cond_signal() error");
    exit(4);
}

if (pthread_join(thid, NULL) != 0) {
    perror("pthread_join() error");
    exit(5);
}

Output:
starting wait at Fri Jun 16 10:54:06 2001
IPT is about ready to release the thread
wait over at Fri Jun 16 10:54:09 2001

int pthread_condattr_destroy(pthread_condattr_t *attr);
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_condattr_destroy(pthread_condattr_t *attr);
```

**General description**

Destroys a condition attribute object. Condition-variable attribute objects are similar to mutex attribute objects because you can use them to manage the characteristics of condition variables in your application. They define the set of values to be used for the condition variable during its creation.

`pthread_condattr_init()` is used to define a condition variable attribute object. `pthread_condattr_destroy()` is used to remove the definition of the condition variable attribute object. These functions are provided for portability purposes.

You can define a condition variable without using these functions by supplying a NULL parameter during the `pthread_cond_init()` call. For more details, refer to "pthread_cond_init() — Initialize a condition variable" on page 1454.

**Returned value**

If successful, `pthread_condattr_destroy()` returns 0.

If unsuccessful, `pthread_condattr_destroy()` returns −1 and sets `errno` to one of the following values:

**Error Code**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
</tr>
</tbody>
</table>

The value specified by `attr` is not valid.

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_condattr_destroy()` returns an error number to indicate the error.

**Example**

CELEBP23
/* CELEBP23 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_condattr_t cond;

    if (pthread_condattr_init(&cond) != 0) {
        perror("pthread_condattr_init() error");
        exit(1);
    }

    if (pthread_condattr_destroy(&cond) != 0) {
        perror("pthread_condattr_destroy() error");
        exit(2);
    }
}

</thead>
<tbody>
<tr>
<td>Language Environment Extension</td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Format

```c
#define _OPEN_THREADS
#define _OPEN_SYS_MUTEX_EXT
#include <pthread.h>

int pthread_condattr_getpshared(const pthread_condattr_t *attr,  
                               int *pshared);

SUSV3:
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_condattr_getpshared(const pthread_condattr_t * __restrict__attr,  
                               int * __restrict__pshared);
```

### General description

Gets the attribute `pshared` for the condition variable attribute object `attr`. By using `attr`, you can determine its process-shared value for a condition variable.

Valid values for the attribute `pshared` are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PTHREAD_PROCESS_SHARED</td>
<td>Permits a condition variable to be operated upon by any thread that has access to the memory where the condition variable is allocated; even if the condition variable is allocated in memory that is shared by multiple processes.</td>
</tr>
<tr>
<td>PTHREAD_PROCESS_PRIVATE</td>
<td>A condition variable can only be operated upon by threads created within the same process as the thread that initialized the condition variable. If threads of differing processes attempt to operate on such a condition variable, only the process to initialize the condition variable will succeed. When a new process is created by the parent process it will receive a different copy of the private condition variable which can only be used to serialize between threads in the child process.</td>
</tr>
</tbody>
</table>

**Note:** This is the default value of `pshared`

### Returned value

If successful, 0 is returned. If unsuccessful, -1 is returned and the errno value is set. The following is the value of errno:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified for <code>attr</code> is not valid.</td>
</tr>
</tbody>
</table>
**pthread_condattr_getpshared**

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_condattr_getpshared()` returns an error number to indicate the error.

```

SUSV3:

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_condattr_init(pthread_condattr_t *attr);
```

General description

Establishes the default values for the condition variables that will be created. A condition attribute (condattr) object contains various condition variable characteristics. You can set up a template of these characteristics and then create a set of condition variables with similar characteristics.

Condition variable attribute objects are similar to mutex attribute objects. You can use them to manage the characteristics of condition variables in your application. They define the set of values to be used for the condition variable during its creation. For a valid condition variable attribute, refer to pthread_condattr_setkind_np() -- Set Kind Attribute from a Condition Variable Attribute Object and pthread_condattr_setpshared() --Set the Process-Shared Condition Variable Attribute

pthread_condattr_init() is used to define a condition variable attribute object. pthread_condattr_destroy() is used to remove the definition of the condition variable attribute object. These functions are provided for portability purposes.

You can define a condition variable without using these functions by supplying a NULL parameter during the pthread_cond_init() call. For more details, refer to “pthread_cond_init() — Initialize a condition variable” on page 1454.

Returned value

If successful, pthread_condattr_init() returns 0.

If unsuccessful, pthread_condattr_init() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>There is not enough memory to initialize the condition variable attributes object.</td>
</tr>
</tbody>
</table>
pthread_condattr_init

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, pthread_condattr_init() returns an error number to indicate the error.

**Example**

```c
CELEBP25
/* CELEBP25 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_condattr_t cond;
    if (pthread_condattr_init(&cond) != 0) {
        perror("pthread_condattr_init() error");
        exit(1);
    }
    if (pthread_condattr_destroy(&cond) != 0) {
        perror("pthread_condattr_destroy() error");
        exit(2);
    }
}

<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#define _OPEN_SYS_MUTEX_EXT
#include <pthread.h>

int pthread_condattr_setpshared(pthread_condattr_t *attr,
                                 int pshared);
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#define _OPEN_SYS_MUTEX_EXT
#include <pthread.h>

int pthread_condattr_setpshared(pthread_condattr_t *attr,
                                 int pshared);
```

**General description**

Sets the attribute `pshared` for the condition variable attribute object `attr`.

A condition variable attribute object (`attr`) allows you to manage the characteristics of condition variables in your application by defining a set of values to be used for a condition variable during its creation. By establishing a condition variable attribute object, you can create many condition variables with the same set of characteristics, without needing to define the characteristics for each and every condition variable. By using `attr`, you can define its process-shared value for a condition variable.

Valid values for the attribute `pshared` are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PTHREAD_PROCESS_SHARED</td>
<td>Permits a condition variable to be operated upon by any thread that has access to the memory where the condition variable is allocated; even if the condition variable is allocated in memory that is shared by multiple processes.</td>
</tr>
<tr>
<td>PTHREAD_PROCESS_PRIVATE</td>
<td>A condition variable can only be operated upon by threads created within the same process as the thread that initialized the condition variable. If threads of differing processes attempt to operate on such a condition variable, only the process to initialize the condition variable will succeed. When a new process is created by the parent process it will receive a different copy of the private condition variable which can only be used to serialize between threads in the child process.</td>
</tr>
</tbody>
</table>
**Note:** This is the default value of *pshared.*

**Returned value**

If successful, 0 is returned. If unsuccessful, -1 is returned and the errno value is set. The following is the value of errno:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified for <em>attr</em> is not valid.</td>
</tr>
</tbody>
</table>

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, *pthread_condattr_setpshared()* returns an error number to indicate the error.

**Usage notes**

It is recommended that you define and initialize *pthread_cond_t* objects in the same compile unit. If you pass a *pthread_cond_t* object around to be initialized, make sure the initialization code has been compiled with the same `_OPEN_SYS_MUTEX_EXT` feature setting as the code that defines the object.

The following sequence may cause storage overlay with unpredictable results:

1. Declare or define a *pthread_cond_t* object (in shared storage) without #define of the `_OPEN_SYS_MUTEX_EXT` feature. The created *pthread_cond_t* object is standard size (i.e. small) without the `_OPEN_SYS_MUTEX_EXT` feature defined.
2. Pass the *pthread_cond_t* object to another code unit, which was compiled with the `_OPEN_SYS_MUTEX_EXT` feature defined, to be initialized as a shared object. The *pthread_cond_t* initialization generally involves the following steps:
   a. *pthread_condattr_init()*
   b. *pthread_condattr_setpshared()* This step sets the attribute of the *pthread_cond_t* as PTHREAD_PROCESS_SHARED and designates the object to be of extended size.
   c. *pthread_cond_init()* This step initializes the passed-in (small) *pthread_cond_t* object as if it is an extended object, causing storage overlay.

## pthread_create() — Create a thread

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_create(pthread_t *thread, pthread_attr_t *attr,
                    void *(*start_routine) (void *arg), void *arg);
```

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_create(pthread_t * __restrict__thread, const pthread_attr_t *attr,
                    void *(*start_routine) (void *arg), void * __restrict__arg);
```

### General description

Creates a new thread within a process, with attributes defined by the thread attribute object, `attr`, that is created by `pthread_attr_init()`.

If `attr` is NULL, the default attributes are used. See [pthread_attr_init() — Initialize a thread attribute object](#) on page 1424 for a description of the thread attributes and their defaults. If the attributes specified by `attr` are changed later, the thread's attributes are not affected.

`pthread_t` is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

The thread is created running `start_routine`, with `arg` as the only argument. If `pthread_create()` completes successfully, `thread` will contain the ID of the created thread. If it fails, no new thread is created, and the contents of the location referenced by `thread` are undefined.

System default for the thread limit in a process is set by MAXTHREADS in the BPXPRMxx parmlib member.

The maximum number of threads is dependent upon the size of the private area below 16M. `pthread_create()` inspects this address space before creating a new thread. A realistic limit is 200 to 400 threads.

**Special behavior for C++:** Because C and C++ linkage conventions are incompatible, `pthread_create()` cannot receive a C++ function pointer as the start routine function pointer. If you attempt to pass a C++ function pointer to `pthread_create()`, the compiler will flag it as an error. You can pass a C or C++ function to `pthread_create()` by declaring it as extern "C".
The started thread provides a boundary with respect to the scope of try-throw-catch processing. A throw done in the start routine or a function called by the start routine causes stack unwinding up to and including the start routine (or until caught). The stack unwinding will not go beyond the start routine back into the thread creator. If the exception is not caught, terminate() is called.

The exception stack (for try-throw-catch) are thread-based. The throw of a condition, or re-throw of a condition by a thread does not affect exception processing on another thread, unless the condition is not caught.

**Returned value**

If successful, pthread_create() returns 0.

If unsuccessful, pthread_create() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The system lacks the necessary resources to create another thread.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by thread is null.</td>
</tr>
<tr>
<td>EEMULTITHREADFORK</td>
<td>pthread_create() was invoked from a child process created by calling fork() from a multi-threaded process. This child process is restricted from becoming multi-threaded.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>There is not enough memory to create the thread.</td>
</tr>
</tbody>
</table>

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, pthread_create() returns an error number to indicate the error.

**Example**

CELEBP27

```c
/* CELEBP27 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdlib.h>
#include <stdio.h>

void *thread(void *arg) { 
    char *ret;
    printf("thread() entered with argument \"%s\n", arg);
    if ((ret = (char*) malloc(20)) == NULL) { 
        perror("malloc() error");
        exit(2);
    }
    strcpy(ret, "This is a test");
    pthread_exit(ret);
}

main() { 
    pthread_t thid;
    void *ret;

    if (pthread_create(&thid, NULL, thread, "thread 1") != 0) { 
        perror("pthread_create() error");
        exit(1);
    }

    if (pthread_join(thid, &ret) != 0) { 
        perror("pthread_create() error");
```
```c
void thread() {
    char* ret = pthread_exit(3);
    printf("thread exited with '%s'\n", ret);
}
```

Output:
- thread() entered with argument 'thread 1'
- thread exited with 'This is a test'

pthread_detach

pthread_detach() — Detach a thread

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>
| Single UNIX Specification, Version 3

Format

#define _OPEN_THREADS
#include <pthread.h>

int pthread_detach(pthread_t *thread);

SUSV3:

#define _UNIX03_THREADS
#include <pthread.h>
int pthread_detach(pthread_t thread);

General description

Allows storage for the thread whose thread ID is in the location thread to be reclaimed when that thread ends. This storage is reclaimed on process exit, regardless of whether the thread was detached, and may include storage for thread’s return value. If thread has not ended, pthread_detach() will not cause it to end.

pthread_t is the data type used to uniquely identify a thread. It is returned by pthread_create() and used by the application in function calls that require a thread identifier.

Returned value

If successful, pthread_detach() returns 0.

If unsuccessful, pthread_detach() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified by thread is not valid.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>A value specified by thread refers to a thread that is already detached.</td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_detach() returns an error number to indicate the error.

Example

CELEBP28

/* CELEBP28 */
#define _OPEN_SYS
#define _OPEN_THREADS
#include <pthread.h>
#include <stdlib.h>
#include <stdio.h>
void *thread(void *arg) {
    char *ret;
    printf("thread() entered with argument '%s'", arg);
    if ((ret = (char*) malloc(20)) == NULL) {
        perror("malloc() error");
        exit(2);
    }
    strcpy(ret, "This is a test");
    pthread_exit(ret);
}

main() {
    pthread_t thid;
    void *ret;
    if (pthread_create(&thid, NULL, thread, "thread 1") != 0) {
        perror("pthread_create() error");
        exit(1);
    }
    if (pthread_join_d4_np(thid, &ret) != 0) {
        perror("pthread_create() error");
        exit(3);
    }
    printf("thread exited with '%s'", ret);
    if (pthread_detach(&thid) != 0) {
        perror("pthread_detach() error");
        exit(4);
    }
}

Output:
thread() entered with argument 'thread 1'
thread exited with 'This is a test'

**pthread_equal**

**pthread_equal() — Compare thread IDs**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_equal(pthread_t t1, pthread_t t2);
```

**General description**

Compares the thread IDs of `t1` and `t2`.

`pthread_t` is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

**Returned value**

If `t1` and `t2` are equal, `pthread_equal()` returns a positive value. Otherwise, the value 0 is returned. If `t1` or `t2` are not valid thread IDs, the behavior is undefined.

If unsuccessful, `pthread_equal()` returns −1.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine the cause of the error.

**Example**

```c
CELEBP29
/* CELEBP29 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

pthread_t thid, IPT;

void *thread(void *arg) {
    if (pthread_equal(IPT, thid))
        puts("the thread is the IPT...?");
    else
        puts("the thread is not the IPT");
}

int main() {

    IPT = pthread_self();

    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create() error");
        exit(1);
    }

    if (pthread_join(thid, NULL) != 0) {
```

1482  z/OS V1R13.0 XL C/C++ Run-Time Library Reference
Output:
the thread is not the IPT

pthread_exit

pthread_exit() — Exit a thread

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

void pthread_exit(void *status);
```

General description

Ends the calling thread and makes `status` available to any thread that calls `pthread_join()` with the ending thread's thread ID.

As part of pthread_exit() processing, cleanup and destructor routines may be run:

- For details on the cleanup routines, refer to [pthread_cleanup_pop() — Remove a cleanup handler](#) on page 1446 and [pthread_cleanup_push() — Establish a cleanup handler](#) on page 1448.
- For details on the destructor routine, refer to [pthread_key_create() — Create thread-specific data key](#) on page 1499.

Special behavior for C++: Destructors for automatic objects on the stack will be run when a thread is canceled. The stack is unwound and the destructors are run in reverse order.

Returned value

`pthread_exit()` cannot return to its caller.

There are no documented errno values. Use `perror()` or `strerror()` to determine the cause of the error.

Example

```c
CELEBP30
/* CELEBP30 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdlib.h>
#include <stdio.h>

void *thread(void *arg) {
    char *ret;
    if ((ret = (char*) malloc(20)) == NULL) {
        perror("malloc() error");
        exit(2);
    }
    strcpy(ret, "This is a test");
    pthread_exit(ret);
}

main() {
```

1484  z/OS V1R13.0 XL C/C++ Run-Time Library Reference
```c
pthread_t thid;
void *ret;

if (pthread_create(&thid, NULL, thread, NULL) != 0) {
    perror("pthread_create() error");
    exit(1);
}

if (pthread_join(thid, &ret) != 0) {
    perror("pthread_create() error");
    exit(3);
}

printf("thread exited with '%s'\n", ret);
}

Output:
thread exited with 'This is a test'
```

pthread_getspecific() — Get the thread-specific value for a key

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>
#include <stdlib.h>

#define _OPEN_THREADS
#include <pthread.h>

int pthread_getspecific(pthread_key_t key, void **value);
```

SUSV3:

```c
#include <stdio.h>
#include <stdlib.h>

#define _UNIX03_THREADS
#include <pthread.h>

void *pthread_getspecific(pthread_key_t key);
```

General description

Returns the thread-specific data associated with the specified `key` for the current thread. If no thread-specific data has been set for `key`, the NULL value is returned in `value`.

Many multithreaded applications require storage shared among threads, where each thread has its own unique value. A thread-specific data key is an identifier, created by a thread, for which each thread in the process can set a unique key `value`.

`pthread_key_t` is a storage area where the system places the key identifier. To create a key, a thread uses `pthread_key_create()`. This returns the key identifier into the storage area of type `pthread_key_t`. At this point, each of the threads in the application has the use of that key, and can set its own unique value by using `pthread_setspecific()`. A thread can get its own unique value using `pthread_getspecific()`.

Returned value

When unsuccessful, `pthread_getspecific()` sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value for <code>key</code> is not valid.</td>
</tr>
</tbody>
</table>

Note: In SUSV3, if the key is invalid, `pthread_getspecific()` returns NULL but does not set or return an `errno` value.

Example

```c
/* CELEBP31 */
#endif
#define _OPEN_THREADS
#include <stdio.h>
#include <stdlib.h>

#include <stdio.h>
#include <stdlib.h>
```

</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

void * pthread_getspecific_d8_np(pthread_key_t key);
```

**General description**

Returns the thread-specific data associated with the specified `key` for the current thread. If no thread-specific data has been set for `key`, the NULL value is returned.

Many multithreaded applications require storage shared among threads, where each thread has its own unique value. A thread-specific data key is an identifier, created by a thread, for which each thread in the process can set a unique key value.

`pthread_key_t` is a storage area where the system places the key identifier. To create a key, a thread uses `pthread_key_create()`. This returns the key identifier into the storage area of type `pthread_key_t`. At this point, each of the threads in the application has the use of that key, and can set its own unique value by using `pthread_setspecific()`. A thread can get its own unique value using `pthread_getspecific_d8_np()` or `pthread_getspecific()`.

The only difference between `pthread_getspecific_d8_np()` and `pthread_getspecific()` is the syntax of the function.

**Returned value**

When successful, `pthread_getspecific_d8_np()` returns the thread-specific data value associated with `key`.

When unsuccessful, `pthread_getspecific_d8_np()` returns NULL and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value for <code>key</code> is not valid.</td>
</tr>
</tbody>
</table>

**Example**

```c
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <pthread.h>

#define threads 3
#define BUFFSZ 48
```
```c
pthread_key_t key;
void *threadfunc(void *);
void destr_fn(void *);

main() {
    int status;
    int i;
    int threadparm[threads];
    pthread_t threadid[threads];
    int thread_stat[threads];

    if ((status = pthread_key_create(&key, destr_fn)) < 0) {
        printf("pthread_key_create failed, errno=%d", errno);
        exit(1);
    }

    /* create 3 threads, pass each its number */
    for (i=0; i<threads; i++) {
        threadparm[i] = i+1;
        status = pthread_create(&threadid[i],
            NULL,
            threadfunc,
            (void *)&threadparm[i]);
        if (status < 0) {
            printf("pthread_create failed, errno=%d", errno);
            exit(2);
        }
    }

    for (i=0; i<threads; i++) {
        status = pthread_join(threadid[i], (void *)&thread_stat[i]);
        if (status < 0) {
            printf("pthread_join failed, thread %d, errno=%d\n", i+1, errno);
        }
        if (thread_stat[i] != 0) {
            printf("bad thread status, thread %d, status=%d\n", i+1,
                thread_stat[i]);
        }
    }
    exit(0);
}

void *threadfunc(void *parm) {
    int status;
    int *void;

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_join(pthread_t thread, void **status);
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_join(pthread_t thread, void **status);
```

**General description**

Allows the calling thread to wait for the ending of the target `thread`.

`pthread_t` is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

`status` contains a pointer to the `status` argument passed by the ending thread as part of `pthread_exit()`. If the ending thread terminated with a return, `status` contains a pointer to the return value. If the thread was canceled, `status` can be set to −1.

**Returned value**

If successful, `pthread_join()` returns 0.

If unsuccessful, `pthread_join()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EDEADLK</td>
<td>A deadlock has been detected. This can occur if the target is directly or indirectly joined to the current thread.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>thread</code> is not valid.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>The value specified by <code>thread</code> does not refer to an undetached thread.</td>
</tr>
</tbody>
</table>

**Notes:**

1. When `pthread_join()` returns successfully, the target thread has been detached.
2. Multiple threads cannot use `pthread_join()` to wait for the same target thread to end. If a thread issues `pthread_join()` for a target thread after another thread has successfully issued `pthread_join()` for the same target thread, the second `pthread_join()` will be unsuccessful.
3. If the thread calling `pthread_join()` is canceled, the target thread is not detached.
pthread_join

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, 
pthread_join() returns an error number to indicate the error.

Example

CELEBP32

/* CELEBP32 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdlib.h>
#include <stdio.h>

void *thread(void *arg) {
    char *ret;
    printf("thread() entered with argument \'\%s\'\n", arg);
    if ((ret = (char*) malloc(20)) == NULL) {
        perror("malloc() error");
        exit(2);
    }
    strcpy(ret, "This is a test");
    pthread_exit(ret);
}

main() {
    pthread_t thid;
    void *ret;
    if (pthread_create(&thid, NULL, thread, "thread 1") != 0) {
        perror("pthread_create() error");
        exit(1);
    }
    if (pthread_join(thid, &ret) != 0) {
        perror("pthread_create() error");
        exit(3);
    }
    printf("thread exited with \'\%s\'\n", ret);
}

Output:
thread() entered with argument 'thread 1'
thread exited with 'This is a test'

<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS
#define _OPEN_SYS
#include <pthread.h>

int pthread_join_d4_np(pthread_t thread, void **status);
```

General description

Allows the calling thread to wait for the ending of the target `thread`.

`pthread_t` is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

`status` contains a pointer to the `status` argument passed by the ending thread as part of `pthread_exit()`. If the ending thread ended by a return, `status` contains a pointer to the return value. If the thread was canceled, `status` can be set to −1.

Returned value

If successful, `pthread_join_d4_np()` returns 0.

If unsuccessful, `pthread_join_d4_np()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EDEADLK</td>
<td>A deadlock has been detected. This can occur if the target is directly or indirectly joined to the current thread.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>thread</code> is not valid.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>The value specified by <code>thread</code> does not refer to an undetached thread.</td>
</tr>
</tbody>
</table>

Notes:

1. When `pthread_join_d4_np()` returns successfully, the target thread has not been detached.
2. Multiple threads can use `pthread_join_d4_np()` to wait for the same target thread to end.

Example

```c
/* CELEBP33 */
#define _OPEN_SYS
#define _OPEN_SYS
#include <pthread.h>
#include <stdlib.h>
#include <stdio.h>
```
void *thread(void *arg) {
    char *ret;
    printf("thread() entered with argument '\"s'\n", arg);
    if ((ret = (char*) malloc(20)) == NULL) {
        perror("malloc() error");
        exit(2);
    }
    strcpy(ret, "This is a test");
    pthread_exit(ret);
}

main() {
    pthread_t thid;
    void *ret;
    if (pthread_create(&thid, NULL, thread, "thread 1") != 0) {
        perror("pthread_create() error");
        exit(1);
    }
    if (pthread_join_d4_np(thid, &ret) != 0) {
        perror("pthread_create() error");
        exit(3);
    }
    printf("thread exited with '\"s'\n", ret);
    if (pthread_detach(&thid) != 0) {
        perror("pthread_detach() error");
        exit(4);
    }
}

Output:
    thread() entered with argument 'thread 1'
    thread exited with 'This is a test'

Related information

- "pthread_cond_wait() — Wait on a condition variable" on page 1462
- "pthread_create() — Create a thread" on page 1477
- "pthread_detach() — Detach a thread" on page 1480
### General description

Creates a key identifier, associated with `key`, and returns the key identifier into the storage area of type `pthread_key_t`. At this point, each of the threads in the application has the use of that key, and can set its own unique value by use of `pthread_setspecific()`. A thread can get its own unique value using `pthread_getspecific()`.

The `destructor` routine may be called when the thread ends. It is called when a non-NULL value has been set for the key for this thread, using `pthread_setspecific()`, and the thread:

- Calls `pthread_exit()`
- Does a return from the start routine
- Is canceled because of a `pthread_cancel()` request.

When called, the destructor routine is passed the value bound to the key by the use of `pthread_setspecific()`.

**Special behavior for C++**: Because C and C++ linkage conventions are incompatible, `pthread_key_create()` cannot receive a C++ function pointer as the start routine function pointer if you attempt to pass a C++ function pointer to `pthread_key_create()`, the compiler will flag it as an error. You can pass a C or C++ function to `pthread_key_create()` by declaring it as extern "C".

### Returned value

If successful, `pthread_key_create()` returns 0 and stores the newly created key identifier in `key`.

If unsuccessful, `pthread_key_create()` returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>

pthread_key_create

**EAGAIN** There were not enough system resources to create another thread-specific data key, or the limit is exceeded for the total number of keys per process.

**ENOMEM** There is not enough memory to create key.

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, pthread_key_create() returns an error number to indicate the error.

**Example**

**CELEBP34**

```c
/* CELEBP34 */
#ifndef _OPEN_THREADS
#define _OPEN_THREADS
#endif
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

Chapter 3. Library functions  1501
**pthread_key_delete**

**pthread_key_delete() — Delete thread-specific data key**

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, version 3</td>
<td>both</td>
<td>z/OS V1R7 POSIX(ON)</td>
</tr>
</tbody>
</table>

### Format

```c
#define _OPEN_THREADS 2
#include <pthread.h>

int pthread_key_delete(pthread_key_t key);
```

### General description

`pthread_key_delete()` deletes thread-specific data keys created with `pthread_key_create()`. The thread-specific data values associated with `key` do not need to be NULL when the `key` is deleted. The application is responsible for freeing any storage or cleaning up data structures referring to thread-specific data associated with the deleted `key` in any thread. After `key` has been deleted, passing it to any function taking a thread-specific data key results in undefined behavior.

`pthread_key_delete()` can be called from destructor functions. Calling `pthread_key_delete()` will not cause any destructor functions to be invoked. Any destructor function associated with `key` when it was created will not be called on thread exit after `key` has been deleted.

### Returned value

If successful, `pthread_key_delete()` returns 0. Upon failure, `pthread_key_delete()` returns an error number to indicate the error:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The key value is invalid.</td>
</tr>
</tbody>
</table>

**pthread_kill() — Send a signal to a thread**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <pthread.h>
#include <signal.h>

int pthread_kill(pthread_t thread, int sig);
```

**SUSV3:**

```c
#include <signal.h>

int pthread_kill(pthread_t thread, int sig);
```

**General description**

Directs a signal `sig` to the thread `thread`. The value of `sig` must be either 0 or one of the symbols defined in `signal.h`. (See Table 46 on page 1908 for a list of signals.) If `sig` is 0, `pthread_kill()` performs error checking but does not send a signal.

`pthread_t` is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

**Special behavior for C++:** If a thread is sent a signal using `pthread_kill()` and that thread does not handle the signal, then destructors for local objects may not be executed.

**Usage notes**

1. The SIGTHSTOP and SIGTHCONT signals can be issued by this function. `pthread_kill()` is the only function that can issue SIGTHSTOP or SIGTHCONT.

**Returned value**

If successful, `pthread_kill()` returns 0.

If unsuccessful, `pthread_kill()` returns −1 sends no signal, and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>One of the following error conditions exists:</td>
</tr>
<tr>
<td></td>
<td>• The thread ID specified by <code>thread</code> is not valid.</td>
</tr>
<tr>
<td></td>
<td>• The value of <code>sig</code> is incorrect or is not the number of a supported signal.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>No thread could be found corresponding to that specified by the given thread ID.</td>
</tr>
</tbody>
</table>
Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_kill() returns an error number to indicate the error.

Example

CELEBP35

/* CELEBP35 */
#define _OPEN_THREADS

#include <errno.h>
#include <pthread.h>
#include <signal.h>
#include <stdio.h>
#include <unistd.h>

void *threadfunc(void *parm)
{
    int threadnum;
    int *tnum;
    sigset_t set;

    tnum = parm;
    threadnum = *tnum;

    printf("Thread \%d executing\n", threadnum);
    sigemptyset(&set);
    if(sigaddset(&set, SIGUSR1) == -1) {
        perror("Sigaddset error");
        pthread_exit((void *)1);
    }

    if(sigwait(&set) != SIGUSR1) {
        perror("Sigwait error");
        pthread_exit((void *)2);
    }

    pthread_exit((void *)0);
}

main() {
    int status;
    int threadparm = 1;
    pthread_t threadid;
    int thread_stat;

    status = pthread_create( &threadid,
                               NULL,
                               threadfunc,
                               (void *)&threadparm);
    if ( status < 0) {

**pthread_mutex_destroy() — Delete a mutex object**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutex_destroy(pthread_mutex_t *mutex);
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutex_destroy(pthread_mutex_t *mutex);
```

**General description**

Deletes a mutex object, which identifies a mutex. Mutexes are used to protect shared resources. `mutex` is set to an invalid value, but can be reinitialized using `pthread_mutex_init()`.

**Returned value**

If successful, `pthread_mutex_destroy()` returns 0.

If unsuccessful, `pthread_mutex_destroy()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBUSY</td>
<td>A request has detected an attempt to destroy the object referenced by <code>mutex</code> while it was locked or referenced by another thread (for example, while being used in a <code>pthread_cond_wait()</code> or <code>pthread_cond_timedwait()</code> function).</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>mutex</code> is not valid.</td>
</tr>
</tbody>
</table>

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_mutex_destroy()` returns an error number to indicate the error.

**Example**

```c
CELEBP36

/* CELEBP36 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_mutex_t mutex;
    if (pthread_mutex_init(&mutex, NULL) != 0) {
        perror("pthread_mutex_init() error");
        exit(1);
    }
    /* Further thread code */
    pthread_mutex_destroy(&mutex);
    /* Further thread code */
}
```
if (pthread_mutex_destroy(&mutex) != 0) {
  perror("pthread_mutex_destroy() error");
  exit(2);
}

pthread_mutex_init

pthread_mutex_init() — Initialize a mutex object

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutex_init(pthread_mutex_t *mutex, pthread_mutexattr_t *attr);
```

SUSV3:
```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutex_init(pthread_mutex_t *__restrict__mutex, const pthread_mutexattr_t *__restrict__attr);
```

General description

Creates a mutex, referenced by `mutex`, with attributes specified by `attr`. If `attr` is NULL, the default mutex attribute (NONRECURSIVE) is used.

Returned value

If successful, `pthread_mutex_init()` returns 0, and the state of the mutex becomes initialized and unlocked.

If unsuccessful, `pthread_mutex_init()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The system lacked the necessary resources (other than memory) to initialize another mutex.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>detected an attempt to re-initialize the object referenced by <code>mutex</code>, a previously initialized, but not yet destroyed, mutex.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>attr</code> is not valid.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>There is not enough memory to acquire a lock. This <code>errno</code> will only occur in the private path.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The caller does not have the privilege to perform the operation.</td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_mutex_init()` returns an error number to indicate the error.

Usage notes

The `_OPEN_SYS_MUTEX_EXT` feature switch can be optionally included. If the feature is set, then significantly larger `pthread_mutex_t` objects will be defined. The feature is used for the management of mutex and condition variables in shared memory.
If the supplied extended pthread_mutex_t object is not in shared memory, pthread_mutex_init() will treat the object as a non-shared object, since it is not accessible to any other process.

It is recommended that you define and initialize the pthread_mutex_t objects in the same compile unit. If you pass a pthread_mutex_t object around to be initialized, make sure the initialization code has been compiled with the same _OPEN_SYS_MUTEX_EXT feature setting as the code that defines the object.

The following sequence may cause storage overlay with unpredictable results:
1. Declare or define a pthread_mutex_t object (in shared storage) without #define of the _OPEN_SYS_MUTEX_EXT feature. The created pthread_mutex_t object is standard size (i.e. small) without the _OPEN_SYS_MUTEX_EXT feature defined.
2. Pass the pthread_mutex_t object to another code unit, which was compiled with the _OPEN_SYS_MUTEX_EXT feature defined, to be initialized as a shared object. The pthread_mutex_t initialization generally involves the following steps:
   a. pthread_mutexattr_init()
   b. pthread_mutexattr_setpshared(). Shared pthread_mutex_t objects can be small or of extended size. The presence of the _OPEN_SYS_MUTEX_EXT feature declares it to be of extended size.
   c. pthread_mutex_init(). This step initializes the passed-in (small) pthread_mutex_t object as if it is an extended object, causing storage overlay.

Example

CELEBP37

/* CELEBP37 */
#ifndef _OPEN_THREADS
#define _OPEN_THREADS
#endif

#include <pthread.h>

main() {
    pthread_mutexattr_t attr;
    pthread_mutex_t mut;
    if (pthread_mutexattr_init(&attr) == −1) {
        perror("mutexattr_init error");
        exit(1);
    }

    if (pthread_mutex_init(&mut, &attr) == −1) {
        perror("mutex_init error");
        exit(2);
    }

    exit(0);
}

</tbody>
</table>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutex_lock(pthread_mutex_t *mutex);
```

SUSV3:

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutex_lock(pthread_mutex_t *mutex);
```

General description

Locks a mutex object, which identifies a mutex. Mutexes are used to protect shared resources. If the mutex is already locked by another thread, the thread waits for the mutex to become available. The thread that has locked a mutex becomes its current owner and remains the owner until the same thread has unlocked it.

When the mutex has the attribute of recursive, the use of the lock may be different. When this kind of mutex is locked multiple times by the same thread, then a count is incremented and no waiting thread is posted. The owning thread must call pthread_mutex_unlock() the same number of times to decrement the count to zero.

The mutex types are described below:

PTHREAD_MUTEX_NORMAL
A normal type mutex does not detect deadlock. That is, a thread attempting to relock this mutex without first unlocking it will deadlock. The mutex is either in a locked or unlocked state for a thread.

PTHREAD_MUTEX_ERRORCHECK
An errorcheck type mutex provides error checking. That is, a thread attempting to relock this mutex without first unlocking it will return with an error. The mutex is either in a locked or unlocked state for a thread. If a thread attempts to relock a mutex that it has already locked, it will return with an error. If a thread attempts to unlock a mutex that is unlocked, it will return with an error.

PTHREAD_MUTEX_RECURSIVE
A recursive type mutex permits a thread to lock many times. That is, a thread attempting to relock this mutex without first unlocking will succeed. This type of mutex must be unlocked the same number of times it is locked before the mutex will be returned to an unlocked state. If locked, an error is returned.

PTHREAD_MUTEX_DEFAULT
The default type mutex is mapped to a normal type mutex which
pthread_mutex_lock

does not detect deadlock. That is, a thread attempting to relock this mutex without first unlocking it will deadlock. The mutex is either in a locked or unlocked state for a thread. The normal mutex is the default type mutex.

Returned value

If successful, pthread_mutex_lock() returns 0.

If unsuccessful, pthread_mutex_lock() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The mutex could not be acquired because the maximum number of recursive locks for mutex has been exceeded. This errno will only occur in the shared path.</td>
</tr>
<tr>
<td>EDEADLK</td>
<td>The current thread already owns the mutex, and the mutex has a kind attribute of __MUTEX_NONRECURSIVE.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by mutex is not valid.</td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_mutex_lock() returns an error number to indicate the error.

Usage notes

If the _OPEN_SYS_MUTEX_EXT feature switch is set, all shared (extended) mutex locks are released when the thread ends, whether normally or abnormally. If the thread ends normally (i.e. pthread_exit() or pthread_cancel()), the first waiter of the mutex lock will be resumed. If the thread ends abnormally, the processes of the mutex waiters for this mutex lock will be terminated.

Example

CELEBP38

/* CELEBP38 */
#ifndef _OPEN_THREADS
#define _OPEN_THREADS
#endif

#include <pthread.h>
#include <stdio.h>

main() {
    pthread_mutex_t mut;

    if (pthread_mutex_init(&mut, NULL) != 0) {
        perror("mutex_lock");
        exit(1);
    }

    if (pthread_mutex_lock(&mut) != 0) {
        perror("mutex_lock");
        exit(2);
    }

    puts("the mutex has been locked");
    exit(0);
}

**pthread_mutex_trylock() — Attempt to lock a mutex object**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutex_trylock(pthread_mutex_t *mutex);
```

**SUSV3:**

```c
#define __UNIX03_THREADS
#include <pthread.h>

int pthread_mutex_trylock(pthread_mutex_t *mutex);
```

**General description**

Locks a mutex object, which identifies a mutex. Mutexes are used to protect shared resources. If pthread_mutex_trylock() is locked, it returns immediately.

For recursive mutexes, pthread_mutex_trylock() will effectively add to the count of the number of times pthread_mutex_unlock() must be called by the thread to release the mutex. (That is, it has the same behavior as a pthread_mutex_lock().)

**Returned value**

If successful, pthread_mutex_trylock() returns 0.

If unsuccessful, pthread_mutex_trylock() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The mutex could not be acquired because the maximum number of recursive locks for mutex has been exceeded. This errno will only occur in the shared path.</td>
</tr>
<tr>
<td>EBUSY</td>
<td>mutex could not be acquired because it was already locked.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by mutex is not valid.</td>
</tr>
</tbody>
</table>

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, pthread_mutex_trylock() returns an error number to indicate the error.

**Usage notes**

1. If the _OPEN_SYS_MUTEX_EXT feature switch is set, all shared (extended) mutex locks are released when the thread ends, whether normally or abnormally. If the thread ends normally (i.e. pthread_exit() or pthread_cancel()), the first waiter of the mutex lock will be resumed. If the thread ends abnormally, the processes of the mutex waiters for this mutex lock will be terminated.
### Example

**CELEBP40**

```c
/* CELEBP40 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>
#include <errno.h>

pthread_mutex_t mutex;

void *thread(void *arg) {
    if (pthread_mutex_trylock(&mutex) != 0)
        if (errno == EBUSY)
            puts("thread was denied access to the mutex");
        else {
            perror("pthread_mutex_trylock() error");
            exit(1);
        }
    else puts("thread was granted the mutex");
}

main() {
    pthread_t thid;

    if (pthread_mutex_init(&mutex, NULL) != 0) {
        perror("pthread_mutex_init() error");
        exit(2);
    }

    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create() error");
        exit(3);
    }

    if (pthread_mutex_trylock(&mutex) != 0)
        if (errno == EBUSY)
            puts("IPT was denied access to the mutex");
        else {
            perror("pthread_mutex_trylock() error");
            exit(4);
        }
    else puts("IPT was granted the mutex");

    if (pthread_join(thid, NULL) != 0) {
        perror("pthread_mutex_trylock() error");
        exit(5);
    }
}
```

**Output:**

IPT was granted the mutex  
thread was denied access to the mutex

</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutex_unlock(pthread_mutex_t *mutex);
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutex_unlock(pthread_mutex_t *mutex);
```

**General description**

Releases a mutex object. If one or more threads are waiting to lock the mutex, `pthread_mutex_unlock()` causes one of those threads to return from `pthread_mutex_lock()` with the mutex object acquired. If no threads are waiting for the mutex, the mutex unlocks with no current owner.

When the mutex has the attribute of recursive the use of the lock may be different. When this kind of mutex is locked multiple times by the same thread, then unlock will decrement the count and no waiting thread is posted to continue running with the lock. If the count is decremented to zero, then the mutex is released and if any thread is waiting it is posted.

**Returned value**

If successful, `pthread_mutex_unlock()` returns 0.

If unsuccessful, `pthread_mutex_unlock()` returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>mutex</code> is not valid.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The current thread does not own the <code>mutex</code>.</td>
</tr>
</tbody>
</table>

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_mutex_unlock()` returns an error number to indicate the error.

**Example**

```c
CELEBP41
/* CELEBP41 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>
#include <errno.h>
```

1516  z/OS V1R13.0 XL C/C++ Run-Time Library Reference
```c
pthread_mutex_t mutex;

void *thread(void *arg) {
  if (pthread_mutex_lock(&mutex) != 0) {
    perror("pthread_mutex_lock() error");
    exit(1);
  }
  puts("thread was granted the mutex");
  if (pthread_mutex_unlock(&mutex) != 0) {
    perror("pthread_mutex_unlock() error");
    exit(2);
  }
}

main() {
  pthread_t thid;
  if (pthread_mutex_init(&mutex, NULL) != 0) {
    perror("pthread_mutex_init() error");
    exit(3);
  }
  if (pthread_create(&thid, NULL, thread, NULL) != 0) {
    perror("pthread_create() error");
    exit(4);
  }
  if (pthread_mutex_lock(&mutex) != 0) {
    perror("pthread_mutex_lock() error");
    exit(5);
  }
  puts("IPT was granted the mutex");
  if (pthread_mutex_unlock(&mutex) != 0) {
    perror("pthread_mutex_unlock() error");
    exit(6);
  }
  if (pthread_join(thid, NULL) != 0) {
    perror("pthread_mutex_lock() error");
    exit(7);
  }
}

Output:
IPT was granted the mutex
thread was granted the mutex

#define _UNIX03_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_mutexattr_destroy(pthread_mutexattr_t *attr);
```

General description

Destroys an initialized mutex attribute object. With a mutex attribute object, you can manage the characteristics of mutexes in your application. It defines the set of values to be used for the mutex during its creation. By establishing a mutex attribute object, you can create many mutexes with the same set of characteristics, without defining those characteristics for each mutex. pthread_mutexattr_init() is used to define a mutex attribute object.

Returned value

If successful, pthread_mutexattr_destroy() returns 0.

If unsuccessful, pthread_mutexattr_destroy() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified for attr is not valid.</td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_mutexattr_destroy() returns an error number to indicate the error.

Example

```c
CELEBP42
/* CELEBP42 */
#define _OPEN_THREADS
#define _OPEN_SYS  /* Needed to identify __MUTEX_RESCURSIVE */
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_mutexattr_t attr;
    pthread_mutex_t mutex;
    if (pthread_mutexattr_init(&attr) != 0) {
```
perror("pthread_mutex_attr_init() error");
exit(1);
}

if (pthread_mutexattr_setkind_np(&attr, __MUTEX_RECURSIVE) != 0) {
    perror("pthread_mutex_attr_setkind_np() error");
    exit(2);
}

if (pthread_mutex_init(&mutex, &attr) != 0) {
    perror("pthread_mutex_init() error");
    exit(3);
}

if (pthread_mutexattr_destroy(&attr) != 0) {
    perror("pthread_mutex_attr_destroy() error");
    exit(4);
}

### pthread_mutexattr_getkind_np

**pthread_mutexattr_getkind_np() — Get kind from a mutex attribute object**

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

#### Format

```c
#define _OPEN_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_mutexattr_getkind_np(pthread_mutexattr_t *attr, int *kind);
```

#### General description

Gets the attribute *kind* from the mutex attribute object *attr*. With a mutex attribute object, you can manage the characteristics of mutexes in your application. It defines the set of values to be used for the mutex during its creation. By establishing a mutex attribute object, you can create many mutexes with the same set of characteristics without defining those characteristics for each and every mutex.

The values for the attribute *kind* are:

- **__MUTEX_NONRECURSIVE**
  - A nonrecursive mutex can be locked only once. That is, the mutex is either in a locked or unlocked state for a thread. If a thread attempts to lock a mutex that it has already locked, an error is returned.

- **__MUTEX_RECURSIVE**
  - A recursive mutex can be locked more than once by the same thread. A count of the number of times the mutex has been locked is maintained. The mutex is unlocked when pthread_mutex_unlock() is performed an equal number of times.

- **__MUTEX_NONRECURSIVE + __MUTEX_NODEBUG**
  - A nonrecursive mutex can be given an additional attribute, NODEBUG. This indicates that state changes to this mutex will not be reported to the debug interface, even if present.

- **__MUTEX_RECURSIVE + __MUTEX_NODEBUG**
  - A recursive mutex can be given an additional attribute, NODEBUG. This indicates that state changes to this mutex will not be reported to the debug interface, even if present.

#### Returned value

If successful, pthread_mutexattr_getkind_np() returns 0.

If unsuccessful, pthread_mutexattr_getkind_np() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified for <em>attr</em> is not valid.</td>
</tr>
</tbody>
</table>
Example

CELEBP43

/* CELEBP43 */

#pragma runopts(TEST(ALL))

#ifndef _OPEN_THREADS
#define _OPEN_THREADS
#define _OPEN_SYS /* Needed to identify __MUTEX_RECURSIVE,

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutexattr_getpshared(const pthread_mutexattr_t __restrict__attr, int __restrict__ pshared);
```

**General description**

The `pthread_mutexattr_getpshared()` function gets the attribute `pshared` for the mutex attribute object `attr`. By using `attr` with the `pthread_mutexattr_getpshared()` function you can determine its **process-shared** value for a mutex.

The valid values for the attribute `pshared` are:

- `PTHREAD_PROCESS_SHARED`:
  
  Permits a mutex to be operated upon by any thread that has access to the memory where the mutex is allocated, even if the mutex is allocated in memory that is shared by multiple processes.

- `PTHREAD_PROCESS_PRIVATE`:
  
  A mutex can only be operated upon by threads created within the same process as the thread that initialized the mutex. When a new process is created by the parent process it will receive a different copy of the private mutex and this new mutex can only be used to serialize between threads in the child process. The default value of the attribute is `PTHREAD_PROCESS_PRIVATE`.

**Returned value**

If successful, `pthread_mutexattr_getpshared()` returns 0.

If unsuccessful, `pthread_mutexattr_getpshared()` returns −1 and sets `errno` to one of the following values:

- **Error Code** | **Description**
  
  `EINVAL` | The value specified for `attr` is not valid.

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_mutexattr_getpshared()` returns an error number to indicate the error.

```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutexattr_gettype(const pthread_mutexattr_t * __restrict__attr, int * __restrict__type);
```

### General description

The `pthread_mutexattr_gettype()` function gets the attribute `type` from the mutex attribute object `attr`.

A mutex attribute object allows you to manage the characteristics of mutexes in your application. It defines the set of values to be used for the mutex during its creation. By establishing a mutex attribute object, you can create many mutexes with the same set of characteristics, without needing to define the characteristics for each and every mutex.

The values for the attribute `type` are:

- **PTHREAD_MUTEX_NORMAL**
  A normal type mutex does not detect deadlock. That is, a thread attempting to relock this mutex without first unlocking it will deadlock. The mutex is either in a locked or unlocked state for a thread.

- **PTHREAD_MUTEX_ERRORCHECK**
  An errorcheck type mutex provides error checking. That is, a thread attempting to relock this mutex without first unlocking it will return with an error. The mutex is either in a locked or unlocked state for a thread. If a thread attempts to relock a mutex that has already locked, it will return with an error. If a thread attempts to unlock a mutex that is unlocked, it will return with an error.

- **PTHREAD_MUTEX_RECURSIVE**
  A recursive type mutex permits a thread to lock many times. That is, a thread attempting to relock this mutex without first unlocking will succeed. This type of mutex must be unlocked the same number to times it is locked before the mutex will be returned to an unlocked state. If locked, an error is returned.

- **PTHREAD_MUTEX_DEFAULT**
  The default type mutex is mapped to a normal type mutex which does not detect deadlock. That is, a thread attempting to relock this
mutex without first unlocking it will deadlock. The mutex is either in
a locked or unlocked state for a thread. The normal mutex is the
default type mutex.

__MUTEX_NONRECURSIVE
A nonrecursive mutex can be locked only once. That is, the mutex
is either in a locked or unlocked state for a thread. If a thread
attempts to lock a mutex that it has already locked, an error is
returned.

__MUTEX_RECURSIVE
A recursive mutex can be locked more than once by the same
thread. A count of the number of times the mutex has been locked
is maintained. The mutex is unlocked when pthread_mutex_unlock()
is performed an equal number of times.

__MUTEX_NONRECURSIVE + __MUTEX_NODEBUG
A nonrecursive mutex can be given an additional attribute,
NODEBUG. This indicates that state changes to this mutex will not
be reported to the debug interface, even if present.

__MUTEX_RECURSIVE + __MUTEX_NODEBUG
A recursive mutex can be given an additional attribute, NODEBUG.
This indicates that state changes to this mutex will not be reported
to the debug interface, even if present.

Returned value

If successful, pthread_mutexattr_gettype() returns 0.

If unsuccessful, pthread_mutexattr_gettype() returns -1 and sets errno to one of the
following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified for attr is not valid.</td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3:

If unsuccessful, pthread_mutexattr_gettype() returns an error number to indicate the
error.

```

SUSV3:

```c
#define _UNIX03_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_mutexattr_init(pthread_mutexattr_t *attr);
```

General description

Initializes a mutex attribute object. With a mutex attribute object, you can manage the characteristics of mutexes in your application. It defines the set of values to be used for the mutex during its creation. By establishing a mutex attribute object, you can create many mutexes with the same set of characteristics, without defining those characteristics for each and every mutex.

For a valid mutex attribute, refer to "pthread_mutexattr_setkind_np() — Set kind for a mutex attribute object" on page 1529.

**Note:** Before freeing up the storage containing the pthread_mutexattr_t object, be sure to destroy it by calling pthread_mutexattr_destroy(). If the pthread_mutexattr_t object is not destroyed before the storage is reused, the results are undefined.

Returned value

If successful, pthread_mutexattr_init() returns 0.

If unsuccessful, pthread_mutexattr_init() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>There is not enough memory to initialize attr.</td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3:

If unsuccessful, pthread_mutexattr_init() returns an error number to indicate the error.

Example

CELEBP44
pthread_mutexattr_init

/* CELEBP44 */

```

SUSV3:

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutexattr_setpshared(pthread_mutexattr_t *attr, int pshared);
```

General description

The `pthread_mutexattr_setpshared()` function sets the attribute `pshared` for the mutex attribute object `attr`.

A mutex attribute object allows you to manage the characteristics of mutexes in your application. It defines the set of values to be used for a mutex during its creation. By establishing a mutex attribute object, you can create many mutexes with the same set of characteristics, without needing to define the characteristics for each and every mutex. By using `attr` with the `pthread_mutexattr_setpshared()` function you can define its process-shared value for a mutex.

The valid values for the attribute `pshared` are:

**PTHREAD_PROCESS_SHARED**

Permits a mutex to be operated upon by any thread that has access to the memory where the mutex is allocated, even if the mutex is allocated in memory that is shared by multiple processes.

**PTHREAD_PROCESS_PRIVATE**

A mutex can only be operated upon by threads created within the same process as the thread that initialized the mutex; if threads of differing processes attempt to operate on such a mutex, only the process to initialize the mutex will succeed. When a new process is created by the parent process it will receive a different copy of the private mutex and this new mutex can only be used to serialize between threads in the child process. The default value of the attribute is PTHREAD_PROCESS_PRIVATE.

Returned value

If successful, `pthread_mutexattr_setpshared()` returns 0.

If unsuccessful, `pthread_mutexattr_setpshared()` returns −1 and sets `errno` to one of the following values:
**pthread_mutexattr_setpshared**

<table>

</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>
pthread_once_t once_control = PTHREAD_ONCE_INIT;

int pthread_once(pthread_once_t *once_control, void(*init_routine)());
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>
pthread_once_t once_control = PTHREAD_ONCE_INIT;

int pthread_once(pthread_once_t *once_control, void(*init_routine)());
```

**General description**

Establishes a function that will be executed only once in a given process. You may have each thread call the function, but only the first call causes the function to run. This is true even if called simultaneously by multiple threads. For example, a mutex or a thread-specific data key must be created exactly once. Calling pthread_once() prevents the code that creates a mutex or thread-specific data from being called by multiple threads. Without this routine, the execution must be serialized so that only one thread performs the initialization. Other threads that reach the same point in the code are delayed until the first thread is finished.

pthread_once() is used in conjunction with a once_control variable of the type pthread_once_t. This variable is a data type that you initialize to the PTHREAD_ONCE_INIT constant. It is then passed as a parameter on the pthread_once() function call.

init_routine is a normal function. It can be invoked directly outside of pthread_once(). In addition, it is the once_control variable that determines if the init_routine has been invoked. Calling pthread_once() with the same routine but with different once_control variables, will result in the routine being called twice, once for each once_control variable.

**Returned value**

If successful, pthread_once() returns 0.

If unsuccessful, pthread_once() returns -1.

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, pthread_once() returns an error number to indicate the error.

```

SUSV3:
```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_destroy(pthread_rwlock_t *rwlock);
```

General description

The pthread_rwlock_destroy() function deletes a read or write lock object, which is identified by `rwlock` and releases any resources used by this read or write lock object. Read/write locks are used to protect shared resources.

Note: `rwlock` is set to an invalid value by pthread_rwlock_destroy() but can be reinitialized using pthread_rwlock_init().

Returned value

If successful, pthread_rwlock_destroy() returns 0.

If unsuccessful, pthread_rwlock_destroy() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBUSY</td>
<td>An attempt was made to destroy the object referenced by <code>rwlock</code> while it is locked or referenced as part of a wait on a condition variable.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>rwlock</code> is not valid.</td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_rwlock_destroy() returns an error number to indicate the error.

</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlock_init(pthread_rwlock_t *rwlock, pthread_rwlockattr_t *attr);

pthread_rwlock_t rwlock=PTHREAD_RWLOCK_INITIALIZER;

SUSV3:
#define __UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_init(pthread_rwlock_t *__restrict__rwlock,
                       const pthread_rwlockattr_t *__restrict__attr);
```

**General description**

The `pthread_rwlock_init()` function creates a read or write lock, referenced by `rwlock`, with attributes specified by `attr`. If `attr` is NULL, the default read or write lock attribute (PTHREAD_PROCESS_PRIVATE) is used. Once initialized, the lock can be used any number of times without being reinitialized. Upon successful initialization, the state of the read or write lock becomes initialized and unlocked.

In cases where default read or write lock attributes are appropriate, the macro PTHREAD_RWLOCK_INITIALIZER can be used to initialize read or write locks that are statically allocated. The effect is equivalent to dynamic initialization by a call to `pthread_rwlock_init()` with parameter `attr` specified as NULL, except that no error checking is done.

**Note:** Although the SUSv3 standard does not specify a static initializer for read or write locks, the implementation-defined macro PTHREAD_RWLOCK_INITIALIZER_NP may be used for that purpose. It is functionally equivalent in the SUSv3 context to the PTHREAD_RWLOCK_INITIALIZER macro.

**Returned value**

If successful, `pthread_rwlock_init()` returns 0, and the state of the read or write lock becomes initialized and unlocked.

If unsuccessful, `pthread_rwlock_init()` returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The system lacked necessary resources (other than memory) to initialize another read or write lock.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>attr</code> is not valid.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>There is not enough memory to initialize the read or write lock.</td>
</tr>
</tbody>
</table>
pthread_rwlock_init

EPERM The caller does not have the privilege to perform the operation.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_rwlock_init() returns an error number to indicate the error.

```

SUSV3:
```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_rdlock(pthread_rwlock_t *rwlock);
```

General description

The pthread_rwlock_rdlock() function applies a read lock to the read or write lock referenced by `rwlock`. The calling thread acquires the read lock if a writer does not hold the lock and there are no writers blocked on the lock. In z/OS UNIX, the calling thread does not acquire the lock when a writer does not hold the lock and there are writers waiting for the lock unless the thread already held `rwlock` for read. It will block and wait until there are no writers holding or waiting for the read or write lock. If a writer holds the lock, the calling thread will not acquire the read lock. If the read lock is not acquired, the calling thread blocks (that is, it does not return from the pthread_rwlock_rdlock() call) until it can acquire the lock.

A thread may hold multiple concurrent read locks on `rwlock` (that is successfully call the pthread_rwlock_rdlock() function n times). If so, the thread must perform matching unlocks (that is, it must call the pthread_rwlock_unlock() function n times). Read/write locks are used to protect shared resources.

Note: If a thread owns locks at the time it is terminated then z/OS UNIX will release those locks.

Returned value

If successful, pthread_rwlock_rdlock() returns 0.

If unsuccessful, pthread_rwlock_rdlock() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The read lock could not be acquired because the maximum number of read locks for <code>rwlock</code> has been exceeded. This errno will only occur in the shared path.</td>
</tr>
<tr>
<td>EDEADLK</td>
<td>The current thread already owns the read or write lock for writing.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value specified by <code>rwlock</code> is not valid.</td>
</tr>
</tbody>
</table>
**ENOMEM**  There is not enough memory to acquire a lock. This errno will only occur in the private path.

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, pthread_rwlock_rdlock() returns an error number to indicate the error.

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlock_tryrdlock(pthread_rwlock_t *rwlock);
```

SUSV3:

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_tryrdlock(pthread_rwlock_t *rwlock);
```

General description

The `pthread_rwlock_tryrdlock()` function applies a read lock as in the `pthread_rwlock_rdlock()` function with the exception that the function fails if any thread holds a write lock on `rwlock` or there are writers blocked on `rwlock` unless the thread already held `rwlock` for read. Read/write locks are used to protect shared resources.

If the read or write lock identified by `rwlock` is locked, `pthread_rwlock_tryrdlock()` returns immediately.

When there are only read locks on the read or write lock, `pthread_rwlock_tryrdlock()` will effectively add to the count of the number of times `pthread_rwlock_unlock()` must be called by the thread to release the mutex (that is, it has the same behavior as a `pthread_rwlock_rdlock()` function).

Returned value

If successful, `pthread_rwlock_tryrdlock()` returns 0.

If unsuccessful, `pthread_rwlock_tryrdlock()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The read lock could not be acquired because the maximum number of read locks for <code>rwlock</code> has been exceeded. This <code>errno</code> will only occur in the shared path.</td>

```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_unlock(pthread_rwlock_t *rwlock);
```

**General description**

The `pthread_rwlock_unlock()` function releases a read or write lock object. If one or more threads are waiting to lock the `rwlock`, `pthread_rwlock_unlock()` causes one or more of these threads to return from the `pthread_rwlock_rdlock()` or the `pthread_rwlock_wrlock()` call with the `rwlock` object acquired. If there are multiple threads blocked on `rwlock` for both read locks and write locks, z/OS UNIX will give the read or write lock to the next waiting call whether it is a read or a write request even when there is a writer blocked waiting for the lock. If no threads are waiting for the `rwlock`, the `rwlock` unlocks with no current owner.

**Returned value**

If successful, `pthread_rwlock_unlock()` returns 0.

If unsuccessful, `pthread_rwlock_unlock()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>

```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_wrlock(pthread_rwlock_t *rwlock);
```

## General description

The `pthread_rwlock_wrlock()` function applies a write lock to the read or write lock referenced by `rwlock`. The calling thread acquires the write lock if no other thread (reader or writer) holds the read or write lock `rwlock`. Otherwise, the thread blocks (that is, does not return from the `pthread_rwlock_wrlock()` call) until it can acquire the lock. In z/OS UNIX the calling thread does not acquire the lock when a writer does not hold the lock and there are writers waiting for the lock. It will block and wait until there are no writers holding or waiting for the read or write lock. If the thread already holds read or write lock for either read or write then a deadlock errno will be returned.

**Note:** If a thread owns locks at the time it is terminated then z/OS UNIX will release those locks.

## Returned value

If successful, `pthread_rwlock_wrlock()` returns 0.

If unsuccessful, `pthread_rwlock_wrlock()` returns −1 and sets `errno` to one of the following values:

<table>

```

**SUSv3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlockattr_destroy(pthread_rwlockattr_t *attr);
```

**General description**

The `pthread_rwlockattr_destroy()` function destroys an initialized rwlock attribute object.

After a read or write lock attributes object has been used to initialize one or more read or write locks any function affecting the attributes object (including destruction) does not affect any previously initialized read or write locks.

The `pthread_rwlockattr_destroy()` function destroys a read or write lock attributes object. Subsequent use of the object will cause an error until the object is reinitialized by another call to `pthread_rwlockattr_init()`.

**Returned value**

If successful, `pthread_rwlockattr_destroy()` returns 0.

If unsuccessful, `pthread_rwlockattr_destroy()` returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlockattr_getpshared(const pthread_rwlockattr_t *attr, int *pshared);
```

SUSV3:

```c
#define _UNIX03_THREADS
#define _POSIX_1_THREADS
#include <pthread.h>

int pthread_rwlockattr_getpshared(const pthread_rwlockattr_t *__restrict__attr, int *__restrict__pshared);
```

General description

The pthread_rwlockattr_getpshared() function gets the attribute `pshared` for the read or write lock attribute object `attr`. By using `attr` with the pthread_rwlockattr_getpshared() function you can determine its process-shared value for a read or write lock.

The valid values for the attribute `pshared` are:

- **PTHREAD_PROCESS_SHARED**
  
  Permits a read or write lock to be operated upon by any thread that has access to the memory where the read or write lock is allocated, even if the read or write lock is allocated in memory that is shared by multiple processes.

- **PTHREAD_PROCESS_PRIVATE**
  
  A read or write lock can only be operated upon by threads created within the same process as the thread that initialized the read or write lock. When a new process is created by the parent process it will receive a different copy of the private read or write lock and this new read or write lock can only be used to serialize between threads in the child process. The default value of the attributed is PTHREAD_PROCESS_PRIVATE.

Returned value

If successful, pthread_rwlockattr_getpshared() returns 0.

If unsuccessful, pthread_rwlockattr_getpshared() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified for <code>attr</code> is not valid.</td>
</tr>
</tbody>
</table>
Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_rwlockattr_getpshared() returns an error number to indicate the error.

```

SUSV3:

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlockattr_init(pthread_rwlockattr_t *attr);
```

General description

The `pthread_rwlockattr_init()` function initializes a read or write lock attribute object. A read or write lock attribute object allows you to manage the characteristics of read or write locks in your application. It defines the set of values to be used for the read or write lock during its creation. By establishing a read or write lock attribute object, you can create many read or write locks with the same set of characteristics, without needing to define the characteristics for each and every read or write lock.

For a valid read or write lock attribute, refer to "pthread_rwlockattr_setpshared() — Set the process-shared read or write lock attribute" on page 1556.

If `pthread_rwlockattr_init()` is called specifying an already initialized read or write lock attributes object the request is rejected and the current lock attributes object is unchanged.

Returned value

If successful, `pthread_rwlockattr_init()` returns 0.

If unsuccessful, `pthread_rwlockattr_init()` returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>There is not enough memory to initialize <code>attr</code></td>
</tr>
</tbody>
</table>

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_rwlockattr_init()` returns an error number to indicate the error.

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlockattr_setpshared(pthread_rwlockattr_t *attr, int pshared);
```

### General description

The `pthread_rwlockattr_setpshared()` function sets the attribute `pshared` for the read or write lock attribute object `attr`.

A read or write lock attribute object allows you to manage the characteristics of read or write locks in your application. It defines the set of values to be used for a read or write lock during its creation. By establishing a read or write lock attribute object, you can create many read or write locks with the same set of characteristics, without needing to define those characteristics for each and every read or write lock. By using `attr` with the `pthread_rwlockattr_setpshared()` function you can define its `process-shared` value for a read or write lock.

The valid values for the attribute `pshared` are:

- **PTHREAD_PROCESS_SHARED**
  - Permits a read or write lock to be operated upon by any thread that has access to the memory where the read or write lock is allocated, even if the read or write lock is allocated in memory that is shared by multiple processes.

- **PTHREAD_PROCESS_PRIVATE**
  - A read or write lock can only be operated upon by threads created within the same process as the thread that initialized the read or write lock. When a new process is created by the parent process it will receive a different copy of the private read or write lock and this new read or write lock can only be used to serialize between threads in the child process. The default value of the attributed is PTHREAD_PROCESS_PRIVATE.

### Returned value

If successful, `pthread_rwlockattr_setpshared()` returns 0.
If unsuccessful, pthread_rwlockattr_setpshared() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified for attr or pshared is not valid.</td>
</tr>
</tbody>
</table>

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, pthread_rwlockattr_setpshared() returns an error number to indicate the error.

Format

```c
#define _OPEN_SYS 1
#include <pthread.h>

int pthread_security_np(int function_code,
    int identity_type,
    size_t identity_length,
    void *identity,
    char *password,
    int options);

int pthread_security_applid_np(int function_code,
    int identity_type,
    size_t identity_length,
    void *identity,
    char *password,
    int options,
    const char *applid);
```

General description

pthread_security_np() creates or deletes a thread-level security environment for the calling thread.

The __pthread_security_applid_np() function is equivalent to pthread_security_np() with the added feature that it also allows the application identifier (APPLID) to be supplied that will be passed on to the security product to assist with authentication. This is useful, for example, in situations where a pass ticket is provided and the pass ticket was created with a USERID/APPLID combination. When applid is NULL or a pointer to NULL, no application identifier will be passed on to the security product.

The function supports the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>function_code</td>
<td>Specify one of the following:</td>
</tr>
<tr>
<td></td>
<td>__CREATE_SECURITY_ENV</td>
</tr>
<tr>
<td></td>
<td>Create a thread-level security environment for the calling thread. If a thread-level security environment already exists, it is deleted before a new one is created.</td>
</tr>
<tr>
<td></td>
<td>__DAEMON_SECURITY_ENV</td>
</tr>
<tr>
<td></td>
<td>Creates a thread-level security environment for the caller's thread without the need for a password if the caller is a superuser and has permission to BPX.DAEMON facility class profile if BPX.DAEMON facility class profile is defined. If a thread-level...</td>
</tr>
</tbody>
</table>
pthread_security_np pthread_security_applid_np

security environment already exists, it is deleted before the new environment is created. Using the _DAEMON_SECURITY_ENV function code and not specifying a password is similar to using the current BPX.SRV.userid surrogate support. The difference is that the installation does not have to setup individual surrogate profiles for each of the clients that desire a thread level identity in the target server process.

The server will be allowed to create any identity without authentication if it is given permission to the BPX.DAEMON facility class profile.

__DELETE_SECURITY_ENV
Delete the thread-level security environment for the calling thread, if one exists. If the security environment was created using the __TLS_TASK_ACEE option, then only the z/OS UNIX security data is deleted (the task-level ACEE is unchanged).

__TLS_TASK_ACEE
Initializes the z/OS UNIX security data for a task that has an existing task-level security environment (task-level ACEE). If the z/OS UNIX security data already exists for the calling task, the existing z/OS UNIX security data is deleted and a new set of z/OS UNIX security data is established.

__TLS_TASK_ACEE_USP
Takes a pre-existing user security packet (USP) from a task-level ACEE and extracts the UID and GID information. This information is then used to build a complete z/OS UNIX security environment for the calling thread. If the calling thread does not have a USP associated with the task-level ACEE, this call is treated as if the __TLS_TASK_ACEE function was specified.

identity_type Specifies the format of the user identity in the argument identity. It can have one of the following values:

__USERID_IDENTITY
User identity in the form of a character string (1 to 8 bytes in length).

__CERTIFICATE_IDENTITY
User identity in the form of a __certificate_t. A __certificate_t is a structure containing the following elements:

__cert_type The type of security certificate. Setting value __CERT_X509, for example, indicates the certificate is an X.509 security certificate.

__userid An output field in the __certificate structure that will be filled with the user ID associated with the certificate. This output will be up to 8 characters long and NULL-terminated.
pthread_security_np pthread_security_applid_np

__cert_length  The length in bytes of the security certificate.
__cert_ptr    A pointer to the start of the security certificate.

identity_length Specifies the length of the identity parameter. If identity_type is
                  __USERID_IDENTITY, identity_length is the length of the user
                  identity character string. If identity_type is
                  __CERTIFICATE_IDENTITY, identity_length is the length of the
                  __certificate structure.

identity     Specifies the user identity according to the identity_type parameter.
password     Specifies a user password or PassTicket, or a password phrase.
options      Specifies options used to tailor the request. options must be set to
              0.
applid       Specifies the application identifier that will be used for
              authentication with the security product.

This function is intended to be used by servers which process requests from
multiple clients. By creating and building a thread-level security environment for the
client, a server can process many client requests without the overhead of issuing
fork/setuid/exec. See usage notes in z/OS UNIX System Services Programming:
Assembler Callable Services Reference for additional information.

Returned value

If successful, pthread_security_np() returns 0.

If unsuccessful, pthread_security_np() returns -1 and sets errno to one the following
values:

Error Code  Description
EACCES      The password or PassTicket, or the password phrase provided is
            not valid for the passed userid.
EINVAL      A parameter is not valid.
EMVSERR     An MVS environmental error or internal error occurred.
EMVSEXPIRE  The password or PassTicket, or the password phrase provided has
            expired.
EMVSSAF2ERR The SAF call to the security product incurred an error.
EMVSSAFEXTRERR The SAF call to the security product incurred an error.
ENOSYS      The function is not implemented.
EPERM
1. The process does not have appropriate privileges to set a
   thread-level security environment. The caller is not permitted to
   the BPX.SERVER FACILITY class profile or BPX.SERVER is
   not defined and the caller is not a superuser. No password or
   PassTicket, or password phrase is provided and the caller is not
   defined as a surrogate of the passed user ID.
2. The caller is not a superuser and permitted to the
   BPX.DAEMON FACILITY class profile or BPX.DAEMON is not
   defined and the caller is not a superuser.
ESRCH  The user ID provided as input is not defined to the security product or does not have an OMVS segment defined.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

pthread_t pthread_self(void);
```

General description

Returns the thread ID of the calling thread.

Returned value

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

Example

```c
CELEBP47
/* CELEBP47 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

pthread_t thid, IPT;

void *thread(void *arg) {
    if (pthread_equal(IPT, pthread_self()))
        puts("the thread is the IPT...?");
    else
        puts("the thread is not the IPT");
    if (pthread_equal(thid, pthread_self()))
        puts("the thread is the one created by the IPT");
    else
        puts("the thread is not the one created by the IPT...?");
}

main() {
    IPT = pthread_self();
    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create() error");
        exit(1);
    }
    if (pthread_join(thid, NULL) != 0) {
        perror("pthread_create() error");
        exit(3);
    }
}
```

Output:
the thread is not the IPT
the thread is the one created by the IPT

pthread_setcancelstate

pthread_setcancelstate() — Set a thread cancelability state format

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, version 3</td>
<td>both</td>
<td>z/OS V1R7 POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS 2
#include <pthread.h>

int pthread_setcancelstate(int state, int *oldstate);
```

General description

pthread_setcancelstate() controls whether the thread acts on a cancelation request caused by a call to pthread_cancel(). The old state is stored into the location pointed to by oldstate. The cancelability states can be:

- **PTHREAD_CANCEL_ENABLE**
  - The thread can be canceled, but is subject to type. The cancelability types can be found in "pthread_setcanceltype() — Set a thread cancelability type format" on page 1565.

- **PTHREAD_CANCEL_DISABLE**
  - The thread cannot be canceled.

Returned value

If successful, pthread_setcancelstate() returns 0. Upon failure, returns the following EINVAL error code:
- *state* is an invalid value.

# pthread_setcanceltype

## pthread_setcanceltype() — Set a thread cancelability type format

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
</table>
| Single UNIX Specification, version 3 | both | z/OS V1R7
| | | POSIX(ON)

### Format

```c
#define _OPEN_THREADS 2
#include <pthread.h>

int pthread_setcanceltype(int type, int *oldtype);
```

### General description

`pthread_setcanceltype()` controls when a cancel request is acted on. The old `type` is stored into the location pointed to by `oldtype`. The cancelability types can be:

- **PTHREAD_CANCELASYNCHRONOUS**
  - The thread can be canceled at any time.

- **PTHREAD_CANCELDEREFERRED**
  - The thread can be canceled, but only at cancelation points introduced by invocation of particular functions. For more information, see the [z/OS XL C/C++ Programming Guide](#).

### Returned value

If successful, `pthread_setcanceltype()` returns 0. Upon failure, returns the following `EINVAL` error code:

- `type` is an invalid value.

### Related information

**pthread_setconcurrency**

**pthread_setconcurrency() — Set the level of concurrency**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, version 3</td>
<td>both</td>
<td>z/OS V1R7 POSIX(ON)</td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS 2
#include <pthread.h>

int pthread_setconcurrency(int new_level);
```

**General description**

`pthread_setconcurrency()` sets the desired thread concurrency level to `new_level`.

**Usage notes**

1. z/OS UNIX does not support multiplexing POSIX threads onto TCBs. If successful, `pthread_setconcurrency()` saves `new_level` for subsequent calls to `pthread_getconcurrency()` but takes no other action. For related information on the relationship between pthreads and TCBs, see [“pthread_attr_setweight_np()” — Set weight of thread attribute object](#) on page 1441 and [“pthread_attr_setsynctype_np() — Set thread sync type” on page 1440](#).

**Returned value**

If successful, `pthread_setconcurrency()` returns 0. Upon failure, returns one of the following error values:

- **EINVAL** – The value specified by `new_level` is negative.
- **EAGAIN** – The value specific by `new_level` would cause a system resource to be exceeded.

**Related information**

- "Thread Cancelation" in the [z/OS XL C/C++ Programming Guide](#)
- "pthread.h" on page 57
- "pthread_getconcurrency() — Get the level of concurrency" on page 1486
**pthread_setintr**

**pthread_setintr() — Set a thread cancelability state**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_setintr(int state);
```

**General description**

Controls whether the thread accepts a cancel request that was produced by a call to `pthread_cancel()`. The cancelability states can be:

- **PTHREAD_INTR_DISABLE**: The thread cannot be canceled.
- **PTHREAD_INTR_ENABLE**: The thread can be canceled, but it is subject to type. The cancelability types can be found in ["pthread_setintrtype() — Set a thread cancelability type" on page 1570](#).

**Usage notes**

1. If you are writing to the Single UNIX Specification, Version 3 standard, use `pthread_setcancelstate()` in place of `pthread_setintr()`.

**Returned value**

If successful, `pthread_setintr()` returns the previous state.

If unsuccessful, `pthread_setintr()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>state is an invalid value.</td>
</tr>
</tbody>
</table>

**Example**

```c
/* CELEBP48 */
#include <stdio.h>
#include <string.h>
#include <pthread.h>
#include <errno.h>
#include <unistd.h>

int thstatus;
char state[68] = "enable/controlled - initial default";

void * thfunc(void *voidptr)
{
    int rc;
    char * parmptr;
```
parmptr = voidptr;
printf("parm = %s\n", parmptr);

strcpy(state, "disable/controlled");
if ( pthread_setintrtype(PTHREAD_INTR_CONTROLLED ) == -1 ) {
    printf("set controlled failed. %s\n", strerror(errno));
    thstatus = 103;
    pthread_exit(&thstatus);
}

if ( pthread_setintr(PTHREAD_INTR_ENABLE) == -1 ) {
    printf("set enable failed. %s\n", strerror(errno));
    thstatus = 104;
    pthread_exit(&thstatus);
}

strcpy(state, "enable/controlled");
strcat(state, " − pthread_testintr");
while (1) {
    pthread_testintr();
    sleep(1);
}

thstatus = 100;
pthread_exit(&thstatus);
}

main(int argc, char *argv[]) {
    int rc;
    pthread_attr_t attrarea;
    pthread_t thid;
    char parm[] = "abcdefghijklmnopqrstuvwxyz";
    int *statptr;

    if ( pthread_attr_init(&attrarea) == -1 ) {
        printf("pthread_attr_init failed. %s\n", strerror(errno));
        exit(1);
    }

    if ( pthread_create(&thid, &attrarea, thfunc, (void *)&parm) == -1) {
        printf("pthread_create failed. %s\n", strerror(errno));
        exit(2);
    }

    sleep(5);

    if ( pthread_cancel(thid) == -1 ) {
        printf("pthread_cancel failed. %s\n", strerror(errno));
        exit(3);
    }

    if ( pthread_join(thid, (void **)&statptr)== -1 ) {
        printf("pthread_join failed. %s\n", strerror(errno));
        exit(4);
    }

    if ( statptr == (int *)−1 )
        printf("thread was cancelled. state = %s\n", state);
    else
        printf("thread was not cancelled. thstatus = %d\n", *statptr);

    exit(0);
}

Output:
parm = abcdefghijklmnopqrstuvwxyz.
thread was canceled. state = enable/controlled - pthread_testintr.

<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_setintrtype(int type);
```

General description

Controls when a cancel request is acted on. The cancelability types can be:

- **PTHREAD_INTRASYNCHRONOUS**
  - The thread can be canceled at any time.

- **PTHREAD_INTRCONTROLLED**
  - The thread can be canceled, but only at specific points of execution. These are:
    - When waiting on a condition variable, which is `pthread_cond_wait()` or `pthread_cond_timedwait()`
    - When waiting for the end of another thread, which is `pthread_join()`
    - While waiting for an asynchronous signal, which is `sigwait()`
    - When setting the calling thread's cancelability state, which is `pthread_setintr()`
    - Testing specifically for a cancel request, which is `pthread_testintr()`
    - When suspended because of POSIX functions or one of the following C standard functions: `close()`, `fcntl()`, `open()`, `pause()`, `read()`, `tcdrain()`, `tcsetattr()`, `sigsuspend()`, `sigwait()`, `sleep()`, `wait()`, or `write()`

Usage notes

1. If you are writing to the Single UNIX Specification, Version 3 standard, use `pthread_setcanceltype()` in place of `pthread_setintrtype()`.

Returned value

If successful, `pthread_setintrtype()` returns the previous type.

If unsuccessful, `pthread_setintrtype()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>

pthread_set_limit_np

**pthread_set_limit_np() — Set task and thread limits**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_SYS
#include <pthread.h>

int pthread_set_limit_np(int action, int maxthreadtasks, int maxthreads);
```

**General description**

The `pthread_set_limit_np()` function allows you to control how many tasks and threads can be created for a process. On a single call, you can specify that you want to update either the maximum number of tasks, the maximum number of threads, or both. The maximum number of tasks and threads is dependent upon the size of the private area below 16M. A realistic limit is 200 to 400 tasks and threads.

The `action` can be set to one of the following symbolics, as defined in the `pthread.h` header file:

- `__STL_MAX_TASKS` Specify this action when only updating the maximum number of tasks.
- `__STL_MAX_THREADS` Specify this action when only updating the maximum number of threads.
- `__STL_SET_BOTH` Specify this action when updating both the maximum number of tasks and the maximum number of threads at the same time.

For more information on the allowable values for `maxthreadtasks` and `maxthreads`, see the `BPX1STL` function in [Z/OS UNIX System Services Programming: Callable Services Reference, SA22-7803](#).

**Returned value**

If successful, `pthread_set_limit_np()` returns 0.

If unsuccessful, `pthread_set_limit_np()` returns -1.

For more information regarding return values and reason codes, see the `BPX1STL` function in [Z/OS UNIX System Services Programming: Callable Services Reference, SA22-7803](#).

**Related information**

- "`pthread.h` on page 57"

**pthread_setspecific**

**pthread_setspecific() — Set the thread-specific value for a key**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_setspecific(pthread_key_t key, void *value);
```

**SUSV3:**

```c
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_setspecific(pthread_key_t key, const void *value);
```

**General description**

Associates a thread-specific value, `value`, with a key identifier, `key`.

Many multithreaded applications require storage shared among threads but a unique value for each thread. A thread-specific data key is an identifier, created by a thread, for which each thread in the process can set a unique key `value`.

`pthread_key_t` is a storage area where the system places the key identifier. To create a key, a thread uses `pthread_key_create()`. This returns the key identifier into the storage area of type `pthread_key_t`. At this point, each of the threads in the application has the use of that key, and can set its own unique value by use of `pthread_setspecific()`. A thread can get its own unique value using `pthread_getspecific()`.

**Returned value**

If successful, `pthread_setspecific()` returns 0.

If unsuccessful, `pthread_setspecific()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The key identifier <code>key</code> is not valid.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Insufficient memory exists to associate the non-NUL value with the key.</td>
</tr>
</tbody>
</table>

**Special behavior for Single UNIX Specification, Version 3:** If unsuccessful, `pthread_setspecific()` returns an error number to indicate the error.

**Example**

```c
CELEBP51
/* CELEBP51 */
#define _OPEN_THREADS
#include <stdio.h>
```
#include <stdlib.h>
#include <errno.h>
#include <pthread.h>

#define threads 3
#define BUFFSZ 48

pthread_key_t key;

void *threadfunc(void *parm)
{
    int status;
    void *value;
    int threadnum;
    int *tnum;
    void *getvalue;
    char Buffer[BUFFSZ];

    tnum = parm;
    threadnum = *tnum;

    printf("Thread %d executing\n", threadnum);

    if (!(value = malloc(sizeof(Buffer))))
        printf("Thread %d could not allocate storage, errno = %d\n", threadnum, errno);
    status = pthread_setspecific(key, (void *) value);
    if (status < 0)
        printf("pthread_setspecific failed, thread %d, errno %d", threadnum, errno);

pthread_sigmask() — Examine or change a thread blocked signals format

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, version 3</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td></td>
<td></td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS 2
#include <signal.h>

int pthread_sigmask(int option, const sigset_t *__restrict__ new_set,
                     sigset_t *__restrict__ old_set);
```

General description

pthread_sigmask() examines, changes, or examines and changes the signal mask of the calling thread. If there is only one thread, it does the same for the calling process.

Typically, pthread_sigmask(SIG_BLOCK, ..., ...) is used to block signals during a critical section of code. At the end of the critical section of code, pthread_sigmask(SIG_SETMASK, ..., ...) is used to restore the mask to the previous value returned by pthread_sigmask(SIG_BLOCK, ..., ...).

option indicates the way in which the existing set of blocked signals should be changed. The following are the possible values for option, defined in the signal.h header file:

- SIG_BLOCK – Indicates that the set of signals given by new_set should be blocked, in addition to the set currently being blocked.
- SIG_UNBLOCK – Indicates that the set of signals given by new_set should not be blocked. These signals are removed from the current set of signals being blocked.
- SIG_SETMASK – Indicates that the set of signals given by new_set should replace the old set of signals being blocked.

new_set points to a signal set giving the new signals that should be blocked or unblocked (depending on the value of option) or it points to the new signal mask if the option was SIG_SETMASK. Signal sets are described in "sigemptyset() — Initialize a Signal Mask to Exclude All Signals" in topic 3.727. If new_set is a NULL pointer, the set of blocked signals is not changed. pthread_sigmask() determines the current set and returns this information in *old_set. If new_set is NULL, the value of option is not significant. The signal set manipulation functions: sigemptyset(), sigfillset(), sigaddset(), and sigdelset() must be used to establish the new signal set pointed to by new_set.

old_set points to a memory location where pthread_sigmask() can store a signal set. If new_set is NULL, old_set returns the current set of signals being blocked. When new_set is not NULL, the set of signals pointed to by old_set is the previous set.
If there are any pending unblocked signals, either at the process level or at the current thread's level after pthread_sigmask() has changed the signal mask, then at least one of those signals is delivered to the thread before pthread_sigmask() returns.

The signals SIGKILL, SIGSTOP, or SIGTRACE cannot be blocked. If you attempt to use pthread_sigmask() to block these signals, the attempt is ignored. pthread_sigmask() does not return an error status.

SIGFPE, SIGILL, and SIGSEGV signals that are not artificially generated by kill(), killpg(), raise(), or pthread_kill() (that is, were generated by the system as a result of a hardware or software exception) will not be blocked.

If an artificially raised SIGFPE, SIGILL, or SIGSEGV signal is pending and blocked when an exception causes another SIGFPE, SIGILL, or SIGSEGV signal, both the artificial and exception-caused signals may be delivered to the application.

If pthread_sigmask() fails, the signal mask of the thread is not changed.

Usage Notes

1. The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If successful, pthread_sigmask() returns 0. Otherwise, pthread_sigmask() returns one of the following error numbers:

EINVAL

option does not have one of the recognized values.

**pthread_tag_np**

**pthread_tag_np() — Set and query thread tag data**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _OPEN_THREADS
#include <pthread.h>

int pthread_tag_np(const char *newtag, char *oldtag);
```

**General description**

The `pthread_tag_np()` function is used to set and query the contents of the calling thread's tag data.

The parameters supported are:

- **newtag**: Specifies the new tag data to be set for the caller's thread. The length of the new tag data must be in the range of 0-65 bytes. If the length is zero (NULL string) the caller's thread tag data will be cleared.

- **oldtag**: Specifies the string where `pthread_tag_np()` returns the old (current) tag data for the caller's thread. Tag data can be up to 66 bytes (including the trailing NULL).

**Returned value**

If successful, `pthread_tag_np()` returns 0.

If unsuccessful, `pthread_tag_np()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>One of the following errors was detected:</td>
</tr>
<tr>
<td></td>
<td>• All or part of the newtag string is not addressable by the caller.</td>
</tr>
<tr>
<td></td>
<td>• All or part of the oldtag string is not addressable by the caller.</td>
</tr>
</tbody>
</table>

| EINVAL     | The length of the newtag string is not within allowable range (0 to 65 bytes). |
| EMVSERR    | An MVS environmental or internal error has occurred. |

<tr>
<td></td>
<td></td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

#### Format

```c
#define _OPEN_THREADS 2
#include <pthread.h>

void pthread_testcancel(void);
```

#### General description

`pthread_testcancel()` allows the thread to solicit cancel requests at specific points within the current thread. You must have the cancelability state set to enabled (PTHREAD_CANCEL_ENABLE) for this function to have any effect.

#### Returned value

`pthread_testcancel()` returns no values.

#### Related information

pthread_testintr

pthread_testintr() — Establish a cancelability point

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_THREADS
#include <pthread.h>

void pthread_testintr(void);
```

General description

Allows the thread to solicit cancel requests at specific points within the current thread. You must have the cancelability state set to enabled (PTHREAD_INTR_ENABLE) for this function to have any effect.

Usage notes

1. If you are writing to the Single UNIX Specification, Version 3 standard, use pthread_testcancel() in place of pthread_testintr().

Returned value

pthread_testintr() returns no values.

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

Example

```c
/* CELEBP52 */
#define _OPEN_THREADS
#include <stdio.h>
#include <string.h>
#include <pthread.h>
#include <errno.h>
#include <unistd.h>

int thstatus;
char state[60] = "enable/controlled - initial default";

void * thfunc(void *voidptr)
{
  int rc;
  char *parmptr;

  parmptr = voidptr;
  printf("parm = %s.\n", parmptr);
  if ( pthread_setintrtype(PTHREAD_INTR_CONTROLLED ) == -1 ) {
      printf("set controlled failed. %s\n", strerror(errno));
      thstatus = 103;
      pthread_exit(&thstatus);
  }
  strcpy(state, "disable/controlled");
  if ( pthread_setintr(PTHREAD_INTR_ENABLE) == -1 ) { 
```
printf("set enable failed. \%s\n", strerror(errno));
thstatus = 104;
pthread_exit(&thstatus);
}
strcpy(state, "enable/controlled");
strcat(state, " − pthread_testintr");

while(1) {
    pthread_testintr();
sleep(1);
}

thstatus = 100;
pthread_exit(&thstatus);
}

main(int argc, char *argv[]) {
    int rc;
    pthread_attr_t attrarea;
    pthread_t thid;
    char parm[ ] = "abcdefghijklmnopqrstuvwxyz"
    int *statptr;

    if ( pthread_attr_init(&attrarea) == −1 ) {
        printf("pthread_attr_init failed. \%s\n", strerror(errno));
        exit(1);
    }

    if ( pthread_create(&thid, &attrarea, thfunc, (void *)&parm) == −1) {
        printf("pthread_create failed. \%s\n", strerror(errno));
        exit(2);
    }

    sleep(5);

    if ( pthread_cancel(thid) == −1 ) {
        printf("pthread_cancel failed. \%s\n", strerror(errno));
        exit(3);
    }

    if ( pthread_join(thid, (void **)&statptr)== −1 ) {
        printf("pthread_join failed. \%s\n", strerror(errno));
        exit(4);
    }

    if ( statptr == (int *)−1 )
        printf("thread was cancelled. state = \%s\n", state);
    else
        printf("thread was not cancelled. thstatus = \%d\n", *statptr);

    exit(0);
}

Output:
parm = abcdefghijklmnopqrstuvwxyz.
thread was canceled. state = enable/controlled - pthread_testintr.

# pthread_yield()

## pthread_yield() — Release the processor to other threads

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4a</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

### Format

```c
#define _OPEN_THREADS
#include <pthread.h>

void pthread_yield(NULL);
```

### General description

The `pthread_yield()` function allows a thread to give up control of a processor so that another thread can have the opportunity to run.

The parameter to the function must be `NULL`, because non-NULL values are reserved.

The speed at which the `pthread_yield()` function releases a processor can be configured by using the `_EDC_PTHREAD_YIELD` and `_EDC_PTHREAD_YIELD_MAX` environment variables. The `_EDC_PTHREAD_YIELD` environment variable is used to configure the `pthread_yield()` function to release the processor immediately, or to release the processor after a delay. The `_EDC_PTHREAD_YIELD_MAX` environment variable is used to change the maximum delay to a value less than the default (32 milliseconds).

For more information about the `_EDC_PTHREAD_YIELD` and `_EDC_PTHREAD_YIELD_MAX` environment variables, see the topic about using environment variables in [z/OS XL C/C++ Programming Guide](https://www.ibm.com/support/knowledgecenter/SSGUGG_1.13.0/com.ibm.zos.v1r13.chm/).  

### Returned value

`pthread_yield()` returns no values.

There are no documented `errno` values.

### Example

```c
#include <stdio.h>
#include <unistd.h>

void *thread(void *arg)
{
  while (1)
  {
    puts((char*) arg);
  }
}

CELEBP53
/* CELEBP53 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>

void *thread(void *arg) {
  /* A simple loop with only puts() would allow a thread to write several lines in a row.
   With pthread_yield(), each thread gives another thread a chance before it writes its next line */
  while (1) {
    puts((char*) arg);
  }

CELEBP53
```
main() {
    pthread_t t1, t2, t3;
    if (pthread_create(&t1, NULL, thread, "thread 1") != 0) {
        perror("pthread_create() error");
        exit(1);
    }
    if (pthread_create(&t2, NULL, thread, "thread 2") != 0) {
        perror("pthread_create() error");
        exit(2);
    }
    if (pthread_create(&t3, NULL, thread, "thread 3") != 0) {
        perror("pthread_create() error");
        exit(3);
    }
    sleep(1);
    exit(0); /* this will tear all threads down */
}

Output:
thread 1
thread 3
thread 2
thread 1
thread 3
thread 2
thread 1
thread 3
thread 3

ptsname

ptsname() — Get name of the slave pseudoterminal device

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

char *ptsname(int fildes);
```

General description

The ptsname() function returns the name of the slave pseudoterminal device associated with a master pseudoterminal device. The `fildes` argument is a file descriptor that refers to the master device. ptsname() returns a pointer to a string containing the path name of the corresponding slave device.

Returned value

If successful, ptsname() returns a pointer to a string which is the name of the pseudoterminal slave device.

If unsuccessful, ptsname() returns a NULL pointer. This could occur if `fildes` is an invalid file descriptor or if the slave device name does not exist in the file system.

No errors are defined.

<td>both</td>
<td></td>
</tr>
</tbody>
</table>
Format

```c
#include <stdio.h>

int putc(int c, FILE *stream);
int putchar(int c);
```

General description

Converts `c` to unsigned char and then writes `c` to the output `stream` at the current position. The `putchar()` function is identical to:

```c
putc(c, stdout);
```

These functions are also available as macros in the z/OS XL C/C++ product. For performance purposes, it is recommended that the macro forms rather than the functional forms be used.

By default, if the stdio.h header file is included, the macro is invoked. Therefore, the stream argument expression should never be an expression with side effects.

The actual function can be accessed using one of the following methods:
- For C only: do not include stdio.h.
- Specify `#undef`, for example, `#undef putc`.
- Surround the function name by parentheses, for example: `(putchar)('a')`.

In a multithread application, in the presence of the feature test macro, `_OPEN_THREADS`, these macros are in an `#undef` status because they are not thread-safe.

`putc()` and `putchar()` are not supported for files opened with `type=record`.

`putc()` and `putchar()` have the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

If the application is not multithreaded, then setting the `_ALL_SOURCE_NO_THREADS` feature test macro may improve performance of the application, because it allows use of the inline version of this function.

Returned value

If successful, `putc()` and `putchar()` return the character written.

If unsuccessful, `putc()` and `putchar()` return EOF.

Example

```c
CELEBP54
/* CELEBP54

This example writes the contents of a buffer to a data stream.
The body of the "for" statement is null because the example carries out the writing operation in the test expression.

*/
#include <stdio.h>
```
```
#include <string.h>
#define LENGTH 80

int main(void)
{
    FILE *stream = stdout;
    int i, ch;
    char buffer[LENGTH + 1] = "Hello world\n";

    /* This could be replaced by using the fwrite routine */
    for (i = 0;
        (i < strlen(buffer)) && ((ch = putc(buffer[i], stream)) != EOF);
            ++i);
}

Output:
Hello world
```

putenv() — Change or add an environment variable

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdlib.h>

int putenv(char *envvar);
```

General description

Adds a new environment variable or changes the value of an existing one. The argument `envvar` is a pointer to a NULL-terminated character string that should be of the form:

```
name=value
```

Where:

1. The first part, `name`, is a character string that represents the name of the environment variable. It is this part of the environment variable that putenv() will use when it searches the array of environment variable to determine whether to add or change this environment variable.
2. The second part, `=`, is a separator character (since the equal sign is used as a separator character it cannot appear in the `name`).
3. The third part, `value`, is a NULL-terminated character string that represents the value that the environment variable, `name`, will be set to.

putenv() is a simplified form of setenv() and is equivalent to

```
setenv(name, value, 1)
```

**Note:** Starting with, z/OS V1R2, the storage used to define the environment variable pointed to by `envvar` is added to the array of environment variables. Previously, the system copied the string into system allocated storage. A new environment variable, `_EDC.PUTENV_COPY`, will allow the previous behavior to continue if set to YES. If `_EDC.PUTENV_COPY` is not set or is set to any other value the new behavior will take place.

**Special behavior for POSIX C:** You can use the external variable `**environ` (defined as extern char **environ) to access the array of pointers to environment variables.

Returned value

If successful, putenv() returns 0.

If unsuccessful, putenv() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>

Chapter 3. Library functions  1589
putenv

ENOMEM Insufficient memory was available.

Special behavior for z/OS UNIX Services:

EINVAL The environment variable pointed to by the argument envvar does not follow the prescribed format. The equal sign (=) separating the environment variable name from the value was not found.

</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int putmsg(int fildes, const struct strbuf *ctlptr,
           const struct strbuf *dataptr, int flags);

int putpmsg(int fildes, const struct strbuf *ctlptr,
           const struct strbuf *dataptr, int band, int flags);
```

General description

The putmsg() function creates a message from a process buffer(s) and sends the message to a STREAMS file. The message may contain either a data part, a control part, or both. The data and control parts are distinguished by placement in separate buffers, as described below. The semantics of each part is defined by the STREAMS module that receives the message.

The putpmsg() function does the same thing as putmsg(), but the process can send messages in different priority bands. Except where noted, all requirements on putmsg() also pertain to putpmsg().

The `fildes` argument specifies a file descriptor referencing an open STREAM. The `ctlptr` and `dataptr` arguments each point to a `strbuf` structure.

The `ctlptr` argument points to the structure describing the control part, if any, to be included in the message. The `buf` member in the `strbuf` structure points to the buffer where the control information resides, and the `len` member indicates the number of bytes to be sent. The `maxlen` member is not used by putmsg(). In a similar manner, the argument `dataptr` specifies the data, if any, to be included in the message. The `flags` argument indicates what type of message should be sent and is described further below.

To send the data part of a message, `dataptr` must not be a NULL pointer and the `len` member of `dataptr` must be 0 or greater. To send the control part of a message, the corresponding values must be set for `ctlptr`. No data (control) part will be sent if either `dataptr` or `ctlptr` is a NULL pointer or the `len` member of `ctlptr` or `len` member of `dataptr` is set to -1.

For putmsg(), if a control part is specified and `flags` is set to `RS_HIPRI`, a high priority message is sent. If no control part is specified, and `flags` is set to `RS_HIPRI`, putmsg() fails and sets errno to EINVAL. If `flags` is set to 0, a normal message (priority band equal to 0) is sent. If a control part and data part are not specified and `flags` is set to 0, no message is sent and 0 is returned.

The STREAM head guarantees that the control part of a message generated by putmsg() is at least 64 bytes in length.
putmsg, putpmsg

For putpmsg(), the flags are different. The flags argument is a bitmask with the following mutually-exclusive flags defined: MSG_HIPRI and MSG_BAND. If flags is set to 0, putpmsg() fails and sets errno to EINVAL. If a control part is specified and flags is set to MSG_HIPRI and band is set to 0, a high-priority message is sent. If flags is set to MSG_HIPRI and either no control part is specified or band is set to a nonzero value, putpmsg() fails and sets errno to EINVAL. If flags is set to MSG_BAND, then a message is sent in the priority band specified by band. If a control part and data part are not specified and flags is set to MSG_BAND, no message is sent and 0 is returned.

The putmsg() function blocks if the STREAM write queue is full due to internal flow control conditions, with the following exceptions:

- For high-priority messages, putmsg() does not block on this condition and continues processing the message.
- For other messages, putmsg() does not block but fails when the write queue is full and O_NONBLOCK is set.

The putmsg() function also blocks, unless prevented by lack of internal resources, while waiting for the availability of message blocks in the STREAM, regardless of priority or whether O_NONBLOCK has been specified. No partial message is sent.

The following symbolic constants are defined under _XOPEN_SOURCE_EXTENDED 1 in <stropts.h>.

- MSG_ANY: Receive any message.
- MSG_BAND: Receive message from specified band.
- MSG_HIPRI: Send/Receive high priority message.
- MORECTL: More control information is left in message.
- MOREDATA: More data is left in message.

Returned value

If successful, putmsg() and putpmsg() return 0.

If unsuccessful, putmsg() and putpmsg() return -1 and set errno to one of the following values.

**Note:** z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for putmsg() and putpmsg() to send a message on a STREAM. It will always return -1 with errno set to indicate the failure. See "open() — Open a file" on page 1343.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>A non-priority message was specified, the O_NONBLOCK flag is set, and the STREAM write queue is full due to internal flow control conditions; or buffers could not be allocated for the message that was to be created.</td>
</tr>
<tr>
<td>EBADF</td>
<td>fildes is not a valid file descriptor open for writing.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal was caught during putmsg().</td>
</tr>
<tr>
<td>EINVAL</td>
<td>An undefined value is specified in flags, or flags is set to RS_HIPRI or MSG_HIPRI and no control part is supplied, or the STREAM or multiplexer referenced by fildes is linked (directly or indirectly)</td>
</tr>
</tbody>
</table>
downstream from a multiplexer, or flags is set to MSG_HIPRI and band is nonzero (for putpmsg() only).

ENOSR Buffers could not be allocated for the message that was to be created due to insufficient STREAMS memory resources.

ENOSTR A STREAM is not associated with fildes.

ENXIO A hang-up condition was generated downstream for the specified STREAM.

EPIPE or EIO The fildes argument refers to a STREAMS-based pipe and the other end of the pipe is closed. A SIGPIPE signal is generated for the calling process.

ERANGE The size of the data part of the message does not fall within the range specified by the maximum and minimum packet sizes of the topmost STREAM module. This value is also returned if the control part of the message is larger than the maximum configured size of the control part of a message, or if the data part of a message is larger than the maximum configured size of the data part of a message.

In addition, putmsg() and putpmsg() will fail if the STREAM head had processed an asynchronous error before the call. In this case, the value of errno does not reflect the result of putmsg() or putpmsg() but reflects the prior error.

</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int puts(const char *string);
```

```c
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int puts_unlocked(const char *string);
```

General description

Writes the string pointed to by `string` to the stream pointed to by `stdout`, and appends the newline character to the output. The terminating NULL character is not written.

If `stdout` points to the text stream, and the output string is longer than the length of the stream's record, the output is *wrapped*. That is, the record is filled with the output characters, the last character of the record is set to a newline character, and the remaining output characters are written to the next record. Such wrapping is repeated until the remaining output characters fit into the record. Please note that the newline character is appended to the last portion of the output string. If the output string is shorter than the record, the remaining characters of the record are filled with blanks—if `stdout` is opened in a text mode—or with NULL characters if the `stdout` is opened in binary mode.

The `puts()` function is not supported for files opened with `type=record`.

`puts()` has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`puts_unlocked()` is functionally equivalent to `puts()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, `puts()` returns the number of bytes written. However, newline characters used to wrap the data are not counted.

If unsuccessful, `puts()` returns EOF.
If a system write-error occurs, the write stops at the point of failure.

After truncation, puts() does not count the truncated characters, but returns the actual number of bytes written.

Example

```c
CELEBP55
/* cCELEBP55

   This example writes "Hello World" to stdout.

*/
#include <stdio.h>
int main(void)
{
   if ( puts("Hello World") == EOF )
      printf( "Error in puts\n" );
}
```

Output:
Hello World

pututxline()

— Write entry to utmpx database

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>C or C++</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *pututxline(const struct utmpx *utmpx);
```

General description

The pututxline() function writes out the structure into the utmpx database, when the calling process has appropriate privileges. The pututxline() function uses getutxid() to search for a record that satisfies the request. If the getutxid() search succeeds, then the entry is replaced. Otherwise, a new entry is made at the end of the database. If the utmpx database does not already exist, then pututxline() creates the utmpx database with file permissions 0644. (See the __utmpxname() function for information on the utmpx structure.)

If the ut_type field in the entry being added is EMPTY, it is always placed at the start of the utmpx database. For this reason, pututxline() should not be used to place EMPTY entries in the utmpx database.

The pututxline() function obtains an exclusive lock in the utmpx database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions getutxent(), getutxid(), and getutxline() might continue to read and are not affected by pututxline().

Because the pututxline() function processes thread-specific data the pututxline() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

The name of the database file defaults to /etc/utmpx. To process a different database file name use the __utmpxname() function.

pututxline() is not supported when all of the following conditions are true:
- The security environment for the current address space has the trusted attribute.
- Either the effective UID is different than the real UID, or the effective GID is different than the real GID.
- The effective UID is not 0.
- The utmpx file is not writable by normal (non-trusted) processes with the current effective UID and GID.
- pututxline() is called after getutxline(), getutxid(), or getutxent(), with no intervening calls to endutxent() or __utmpxname().
For all entries that match a request, the ut_type member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the ut_type member as follows:

- **EMPTY** No other members have meaningful data.
- **BOOT_TIME** ut_tv is meaningful.
- **__RUN_LVL** ut_tv and ut_line are meaningful
- **OLD_TIME** ut_tv is meaningful.
- **NEW_TIME** ut_tv is meaningful.
- **USER_PROCESS** ut_id, ut_user (login name of the user), ut_line, ut_pid, and ut_tv are meaningful.
- **INIT_PROCESS** ut_id, ut_pid, and ut_tv are meaningful.
- **LOGIN_PROCESS** ut_id, ut_user (implementation-specific name of the login process), ut_pid, and ut_tv are meaningful.
- **DEAD_PROCESS** ut_id, ut_pid, and ut_tv are meaningful.

**Returned value**

If successful, pututxline() returns a pointer to a utmpx structure containing a copy of the entry written to the database.

If unsuccessful, pututxline() returns a NULL pointer.

pututxline() may fail if the process does not have appropriate privileges.

putw

putw() — Put a machine word on a stream

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdio.h>

int putw(int w, FILE *stream);
```

General description

The putw() function writes the word `w` to the output `stream` (at the position at which the file offset, if defined, is pointing). The size of the word is the size of a type int, and varies from machine to machine. The putw() function neither assumes nor causes special alignment in the file. The `st_ctime` and `st_mtime` fields of the file will be marked for update between the successful execution of putw() and the next successful call to fflush() or fclose() on the same stream or a call to exit() or abort().

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use character-based output functions to replace putw() for portability.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `__UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, putw() returns 0.

If unsuccessful, putw() returns a nonzero value, sets the error indicators for `stream`, and sets errno to indicate the error. Refer to "fread() — Read items” on page 689 for errno values.

Format

**Non-XPG4:**
```c
#include <stdio.h>
#include <wchar.h>

wint_t putwc(wchar_t wc, FILE *stream);
```
```c
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t putwc_unlocked(wchar_t wc, FILE *stream);
```

**XPG4:**
```c
#define _XOPEN_SOURCE
#include <stdio.h>
#include <wchar.h>

wint_t putwc(wint_t wc, FILE *stream);
```
```c
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t putwc_unlocked(wchar_t wc, FILE *stream);
```

**XPG4 and MSE:**
```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

wint_t putwc(wchar_t wc, FILE *stream);
```
```c
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t putwc_unlocked(wchar_t wc, FILE *stream);
```

**General description**

The putwc() function is equivalent to the fputwc() function, except that if it is implemented as a macro, it may evaluate stream more than once. Therefore, the argument should never be an expression with side effects. The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you use a non-wide-oriented function with putwc(), undefined results can occur.

putwc() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a
putwc

subsequent read, there must be an intervening flush or reposition. Between a read
and a subsequent write, there must also be an intervening flush or reposition unless
an EOF has been reached.

putwc_unlocked() is functionally equivalent to putwc() with the exception that it is
not thread-safe. This function can safely be used in a multithreaded application if
and only if it is called while the invoking thread owns the (FILE*) object, as is the
case after a successful call to either the flockfile() or ftrylockfile() function.

Special behavior for XPG4: If you define any feature test macro specifying XPG4
behavior before the statement in your program source file to include the wchar
header, then the compiler assumes that your program is using the XPG4 variety of
the putwc() function, unless you also define the _MSE_PROTOS feature test macro. Please see Table 2 on page 4 for a list of XPG4 and other feature test
macros.

The prototype for the XPG4 variety of the putwc() function is:

\[
\text{wint_t putwc(wint_t wc, FILE *stream);} \\
\]

The difference between this variety and the MSE variety of the putwc() function is
that the first parameter has type wint_t rather than type wchar_t.

Returned value

If successful, putwc() returns the wide character written.

If a write error occurs, the error indicator for the stream is set and WEOF is
returned. If an encoding error occurs when converting from a wide character to a
multibyte character, the value of the macro EILSEQ is stored in errno and WEOF is
returned.

Example

CELEBP56

/* CELEBP56 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#include <errno.h>

int main(void)
{
    FILE *stream;
    wchar_t *wcs = L"This test string should not cause a WEOF condition";
    int i;
    int rc;
    if ((stream = fopen("myfile.dat", "w")) == NULL) {
        printf("Unable to open file\n");
        exit(1);
    }
    for (i=0; wcs[i] != L'\0'; i++) {
        errno = 0;
        if ((rc = putwc(wcs[i], stream)) == WEOF) {
            printf("Unable to putwc() the wide character.\n");
            printf("wcs[%d] = 0x%X\n", i, wcs[i]);
            if (errno == EILSEQ)
                printf("An invalid wide character was encountered.\n");
            exit(1);
        }
    }
}

wint_t putwchar(wchar_t wc);
```

```c
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t putwchar_unlocked(wchar_t wc);
```

General description

The putwchar() function is equivalent to: putwc(wc, stdout).

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you use a non-wide-oriented function with putwchar(), undefined results can occur.
putwchar() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

You may not use putwc() or putwchar() with files opened as type=record.

putwchar_unlocked() is functionally equivalent to putwchar() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

**Special behavior for XPG4:** If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then the compiler assumes that your program is using the XPG4 variety of the putwchar() function, unless you also define the _MSE_PROTOS feature test macro. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

The prototype for the XPG4 variety of the putwchar() function is:

```c
wint_t putwchar(wint_t wc);
```

The difference between this variety and the MSE variety of the putwchar() function is that its parameter has type wint_t rather than type wchar_t.

**Returned value**

If successful, putwchar() returns the wide character written.

If a write error occurs, the error indicator for the stream is set and WEOF is returned. If an encoding error occurs when converting from a wide character to a multibyte character, the value of the macro EILSEQ is stored in errno and WEOF is returned.

**Example**

```c
CELEBP57
/* CELEBP57 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#include <errno.h>

int main(void)
{
    wchar_t *wcs = L"This test string should not cause a WEOF condition";
    int i;
    int rc;

    for (i=0; wcs[i] != L'\0'; i++) {
        errno = 0;
        if ((rc = putwchar(wcs[i])) == WEOF) {
            printf("Unable to putwchar() the wide character.\n");
            printf("wcs[%d] = 0x%X, i, wcs[i]);
            if (errno == EILSEQ)
                printf("An invalid wide character was encountered.\n");
        }
    }
}
```

<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>OS/390 V2R10</td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <unistd.h>

ssize_t pwrite(int fildes, const void *buf, size_t nbyte, off_t offset);
```

General description

The pwrite() function performs the same action as write(), except that it writes into a given position without changing the file pointer.

The first three arguments to pwrite() are the same as write() with the addition of a fourth argument `offset` for the desired position inside the file.

Returned value

If successful, pwrite() returns the number of bytes actually written to the file associated with `fildes`. This number will never be greater than `nbyte`.

If unsuccessful, pwrite() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>Resources temporarily unavailable. Subsequent requests may complete normally.</td>
</tr>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid file or socket descriptor.</td>
</tr>
<tr>
<td>ECONNRSET</td>
<td>A connection was forcibly closed by a peer.</td>
</tr>
<tr>
<td>EDESTADDRREQ</td>
<td>The socket is not connection-oriented and no peer address is set.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using the <code>buf</code> and <code>nbyte</code> parameters would result in an attempt to access storage outside the caller's address space.</td>
</tr>
<tr>
<td>EFBIG</td>
<td>An attempt was made to write a file that exceeds the system-established maximum file size or the process's file size limit supported by the implementation. The file is a regular file, <code>nbyte</code> is greater than 0 and the starting position is greater than or equal to the offset maximum established in the open file description associated with fields.</td>
</tr>
<tr>
<td>EINTR</td>
<td>pwrite() was interrupted by a signal before it had written any output.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The request is invalid or not supported. The STREAM or multiplexer referenced by <code>fildes</code> is linked (directly or indirectly) downstream from a multiplexer. The <code>offset</code> argument is invalid. The value is negative.</td>
</tr>
</tbody>
</table>
pwrite

EIO The process is in a background process group and is attempting to 
write to its controlling terminal, but TOSTOP (defined in the 
termios.h header file) is set, the process is neither ignoring nor 
blocking SIGTTOU signals, and the process group of the process is 
orphaned. An I/O error occurred.

EMSGSIZE The message was too big to be sent as a single datagram.

ENOBUFS Buffer space is not available to send the message.

ENOSPC There is no available space left on the output device.

ENOTCONN The socket is not connected.

ENXIO A hang-up occurred on the STREAM being written to.

EPIPE pwrite() is trying to write to a pipe that is not open for reading by 
any other process. This error also generates a SIGPIPE signal. For 
a connected stream socket the connection to the peer socket has 
been lost.

ERANGE The transfer request size was outside the range supported by the 
STREAMS file associated with fildes.

ESPIPE fildes is associated with a pipe or FIFO.

EWOULDBLOCK 
socket is in nonblocking mode and no data buffers are available or 
the SO_SNDTIMEO timeout value was reached before buffers 
became available.

```c
#include <stdlib.h>

void qsort(void *base, size_t num, size_t width,
           int(*compare)(const void *element1, const void *element2));
```

General description

The `qsort()` function sorts an array of `num` elements, each of `width` bytes in size, where the first element of the array is pointed to by `base`.

The `compare` pointer points to a function, which you supply, that compares two array elements and returns an integer value specifying their relationship. The `qsort()` function calls the comparison function one or more times during the sort, passing pointers to two array elements on each call. The comparison function must compare the elements and return one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td><code>element1</code> less than <code>element2</code></td>
</tr>
<tr>
<td>0</td>
<td><code>element1</code> equal to <code>element2</code></td>
</tr>
<tr>
<td>&gt; 0</td>
<td><code>element1</code> greater than <code>element2</code></td>
</tr>
</tbody>
</table>

The sorted array elements are stored in increasing order, as returned by the comparison function. You can sort in reverse order by reversing the “greater than” and “less than” logic in the comparison function. If two elements are equal, their order in the sorted array is unspecified. The `qsort()` function overwrites the contents of the array with the sorted elements.

**Special behavior for C++**: C++ and C linkage conventions are incompatible, and therefore the `qsort()` function cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to the `qsort()` function, the compiler will flag it as an error. To use the C++ `qsort()` function, you must ensure that the comparison function has C linkage, by declaring it as `extern "C"`.

Returned value

The `qsort()` function returns no values.

Example

```c
CELEB01
/* CELEB01 */

This example sorts the arguments (argv) in ascending sequence, based on
```
# qsort

the ASCII value of each character and string, and using the comparison
function compare() supplied in the example.

*/
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/* Declaration of compare() as a function */
#ifdef __cplusplus
extern "C" int compare(const void *, const void *);
#else
int compare(const void *, const void *); /* macro is automatically */
#endif /* defined by the C++/MVS compiler */

int main (int argc, char *argv[ ])
{
    int i;
    argv++;  
    argc--;  
    qsort((char *)argv, argc, sizeof(char *), compare);
    for (i = 0; i < argc; ++i)
        printf("%s\n", argv[i]);
    return 0;
}

int compare (const void *arg1, const void *arg2)
{
    /* Compare all of both strings */
    return(strcmp(*(char **)arg1, *(char **)arg2));
}

Output

If the program is passed the arguments:
Does, this, really, sort, the, arguments, correctly?
then expect the following output.
arguments
really
sort
the
this
Does

</table>

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

int quantexpd32(_Decimal32 x);
int quantexpd64(_Decimal64 x);
int quantexpd128(_Decimal128 x);

int quantexp(_Decimal32 x); /* C++ only */
int quantexp(_Decimal64 x); /* C++ only */
int quantexp(_Decimal128 x); /* C++ only */
```

General description

The quantexp() functions compute the quantum exponent of a finite argument.

Notes:

1. These functions work in IEEE decimal floating-point format. See "IEEE decimal floating-point" on page 95 IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
3. The "quantum" when referring to a finite decimal floating-point number is defined as the "magnitude of a value of one in the rightmost digit position of the significand". For example, pennies and dollars can be represented respectively as 1 * 10 with a quantum of -2 and 0, or 1*10^-2 and 1*10^0. For more information on the term quantum, see [z/Architecture Principles of Operation](https://www.ibm.com/systems/z/Architecture%20Principles%20of%20Operation).

Returned value

The quantexp() functions return the quantum exponent of x.

If x is infinite or NaN, they compute INT_MIN and a domain error occurs.

Example

```c
/* CELEBQ03
   This example illustrates the quantexpd128() function.
*/

#define __STDC_WANT_DEC_FP__
#include <stdio.h>
#include <math.h>

void main(void)
{
   _Decimal128 x, y;
   x = 4.56DL;
```
quantexpd

```c
y = quantexpd128(x);
printf("quantexpd128( %DDf ) = %DDf\n", x, y);
```

quantized32(), quantized64(), quantized128() — Set the exponent of X to the exponent of Y

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.8</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 quantized32(_Decimal32 x, _Decimal32 y);
_Decimal64 quantized64(_Decimal64 x, _Decimal64 y);
_Decimal128 quantized128(_Decimal128 x, _Decimal128 y);
```

General description

The quantize functions set the exponent of argument x to the exponent of argument y, while trying to keep the value the same. If the exponent is being increased, the value is correctly rounded according to the current rounding mode. If the result does not have the same value as x, the "inexact" (FP_INEXACT) floating-point exception is raised. If the exponent is being decreased, and the significand of the result has more digits than the type would allow, the result is NaN and the "invalid" (FP_INVALID) floating-point exception is raised.

If one of both operands are NaN, the result is NaN, and the "invalid" floating-point exception may be raised. Otherwise, if only one operand is infinity, the result is NaN, and the "invalid" floating-point exception is raised. If both operands are infinity, the result is DEC_INFINITY, and the sign is the same as x.

The quantize functions do not signal underflow (FP_UNDERFLOW) or overflow (FP_OVERFLOW).

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Input value to be converted and perhaps rounded using the exponent of y.</td>
</tr>
<tr>
<td>y</td>
<td>Input value whose exponent is used for the output value</td>
</tr>
</tbody>
</table>

Usage notes

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The quantize functions return the number which is equal in value (except for any rounding) and sign to x, and which has been set to be equal to the exponent of y.
quantized32, quantized64, quantized128

Example

/* CELEBQ02 */

    This example illustrates the quantized128() function.

*/

#define __STDC_WANT_DEC_FP__

QueryMetrics() — Query WLM system information

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__wlm.h>

int QueryMetrics(struct sysi *sysi_ptr, int *anslen);
```

General description

The QueryMetrics() function provides the ability for an application to query WLM system information.

*sysi_ptr Points to a buffer that the service is to return the WLM system information. The data returned is in the format of the structure sysi.

*anslen Points to an integer data field that contains the length of the buffer to return the WLM system information into.

Returned value

If successful, QueryMetrics() returns 0.

If unsuccessful, QueryMetrics() returns -1 and sets errno to one of the following values. If the returned errno and __errno2() indicate the supplied buffer is too small, the anslen argument is updated to contain the length required to hold WLM system information.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>

QueryWorkUnitClassification

QueryWorkUnitClassification() — WLM query enclave classification service

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R9</td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/__wlm.h>

int QueryWorkunitClassification(wlmetok_t *e_token,
  struct sysec *sysec_ptr,
  int *ans_len);
```

General description

Returns the classification attributes of an enclave, using the following parameters:

*e_token*  
Points to a work unit enclave token.

*sysec_ptr*  
Points to the enclave classification data (mapped by *sysec*) returned by the QueryWorkunitClassification function.

*anslen*  
The length of the data area provided by the caller to receive the information generated by the service. WLM will update this value with the size of the area needed for the service to work. The minimum area should hold the entire *sysec* structure through version 3. The existing area will be populated with as much of the information as can be returned.

Returned value

If successful, QueryWorkunitClassification() returns 0.

If unsuccessful, QueryWorkunitClassification() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>An argument of this function contained a value that is not correct.</td>
</tr>
<tr>
<td>EMVSSAF2ERR</td>
<td>An error occurred in the security product.</td>
</tr>
<tr>
<td>EMVSWLMERROR</td>
<td>A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class, if the BPX.WLMSERVER class is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).</td>
</tr>
</tbody>
</table>

### raise() — Raise signal

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#include <signal.h>

int raise(int sig);
```

#### General description

Sends the signal `sig` to the program that issued `raise()`. See Table 48 on page 1947 for the list of signals supported.

You can use `signal()` to specify how a signal will be handled when `raise()` is invoked.

In C++ only, the use of `signal()` and `raise()` with `try()`, `catch()`, or `throw()` is undefined. The use of `signal()` and `raise()` with destructors is also undefined.

**Special behavior for POSIX:**

To obtain access to the special POSIX behavior for `raise()`, the POSIX run-time option must be set ON, and the version of MVS must be 4.3 or higher.

The `raise()` function sends the signal, `sig`, to the process that issued the `raise()`. If the signal is not blocked, it is delivered to the sender before `raise()` returns. See Table 46 on page 1908 in the description of the `sigaction()` function for the list of signals supported.

You can use `signal()` or `sigaction()` to specify how a signal will be handled when `raise()` is invoked.

**Special behavior for XPG4.2:**

To obtain access to the special POSIX behavior for `raise()`, the POSIX run-time option must be set ON, and the version of MVS must be 4.3 or higher.

Several other functions are available to the XPG4.2 application for affecting the behavior of a signal:

- `bsd_signal()`
- `sigignore()`
- `sigset()`

**Special behavior for C++:**
raise

The behavior when mixing signal-handling with C++ exception handling is undefined. Also, the use of signal-handling with constructors and destructors is undefined.

Usage notes

1. The use of the SIGTSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If successful, raise() returns 0.

If unsuccessful, raise() returns nonzero.

Special behavior for XPG4:

The raise() function sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of the sig argument is an invalid signal number.</td>
</tr>
</tbody>
</table>

Example

CELEBR01:

/* CELEBR01

This example establishes a signal handler called sig_hand for the signal SIGUSR1.
The signal handler is called whenever the SIGUSR1 signal is raised and will ignore the first nine occurrences of the signal.
On the tenth raised signal, it exits the program with an error code of 10.
Note that the signal handler must be reestablished each time it is called.
*/

#include <signal.h>
#include <stdio.h>
#include <stdlib.h>

#ifdef __cplusplus
extern "C" {
#endif

void sig_hand(int);

#ifdef __cplusplus
}
#endif

int main(void)
{
    int i;

    signal(SIGUSR1, sig_hand); /* set up handler for SIGUSR1 */
    for (i=0; i<10; ++i)
    {
        raise(SIGUSR1);       /* signal SIGUSR1 is raised */
    }

    void sig_hand(int dummy)
    {
        static int count = 0;    /* initialized only once */

        count++;
        if (count == 10) /* ignore the first 9 occurrences of this signal */
        {
            printf("reached 10th signal\n");
        }
    }

} /* sig_hand() is called */

```c
    exit(10);
}
else
    signal(SIGUSR1, sig_hand); /* set up the handler again */
```

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

int rand(void);
```

General description

Generates a pseudo-random integer in the range 0 to RAND_MAX. Use the srand() function before calling rand() to set a seed for the random number generator. If you do not make a call to srand(), the default seed is 1.

Returned value

Returns the calculated value.

Example

```c
CELEBR02:

/* CELEBR02
   This example prints the first 10 random numbers generated.
*/

#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    int x;

    for (x = 1; x <= 10; x++)
        printf("iteration %d, rand=%d\n", x, rand());
}
```

Output:

```plaintext
iteration 1, rand=16838
iteration 2, rand=5758
iteration 3, rand=10113
iteration 4, rand=17515
iteration 5, rand=31051
iteration 6, rand=5627
iteration 7, rand=23010
iteration 8, rand=7419
iteration 9, rand=16212
iteration 10, rand=4886
```

rand_r

rand_r() — Pseudo-random number generator

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <stdlib.h>

int rand_r(unsigned int *seed);
```

General description

The rand_r() function generates a sequence of pseudo-random integers in the range 0 to \texttt{RAND_MAX}. (The value of the \texttt{RAND_MAX} macro will be at least 32767.)

If rand_r() is called with the same initial value for the object pointed to by seed and that object is not modified between successive returns and calls to rand_r(), the same sequence shall be generated.

Returned value

rand_r() returns a pseudo-random integer.

There are no documented errno values.

</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

long random(void);
```

General description

The random() function uses a nonlinear additive feedback random-number generator employing a default state array size of 31 long integers to return successive pseudo-random numbers in the range from 0 to $2^{31}$-1. The period of this random-number generator is approximately $16 	imes (2^{31}-1)$. The size of the state array determines the period of the random-number generator. Increasing the state array size increases the period.

With 256 bytes of state information, the period of the random-number generator is greater than $2^{69}$.

Like rand(), random() produces by default a sequence of numbers that can be duplicated by calling srandom() with 1 as the seed. The state information for the random functions is maintained on a per-thread basis. For example, calls to srandom() in one thread will have no effect on the numbers generated by calls to random() in another thread.

Returned value

random() returns the generated pseudo-random number.

#define _OE_SOCKETS
#include <unistd.h>

ssize_t read(int socket, void *buf, ssize_t N);
```

General description

From the file indicated by the file descriptor `fs`, the `read()` function reads `N` bytes of input into the memory area indicated by `buf`. A successful `read()` updates the access time for the file.

If `fs` refers to a regular file or any other type of file on which the process can seek, `read()` begins reading at the file offset associated with `fs`. If successful, `read()` changes the file offset by the number of bytes read. `N` should not be greater than `INT_MAX` (defined in the `limits.h` header file).

If `fs` refers to a file on which the process cannot seek, `read()` begins reading at the current position. There is no file offset associated with such a file.

If `fs` refers to a socket, `read()` is equivalent to `recv()` with no flags set.

Parameter

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fs</code></td>
</tr>
<tr>
<td><code>buf</code></td>
</tr>
<tr>
<td><code>N</code></td>
</tr>
</tbody>
</table>

Behavior for sockets:

The `read()` call reads data on a socket with descriptor `fs` and stores it in a buffer. The `read()` call applies only to connected sockets. This call returns up to `N` bytes of
data. If there are fewer bytes available than requested, the call returns the number currently available. If data is not available for the socket, and the socket is in blocking mode, the read() call blocks the caller until data arrives. If data is not available, and the socket is in nonblocking mode, read() returns a −1 and sets the error code to EWOULDBLOCK. See \texttt{ioctl() — Control device} on page 1002 or \texttt{fcntl() — Control open file descriptors} on page 539 for a description of how to set nonblocking mode.

For datagram sockets, this call returns the entire datagram that was sent, provided that the datagram fits into the specified buffer. Excess datagram data is discarded. Stream sockets act like streams of information with no boundaries separating data. For example, if applications A and B are connected with a stream socket and application A sends 1000 bytes, each call to this function can return 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been received.

\textbf{Behavior for streams:}

A read() from a STREAMS file can read data in three different modes: byte-stream mode, message-nondiscard mode, and message-discard mode. The default is byte-stream mode. This can be changed using the \texttt{I_SRDOPT ioctl()} request, and can be tested with the \texttt{I_GROOPT ioctl()}. In byte-stream mode, read() retrieves data from the STREAM until as many bytes as were requested are transferred, or until there is no more data to be retrieved. Byte-stream mode ignores message boundaries.

In STREAMS message-nondiscard mode, read() retrieves data until as many bytes as were requested are transferred, or until a message boundary is reached. If read() does not retrieve all the data in a message, the remaining data is left on the STREAM, and can be retrieved by the next read() call. Message-discard mode also retrieves data until as many bytes as were requested are transferred, or a message boundary is reached. However, unread data remaining in a message after the read() returns is discarded, and is not available for a subsequent read(), readv() or getmsg() call.

How read() handles zero-byte STREAMS messages is determined by the current read mode setting. In byte-stream mode, read() accepts data until it has read \( N \) bytes, or until there is no more data to read, or until a zero-byte message block is encountered. The read() function then returns the number of bytes read, and places the zero-byte message back on the STREAM to be retrieved by the next read(), readv() or getmsg(). In message-nondiscard mode or message-discard mode, a zero-byte message returns 0 and the message is removed from the STREAM. When a zero-byte message is read as the first message on a STREAM, the message is removed from the STREAM and 0 is returned, regardless of the read mode.

A read() from a STREAMS file returns the data in the message at the front of the STREAM head read queue, regardless of the priority band of the message.

By default, STREAMs are in control-normal mode, in which a read() from a STREAMS file can only process messages that contain a data part but do not contain a control part. The read() fails if a message containing a control part is encountered at the STREAM head. This default action can be changed by placing the STREAM in either control-data mode or control-discard mode with the \texttt{I_SRDOPT ioctl()} command. In control-data mode, read() converts any control part to data and passes it to the application before passing any data part originally present in the

\textit{read}
same message. In control-discard mode, read() discards message control parts but returns to the process any data part in the message.

In addition, read() and readv() will fail if the STREAM head had processed an asynchronous error before the call. In this case, the value of errno does not reflect the result of read() or readv() but reflects the prior error. If a hang-up occurs on the STREAM being read, read() continues to operate normally until the STREAM head read queue is empty. Thereafter, it returns 0.

**Large file support for z/OS UNIX files:**

Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLEVEL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

**Returned value**

If successful, read() returns the number of bytes actually read and placed in buf. This number is less than or equal to N. It is less than N only if:

- read() reached the end of the file before reading the requested number of bytes.
- read() was interrupted by a signal.
- In POSIX C programs only, the file is a pipe, FIFO special file, or a character special file that has fewer than N bytes immediately available for reading.
- If the Physical File System does not support simple reads from directories, read() will return 0 if it is used for a directory. Users should use Opendir() and readdir() instead.

In POSIX C programs only, if read() is interrupted by a signal, the effect is one of the following:

- If read() has not read any data yet, it returns −1 and sets errno to EINTR.
- If read() has successfully read some data, it returns the number of bytes it read before it was interrupted.

If the starting position for the read operation is at the end of the file or beyond, read() returns 0.

In POSIX C programs, if read() attempts to read from an empty pipe or a FIFO special file, it has one of the following results:

- If no process has the pipe open for writing, read() returns 0 to indicate the end of the file.
- If some process has the pipe open for writing and O_NONBLOCK is set to 1, read() returns −1 and sets errno to EAGAIN.
- If some process has the pipe open for writing and O_NONBLOCK is set to 0, read() blocks (that is, does not return) until some data is written, or the pipe is closed by all other processes that have the pipe open for writing.

With other files that support nonblocking read operations (for example, character special files), a similar principle applies:

- If data is available, read() reads the data immediately.
If no data is available and O_NONBLOCK is set to 1, read() returns −1 and sets errno to EAGAIN.
If no data is available and O_NONBLOCK is set to 0, read() blocks until some data becomes available.

read() causes the signal SIGTTIN to be sent when all these conditions exist:
- The process is attempting to read from its controlling terminal.
- The process is running in a background process group.
- The SIGTTIN signal is not blocked or ignored.
- The process group of the process is not orphaned.

If read() is reading a regular file and encounters a part of the file that has not been written (but before the end of the file), read() places 0 bytes into buf in place of the unwritten bytes.

If the number of bytes of input that you want to read is 0, read() simply returns 0 without attempting any other action.

If the connection is broken on a stream socket, but data is available, then the read() function reads the data and gives no error. If the connection is broken on a stream socket, but no data is available, then the read() function returns 0 bytes as EOF.

**Note:** z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for read() to read any data from a STREAMS-based file indicated by fs. It will always return -1 with errno set to EBADF. EINVAL will never be set because there are no multiplexing STREAMS drivers. See "open() — Open a file" on page 1343 for more information.

If unsuccessful, read() returns −1 and sets errno to one of the following:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>O_NONBLOCK is set to 1, but data was not available for reading.</td>
</tr>
<tr>
<td>EBADF</td>
<td>fs is not a valid file or socket descriptor.</td>
</tr>
<tr>
<td>ECONNRESET</td>
<td>A connection was forcibly closed by a peer.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using the buf and N parameters would result in an attempt to access memory outside the caller's address space.</td>
</tr>
<tr>
<td>EINTR</td>
<td>read() was interrupted by a signal that was caught before any data was available.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>N contains a value that is less than 0, or the request is invalid or not supported, or the STREAM or multiplexer referenced by fs is linked (directly or indirectly) downstream from a multiplexer.</td>
</tr>
<tr>
<td>EIO</td>
<td>The process is in a background process group and is attempting to read from its controlling terminal, and either the process is ignoring or blocking the SIGTTIN signal or the process group of the process is orphaned. For sockets, an I/O error occurred.</td>

<td>ENOTCONN</td>
<td>A receive was attempted on a connection-oriented socket that is not connected.</td>
</tr>
<tr>
<td>EOVERFLOW</td>
<td>The file is a regular file and an attempt was made to read or write at or beyond the offset maximum associated with the file.</td>
</tr>
</tbody>
</table>
ETIMEDOUT  The connection timed out during connection establishment, or due to a transmission timeout on active connection.

EWOULDBLOCK  
socket is in nonblocking mode and data is not available to read. or the SO_RCVTIMEO timeout value was been reached before data was available.

Example

CELEBR03:
/* CELEBR03
 * This example opens a file and reads input.
 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    int ret, fd;
    char buf[1024];
    system("ls -l >| ls.output");
    if ((fd = open("ls.output", O_RDONLY)) < 0)
        perror("open() error");
    else {
        while ((ret = read(fd, buf, sizeof(buf)-1)) > 0) {
            buf[ret] = 0x00;
            printf("block read: <\n<%=s\n", buf);
        }
        close(fd);
    }
    unlink("ls.output");
}

Output:
block read:

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define_POSIX_SOURCE
#include <dirent.h>

struct dirent *readdir(DIR *dir);
```

General description

Returns a pointer to a dirent structure describing the next directory entry in the directory stream associated with `dir`.

A call to readdir() overwrites data produced by a previous call to readdir() or __readdir2() on the same directory stream. Calls for different directory streams do not overwrite each other's data.

Each call to readdir() updates the st_atime (access time) field for the directory.

A dirent structure contains the character pointer `d_name`, which points to a string that gives the name of a file in the directory. This string ends in a terminating NULL, and has a maximum of NAME_MAX characters.

Save the data from readdir(), if required, before calling closedir(), because closedir() frees the data.

If the contents of a directory have changed since the directory was opened (files added or removed); a call should be made to rewinddir() so that subsequent readdir() requests can read the new contents.

Special behavior for XPG4:

If entries for dot or dot-dot exist, one entry will be returned for dot and one entry will be returned for dot-dot; otherwise they will not be returned.

After a call to fork(), either the parent or child (but not both) may continue processing the directory stream using __readdir2(), readdir(), rewinddir(), or seekdir(). If both the parent and child processes use these functions, the result is undefined.

Special behavior for XPG4.2:

If the entry names a symbolic link, the value of d_ino member in dirent structure is unspecified.
Returned value

If successful, readdir() returns a pointer to a dirent structure describing the next directory entry in the directory stream. When readdir() reaches the end of the directory stream, it returns a NULL pointer.

If unsuccessful, readdir() returns a NULL pointer and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>dir does not yield an open directory stream.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The buffer was too small to contain any directories.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>The current position of the directory stream is invalid.</td>
</tr>
<tr>
<td>EOVERFLOW</td>
<td>One of the values in the structure to be returned cannot be represented correctly.</td>
</tr>
</tbody>
</table>

Note: The environment variable _EDC_SUSV3 can be used to control the behavior of readdir() with respect to detecting an EOVERFLOW condition. By default, readdir() will not detect that values in the structure returned can be represented correctly. When _EDC_SUSV3 is set to 1, readdir() will check for overflow conditions.

Example

CELEBR04:

```c
/* CELEBR04
   This example reads the contents of a root directory.
*/
#define _POSIX_SOURCE
#include <dirent.h>
#include <errno.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

tabfunc() { 
  DIR *dir;
  struct dirent *entry;
  if ((dir = opendir("/")) == NULL)
    perror("opendir() error");
  else { 
    puts("contents of root:");
    while ((entry = readdir(dir)) != NULL)
      printf(" %s\n", entry->d_name);
    closedir(dir);
  }
}
```

Output:

contents of root:
  .
  ..
  bin
  dev
  etc
readdir

</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R6</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_DIR_EXT
#include <dirent.h>

struct dirent *__readdir2(DIR *dir, struct stat *info);
```

General description

The __readdir2() function returns a pointer to a dirent structure describing the next directory entry in the directory stream associated with `dir`.

A dirent structure contains the character pointer `d_name`, which points to a string that gives the name of a file in the directory. This string ends in a terminating NULL, and has a maximum of NAME_MAX characters.

The `info` argument points to an area of storage that will be filled in with information about the file `d_name`. This information is returned in a stat structure defined in the `sys/stat.h` header file. The format of this structure is described in the section about the `lstat()` function. If `info` is NULL, no stat information is passed back.

If entries for dot or dot-dot exist, one entry will be returned for dot and one entry will be returned for dot-dot; otherwise they will not be returned.

A call to __readdir2() overwrites data produced by a previous call to __readdir2() or readdir() on the same directory stream. Calls for different directory streams do not overwrite each other's data.

Save the dirent data from __readdir2(), if required, before calling closedir(), because closedir() frees the dirent data.

The __readdir2() function may buffer several directory entries per actual read operation. __readdir2() updates the st_atime (access time) field of the directory each time the directory is actually read.

After a call to fork(), either the parent or child (but not both) may continue processing the directory stream using __readdir2(), readdir(), rewinddir() or seekdir(). If both the parent and child processes use these functions, the result is undefined.

If the entry names a symbolic link, the value of d_ino member in dirent structure is unspecified.

Unpredictable results can occur if closedir() is used to close the directory stream before __readdir2() is called. If the contents of a directory have changed since the directory was opened (files added or removed), a call should be made to rewinddir() so that subsequent __readdir2() requests can read the new contents.
__readdir2

The output from this function is similar to a combination of readdir() and lstat(). In some cases, certain information in the output stat structure differs from what lstat() would return. Also, the d_extra field in dir is always NULL for __readdir2().

Returned value

If successful, __readdir2() returns a pointer to a dirent structure describing the next directory entry in the directory stream. When __readdir2() reaches the end of the directory stream, it returns a NULL pointer.

If unsuccessful, __readdir2() returns a NULL pointer and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>dir does not yield an open directory stream.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The buffer was too small to contain any directories.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error occurs if the number of symbolic links in a file name in the directory is greater than POSIX_SYMLOOP.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>The current position of the directory stream is invalid.</td>
</tr>
</tbody>
</table>

readdir_r() — Read an entry from a directory

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <dirent.h>

int readdir_r(DIR *__restrict__dir, struct dirent *__restrict__entry,
               struct dirent **__restrict__result);
```

General description

The readdir_r() function initializes the dirent structure referenced by entry to represent the directory entry at the current position in the directory stream referred to by dir, stores a pointer to this structure at the location referenced by result, and positions the directory stream at the next entry.

The storage pointed to by entry will be large enough for a dirent with an array of char d_name member containing at least NAME_MAX+1 elements.

On successful return, the pointer returned at *result will have the same value as the argument entry. Upon reaching the end of the directory stream, this pointer will have the value NULL.

The readdir_r() function will not return directory entries containing empty names. It is unspecified whether entries are returned for dot or dot-dot.

If a file is removed from or added to the directory after the most recent call to opendir() or rewinddir(), whether a subsequent call to readdir_r() returns an entry for that file is unspecified.

The readdir_r() function may buffer several directory entries per actual read operation. The readdir_r() function marks for update the st_atime field of the directory each time the directory is actually read.

Applications wishing to check for error situations should set errno to 0 before calling readdir(). If errno is set to non-zero on return, an error occurred.

Returned value

If successful, readdir_r() returns 0.

If unsuccessful, readdir_r() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>dir does not refer to an open directory stream.</td>
</tr>

</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1a</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX1_SOURCE 2
#include <unistd.h>

int readlink(const char *path, char *buf, size_t bufsiz);
```

```c
#define _POSIX_C_SOURCE 200112L
#include <unistd.h>

ssize_t readlink(const char *__restrict__path, char *__restrict__buf, size_t bufsiz);
```

General description

Places the contents of the symbolic link `path` in the buffer `buf`. The size of the buffer is set by `bufsz`. The result stored in `buf` does not include a terminating NULL character.

If the buffer is too small to contain the value of the symbolic link, that value is truncated to the size of the buffer (`bufsz`). If the value returned is the size of the buffer, use `lstat()` to determine the actual size of the symbolic link.

Returned value

If successful, when `bufsz` is greater than 0, `readlink()` returns the number of bytes placed in the buffer. When `bufsz` is 0 and `readlink()` completes successfully, it returns the number of bytes contained in the symbolic link and the buffer is not changed.

If the returned value is equal to `bufsz`, you can determine the contents of the symbolic link with either `lstat()` or `readlink()`, with a 0 value for `bufsz`.

If unsuccessful, `readlink()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for a component of the path prefix.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The named file is not a symbolic link.</td>
</tr>
<tr>
<td>EIO</td>
<td>An I/O error occurred while reading from the file system.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP symbolic links are encountered during resolution of the <code>path</code> argument.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td><code>pathname</code> is longer than <code>PATH_MAX</code> characters, or some component of <code>pathname</code> is longer than <code>NAME_MAX</code> characters</td>
</tr>
</tbody>
</table>
readlink

while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined using pathconf().

ENOENT The named file does not exist.
ENOTDIR A component of the path prefix is not a directory.

Example

CELEBR05:

/* CELEBR05 */
#define _POSIX_SOURCE 1
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE

main() {
    char fn[]="readlink.file";
    char sl[]="readlink.symlink"
    char buf[30];
    int fd;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        if (symlink(fn, sl) != 0)
            perror("symlink() error");
        else {
            if (readlink(sl, buf, sizeof(buf)) < 0)
                perror("readlink() error");
            else printf("readlink() returned '\%s' for '\%s'\n", buf, sl);

            unlink(sl);
        }
        unlink(fn);
    }
}

Output:
readlink() returned 'readlink.file' for 'readlink.symlink'

readv() — Read data on a file or socket and store in a set of buffers

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

**X/Open:**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/uio.h>

ssize_t readv(int fs, const struct iovec *iov, int iovcnt);
```

**Berkeley sockets:**

```c
#define _OE_SOCKETS
#include <sys/uio.h>

int readv(int fs, struct iovec *iov, int iovcnt);
```

General description

The readv() function reads data from a file or a socket with descriptor `fs` and stores it in a set of buffers. The data is scattered into the buffers specified by `iov[0]...iov[iovcnt-1]`.

**Parameter**  
**Description**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fs</code></td>
<td>The file or socket descriptor.</td>
</tr>
<tr>
<td><code>iov</code></td>
<td>A pointer to an <code>iovec</code> structure.</td>
</tr>
<tr>
<td><code>iovcnt</code></td>
<td>The number of buffers pointed to by the <code>iov</code> parameter.</td>
</tr>
</tbody>
</table>

The `iovec` structure is defined in `uiot.h` and contains the following fields:

**Element**  
**Description**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iov_base</code></td>
<td>The pointer to the buffer.</td>
</tr>
<tr>
<td><code>iov_len</code></td>
<td>The length of the buffer.</td>
</tr>
</tbody>
</table>

If the descriptor refers to a socket, then it must be a connected socket.

This call returns a number of bytes of data equal to but not exceeding the sum of all the `iov_len` fields. If less than the number of bytes requested is available, the call returns the number currently available. If data is not available for the socket `fs`, and the socket is in blocking mode, `readv()` call blocks the caller until data arrives. If data is not available and `fs` is in nonblocking mode, `readv()` returns a -1 and sets the error code to EWOULDBLOCK. See "fcntl() — Control open file descriptors" on page 539 or "ioctl() — Control device" on page 1002 for a description of how to set nonblocking mode.

For datagram sockets, this call returns the entire datagram that was sent, provided that the datagram fits into the specified buffer. Excess datagram data is discarded. Stream sockets act like streams of information with no boundaries separating data.
For example, if applications A and B are connected with a stream socket and application A sends 1000 bytes, each call to this function can return 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been received.

For X/Open sockets, if the total number of bytes to read is 0, readv() returns 0. If readv() is for a file and no data is available, readv() returns 0. If a readv() is interrupted by a signal before it reads any data, it returns -1 with errno set to EINTR. If readv() is interrupted by a signal after it has read data, it returns the number of bytes read. If fs refers to a socket, readv() is the equivalent of recv() with no flags set.

**Special behavior for C++:**

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

**Returned value**

If successful, readv() returns the number of bytes read into the buffer.

If the connection is broken on a stream socket and data is available, then the readv() function reads the data and gives no error. If the connection is broken on a stream socket and no data is available, then the readv() function returns 0 bytes as EOF.

If unsuccessful, readv() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The O_NONBLOCK flag is set for the file descriptor and the process would be delayed by the readv().</td>
</tr>
<tr>
<td>EBADF</td>
<td>fs is not a valid file or socket descriptor.</td>
</tr>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

void *realloc(void *ptr, size_t size);
```

General description

Changes the size of a previously reserved storage block. The `ptr` argument points to the beginning of the block. The `size` argument gives the new size of the block in bytes. The contents of the block are unchanged up to the shorter of the new and old sizes.

If the `ptr` is NULL, `realloc()` reserves a block of storage of `size` bytes. It does not give all bits of each element an initial value of 0.

If `size` is 0 and `ptr` is not NULL, the storage pointed to by `ptr` is freed and NULL is returned.

If you use `realloc()` with a pointer that does not point to a `ptr` created previously by `malloc()`, `calloc()`, or `realloc()`, or if you pass `ptr` to storage already freed, you get undefined behavior—usually an exception.

If you ask for more storage, the contents of the extension are undefined and are not guaranteed to be 0.

The storage to which the returned value points is aligned for storage of any type of object. Under z/OS XL C only, if 4K alignment is required, the `_4kmalc()` function should be used. (This function is only available to C applications in stand-alone System Programming C (SPC) Facility applications.) The library functions specific to the System Programming C (SPC) environment are described in the z/OS XL C/C++ Programming Guide.

To investigate the cause of `realloc()` running out of heap storage, see z/OS Language Environment Programming Reference.

Note: The environment variable `_CEE_REALLOC_CONTROL` controls reallocation that can lead to improved application performance. For more information about the `_CEE_REALLOC_CONTROL` environment variable, see z/OS XL C/C++ Programming Guide.

Special behavior for C++:
The C++ keywords new and delete are not interoperable with calloc(), free(), malloc(), or realloc().

**Returned value**

If successful, realloc() returns a pointer to the reallocated storage block. The storage location of the block might be moved. Thus, the returned value is not necessarily the same as the ptr argument to realloc().

The returned value is NULL if size is 0. If there is not enough storage to expand the block to the given size, the original block is unchanged and a NULL pointer is returned. If realloc() returns NULL because there is not enough storage, it will also set errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>Insufficient memory is available</td>
</tr>
</tbody>
</table>

**Example**

**CELEBR06:**

/* CELEBR06

This example allocates storage for the prompted size of array and then uses &realloc. to reallocate the block to hold the new size of the array. The contents of the array are printed after each allocation.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    long * array; /* start of the array */
    long * ptr; /* pointer to array */
    int  i;     /* index variable */
    int num1, num2; /* number of entries of the array */

    void print_array( long *ptr_array, int size);

    printf( "Enter the size of the array\n" );
    scanf( "%i", &num1 );

    /* allocate num1 entries using malloc() */
    if ( (array = (long*)malloc( num1 * sizeof( long ))) != NULL ) {
        for ( ptr = array, i = 0; i < num1 ; ++i ) /* assign values */
            *ptr++ = i;
        print_array( array, num1 );
        printf("\n");
    }
    else { /* malloc error */
        printf( "Out of storage\n" );
        abort();
    }

    /* Change the size of the array ... */
    printf("Enter the size of the new array\n" );
    scanf( "%i", &num2 );

    if ( (array = (long*)realloc( array, num2* sizeof( long ))) != NULL )
    {
        for ( ptr = array + num1, i = num1; i <= num2; ++i )
            *ptr++ = i + 2000; /* assign values to new elements */
    }

    return 0;
}

Chapter 3. Library functions  1645
realloc

    print_array( array, num2 );
}

else /* realloc error */
    printf( "Out of storage\n" );
    abort();
}

void print_array( long * ptr_array, int size )
{
    int i;
    long * index = ptr_array;

    printf("The array of size %d is:\n", size);
    for ( i = 0; i < size; ++i ) /* print the array out */
        printf( "  array[ %i ] = %li\n", i, ptr_array[i] );
}

Output:

If the initial value entered is 2 and the second value entered is 4, then expect the following output:

Enter the size of the array
The array of size 2 is:
array[ 0 ] = 0
array[ 1 ] = 1

Enter the size of the new array
The array of size 4 is:
array[ 0 ] = 0
array[ 1 ] = 1

realpath() — Resolve path name

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *realpath(const char *__restrict__file_name, char *__restrict__resolved_name);
```

General description

The realpath() function derives, from the path name pointed to by `file_name`, an absolute path name that names the same file, whose resolution does not involve ".", "..", or symbolic links. The generated path name is stored, up to a maximum of `PATH_MAX` bytes, in the buffer pointed to by `resolved_name`.

Returned value

If successful, realpath() returns a pointer to the resolved name.

If unsuccessful, the contents of the buffer pointed to by `resolved_name` are undefined, realpath() returns a NULL pointer and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Read or search permission was denied for a component of <code>file_name</code>.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>Either the <code>file_name</code> or <code>resolved_name</code> argument is a NULL pointer.</td>
</tr>
<tr>
<td>EIO</td>
<td>An error occurred while reading from the file system.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>Too many symbolic links were encountered in resolving <code>path</code>.</td>
</tr>
</tbody>
</table>
| ENAMETOOLONG | Path name is longer than `PATH_MAX` characters, or some component of path name is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values are determined using `pathconf()`.
| ENOENT     | A component of `file_name` does not name an existing file or `file_name` points to an empty string. |
| ENOTDIR    | A component of the path prefix is not a directory.                           |
| ERANGE     | File system will return ERANGE if the result to be stored in 'resolved_name' is larger than `PATH_MAX`. |

re_comp() — Compile regular expression

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <re_comp.h>

char *re_comp(const char *string);
```

General description

**Restriction:** This function is not supported in AMODE 64.

The `re_comp()` function converts a regular expression string into an internal form suitable for pattern matching by `re_exec()`.

The parameter `string` is a pointer to a character string defining a source regular expression to be compiled.

If `re_comp()` is called with a NULL argument, the current regular expression remains unchanged.

Strings passed to `re_comp()` must be terminated by a NULL byte, and may include newline characters.

**Notes:**
1. The `re_comp()` and `re_exec()` functions are supported on the thread-level. They must be issued from the same thread to work properly.
2. The `re_comp()` and `re_exec()` functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions `fnmatch()`, `glob()`, `regcomp()` and `regexec()`, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.
3. The z/OS UNIX implementation of the `re_comp()` function supports only the POSIX locale. Any other locales will yield unpredictable results.

The `re_comp()` function supports simple regular expressions, which are defined below.

**Simple regular expressions:**

A Simple Regular Expression (SRE) specifies a set of character strings. The simplest form of regular expression is a string of characters with no special meaning. A small set of special characters, known as metacharacters, do have special meaning when encountered in patterns.

The following one-character regular expressions (RE) match a single character:
1. An ordinary character $c$ (not a special character) is a one character regular expression that matches itself.

2. A backslash (\) followed by any special character (that is, \c where $c$ is any special character) is a one character regular expression that matches the special character itself. The special characters are:
   a. \., *, [, and \ (period, asterisk, left square bracket, and backslash, respectively) which are always special, except when they appear within square brackets ([]).
   b. ^ (caret or circumflex), which is special at the beginning of the entire regular expression, or when it immediately follows the left of a pair of square brackets ([]).
   c. $ (dollar symbol), which is special at the end of the regular expression.
   d. The character used to bound (delimit) an entire regular expression, which is special for that regular expression.

**Note:** A backslash (\) followed by an ordinary character is a one character regular expression that matches the ordinary character itself.

3. A period (.) is a one-character RE that matches any character, except newline.

4. A non-empty string within square brackets ([string]) is a one-character RE that matches any one character in that string. Thus, [abc], if compared to other strings, would match any which contained a, b, or c.

   If the caret symbol (^) is the first character of the string within square brackets (that is, [^string]), the one-character RE matches any characters except newline and the remaining characters within the square brackets. Thus, [^abc], if compared to other strings, would fail to match any which contains even one a, b, or c.

   Ranges may be specified as $c$–$c$. The hyphen symbol, within square brackets, means "through". It may be used to indicate a range of consecutive ASCII characters. For example, [0–9] is equivalent to [0123456789].

   The – (hyphen) can be used by itself, but only if it is the first (after an initial ^, if any), or last character in the expression.

   The right square bracket (]) can be used as part of the string but only if it is the first character within it (after an initial ^, if any). For example, the expression [a–d] matches either a right square bracket or one of the characters a through d.

The following rules may be used to construct REs from one character REs:

1. A one-character RE is a RE that matches whatever the one-character RE matches.

2. A one-character RE followed by an asterisk symbol (*) is a RE that matches 0 or more occurrences of the one-character RE. For example, (a*e) will match any of the following: e, ae, aaaa. The longest leftmost match is chosen.

3. A one-character RE followed by \{m\}, \{m,\}, or \{m,u\} is a RE that matches a range of occurrences of the one-character RE. Nonnegative integer values enclosed in \{\} indicate the number of times to apply the preceding one-character RE. $m$ is the minimum number and $u$ is the maximum number. $u$ must be less than 256. If you specify only $m$, it indicates the exact number of times to apply the regular expression.

   \{m,\} is equivalent to \{m,u\}. They both match $m$ or more occurrences of the expression. The * (asterisk) operation is equivalent to \{0,\}.

   The maximum number of occurrences is matched.
4. REs can be concatenated. The concatenation of REs is a RE that matches the concatenation of the strings matched by each component of the RE.
5. A RE enclosed between the character sequences \( and \) is a RE that matches whatever the unadorned RE matches. The \( and \) sequences are ignored.
6. The expression \( n \) (where \( 1 \leq n \leq 9 \)) matches the same string of characters as was matched by an expression enclosed between \( \) and \( \) earlier in the same regular expression. The sub-expression it specified is that beginning with the \( n \)th occurrence of \( \) counting from the left. For example, in the expression, \( (a)\backslash\backslash(e)\backslash\)1, the \( \) is equivalent to \( a \), giving \( area \).

An entire RE may be constrained to match only an initial segment or final segment of a line (or both).
1. A caret (\^) at the beginning of an entire RE constrains that RE to match an initial segment of a line.
2. A dollar symbol ($) at the end of an entire RE constrains that RE to match a final segment of a line. For example, the construct \(^entire \ RE\$\) constrains the entire RE to match the entire line.

**Returned value**

If the string pointed to by the string argument is successfully converted, re_comp() returns a NULL pointer.

If unsuccessful, re_comp() returns a pointer to an error message string (NULL-terminated).

The following re_comp() error messages are defined:

- EDC7008E No previous regular expression
- EDC7009E Regular expression too long
- EDC7010E \( \) imbalance
- EDC7011E \( \) imbalance
- EDC7012E \( \) imbalance
- EDC7013E Too many \( \) pairs.
- EDC7014E Incorrect range values in \( \)\( \)
- EDC7015E Back reference number in \( \)\( \) incorrect
- EDC7016E Incorrect endpoint in range expression

**Note:** The error message string is not to be freed by the application. It will be freed when the thread terminates.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

ssize_t recv(int socket, void *buffer, size_t length, int flags);
```

Berkeley sockets:

```c
#define _OE_SOCKETS
#include <sys/socket.h>

int recv(int socket, char *buffer, int length, int flags);
```

General description

The recv() function receives data on a socket with descriptor `socket` and stores it in a buffer. The recv() call applies only to connected sockets.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>socket</td>
<td>The socket descriptor.</td>
</tr>
<tr>
<td>buf</td>
<td>The pointer to the buffer that receives the data.</td>
</tr>
<tr>
<td>len</td>
<td>The length in bytes of the buffer pointed to by the buf parameter.</td>
</tr>
<tr>
<td>flags</td>
<td>The flags parameter is set by specifying one or more of the following flags. If more than one flag is specified, the logical OR operator (</td>
</tr>
</tbody>
</table>

- **MSG_OOB** Reads any out-of-band data on the socket. Out-of-band data is sent when the MSG_OOB flag is on for a send(), sendto(), or sendmsg().

  The fcntl() command should be used with F_SETOWN to specify the recipient, either a pid or a gid, of a SIGURG signal that will be sent when out-of-band data is sent. If no recipient is set, no signal will be sent. For more information, see the fcntl() command. The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the SO_OOBINLINE option of setsockopt(). If SO_OOBINLINE is set off and the MSG_OOB flag is set on, the out-of-band data byte will be read out-of-line. It is invalid for the MSG_OOB flag to be set on when SO_OOBINLINE is set on. If there is out-of-band data available, and the MSG_OOB flag is not set (SO_OOBINLINE can be on or off), then...
the data up to, but not including, the out-of-band data will be read. When the read cursor has reached the out-of-band data byte, then only the out-of-band data will be read on the next read. The SIOCATMARK option of ioctl() can be used to determine if the read cursor is currently at the out-of-band data byte. For more information, refer to the setsockopt() and ioctl() commands.

**MSG_PEEK** Peeks at the data present on the socket; the data is returned but not consumed, so that a subsequent receive operation sees the same data.

**MSG_WAITALL** Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, the connection is terminated, an error is pending, or SO_RCVTIMEO is set and the timer is expired for the socket.

This call returns the length of the incoming message or data. If a datagram packet is too long to fit in the supplied buffer, datagram sockets discard excess bytes. If data is not available for the socket *socket*, and *socket* is in blocking mode, the recv() call blocks the caller until data arrives. If data is not available and *socket* is in nonblocking mode, recv() returns a −1 and sets the error code to EWOULDBLOCK. See “fcntl() — Control open file descriptors” on page 539 or “ioctl() — Control device” on page 1002 for a description of how to set nonblocking mode.

For datagram sockets, this call returns the entire datagram that was sent, provided that the datagram fits into the specified buffer. Stream sockets act like streams of information with no boundaries separating data. For example, if applications A and B are connected with a stream socket and application A sends 1000 bytes, each call to this function can return 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been received.

**Special behavior for C++:**

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

**Returned value**

If successful, recv() returns the length of the message or datagram in bytes. The value 0 indicates the connection is closed.

If unsuccessful, recv() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>socket is not a valid socket descriptor.</td>
</tr>
<tr>
<td>ECONNRESET</td>
<td>A connection was forcibly closed by a peer.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using the <em>buf</em> and <em>len</em> parameters would result in an attempt to access storage outside the caller's address space.</td>
</tr>
</tbody>
</table>
recv

EINTR  The recv() call was interrupted by a signal that was caught before any data was available.
EINVAL  The request is invalid or not supported. The MSG_OOB flag is set and no out-of-band data is available.
EIO  There has been a network or transport failure.
ENOBUFS  Insufficient system resources are available to complete the call.
ENOTCONN  A receive is attempted on a connection-oriented socket that is not connected.
ENOTSOCK  The descriptor is for a file, not for a socket.
EOPNOTSUPP  The specified flags are not supported for this socket type or protocol.
ETIMEDOUT  The connection timed out during connection establishment, or due to a transmission timeout on active connection.
EWOULDBLOCK  socket is in nonblocking mode and data is not available to read. or the SO_RCVTIMEO timeout value was been reached before data was available.

**X/Open:**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int recvfrom(int socket, void *__restrict__ buffer,
              size_t length, int flags,
              struct sockaddr *__restrict__ address,
              socklen_t *__restrict__ address_length);
```

**Berkeley sockets:**

```c
#define _OE_SOCKETS
#include <sys/socket.h>

int recvfrom(int socket, char *buffer,
              int length, int flags,
              struct sockaddr *address,
              int *address_length);
```

General description

The recvfrom() function receives data on a socket named by descriptor `socket` and stores it in a buffer. The recvfrom() function applies to any datagram socket, whether connected or unconnected.

**Parameter** | **Description**
---|---
socket | The socket descriptor.
buffer | The pointer to the buffer that receives the data.
length | The length in bytes of the buffer pointed to by the `buffer` parameter.
flags | A parameter that can be set to 0 or MSG_PEEK or MSG_OOB, or MSG_WAITALL.

MSG_OOB | Reads any out-of-band data on the socket. Out-of-band data is sent when the MSG_OOB flag is on for a send(), sendto(), or sendmsg().

The fcntl() command should be used with F_SETOWN to specify the recipient, either a pid or a gid, of a SIGURG signal that will be sent when out-of-band data is sent. If no recipient is set, no signal will be sent. For more information, see the fcntl() command. The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the SO_OOBINLINE option of setsockopt(). If SO_OOBINLINE is set off and the MSG_OOB flag
is set on, the out-of-band data byte will be read out-of-line. It is invalid for the MSG_OOB flag to be set on when SO_OOBINLINE is set on. If there is out-of-band data available, and the MSG_OOB flag is not set (SO_OOBINLINE can be on or off), then the data up to, but not including, the out-of-band data will be read. When the read cursor has reached the out-of-band data byte, then only the out-of-band data will be read on the next read. The SIOCATMARK option of ioctl() can be used to determine if the read cursor is currently at the out-of-band data byte. For more information, refer to the setsockopt() and ioctl() commands.

**MSG_PEEK**  Peeks at the data present on the socket; the data is returned but not consumed, so that a subsequent receive operation sees the same data.

**MSG_WAITALL**  Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, the connection is terminated, an error is pending or SO_RCVTIMEO is set and the timer is expired for the socket. For AF_UNIX, the function may also return earlier if out-of-band (OOB) data is inline and there is OOB data to be read. In this case, the data up to the OOB data is returned on the first recvfrom(). The OOB data is returned on the subsequent read request.

**address**  A pointer to a socket address structure from which data is received. If *address* is nonzero, the source address is returned.

**address_length**  Must initially point to an integer that contains the size in bytes of the storage pointed to by *address*. On return, that integer contains the size required to represent the address of the connecting socket. If this value is larger than the size supplied on input, then the information contained in sockaddr is truncated to the length supplied on input. If *address* is NULL, *address_length* is ignored.

If *address* is nonzero the source address of the message is filled. *address_length* must first be initialized to the size of the buffer associated with *address* and is then modified on return to indicate the actual size of the address stored there.

If either *address* or *address_length* is a NULL pointer, then *address* and *address_length* are unchanged.

If *address* is nonzero, the source address of the message is filled. *address_length* must first be initialized to the size of the buffer associated with *address*, and is then modified on return to indicate the actual size of the address stored there.

This call returns the length of the incoming message or data. If a datagram packet is too long to fit in the supplied buffer, datagram sockets discard excess bytes. If data is not available for the socket *socket*, and *socket* is in blocking mode, the recvfrom() call blocks the caller until data arrives. If data is not available and *socket* is in nonblocking mode, recvfrom() returns a −1 and sets the error code to
**recvfrom**

**EWOULDBLOCK.** See [fcntl() — Control open file descriptors](#) or [ioctl() — Control device](#) for a description of how to set nonblocking mode.

For datagram sockets, this call returns the entire datagram that was sent, provided that the datagram fits into the specified buffer. Stream sockets act like streams of information with no boundaries separating data. For example, if applications A and B are connected with a stream socket and application A sends 1000 bytes, each call to this function can return 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been received.

**Socket address structure for IPv6:**

For an AF_INET6 socket, the address is returned in a sockaddr_in6 address structure. The sockaddr_in6 structure is defined in the header file netinet/in.h.

**Special behavior for C++:**

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

**Note:** The recvfrom() function has a dependency on the level of the Enhanced ASCII Extensions. See [Enhanced ASCII support](#) for details.

**Returned value**

- If successful, recvfrom() returns the length of the message or datagram in bytes. The value 0 indicates the connection is closed.

  - If unsuccessful, recvfrom() returns -1 and sets errno to one of the following values:

    **Error Code** | **Description**
    --- | ---
    EBADF | socket is not a valid socket descriptor.
    ECONNRESET | The connection was forcibly closed by a peer.
    EFAULT | Using the buffer and length parameters would result in an attempt to access storage outside the caller’s address space.
    EINTR | A signal interrupted recvfrom() before any data was available.
    EINVAL | The request is invalid or not supported. The MSG_OOB flag is set and no out-of-band data is available.
    EIO | There has been a network or transport failure.
    ENOBUFS | Insufficient system resources are available to complete the call.
    ENOTCONN | A receive is attempted on a connection-oriented socket that is not connected.
    ENOTSOCK | The descriptor is for a file, not for a socket.
    EOPNOTSUPP | The specified flags are not supported for this socket type.
    ETIMEDOUT | The connection timed out during connection establishment, or due to a transmission timeout on active connection.
EWOULDBLOCK

_socket is in nonblocking mode and data is not available to read. or
the SO_RCVTIMEO timeout value was been reached before data
was available.

<td>The flags parameter is set by specifying one or more of the following flags. If more than one flag is specified, the logical OR operator (</td>
</tr>
<tr>
<td>MSG_OOB</td>
<td>Reads any out-of-band data on the socket. Out-of-band data is sent when the MSG_OOB flag is on for a send(), sendto() or sendmsg().</td>
</tr>
</tbody>
</table>

The fcntl command should be used with F_SETOWN to specify the recipient, either a pid or a gid, of a SIGURG signal that will be sent when out-of-band data is sent. If no recipient is set, no signal will be sent. For more information, see the fcntl() command. The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the SO_OOBINLINE option of setsockopt(). If SO_OOBINLINE is set off and the MSG_OOB flag is set on, the out-of-band data byte will be read out-of-line. It is invalid for the MSG_OOB flag to be set on when SO_OOBINLINE is set on. If there is out-of-band data available, and the MSG_OOB flag is not set (SO_OOBINLINE can be on or off), then...
recvmsg

the data up to, but not including, the out-of-band data will be read. When the read cursor has reached the out-of-band data byte, then only the out-of-band data will be read on the next read, and the output MSG_OOB msg_flag in the message header will be set on. The SIOCATMARK option of ioctl() can be used to determine if the read cursor is currently at the out-of-band data byte. For more information, refer to the setsockopt() and ioctl() commands.

MSG_PEEK     Peeks at the data present on the socket; the data is returned but not consumed, so that a subsequent receive operation will see the same data.

MSG_WAITALL  Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, the connection is terminated, an error is pending or SO_RCVTIMEO is set and the timer is expired for the socket.

A message header is defined by a msghdr structure. A definition of this structure can be found in the sys/socket.h include file and contains the following elements:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg_iov</td>
<td>An array of iovec buffers into which the message is placed.</td>
</tr>
<tr>
<td>msg_iovlen</td>
<td>The number of elements in the msg_iov array.</td>
</tr>
<tr>
<td>msg_name</td>
<td>An optional pointer to a buffer where the sender's address is stored.</td>
</tr>
<tr>
<td>msg_namelen</td>
<td>The size of the address buffer.</td>
</tr>
<tr>
<td>caddr_t</td>
<td>Access rights sent/received (ignored if specified by the user).</td>
</tr>
<tr>
<td>msg_accrightslen</td>
<td>Length of access rights data (ignored if specified by the user).</td>
</tr>
<tr>
<td>msg_control</td>
<td>Ancillary data, see below.</td>
</tr>
<tr>
<td>msg_controllen</td>
<td>Ancillary data buffer length.</td>
</tr>
<tr>
<td>msg_flags</td>
<td>Flags on received message.</td>
</tr>
</tbody>
</table>

Ancillary data consists of a sequence of pairs, each consisting of a cmsghdr structure followed by a data array. The data array contains the ancillary data message, and the cmsghdr structure contains descriptive information that allows an application to correctly parse the data.

The sys/socket.h header file defines the cmsghdr structure that includes at least the following members:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmsg_len</td>
<td>Data byte count, including header.</td>
</tr>
<tr>
<td>cmsg_level</td>
<td>Originating protocol.</td>
</tr>
<tr>
<td>cmsg_type</td>
<td>Protocol-specific type.</td>
</tr>
</tbody>
</table>
The following ancillary data are available at the IPv4 level:

<table>
<thead>
<tr>
<th>Ancillary data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_PKTINFO</td>
<td>(RAW and UDP) Returns the source IP address for an outgoing packet and the</td>
</tr>
<tr>
<td></td>
<td>outgoing interface. The data is passed in an in_pktinfo structure as defined</td>
</tr>
<tr>
<td></td>
<td>in netinet/in.h.</td>
</tr>
</tbody>
</table>

The following ancillary data are available at the IPv6 level:

<table>
<thead>
<tr>
<th>Ancillary data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPV6_HOPLIMIT</td>
<td>(RAW, TCP, and UDP) Returns the maximum hop limit for an incoming packet.</td>
</tr>
<tr>
<td></td>
<td>The data is passed in a structure as defined in netinet/in.h.</td>
</tr>
<tr>
<td>IPV6_PATHMTU</td>
<td>(RAW and UDP) Returns the path MTU value for the source of a connected</td>
</tr>
<tr>
<td></td>
<td>socket. The data is passed in a structure as defined in netinet/in.h.</td>
</tr>
<tr>
<td>IPV6_PKTINFO</td>
<td>(RAW and UDP) Returns the source IP address for an outgoing packet and the</td>
</tr>
<tr>
<td></td>
<td>outgoing interface. The data is passed in an in6_pktinfo structure as defined</td>
</tr>
<tr>
<td></td>
<td>in netinet/in.h.</td>
</tr>
</tbody>
</table>

The following ancillary data are available at the socket level:

<table>
<thead>
<tr>
<th>Ancillary data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCM_RIGHTS</td>
<td>Returns the data array that contains the access rights to be sent or received.</td>
</tr>
<tr>
<td></td>
<td>This ancillary data is valid only for the AF_UNIX domain. The structure is</td>
</tr>
<tr>
<td></td>
<td>defined in sys/socket.h.</td>
</tr>
</tbody>
</table>

The sys/socket.h header file defines the following macros to gain access to the data arrays in the ancillary data associated with a message header:

- CMSG_DATA(cmsg) If the argument is a pointer to a cmsghdr structure, this macro returns an unsigned character pointer to the data array associated with the cmsghdr structure.

- CMSG_NXTHDR(mhdr,cmsg) If the first argument is a pointer to a msghdr structure and the second argument is a pointer to a cmsghdr structure in the ancillary data, pointed to by the msg_control field of that msghdr structure, this macro returns a pointer to the next cmsghdr structure, or a NULL pointer if this structure is the last cmsghdr in the ancillary data.

- CMSG_FIRSTHDR(mhdr) If the argument is a pointer to a msghdr structure, this macro returns a pointer to the first cmsghdr structure in the ancillary data associated with this msghdr structure, or a NULL pointer if there is no ancillary data associated with the msghdr structure.

The recvmsg() function applies to sockets, regardless of whether they are in the connected state.
This call returns the length of the data received. If data is not available for the socket, and socket is in blocking mode, the recvmsg() call blocks the caller until data arrives. If data is not available and socket is in nonblocking mode, recvmsg() returns a −1 and sets the error code to EWOULDBLOCK. See fcntl() — Control open file descriptors” on page 539 or ioctl() — Control device” on page 1002 for a description of how to set nonblocking mode.

For datagram sockets, this call returns the entire datagram that was sent, provided that the datagram fits into the specified buffer. Stream sockets act like streams of information with no boundaries separating data. For example, if applications A and B are connected with a stream socket and application A sends 1000 bytes, each call to this function can return 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been received.

On successful completion, the msg_flags member for the message header is the bitwise inclusive-OR of all of the following flags that indicate conditions detected for the received message:

MSG_OOB Out-of-band data was received.
MSG_TRUNC Normal data was truncated.
MSG_CTRUNC Control data was truncated.

Socket address structure for IPv6:

For an AF_INET6 socket, the address is returned in a sockaddr_in6 address structure. The sockaddr_in6 structure is defined in the header file netinet/in.h.

Special behavior for C++:

To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The recvmsg() function has a dependency on the level of the Enhanced ASCII Extensions. See Enhanced ASCII support on page 2543 for details.

Returned value

If successful, recvmsg() returns the length of the message in bytes. The value 0 indicates the connection is closed.

If unsuccessful, recvmsg() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>socket is not a valid socket descriptor.</td>
</tr>
<tr>
<td>ECONNRESET</td>
<td>The connection was forcibly closed by a peer.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using msg would result in an attempt to access storage outside the caller's address space.</td>
</tr>
<tr>
<td>EINTR</td>
<td>The function was interrupted by a signal before any data was available.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The request is invalid or not supported. The sum of the iov_len values overflows a ssize_t.</td>
</tr>
</tbody>
</table>
There has been a network or transport failure.

Insufficient system resources are available to complete the call.

A receive is attempted on a connection-oriented socket that is not connected.

The descriptor is for a file, not for a socket.

The specified flags are not supported for this socket type.

The connection timed out during connection establishment, or due to a transmission timeout on active connection.

Socket is in nonblocking mode and data is not available to read, or the SO_RCVTIMEO timeout value has been reached before data was available.

re_exec

re_exec() — Match regular expression

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <re_comp.h>

int re_exec(const char *string);
```

General description

**Restriction:** This function is not supported in AMODE 64.

The `re_exec()` function attempts to match the string pointed to by the `string` argument with the last regular expression passed to `re_comp()`.

The parameter `string` is a pointer to a character string to be compared.

Strings passed to `re_exec()` must be terminated by a NULL byte, and may include newline characters.

**Notes:**

1. The `re_comp()` and `re_exec()` functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions `fnmatch()`, `glob()`, `regcomp()` and `regexec()`, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.

2. The z/OS UNIX implementation of the `re_exec()` function supports only the POSIX locale. Any other locales will yield unpredictable results.

3. The `re_comp()` and `re_exec()` functions are supported on the thread-level. They must be issued from the same thread to work properly.

The `re_exec()` function supports simple regular expressions, which are defined in "re_comp() — Compile regular expression" on page 1649.

Returned value

If successful, `re_exec()` returns 1 if the input `string` matches the last compiled regular expression.

If unsuccessful, `re_exec()` returns 0 if the input `string` fails to match the last compiled regular expression, and −1 if the compiled regular expression is invalid (indicating an internal error).

### regcmp

### regcmp() — Compile regular expression

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <libgen.h>

char *regcmp(const char *pattern[,...], (char *)0);
char *regex(const char *cmppat, const char *subject[,subexp,...]);

extern char *__loc1;
```

#### General description

**Restriction:** This function is not supported in AMODE 64.

The regcmp() function concatenates regular expression (RE) patterns specified by a list of one or more `pattern` arguments. The end of this list must be delimited by a NULL pointer. The regcmp() function then converts the concatenated RE pattern into an internal form suitable for use by the pattern matching `regex()` function. If conversion is successful, regcmp() returns a pointer to the converted pattern. Otherwise, it returns a NULL pointer. The regcmp() function uses malloc() to obtain storage for the converted pattern. It is the application's responsibility to free unneeded space so allocated.

The regex() function executes a converted pattern `cmppat` against a `subject` string. If `cmppat` matches all or part of the `subject` string, the regex() function returns a pointer to the next unmatched character in the `subject` string and sets the external variable `__loc1` to point the first matched character in the `subject` string. If no match is found between `cmppat` and the `subject` string, the regex() function returns a NULL pointer.

The regcmp() and regex() functions are supported in any locale. However, results are unpredictable if they are not run in the same locale.

Following are valid RE symbols and their meaning to the regcmp() and regex() functions:

**Expression**

<table>
<thead>
<tr>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUL</td>
</tr>
<tr>
<td>c</td>
</tr>
<tr>
<td>s</td>
</tr>
</tbody>
</table>

The following characters are special:

- period, ., asterisk, *, plus, +, dollar, $, left square bracket, [, left brace, {, right brace, }, left parenthesis, (, right parenthesis, ), and backslash, \, are always special except when they appear within square brackets ([]).
caret (^) is special at the beginning of an entire RE (which is another name for a pattern).

**Note:** An non-special character preceded by \ is a one-character RE which matches the non-special character.

\( yz \) Concatenation of REs y and z matches concatenation of strings matched by y and z.

. The period (.) special character RE matches any single character except the <newline> character.

\( ^ \) The caret (^) at the beginning of an entire RE is an RE which matches the beginning of a string. Thus, it **anchors** or limits matches by the entire RE to the beginning of strings.

\( $ \) The dollar ($) at the end of an entire RE is an RE which only the end of a string (delimited by the <NUL> character). Thus, it **anchors** or limits matches by the entire RE to the end of strings.

**Note:** \( \backslash n \) (the C language designation for a <newline> character) must be used in an entire RE to match any embedded or trailing <newline> character in a text string.

(...). Parentheses are used to delimit a sub-expression which matches whatever the REs comprising the sub-expression would have matched without the delimiting parentheses.

(...)$n $n, where n is a digit between 0 and 9, inclusive, may be used to tag a sub-expression. The tag tells the regex() function to return the sub-string matched by the sub-expression at address specified by (n+1)th argument after subject.

* A one-character RE or sub-expression followed by an asterisk (*) is a RE that matches zero or more occurrences of the one-character RE or sub-expression. If there is any choice, the longest leftmost string that permits a match is chosen.

+ A one-character RE or sub-expression followed by a plus (+) is a RE that matches one or more occurrences of the one-character RE or sub-expression. Whenever a choice exists, the RE matches as many occurrences as possible.

\( \{m,n\} \) A one-character RE or sub-expression followed by integer values, m and n, enclosed in braces is a RE which matches repeated occurrences of whatever the preceding one-character RE or sub-expression matched. The value of m, which must be in the range 0 to 255, inclusive, is the minimum number of occurrences required for a match. The value of n which, if specified, must also be in the range 0 to 255, inclusive, is the maximum. The value of n, if specified, must be greater than or equal to the value m. The following brace expressions are valid:

\( \{m\} \) Matches exactly m occurrences of the preceding one-character RE or sub-expression.

\( \{m,\} \) Matches m or more occurrences of the preceding one-character RE or sub-expression. There is no limit on the number of occurrences which will be matched. The plus (+) and asterisk (*) operations are equivalent to \( \{1,\} \) and \( \{0,\} \), respectively.

\( \{m,n\} \) Matches between m and n occurrences, inclusive.
Whenever a choice exists, the RE matches as many occurrence as possible.

A non-empty list of characters enclosed by square brackets is a one-character RE that matches any one character in the list.

A non-empty list of characters preceded by a caret (^) enclosed by square brackets is a one-character RE that matches any character except <newline> and the characters in the list. The ^ has special meaning only if it is the first character after the left bracket (\[).

The hyphen (-) between two characters c1 and c2 within square brackets designates the list of characters whose collating values fall between the collating values of c1 and c2 in the current locale. The collating value of c2 must be greater than or equal to c1. Also, c2 may not be used as the ending point of one range and the starting point of another range. In other words, c1-c2-c3 is invalid.

The - loses special meaning if it occurs first or last in the bracket expression or if it is used for c1 or c2.

The right bracket, \], does not terminate a bracket expression when it is the first character within it (after an initial ^, if any). For example, the expression \[\]0-9\] matches a right bracket or a digit in the range 0-9, inclusive.

Notes:
1. Multiple duplication symbols applied to the same RE will be interpreted in the following order of precedence:
   a. *
   b. +
   c. {}
2. RE Order of precedence is as follows, from high to low:
   a. escaped character \character
   b. bracket expression [...]
   c. sub-expression (...)
   d. duplication * + {}
   e. concatenation yz
   f. anchors ^ $
Returned value

If the pattern formed by concatenating the list of pattern arguments is successfully converted, regcmp() returns a pointer to the converted pattern. Otherwise, it returns a NULL pointer. If regcmp() is unable to allocate storage for the converted pattern, it sets errno to ENOMEM.

If regex() successfully matches the converted pattern cmppat to all or part of the subject string, it returns a pointer to the next unmatched character in subject. Otherwise, it returns a NULL pointer.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <regex.h>

int regcomp(regex_t *restrict_ preg, const char *restrict_ pattern, int cflags);
```

General description

Compiles the regular expression specified by `pattern` into an executable string of op-codes.

`preg` is a pointer to a compiled regular expression.

`pattern` is a pointer to a character string defining a source regular expression (described below).

`cflags` is a bit flag defining configurable attributes of compilation process:

- **REG_EXTENDED** Support extended regular expressions.
- **REG_ICASE** Ignore case in match.
- **REG_NEWLINE** Eliminate any special significance to the newline character.
- **REG_NOSUB** Report only success or fail in regexec(), that is, verify the syntax of a regular expression. If this flag is set, the regcomp() function sets `re_nsub` to the number of parenthesized sub-expressions found in `pattern`. Otherwise, a sub-expression results in an error.

The regcomp() function under z/OS XL C/C++ will use the definition of characters according to the current LC_SYNTAX category. The characters, `[, ], {, }, |, ^, and $, have varying code points in different encoded character sets.

Regular expressions

The functions regcomp(), regerror(), regexec(), and regfree() use regular expressions in a similar way to the UNIX awk, ed, grep, and egrep commands.

The simplest form of regular expression is a string of characters with no special meaning. The following characters do have special meaning; they are used to form extended regular expressions:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>The period symbol matches any one character except the terminal newline character.</td>
</tr>
</tbody>
</table>
The hyphen symbol, within square brackets, means “through”. It fills in the intervening characters according to the current collating sequence. For example, [a–z] can be equivalent to [abc...xyz] or, with a different collating sequence, it can be equivalent to [aAbBcC...xXyYzZ].

A string within square brackets specifies any of the characters in string. Thus [abc], if compared to other strings, would match any that contained a, b, or c.

No assumptions are made at compile time about the actual characters contained in the range.

Integer values enclosed in {} indicate the number of times to apply the preceding regular expression. m is the minimum number, and u is the maximum number. u must not be greater than RE_DUP_MAX (see “limits.h” on page 38).

If you specify only m, it indicates the exact number of times to apply the regular expression. {m} is equivalent to {m,u}. They both match m or more occurrences of the expression.

The asterisk symbol indicates 0 or more of any characters. For example, [a*e] is equivalent to any of the following: 99ae9, aaaaae, a999e99.

The dollar symbol matches the end of the string. (Use \n to match a newline character.)

The plus symbol specifies one or more occurrences of a character. Thus, smith+ern is equivalent to, for example, smithhhern.

The caret symbol, when inside square brackets, negates the characters within the square brackets. Thus [^abc], if compared to other strings, would fail to match any that contains even one a, b, or c.

Stores the value matched by the enclosed regular expression in the (n+1)th ret parameter. Ten enclosed regular expressions are allowed. Assignments are made unconditionally.

Groups a sub-expression allowing an operator, such as *, +, or [], to work on the sub-expression enclosed in parentheses. For example, (a*(cb+)+)\$0.

Notes:
1. Do not use multibyte characters.
2. You can use the ] (right square bracket) alone within a pair of square brackets, but only if it immediately follows either the opening left square bracket or if it immediately follows [^.. For example: [^–] matches the ] and – characters.
3. All the preceding symbols are special. You precede them with \ to use the symbol itself. For example, a\.
4. You can use the – (hyphen) by itself, but only if it is the first or last character in the expression. For example, the expression [–−0] matches either the ] or else the characters – through 0. Otherwise, use \–.
Returned value

If successful, regcomp() returns 0.

If unsuccessful, regcomp() returns nonzero, and the content of preg is undefined.

Example

CELEBR07:
/* CELEBR07
 * This example compiles an extended regular expression.
 */
#include <regex.h>
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>
main() {
    regex_t preg;
    char *string = "a simple string";
    char *pattern = ".\*(simple)\*";
    int rc;
    if ((rc = regcomp(&preg, string, REG_EXTENDED)) != 0) {
        printf("regcomp() failed, returning nonzero (%d)\n", rc);
        exit(1);
    }
}

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <regex.h>

size_t regerror(int errcode, const regex_t *restrict_preg,
                char *restrict_errbuf, size_t errbuf_size);
```

General description

Finds the description for **errcode**. (For a description of regular expressions, see "Regular expressions" on page 1670.)

Returned value

`regerror()` returns the integer value that is the size of the buffer needed to hold the generated description string for the error condition corresponding to `errcode`.

`regerror()` returns the following messages.

<table>
<thead>
<tr>
<th><strong>errcode</strong></th>
<th><strong>Description String</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>REG_BADBR</td>
<td>Invalid { } range exp</td>
</tr>
<tr>
<td>REG_BADPAT</td>
<td>Invalid regular expression</td>
</tr>
<tr>
<td>REG_BADRPT</td>
<td>?*+ not preceded by valid RE</td>
</tr>
<tr>
<td>REG_EBOL</td>
<td>~ anchor and not BOL</td>
</tr>
<tr>
<td>REG_EBRACE</td>
<td>{ } or { } imbalance</td>
</tr>
<tr>
<td>REG_EBRACK</td>
<td>[] imbalance</td>
</tr>
<tr>
<td>REG_ECHAR</td>
<td>Invalid multibyte character</td>
</tr>
<tr>
<td>REG_ECOLLATE</td>
<td>Invalid collating element</td>
</tr>
<tr>
<td>REG_ECTYPE</td>
<td>Invalid character class</td>
</tr>
<tr>
<td>REG_EEOL</td>
<td>$ anchor and not EOL</td>
</tr>
<tr>
<td>REG_EESCAPE</td>
<td>Last character is \</td>
</tr>
<tr>
<td>REG_EPAREN</td>
<td>( ) or () imbalance</td>
</tr>
<tr>
<td>REG_ERANGE</td>
<td>Invalid range exp endpoint</td>
</tr>
<tr>
<td>REG_ESPACE</td>
<td>Out of memory</td>
</tr>
<tr>
<td>REG_ESUBREG</td>
<td>Invalid number in \d</td>
</tr>
<tr>
<td>REG_NOMATCH</td>
<td>RE pattern not found</td>
</tr>
</tbody>
</table>

The LC_SYNTAX characters in the messages will be converted to the code points from the current LC_SYNTAX category.
Example

CELEBR08:

/* CELEBR08

This example compiles an invalid regular expression, and
print error message &regerror.

*/
#include <regex.h>
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>

main() {
    regex_t preg;
    char *pattern = "a[missing.bracket";
    int rc;
    char buffer[100];
    if ((rc = regcomp(&preg, pattern, REG_EXTENDED)) != 0) {
        regerror(rc, &preg, buffer, 100);
        printf("regcomp() failed with '%s'\n", buffer);
        exit(1);
    }
}

regex() — Execute compiled regular expression

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <libgen.h>
char *regex(const char *cmppat, const char *subject[,subexp,...]);
extern char *__loc1;
```

General description

**Restriction:** This function is not supported in AMODE 64.

The regex() function executes a converted pattern `cmppat` produced by the `regcomp()` function against a `subject` string. If `cmppat` matches all or part of the `subject` string, the regex() function returns a pointer to the next unmatched character in the `subject` string and sets the external variable `__loc1` to point the first matched character in the `subject` string. If no match is found between `cmppat` and the `subject` string, the regex() function returns a NULL pointer.

The regex() and regcomp() functions are supported in any locale. However, results are unpredictable if they are not run in the same locale.

Refer to "regcmp() — Compile regular expression" on page 1666 for a description of regular expression syntax and semantics supported by the regex() and regcomp() functions.

**Note:**

The regcmp() and regex() functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions fnmatch(), glob(), regcomp() and regexec(), which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.

If it is necessary to continue using these functions in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

**Returned value**

If regex() successfully matches the converted pattern `cmppat` to all or part of the `subject` string, it returns a pointer to the next unmatched character in `subject`. 

Chapter 3. Library functions 1675
If unsuccessful, regex() returns a NULL pointer.

<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <regex.h>

int regexec(const regex_t *preg, const char *string,
             size_t nmatch, regmatch_t *pmatch, int eflags);
```

XPG4:

```c
#define _XOPEN_SOURCE
#include <regex.h>

int regexec(const regex_t *__preg,
             const char *__string,
             size_t nmatch, regmatch_t *__pmatch, int eflags);
```

General description

Compare the NULL-terminated string specified by `string` against the compiled regular expression, `preg`. (For a description of regular expressions, see "Regular expressions" on page 1670.)

`preg` is a pointer to a compiled regular expression to compare against `STRING`.

`string` is a pointer to a string to be matched.

`nmatch` is the number of sub-expressions to match.

`pmatch` is an array of offsets into `STRING` which matched the corresponding sub-expressions in `preg`.

`eflags` is a bit flag defining customizable behavior of `regexec()`.

REG_NOTBOL

Indicates that the first character of `STRING` is not the beginning of the line.

REG_NOTEOL

Indicates that the first character of `STRING` is not the end of the line.

If `nmatch` parameter is 0 or REG_NOSUB was set on the call to `regcomp()`, `regexec()` ignores the `pmatch` argument. Otherwise, the `pmatch` argument points to an array of at least `nmatch` elements. The `regexec()` function fills in the elements of the array with offsets of the substrings of `STRING` that correspond to the parenthesized sub-expressions of the original pattern specified to `regcomp()`. The 0th element of the array corresponds to the entire pattern. If there are more than `nmatch` sub-expressions, only the first `nmatch–1` are recorded.
When matching a basic or extended regular expression, any given parenthesized sub-expression of pattern might participate in the match of several different substrings of STRING. The following rules determine which substrings are reported in pmatch.

1. If a sub-expression participated in a match several times, the offset of the last matching substring is reported in pmatch.
2. If a sub-expression did not match in the source STRING, the offset shown in pmatch is set to −1.
3. If a sub-expression contains sub-expressions, the data in pmatch refers to the last such sub-expression.
4. If a sub-expression matches a zero-length string, the offsets in pmatch refer to the byte immediately following the matching string.

If EREG_NOSUB was set when regcomp() was called, the contents of pmatch are unspecified.

If REG_NEWLINE was set when regcomp() was called, newline characters are allowed in STRING.

Notes:
1. With z/OS XL C/C++, the string passed to the regexec() function is assumed to be in the initial shift state, unless REG_NOTBOL is specified. If REG_NOTBOL is specified, the shift state used is the shift state after the last call to the regexec() function.
2. The information returned by the regexec() function in the regmatch_t structure has the shift-state at the start and end of the string added. This will assist an application to perform replacements or processing of the partial string. To perform replacements, the application must add the required shift-out and shift-in characters where necessary. No library functions are available to assist the application.
3. If MB_CUR_MAX is specified as 4, but the charmap file does not specify the DBCS characters, and a collating-element (for example, [:a:]) is specified in the pattern, the DBCS characters will not match against the collating-element even if they have an equivalent weight to the collating-element.

Returned value

If a match is found, regexec() returns 0.

If unsuccessful, regexec() returns nonzero indicating either no match or an error.

Example

CELEBR09:
/* CELEBR09
   This example compiles an extended regular expression, and
   match against a string.
 */
#include <regex.h>
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>

main() {
   regex_t preg;

   /*...*/
```c
char *string = "a simple string";
char *pattern = ".*(simple).*";
int rc;
size_t nmatch = 2;
regmatch_t pmatch[2];

if ((rc = regcomp(&preg, pattern, REG_EXTENDED)) != 0) {
    printf("regcomp() failed, returning nonzero (%d)\n", rc);
    exit(1);
}

if ((rc = regexec(&preg, string, nmatch, pmatch, 0)) != 0) {
    printf("failed to ERE match '%s' with '%s',returning %d.\n", string, pattern, rc);
}

regfree(&preg);
```

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <regex.h>

void regfree(regex_t *preg);
```

**General description**

Frees any memory that was allocated by regcomp() to implement `preg`. The expression defined by `preg` is no longer a compiled regular or extended expression.

(For a description of regular expressions, see "Regular expressions" on page 1670.)

**Example**

**CELEBR10:**

```c
/* CELEBR10

This example compiles an extended regular expression and a
free regular expression.

*/
#include <regex.h>
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>
main() {
    regex_t preg;
    char *pattern = ".*(simple).*";
    int rc;
    if ((rc = regcomp(&preg, pattern, REG_EXTENDED)) != 0) {
        printf("regcomp() failed, returning nonzero (%d)\n", rc);
        exit(1);
    }
    regfree(&preg);
}
```

release() — Delete a load module

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

int release(void(*fetch_ptr)());
```

General description

Removes from memory the load modules retrieved by fetch() or fetch control blocks created by fetchep(). The `fetch_ptr` parameter is obtained from a call to fetch() or fetchep(). Once released, the fetch() and any associated fetchep() pointers are no longer valid.

To avoid infringing on the user's name space, this nonstandard function has two names. One name, the external entry point name is prefixed with two underscore characters, and the other name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

**Note:** The external entry point name for release() is `__rlse()`, *NOT* `__release()`.

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters `__rlse()`), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

All fetched modules and fetch control blocks created by fetchep() are released automatically on program termination.

Using release() on a module obtained by using fetch() will also cause the release() of any child fetch control blocks created by fetchep() for this module. However, using release() on a child fetch control block will have no effect on the parent modules or sibling fetch control blocks obtained by using fetch(). Trying to use a fetch control block after it has been released will result in undefined behavior. (A Fetch Control Block (FECB) is an internal executable control block. The fetch pointer points to it.

When non-reentrant modules have been fetched multiple times, you should release them in the reverse order; otherwise, the load modules may not be deleted immediately.

Returned value

If successful, release() returns 0.

If unsuccessful, release() returns nonzero.
release

Example

/* The following C example uses the fetch() function to load a module, and
later uses release() to delete the module from memory.
*/
#include <stdlib.h>

void (*fetch_ptr());

int main(void) {
    fetch_ptr = fetch("sample");
    release(fetch_ptr); /* all modules are released */
}

Related information

- "stdlib.h" on page 69

- "fetchep() — Share writable static" on page 590
remainder(), remainderf(), remainderl() — Computes the remainder \( x \) REM \( y \)

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>C++ TR1 C99</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double remainder(double x, double y);

C99:
#define _ISOC99_SOURCE
#include <math.h>

float remainderf(float x, float y);
long double remainderl(long double x, long double y);

C++ TR1 C99:
#define _TR1_C99
#include <math.h>

float remainderf(float x, float y);
long double remainderl(long double x, long double y);
```

General description

The `remainder()` function returns the floating-point remainder when \( y \) is nonzero and following the relation

\[
r = x - ny
\]

The value \( n \) is the integral value nearest the exact value \( x/y \) and when

\[
| n - x/y | = 1/2
\]

then the value of \( n \) is even.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>remainder</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>remainderf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>remainderl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>
remainder

**Restriction:** The remainderf() function does not support the 
_FP_MODE_VARIABLE feature test macro.

**Returned value**

If successful, remainder() returns the remainder of the division of \( x \) by \( y \) as described.

If \( y \) is zero, remainder() returns HUGE_VAL and sets errno to EDOM.

If \( r = 0 \), then its sign will be that of \( x \).

**Special behavior for IEEE:**

If successful, remainder() returns the remainder of the division of \( x \) by \( y \).

If \( y \) is zero, remainder() returns NaNQ and sets errno to EDOM.

**Example**

```c
/*
 * This program illustrates the use of remainder() function
 * /
#define _ISOC99_SOURCE
#include <math.h>
#include <stdio.h>

void main() {
    double number1=3.0, number2=3.5;
    printf("Illustrates the remainder() function");
    ifdef _BFP
        printf(" (IEEE version)\n\n");
    else
        printf(" (HFP version)\n\n");
    endif

    printf("remainder(%.2f,%.2f)=%.2f\n",number1,number2,
        remainder(number1,number2));

    number1=1; number2=2;
    printf("remainder(%.2f,%.2f)=%.2f\n",number1,number2,
        remainder(number1,number2));
    number1=1; number2=0;
    printf("remainder(%.2f,%.2f)=%.2f\n",number1,number2,
        remainder(number1,number2));
}
```

**Output**

Illustrates the remainder() function (IEEE version)

remainder(3.00,3.50)=-0.50
remainder(1.00,2.00)=1.00
remainder(1.00,0.00)=NaNQ(1)

_Decimal32 remainder(_Decimal32 \(x\), _Decimal32 \(y\)); /* C++ only */
_Decimal64 remainder(_Decimal64 \(x\), _Decimal64 \(y\)); /* C++ only */
_Decimal128 remainder(_Decimal128 \(x\), _Decimal128 \(y\)); /* C++ only */
```

### General description

The remainder() function returns the decimal floating-point remainder when \( y \) is nonzero and following the relation

\[
r = x - ny
\]

The value \( n \) is the integral value nearest the exact value \( x/y \) and when then the value of \( n \) is even.

\[
| n - x/y | = 1/2
\]

These functions work in IEEE decimal floating-point format. See [IEEE decimal floating-point](#) on page 95 for more information.

**Note:** To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

### Returned value

If successful, remainder() returns the remainder of the division of \( x \) by \( y \).

If \( y \) is zero, remainder() returns NaNQ and sets errno to EDOM.

### Example

**CELEBR23:**

```c
/* CELEBR23
   This example illustrates the remainderd32() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
```
void main() {
    _Decimal32 n1=3.0DF, n2=3.5DF;
    printf("Illustrates the remainder32() function\n");
    printf("remainder32(%.2Hf,%.2Hf)=%.2Hf\n",n1,n2,remainder32(n1,n2));
    n1=1.0DF; n2=2.0DF;
    printf("remainder32(%.2Hf,%.2Hf)=%.2Hf\n",n1,n2,remainder32(n1,n2));
    n1=1.0DF; n2=0.0DF;
    printf("remainder32(%.2Hf,%.2Hf)=%.2Hf\n",n1,n2,remainder32(n1,n2));
}

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

    #include <stdio.h>

    int remove(const char *filename);

General description

Deletes the file specified by filename, unless the file is open. The remove( ) function removes memory files and DASD data sets. (Non-DASD data sets, such as tapes, are not supported.) It also removes individual members of PDSs and PDSEs, and even removes memory files that simulate PDSs.

The interpretation of the file name passed to remove( ) depends on whether POSIX(ON) is specified. For full details about filename considerations, see the topics about opening files in z/OS XL C/C++ Programming Guide.

Memory files must exist and they must be closed. However, if you have z/OS UNIX C application running POSIX(ON), memory files don't need to be closed when removing an HFS memory file. The z/OS UNIX services rules of interoperability apply. See the topics about opening files in z/OS XL C/C++ Programming Guide for specifying file names for MVS data sets and HFS files.

Special behavior for XPG4:

If filename does not name a directory, remove(filename) is equivalent to unlink(filename). If filename names a directory, remove(filename) is equivalent to rmdir(filename).

Returned value

If successful, remove() returns 0.

If unsuccessful, remove() returns nonzero to indicate an error.

Example

CELEBR12:

    /* CELEBR12

        When you invoke this example with a file name, the program attempts to
        remove that file.
        It issues a message if an error occurs.

    */
#include <stdio.h>

int main(int argc, char ** argv)
{
  if ( argc != 2 )
    printf( "Usage: %s fn\n", argv[0] );
  else
    if ( remove( argv[1] ) != 0 )
      printf( "Could not remove file\n" );
}

remque() — Remove an element from a double linked list

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <search.h>

void remque(void *element);
```

General description

The remque() function removes the element pointed to by `element` from a doubly-linked list. The function operates on pointers to structures which have a pointer to their successor in the list as their first element, and a pointer to their predecessor as the second. The application is free to define the remaining contents of the structure, and manages all storage itself.

Returned value

remque() returns no values.

Related information

- [“search.h” on page 62](#)
- [“insque() — Insert an element into a doubly-linked list” on page 1001](#)
remquo, remquof, remquol

remquo(), remquof(), remquol() — Computes the remainder.

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R5</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <math.h>

double remquo(double x, double y, int *quo);
float remquof(float x, float y, int *quo);
long double remquol(long double x, long double y, int *quo);
```

C++ TR1 C99:

```c
#define _TR1_C99
#include <math.h>

float remquo(float x, float y, int *quo);
long double remquol(long double x, long double y, int *quo);
```

General description

The remquo functions compute the same remainder as the remainder functions. In the object pointed to by *quo* they store a value whose sign is the sign of \( x/y \) and whose magnitude is congruent modulo 2 to the power \( n \) to the magnitude of the integral quotient of \( x/y \), where \( n \) is an implementation defined integer greater than or equal to 3.

Note: The following table shows the viable formats for these functions. See [IEEE binary floating-point](#) on page 94 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>remquo</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>remquof</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>remquol</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Restriction: The remquof() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

The remquo functions return \( x \) REM \( y \).

Example

```c
/*
 * This program illustrates the use of remquol() function
 *
*/
#define _ISOC99_SOURCE
#include <math.h>
#include <stdio.h>
```
void main() {
    long double number1=3.0L, number2=3.5L;
    int quo=0;
    printf("Illustrates the remquol() function");
    #ifdef __BFP__
        printf(" (IEEE version)\n\n");
    #else
        printf(" (HFP version)\n\n");
    #endif
    printf("remquol(%.2Lf,%.2Lf,&quo)=%.2Lf quo=%i",number1,number2,remquol(number1,number2,&(quo)));
    number1=1.0L; number2=2.0L;
    printf("remquol(%.2Lf,%.2Lf,&quo)=%.2Lf quo=%i",number1,number2,remquol(number1,number2,&(quo)));
    number1=1.0L; number2=0.0L;
    printf("remquol(%.2Lf,%.2Lf,&quo)=%.2Lf quo=%i",number1,number2,remquol(number1,number2,&(quo)));
}

Output
Illustrates the remquol() function (IEEE version)
remquol(3.00,3.50,&quo)=-0.50 quo=1
remquol(1.00,2.00,&quo)=1.00 quo=0
remquol(1.00,0.00,&quo)=NaNQ(1) quo=0

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td>z/OS V1.11</td>
</tr>
</tbody>
</table>

Format

#define __STDC_WANT_DEC_FP__
#include <math.h>

Decimal32 __remquod32(_Decimal32 x, _Decimal32 y, int *quo);
Decimal64 __remquod64(_Decimal64 x, _Decimal64 y, int *quo);
Decimal128 __remquod128(_Decimal128 x, _Decimal128 y, int *quo);

General description

The __remquo() functions compute the same remainder as the remainder functions. In the object pointed to by quo they store a value whose sign is the sign of x or y and whose magnitude is congruent modulo 2 to the power n to the magnitude of the integral quotient of x or y, where n is an implementation defined integer greater than or equal to 3.

Notes:
1. These functions work in IEEE decimal floating-point format. See "IEEE decimal floating-point" on page 95 for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

The __remquo() functions return x REM y.

Example

/* CELEBR24

   This example illustrates the __remquod64() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
void main() {
   _Decimal64 x, y, z;
   int n;
   x = 3.000D;
   y = 3.500D;
   z = __remquod64(x, y, &n);
   printf("__remquod64( %Df, %Df, %d ) = %Df\n", x, y, n, z);
}

rename() — Rename file

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <stdio.h>

int rename(const char *oldname, const char *newname);
```

General description

Changes the name of the file, from the name pointed to by `oldname` to the name pointed to by `newname`.

The `oldname` pointer must point to the name of an existing file. The `newname` pointer must not specify the name of an existing file. You cannot rename an open file. In case of an error, the name of the file is not changed.

The `rename()` function renames memory files and DASD data sets. (Non-DASD data sets, such as tapes, are not supported.) It also renames individual members of PDSs (and PDSEs); it even renames files that simulate PDSs.

**Special behavior for POSIX C:**

Memory files must be closed unless you are working under z/OS UNIX services.

The interpretation of the file name passed to `rename()` depends on whether the program is running POSIX(ON) or POSIX(OFF).

You cannot rename an HFS file to an MVS data set name or rename an MVS data set to an HFS file name.

Both `oldname` and `newname` must be of the same type, that is, both directories or both files.

If `newname` already exists, it is removed before `oldname` is renamed to `newname`. Thus, if `newname` specifies the name of an existing directory, it must be an empty directory.

If the `oldname` argument points to a symbolic link, the symbolic link is renamed. If the `newname` argument points to a symbolic link, the link is removed and `oldname` is renamed to `newname`. `rename()` does not affect any file or directory named by the contents of the symbolic link.
rename

For rename() to succeed, the process needs write permission on the directory containing oldname and the directory containing newname. If oldname and newname are directories, rename() also needs write permission on the directories themselves.

If oldname and newname both refer to the same file, rename() returns successfully and performs no other action.

When rename() is successful, it updates the change and modification times for the parent directories of oldname and newname.

Returned value

If successful, rename() returns 0.

If unsuccessful, rename() returns nonzero and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>
| EACCES     | An error occurred for one of these reasons:
  • The process did not have search permission on some component of the old or new path name.
  • The process did not have write permission on the parent directory of the file or directory to be renamed.
  • oldname or newname were directories.
  • The process did not have write permission on oldname or newname. |
| EBUSY      | oldname and newname specify directories, but one of them cannot be renamed because it is in use as a root or a mount point. |
| EINVAL     | This error occurs for one of these reasons:
  • oldname is part of the path name prefix of newname.
  • oldname or newname refers to either . (dot) or .. (dot-dot). |
| EIO        | A physical I/O error has occurred. |
| EISDIR     | newname is a directory, but oldname is not a directory. |
| ELOOP      | A loop exists in symbolic links. This error is issued if the number of symbolic links encountered during resolution of oldname or newname is greater than POSIX_SYMLOOP. |
| ENAMETOOLONG | pathname is longer than PATH_MAX characters, or some component of pathname is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined using pathconf(). |
| ENOENT     | No file or directory named oldname was found, or either oldname or newname was not specified. |
| ENOSPC     | The directory intended to contain newname cannot be extended. |
| ENOTDIR    | A component of the path name prefix for oldname or newname is not a directory, or oldname is a directory and newname is a file that is not a directory. |
**rename**

**ENOTEMPTY**  `newname` specifies a directory, but the directory is not empty.

**EPERM** or **EACCES**  
The S_ISVTX flag is set on the directory containing the file referred to by `oldname` and the caller is not the file owner, nor is the caller the directory owner, nor does the caller have appropriate privileges; or `newname` refers to an existing file, the S_ISVTX flag is set on the directory containing this file and the caller is not the file owner, nor is the caller the directory owner, nor does the caller have appropriate privileges.

**EROF S**  Renaming would require writing on a read-only file system.

**EXDEV**  `oldname` and `newname` identify files or directories on different file systems. z/OS UNIX services do not support links between different file systems.

### Example

**CELEBR13:**

```c
/* CELEBR13
   This example takes two file names as input and uses rename() to change
   the file name from the first name to the second name.
*/
#include <stdio.h>
int main(int argc, char ** argv )
{
    if ( argc != 3 )
        printf( "Usage: %s old_fn new_fn\n", argv[0] );
    else if ( rename( argv[1], argv[2] ) != 0 )
        printf( "Could not rename file\n" );
}
```

res_init

res_init() — Domain name resolver initialization

General description
The _res_init() function is the Resolver function that initializes the __res_state structure for use by other Resolver functions. Initialization normally occurs on the first call to any of the IP address resolution routines commonly called the XL C/C++ Run-Time Library Resolver.

The _res_init() routine does its initialization by passing the __res_state structure to the CS for z/OS Resolver. The Resolver reads the "TCPIP.DATA" configuration file and updates the __res_state structure. The data in the __res_state structure is filled in based on the contents of the "TCPIP.DATA" configuration file and can then be referenced in the _res variable. Global configuration and state information that is used by the Resolver routines is kept in the structure __res. Most of the values have reasonable defaults and can be left unchanged.

Value Description
_res.retrans Retransmission time interval is taken from the ResolverTimeout statement found in the "TCPIP.DATA" configuration file.
_res.retry The number of times to retransmit a request. It is taken from the ResolverUDPRetries statement found in the "TCPIP.DATA" configuration file.
_res.options Options stored in _res.options are defined in <resolv.h> and are listed below. Options are stored as a simple bit mask containing the bitwise OR of the options enabled.

Option Description
RES_INIT True after the initial name server address and default domain name are initialized, because _res_init() has been called. This option should only be tested but not set, except by the _res_init() function.
RES_DEBUG Print debugging messages.
RES_AAAONLY Accept authoritative answers only. With this option, res_send() should continue until it finds an authoritative answer or finds an error. Currently this is not implemented.
res_init

RES_USEVC Use TCP connections for queries instead of UDP datagrams.

RES_STAYOPEN
Used with RES_USEVC to keep the TCP connection open between queries. This is useful only in programs that regularly do many queries. UDP should be the normal mode used.

RES_IGNTC Ignore truncation errors, that is, don't retry with TCP. Currently unused.

RES_RECURSE
Set the recursion-desired bit in queries. This is the default. (res_send() does not do iterative queries and expects the name server to handle recursion.)

RES_DEFNAMES
If set, res_search() will append the default domain name to single-component names (those that do not contain a dot). This option is enabled by default.

RES_DNSRCH
If this option is set, res_search() will search for host names in the current domain and in parent domains. This is used by the standard host lookup routine gethostbyname(). This option is enabled by default.

RES_NOALIASES
This option turns off the user level aliasing feature controlled by the "HOSTALIASES" environment variable. Network daemons should set this option.

_res.nscout The number of name servers specified in the "TCPIP.DATA" configuration file.

_res.*nsaddr_list[0] The addresses of name servers specified by the NSINTERADDR or NameServer statements found in the "TCPIP.DATA" configuration file.

_res.dnsrch[0] The beginning of the list of domains to be searched, as specified in the SEARCH statement found in the "TCPIP.DATA" configuration file. The structure will have either a Default DOMAIN or SEARCH.

_res.defdname[0] The Default Domain name, as specified in the Domain or DomainOrigin statement found in the "TCPIP.DATA" configuration file. The structure will have either a Default DOMAIN or SEARCH.

_res.pfcode Currently this is not implemented.

_res.ndots The threshold for the number of dots in the domain name, as specified by the OPTIONS statement value ndots:n found in the "TCPIP.DATA" configuration file. The default is 1.

_res.nsort The number of elements in sort_list[] as listed in the SORTLIST statement found in the "TCPIP.DATA" configuration file.

_res.sort_list[0] The network address and subnet mask in the SORTLIST statement found in the "TCPIP.DATA" configuration file.
res_init

Returned value

If successful, res_init() returns 0.

If unsuccessful, res_init() returns -1 and sets h_errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO_RECOVERY</td>
<td>An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the _res structure.</td>
</tr>
<tr>
<td>TRY_AGAIN</td>
<td>An error occurred while initializing the __res_state structure name selected, which can be retried.</td>
</tr>
</tbody>
</table>

If successful, _res returns the address of __res_state structure.

If unsuccessful, _res returns NULL and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>The storage needed to define the _res structure could not be obtained.</td>
</tr>
</tbody>
</table>

res_mkquery() — Make resolver query for domain name servers

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSD 4.3</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_mkquery(int op, const char *dname, int class, int type, const u_char *data,
    int datalen, const u_char *newrr_in, u_char *buf, int buflen);
```

General description

This routine is one of several functions used for making, sending and interpreting query and reply messages with Internet domain name servers (DNS).

The res_mkquery() function constructs a standard query message and places it in `buf`. It returns the size of the query, or -1 if the query is larger than `buflen`. The query type `op` is usually QUERY, but can be any of the query types defined in `<arpa/nameser.h>`. The domain name for the query given by `dname`. The argument `newrr_in` is currently unused but is intended for making update messages.

**Note:** The res_mkquery() function has a dependency on the level of the Enhanced ASCII Extensions. See [Enhanced ASCII support](#) on page 2543 for details.

Returned value

If successful, res_mkquery() returns the size of the query.

If unsuccessful, res_mkquery() returns -1. The errors defined in `<arpa/nameser.h>` can be found in the `buf.rcode`, if an answer was supplied in the `buf` buffer.

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSD 4.3</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
</tbody>
</table>

### Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_query(const char *dname, int class, int type, u_char *answer, int anslen);
```

### General description

This routine is one of several functions used for making, sending and interpreting query and reply messages with Internet domain name servers (DNS).

The res_query() function provides an interface to the server query mechanism. It constructs a query, sends it to the local server, awaits a response, and makes preliminary checks on the reply. The query requests information of the specified type and class for the specified fully-qualified domain name `dname`. The reply message is left in the `answer` buffer with length `anslen` supplied by the caller.

**Note:** The res_query() function has a dependency on the level of the Enhanced ASCII Extensions. See [Enhanced ASCII support](#) on page 2543 for details.

### Returned value

If successful, res_query() returns the reply message in the `answer` buffer with length `anslen`.

If unsuccessful, res_query() returns -1 and sets herrno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOST_NOT_FOUND</td>
<td>The host name provided is not known at any of the domain name servers queried for this request.</td>
</tr>
<tr>
<td>NO_DATA</td>
<td>An answer was received but no data was supplied in the <code>answer</code> buffer.</td>
</tr>
<tr>
<td>NO_RECOVERY</td>
<td>An error occurred that will continue to fail if tried again.</td>
</tr>
<tr>
<td>TRY_AGAIN</td>
<td>A error occurred querying the name selected, which can be retried.</td>
</tr>
</tbody>
</table>

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_querydomain(const char *name, const char *domain, int class, int type,
                     u_char *answer, int anslen);
```

General description

This routine is one of several functions used for making, sending and interpreting query and reply messages with Internet domain name servers (DNS).

The res_querydomain() function builds a fully qualified domain name and returns a res_query() to the caller.

**Note:** The res_querydomain() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2543 for details.

Returned value

If successful, res_querydomain() returns a res_query() to the caller.

If unsuccessful, res_querydomain() returns -1 and sets herrno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOST_NOT_FOUND</td>
<td>The host name provided is not known at any of the domain name servers queried for this request.</td>
</tr>
<tr>
<td>NO_DATA</td>
<td>An answer was received but no data was supplied in the answer buffer.</td>
</tr>
<tr>
<td>NO_RECOVERY</td>
<td>An error occurred that will continue to fail if tried again.</td>
</tr>
<tr>
<td>TRY_AGAIN</td>
<td>A error occurred querying the name selected, which can be retried.</td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_search(const char *dname, int class, int type, u_char *answer, int anslen);
```

General description

This routine is one of several functions used for making, sending and interpreting query and reply messages with Internet domain name servers (DNS).

The res_search() routine makes a query and awaits a response like res_query() but, in addition, it implements the default and search rules controlled by the RES_DEFNAMES and RES_DNSRCH options. It returns the first successful reply.

**Note:** The res_search() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2543 for details.

Returned value

If successful, res_search() returns the first successful reply.

If unsuccessful, res_search() returns -1 and sets herrno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOST_NOT_FOUND</td>
<td>The host name provided is not known at any of the domain name servers queried for this request.</td>

</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_send(const u_char *msg, int msglen, u_char *answer, int anslen);
```

General description

This routine is one of several functions used for sending query and reply messages with Internet domain name servers (DNS).

The res_send() routine sends a pre-formatted query and returns an answer. It will call res_init() if RES_INIT is not set, send the query to the local name server, and handle timeouts and retries. The length of the reply message is returned, or -1 if there were errors.

**Note:** The res_send() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support " on page 2543 for details.

Returned value

If successful, res_send() returns the length of the reply message.

If unsuccessful, res_send() returns -1. The errors defined in <arpa/nameser.h> can be found in the buf.rcode, if an answer was supplied in the answer buffer.

__reset_exception_handler

__reset_exception_handler() — Unregister an exception handler routine

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <__le_api.h>

int __reset_exception_handler(void);
```

General description

A nonstandard function that unregisters the 'Exception Handler' function, that was previously registered via the __set_exception_handler() function, for the current stack frame.

Returned value

If successful, __reset_exception_handler() returns 0. Otherwise, -1 is returned and errno is set to indicate the error. The following is a possible value for errno:

- EINVAL — No Exception Handler is registered in the current stack frame.

Related information

- "__set_exception_handler() — Register an exception handler routine" on page 1815
rewind

rewind() — Set file position to beginning of file

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Language Environment</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

void rewind(FILE *stream);
```

```c
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

void rewind_unlocked(FILE *stream);
```

General description

Repositions the file position indicator of the stream pointed to by stream. A call to rewind() is the same as the statement below, except that rewind() also clears the error indicator for the stream.

```c
(void) fseek(stream, 0L, SEEK_SET);
```

rewind_unlocked() is functionally equivalent to rewind() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

rewind() returns no values.

If an error occurs, errno is set. After the error, the file position does not change. The next operation may be either a read or a write operation.

Special behavior for XPG4.2:

The rewind() function returns -1 and sets errno to ESPIPE if the underlying file type for the stream is a PIPE or a socket.

Example

```c
CELEBR14:
/* CELEBR14

This example first opens a file myfile for input and output.
It writes integers to the file, uses &rewind. to reposition
the file pointer to the beginning of the file, and then reads
```
/*
#include <stdio.h>

int main(void)
{
    FILE *stream;
    int data1, data2, data3, data4;
    data1 = 1; data2 = -37;
    /* Place data in the file */
    stream = fopen("myfile.dat", "w");
    fprintf(stream, "%d %d\n", data1, data2);
    /* Now read the data file */
    rewind(stream);
    fscanf(stream, "%d", &data3);
    fscanf(stream, "%d", &data4);
    printf("The values read back in are: %d and %d\n", data3, data4);
}

Output:
The values read back in are: 1 and -37

rewinddir

rewinddir() — Reposition a directory stream to the beginning

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define_POSIX_SOURCE
#include <dirent.h>

void rewinddir(DIR *dir);
```

General description

Repositions an open directory stream to the beginning. `dir` points to a `DIR` object associated with an open directory.

The next call to `readdir()` reads the first entry in the directory. If the contents of the directory have changed since the directory was opened, a call to `rewinddir()` updates the directory stream so that a subsequent `readdir()` can read the new contents.

Returned value

`rewinddir()` returns no values.

Example

**CELEBR15:**

```c
/* CELEBR15

This example produces the contents of a directory by opening it, rewinding it, and closing it.

*/
#define_POSIX_SOURCE
#include <dirent.h>
#include <errno.h>
#include <sys/types.h>
#undef_POSIX_SOURCE
#include <stdio.h>

main() { 
  DIR *dir;
  struct dirent *entry;
  if ((dir = opendir("/")) == NULL) 
    perror("opendir() error");
  else {
    puts("contents of root:");
    while ((entry = readdir(dir)) != NULL) 
      printf("%s ", entry->d_name);
    rewinddir(dir);
    puts(" ");
    while ((entry = readdir(dir)) != NULL)
```

1710   z/OS V1R13.0 XL C/C++ Run-Time Library Reference
rewinddir

```c
    printf("%s ", entry->d_name);
    closedir(dir);
    puts("\n");
}
```

Output:

contents of root:
```
  .. bin dev etc lib tmp u usr
  .. bin dev etc lib tmp u usr
```

rexec

rexec() — Execute commands one at a time on a remote host

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```
#include <rexec.h>

int rexec(char **Host, int Port, char *User, char *Password,
           char *Command, int *ErrFileDescParam)
```

General description

The rexec (remote execution) subroutine allows the calling process to execute
commands on a remote host. If the rexec connection succeeds, a socket in the
Internet domain of type SOCK_STREAM is returned to the calling process and is
given to the remote command as standard input and standard output.

Host contains the name of a remote host that is listed in the /etc/hosts file or
/etc/resolv.config file. If the name of the host is not found in either file, the rexec
fails.

Port specifies the well-known Defense Advanced Research Projects Agency
(DARPA) Internet port to use for the connection. A pointer to the structure that
contains the necessary port can be obtained by issuing the following library call:
getservbyname("exec","tcp").

User and Password points to a user ID and password valid at the host. Password
phrases are not supported.

Command points to the name of the command to be executed at the remote host.

ErrFileDescParam specifies one of the following values:

- Not 0 (zero) = an auxiliary channel to a control process is set up, and a
descriptor for it is placed in the ErrFileDescParam parameter. The control
process provides diagnostic output from the remote command on this channel
and also accepts bytes as signal numbers to be forwarded to the process group
of the command. This diagnostic information does not include remote
authorization failure, since this connection is set up after authorization has been
verified.
- 0 (zero) = the standard error of the remote command is the same as standard
output, and no provision is made for sending arbitrary signals to the remote
process. In this case, however, it may be possible to send out-of-band data to
the remote command.

This function is supported only in a POSIX program.

**Note:** The rexec() function has a dependency on the level of the Enhanced ASCII
Extensions. See [Enhanced ASCII support on page 2543](#) for details.
Returned value

If `rexec()` is successful, the system returns a socket to the remote command.

If `rexec()` is unsuccessful, the system returns a −1 indicating that the specified host name does not exist.

Related information

- "rexec.h" on page 61
- "getservbyname() — Get a server entry by name" on page 873
- "rexec_af() — Execute commands one at a time on a remote host" on page 1714
rexec_af

rexec_af() — Execute commands one at a time on a remote host

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RCF2292</td>
<td>both</td>
<td>z/OS V1R4</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_IPV6
#include <rexec.h>

int rexec_af(char **ahost, unsigned short rport,
              const char *name, const char *pass, const char *cmd,
              int *fd2p, int af);
```

General description

The rexec_af() function behaves the same as the rexec() function. Instead of creating an AF_INET socket, rexec_af can also create an AF_INET6 socket. The `af` argument specifies the address family. It is set to either AF_INET or AF_INET6.

Note: The rexec_af() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2543 for details.

Returned value

When successful, rexec_af() returns a socket to the remote command. If unsuccessful, rexec_af() returns -1 and may set errno to one of the following:

- **EAFNOSUPPORT**
  The specified address family is not supported.

Related information

- "rexec.h" on page 61
- "getservbyname() — Get a server entry by name" on page 873
- "rexec() — Execute commands one at a time on a remote host" on page 1712
rindex() — Search for character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

cchar *rindex(const char *string, int c);
```

General description

The rindex() function locates the last occurrence of `c` (converted to an unsigned char) in the string pointed to by `string`.

The string argument to the function must contain a NULL character (\0) marking the end of the string.

The rindex() function is identical to `strchr() — Find last occurrence of character in string` on page 2089.

**Note:** The rindex() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `strchr()` function is preferred for portability.

Returned value

If successful, rindex() returns a pointer to the first occurrence of `c` (converted to an unsigned character) in the string pointed to by `string`.

If `c` was not found, rindex() returns a NULL pointer.

There are no errno values defined.

Related information

- "strings.h" on page 71

rint

rint(), rintf(), rintl() — Round to nearest integral value

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double rint(double x);

C99:
#define _ISOC99_SOURCE
#include <math.h>

float rintf(float x);
long double rintl(long double x);

C++ TR1 C99:
#define _TR1_C99
#include <math.h>

float rint(float x);
long double rintl(long double x);
```

General description

The rint() functions return the integral value (represented in a floating-point mode) nearest \( x \) using the round to nearest mode and may raise the “inexact” floating-point exception if the result differs in value from the argument.

**Note:** The following table shows the viable formats for these functions. See [IEEE binary floating-point on page 94](#) for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>rint</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>rintf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>rintl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned value

rint() is always successful in IEEE.

**Special behavior for hex:**

The rint() functions always round toward zero in hexadecimal math.
Related information

- "math.h" on page 43
- "abs(), absf(), absl() — Calculate integer absolute value" on page 104
- "isnan() — Test for NaN" on page 1056
rintd32(), rintd64(), rintd128() — Round to nearest integral value

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.8</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  rintd32(_Decimal32  x);
_Decimal64  rintd64(_Decimal64  x);
_Decimal128 rintd128(_Decimal128 x);

_Decimal32  rint(_Decimal32  x); /* C++ only */
_Decimal64  rint(_Decimal64  x); /* C++ only */
_Decimal128 rint(_Decimal128 x); /* C++ only */
```

General description

These functions return the integral value (represented in a decimal floating-point mode) nearest x according to the rounding mode and might raise the “inexact” decimal floating-point exception if the result differs in value from the argument.

Notes:
1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

These functions are always successful.

Example

```c
/* CELEBR21
   This example illustrates the rintd32() function.
*/

#pragma strings(readonly)
#define __STDC_WANT_DEC_FP__
#include <fenv.h>
#include <math.h>
#include <stdio.h>

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define_POSIX_SOURCE
#include <unistd.h>

int rmdir(const char *pathname);
```

General description

Removes a directory, `pathname`, provided that the directory is empty. `pathname` must not end in . (dot) or .. (dot-dot).

If `pathname` refers to a symbolic link, `rmdir()` does not affect any file or directory named by the contents of the symbolic link. `rmdir()` does not remove a directory that still contains files or subdirectories.

**Special behavior for XPG4.2:**

If `pathname` refers to a symbolic link, `rmdir()` fails and sets errno to ENOTDIR.

If no process currently has the directory open, `rmdir()` deletes the directory itself. The space occupied by the directory is freed for new use. If one or more processes have the directory open when it is removed, the directory itself is not removed until the last process closes the directory. New files cannot be created under a directory after the last link is removed, even if the directory is still open.

`rmdir()` removes the directory even if it is the working directory of a process.

If `rmdir()` is successful, the change and modification times for the parent directory are updated.

Returned value

If successful, `rmdir()` returns 0.

If unsuccessful, `rmdir()` returns −1 and sets errno to one of the following values:

<table>

<tbody>
<tr>
<td>EACCES</td>
<td>The process did not have search permission for some component of <code>pathname</code>, or it did not have write permission for the directory containing the directory to be removed.</td>
</tr>
<tr>
<td>EBUSY</td>
<td><code>pathname</code> cannot be removed, because it is currently being used by the system or a process.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The last component of <code>pathname</code> contains a . (dot) or a .. (dot-dot).</td>
</tr>
<tr>
<td>EIO</td>
<td>A physical I/O error has occurred.</td>
</tr>
</tbody>
</table>
ELOOP A loop exists in symbolic links. More than POSIX_SYMLOOP (an integer defined in the limits.h header file) symbolic links are detected in the resolution of *pathname*.

ENAMETOOLONG *pathname* is longer than **PATH_MAX** characters or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using pathconf().

ENOENT *pathname* does not exist, or it is an empty string.

ENOTDIR Some component of the *pathname* prefix is not a directory.

ENOTEMPTY The directory still contains files or subdirectories.

EPERM or EACCES The S_ISVTX flag is set on the parent directory of the directory to be removed and the caller is not the owner of the directory to be removed, nor is the caller the owner of the parent directory, nor does the caller have the appropriate privileges.

EROFS The directory to be removed is on a read-only file system.

Example

**CELEBR16:**
/* CELEBR16

This example removes a directory.

*/
#define _OPEN_SYS
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char new_dir[]="new_dir";
    char new_file[]="new_dir/new_file";
    int fd;

    if (mkdir(new_dir, S_IRWXU|S_IRGRP|S_IXGRP) != 0)
        perror("mkdir() error");
    else if ((fd = creat(new_file, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        unlink(new_file);
    }

    if (rmdir(new_dir) != 0)
        perror("rmdir() error");
    else
        puts("removed!");}
rmdir

C++ TR1 C99:
#define _TR1_C99
#include <math.h>

float round(float x);
long double roundl(long double x);
```

General description

The round() family of functions round $x$ to the nearest integer, in floating-point format and rounding halfway cases away from zero, regardless of the current rounding mode.

Note: The following table shows the viable formats for these functions. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>

rpmatch()

— Test for a yes or no response match

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>
int rpmatch(const char *response);
```

External entry point:

@RPMATCH, __rpmatch

General description

Tests whether a string pointed to by `response` matches either the affirmative or the negative response set by LC_MESSAGES category in the current locale.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Returned value

If the string pointed to by `response` matches the affirmative expression in the current locale, `rpmatch()` returns:

-1 If the response string does not match either the affirmative or the negative expression.

Example

**CELEBR17:**

```c
#include "locale.h"
#include "stdio.h"
#include "stdlib.h"

main() {
    char *response;
    char buffer??(100??);
```
```c
int rc;
printf("Enter reply");
response = fgets(buffer, 100, stdin);
rc = rpmatch(response);
if (rc > 0)
    printf("Response was affirmative\n");
else if (rc == 0)
    printf("Response was negative\n");
else
    printf("Response was neither negative or affirmative\n");
```

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.8</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Bool samequantumd32(_Decimal32 x, _Decimal32 y);
_Bool samequantumd64(_Decimal64 x, _Decimal64 y);
_Bool samequantumd128(_Decimal128 x, _Decimal128 y);
```

General description

The samequantum functions determine if the representation exponents of x and y are the same. If both x and y are NaN or infinity, they have the same representation exponents. If exactly one operand is infinity or exactly one operand is NaN, they do not have the same representation exponents. The samequantum functions raise no floating point exceptions.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>First input value</td>
</tr>
<tr>
<td>y</td>
<td>Second input value</td>
</tr>
</tbody>
</table>

Note:
- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The samequantum functions return true when x and y have the same representation exponents, and false otherwise.

Example

```c
/* CELEBS72

This example illustrates the samequantumd64() function
*/

#define __STDC_WANT_DEC_FP__

sbrk

sbrk() — Change space allocation

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

Non-Single UNIX Specification, Version 2:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

void *sbrk(int incr);
```

Single UNIX Specification, Version 2:

```c
#define _XOPEN_SOURCE 500
#include <unistd.h>

void *sbrk(intptr_t incr);
```

General description

**Restriction:** This function is not supported in AMODE 64.

The sbrk() function is used to change the space allocated for the calling process. The change is made by adding incr bytes to the process's break value and allocating the appropriate amount of space. The amount of allocated space increases when incr is positive and decreases when incr is negative. If incr is zero the current value of the program break is returned by sbrk(). The newly-allocated space is set to 0. However, if the application first decrements and then increments the break value, the contents of the reallocated space are not zeroed.

The storage space from which the brk() and sbrk() functions allocate storage is separate from the storage space that is used by the other memory allocation functions (malloc(), calloc(), etc.). Because this storage space must be a contiguous segment of storage, it is allocated from the initial heap segment only and thus is limited to the initial heap size specified for the calling program or the largest contiguous segment of storage available in the initial heap at the time of the first brk() or sbrk() call. Since this is a separate segment of storage, the brk() and sbrk() functions can be used by an application that is using the other memory allocation functions. However, it is possible that the user's region may not be large enough to support extensive usage of both types of memory allocation.

Prior usage of the sbrk() function has been limited to specialized cases where no other memory allocation function performed the same function. Because the sbrk() function may be unable to sufficiently increase the space allocation of the process when the calling application is using other memory functions, the use of other memory allocation functions, such as mmap(), is now preferred because it can be used portably with all other memory allocation functions and with any function that uses other allocation functions. Applications that require the use of brk() and/or sbrk() should refrain from using the other memory allocation functions and should be run with an initial heap size that will satisfy the maximum storage requirements of the program.
The sbrk() function is not supported from a multithreaded environment, it will return in error if it is invoked in this environment.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use malloc() instead of brk() or sbrk().

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, sbrk() returns the previous break value.

If unsuccessful, sbrk() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>The requested change would allocate more space than allowed for the calling process.</td>
</tr>
</tbody>
</table>

scalb

scalb() — Load exponent

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double scalb(double x, double n);
```

General description

The scalb() function computes

\[ x \times r \]

If \( n \) is not an integer, it is silently truncated.

**Note:** This function works in both IEEE Binary Floating-Point and hexadecimal floating-point formats. The \( r \) is 16 for hexadecimal floating-point and 2 for IEEE Binary Floating-Point. See "IEEE binary floating-point " on page 94 for more information about IEEE Binary Floating-Point.

Returned value

If it succeeds, scalb() returns the function of its arguments as described above.

scalb() will fail under the following conditions:

- If the result would underflow, scalb() will return 0 and set errno to ERANGE.
- If the result would overflow, scalb() will return ±HUGE_VAL according to the sign of \( x \) and set errno to ERANGE.

**Special behavior for IEEE:** If successful, scalb() returns the value of the \( x \) parameter times 2 to the power of the \( y \) parameter.

If the result would overflow, scalb() returns ±HUGE_VAL according to the sign of \( x \) and sets errno to ERANGE. No other errors can occur.

</tr>
</tbody>
</table>

Format

```c
#define _UNIX03_SOURCE
#include <sched.h>

int sched_yield(void);
```

General description

The sched_yield() function allows a thread to give up control of a processor so that another thread can have the opportunity to run. It takes no arguments.

The speed at which the sched_yield() function releases a processor can be configured by using the _EDC_PTHREAD_YIELD and _EDC_PTHREAD_YIELD_MAX environment variables. The _EDC_PTHREAD_YIELD environment variable is used to configure the sched_yield() function to release the processor immediately, or to release the processor after a delay. The _EDC_PTHREAD_YIELD_MAX environment variable is used to change the maximum delay to a value less than the default (32 milliseconds).

For more information about the _EDC_PTHREAD_YIELD and _EDC_PTHREAD_YIELD_MAX environment variables, see the topic about using environment variables in z/OS XL C/C++ Programming Guide.

Returned value

sched_yield() always returns 0.

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

**Format**

```c
#define _XOPEN_SOURCE
#include <stdlib.h>

unsigned short int *seed48(unsigned short int seed16v[3]);
```

**General description**

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The lcong48(), seed48(), and srand48() functions are initialization functions, one of which should be invoked before either the drand48(), lrand48() or mrand48() function is called.

The drand48(), lrand48() and mrand48() functions generate a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

\[
X(n+1) = (aX(n) + c) \mod (2^{48}) \quad n \geq 0
\]

The initial values of X, a, and c are:

- \( X(0) = 1 \)
- \( a = 5deece66d \) (base 16)
- \( c = b \) (base 16)

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The seed48() function is used to reinitialize the most recent 48-bit value in this storage. The seed48() function replaces the low-order (rightmost) 16 bits of this storage with seed16v[0], the middle-order 16 bits with seed16v[1], and the high-order 16 bits with seed16v[2].

The values a and c, may be changed by calling the lcong48() function. The seed48() function restores the initial values of a and c.

**Special behavior for z/OS UNIX Services:** You can make the seed48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.
If thread-specific behavior is requested, calls to the drand48(), lrand48() and mrand48() functions from thread t generate a sequence of 48-bit integer values, X(t,i), according to the linear congruential formula:

\[ X(t,n+1) = (a(t)X(t,n) + c(t)) \mod (2^{48}) \quad n \geq 0 \]

C/370 provides thread-specific storage to save the most recent 48-bit integer value of the sequence, X(t,i). When the seed48() function is called from thread t, it reinitializes the most recent 48-bit value in this storage. The seed48() function replaces the low-order (rightmost) 16 bits of this storage with seed16v[0], the middle-order 16 bits with seed16v[1], and the high-order 16 bits with seed16v[2].

The values of a(t) and c(t) may be changed by calling the lcong48() function from thread t. When the seed48() function is called from this thread, it restores the initial values of a(t) and c(t) for the thread which are:

\[
\begin{align*}
a(t) &= 5\text{dece66d (base 16)} \\
c(t) &= b \quad (base 16)
\end{align*}
\]

**Returned value**

When seed48() is called, it saves the most recent 48-bit integer value in the sequence, X(i), in an array of unsigned short ints provided by C/370 before reinitializing storage for the most recent value in the sequence, X(i). seed48() returns a pointer to the array containing the saved value.

**Special behavior for z/OS UNIX Services:** If thread-specific behavior is requested for the drand48 family and seed48() is called on thread t, it saves the most recent 48-bit integer value in the sequence, X(t,i), for the thread in a thread-specific array of unsigned short ints before reinitializing storage for the most recent value in the sequence, X(t,i). seed48() returns a pointer to this thread-specific array containing the saved value.

seekdir() — Set position of directory stream

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <dirent.h>

void seekdir(DIR *dirp, long int loc);
```

General description

The seekdir() function sets the position of the next readdir() operation on the directory stream specified by `dirp` to the position specified by `loc`. The value of `loc` should have been returned from an earlier call to telldir(). The new position reverts to the one associated with the directory stream when telldir() was performed. If the value of `loc` was not obtained from an earlier call to telldir() or if a call to rewinddir() occurred between the call to telldir() and the call to seekdir(), the result of subsequent calls to readdir() are unspecified.

**Note:** If files were added or removed from the directory after telldir() was called and before seekdir() is done, the results are also unspecified.

Returned value

seekdir() returns no values.

If the `loc` argument is negative, the directory stream is unchanged.

<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#define _OPEN_MSGQ_EXT
#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>

int select(int nmsgsfds, fd_set *__restrict__ readlist,
           fd_set *__restrict__ writelist, fd_set *__restrict__ exceptlist,
           struct timeval *__restrict__ timeout);
```

SUSV3:

```c
#define _POSIX_C_SOURCE 200112L
#include <sys/select.h>

int pselect(int nmsgsfds, fd_set *__restrict__ readlist,
            fd_set *__restrict__ writelist, fd_set *__restrict__ exceptlist,
            const struct timespec *__restrict__ timeout,
            const sigset *__restrict__ sigmask);
```

Berkeley sockets:

```c
#define _OE_SOCKETS
#define _OPEN_MSGQ_EXT
#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>

int select(int nmsgsfds, fd_set *readlist,
           fd_set *writelist, fd_set *exceptlist,
           struct timeval *timeout);
```

_OPEN_MSGQ_EXT must be defined if message queues are to be monitored (X/Open sockets only).

General description

The pselect() and select() functions monitor activity on a set of sockets and/or a set of message queue identifiers until a timeout occurs, to see if any of the sockets and message queues have read, write, or exception processing conditions pending. This call also works with regular file descriptors, pipes, and terminals.

The select() function is equivalent to the pselect() function, except as follows:

- For the select() function, the timeout period is given in seconds and microseconds in an argument of type struct timeval, whereas for the pselect() function the timeout period is given in seconds and nanoseconds in an argument of type struct timespec.
The select() function has no `sigmask` argument; it will behave as pselect() does when `sigmask` is a null pointer.

Upon successful completion, the select() function can modify the object pointed to by the timeout argument.

The pselect() function always behaves as if `_OPEN_MSGQ_EXT` and `_OPEN_SYS_HIGH_DESCRIPTORS` feature test macros are NOT defined.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `nmsgsfds` | The number of message queues and the number of file or socket descriptors to check. This parameter is divided into two parts. The first half (the high-order 16 bits) gives the number of elements of an array that contains message queue identifiers. This number must not exceed the value 32767. The second half (the low-order 16 bits) gives the number of bits within a bit set that correspond to the file or socket descriptors to check. This value should equal the greatest descriptor number to check + 1. If either half of the `nmsgsfds` parameter is equal to a value of 0, the corresponding bit sets or arrays are assumed not to be present. If `_OPEN_MSGQ_EXT` is not defined, only file or socket descriptors may be monitored. In this case `nmsgsfds` must be less than or equal to `FD_SETSIZE` (defined to be 2048 in `sys/time.h`), and greater than or equal to zero. Also, `FD_SETSIZE` may not be defined by your program. The bit set used to specify file or socket descriptors is fixed in size with 1 bit for every possible file or socket. Use the `nmsgsfds` parameter to force pselect() or select() to check only a subset of the allocated bit set. If your application allocates sockets 3, 4, 5, 6, and 7 and you want to check all of your allocations, the second half of `nmsgsfds` should be set to 8, the highest descriptor you specified + 1. If your application checks sockets 3 and 4, the second half of `nmsgsfds` should be set to 5. To select on descriptor numbers between 2048 and 65534, either the `_OPEN_MSGQ_EXT` or `_OPEN_SYS_HIGH_DESCRIPTORS` feature test macro must be defined, and a bit set larger than the default size must be used. Note that when you are also selecting on message queues, as is possible when `_OPEN_MSGQ_EXT` is defined, the largest descriptor number is restricted to 2047. To select on descriptor numbers between 65535 and 524287, feature test macro `_OPEN_SYS_HIGH_DESCRIPTORS` must be defined and feature test macro `_OPEN_MSGQ_EXT` must not be defined. In addition, the process' MAXFILEPROC limit must be greater than 65536. With this feature, any number of sockets can be selected on (without message queues). `FD_SETSIZE` may also be redefined in this case, though it is recommended that the application explicitly allocate the larger bit set using malloc().

`readlist`, `writelist`, `exceptlist`  
Pointers to `fd_set` types, arrays of message queue identifiers, or `sellist` structures to check for reading, writing, and exceptional
conditions, respectively. The type of parameter to pass depends on whether you want to monitor file/socket descriptors, message queue identifiers, or both. To monitor file/socket descriptors only, set the high-order halfword of `nmsgsfds` to 0, the low-order halfword to (highest descriptor number + 1), and use `fd_set` pointers. To monitor message queues only, set the low-order halfword of `nmsgsfds` to 0, the high-order halfword to the number of elements in each array you want `select()` to consider, and pass pointers to arrays of message queue identifiers. To monitor both, set `nmsgsfds` as described above, and pass pointers to `sellist` structures.

The `sellist` structure allows you to specify both file/socket descriptors and message queues. Your program must define the `sellist` structure in the following form:

```c
struct sellist {
    fd_set fdset;  /* file/socket descriptor bit set */
    int msgids[max_size]; /* array of message queue identifiers */
};
```

If you use a `sellist` structure, the highest descriptor you can monitor is 2047.

The description of the type `fd_set` is given below. Each integer of the `msgids` array specifies a message queue identifier whose status is to be checked. Elements with a value of -1 are acceptable and will be ignored. The value contained in the first half of `nmsgsfds` determines exactly how many elements of the array are to be checked.

`timeout`  The pointer to the time to wait for the `pselect()` or `select()` call to complete.

`sigmask`  The signal mask of the caller by the set of signals pointed to by `sigmask` before examining the descriptors, and will restore the signal mask of the calling thread before returning.

If `timeout` is not a NULL pointer, it specifies a maximum interval to wait for the selection to complete. The maximum timeout value is 31 days. If `timeout` is a NULL pointer, the `pselect()` and `select()` call blocks until a socket or message becomes ready. To poll the sockets and return immediately, `timeout` should be a non-NULL pointer to a zero-valued `timeval` structure or `timespec` structure.

If `sigmask` is not a null pointer, then the `pselect()` function will replace the signal mask of the caller by the set of signals pointed to by `sigmask` before examining the descriptors, and will restore the signal mask of the calling thread before returning.

To allow you to test more than one socket at a time, the sockets to test are placed into a bit set of type `fd_set`. A bit set is a string of bits such that if `x` is an element of the set, the bit representing `x` is set to 1. If `x` is not an element of the set, the bit representing `x` is set to 0. For example, if socket 33 is an element of a bit set, then bit 33 is set to 1. If socket 33 is not an element of a bit set, then bit 33 is set to 0.

Because the bit sets contain a bit for every socket that a process can allocate, the size of the bit sets is constant. If your program needs to allocate a large number of sockets, you may need to increase the size of the bit sets. Increasing the size of the bit sets should be done when you compile the program. To increase the size of the bit sets, define `FD_SETSIZE` before including `sys/time.h`. `FD_SETSIZE` is the largest value of any socket that your program expects to use `pselect()` or `select()` on. It is defined to be 2048 in `sys/time.h`. 
**Note:** FD_SETSIZE may only be defined by the application program if the extended version of select() is used (by defining _OPEN_MSGQ_EXT). Do NOT define FD_SETSIZE in your program if a selld list structure will be used.

**Note:** The z/OS UNIX POSIX.1 implementation allows you to control the maximum number of open descriptors allowed per process. This maximum possible value is 524288. If your application program requires a large number of either socket or file descriptors, you should protect your code from possible run-time errors by:

- Adding a check before your pselect(), select() or selectex() calls to see if the bit set size contained in nmsgsfds is larger than FD_SETSIZE.
- Dynamically allocate bit strings large enough to hold the largest descriptor value in your application program, rather than rely on the static bit strings created at compile time. When allocating your own bit strings, use malloc() to define an area large enough to represent each bit, rounded up to the next 4-byte multiple. For example, if your largest descriptor value is 31, you need 4 bytes; if your largest descriptor is 32, you need 8 bytes.
- If you dynamically allocate your own bit strings, the FD_ZERO() macro will not work. The application must zero that storage, by using the memset function—that is, memset(ptr,0,mallocsize). The other macros can be used with the dynamically allocated bit strings, as long as the descriptor you are manipulating is within the bit string. If the descriptor number is larger than the bit string, unpredictable results can occur.

The application program must make sure that the parameters readlist, writelist, and exceptlist point to bit strings that are as large as the bit string size in parameter nmsgsfds z/OS UNIX services will try to access bits 0 through \( n-1 \) (where \( n \) = the value of the second halfword of nmsgsfds), for each of the bit strings. If the bit strings are too short, you will receive unpredictable results when you run your application program.

The following macros are provided to manipulate bit sets.

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
</table>
| FD_ZERO(&fdset) | Sets all bits in the bit set fdset to zero. After this operation, the bit set does not contain sockets as elements. This macro should be called to initialize the bit set before calling FD_SET() to set a socket as a member.  
**Note:** If you used malloc() to dynamically allocate a new area, the FD_ZERO() macro can cause unpredictable results and should not be used. You should zero the area using the memset() function. |
| FD_SET(sock, &fdset) | Sets the bit for the socket sock to a 1, making sock a member of the bit set fdset. |
| FD_CLR(sock, &fdset) | Clears the bit for the socket sock in bit set fdset. This operation sets the appropriate bit to a zero. |
| FD_ISSET(sock, &fdset) | Returns nonzero if sock is a member of the bit set fdset. Returns 0 if sock is not a member of fdset. (This operation returns the bit representing sock.) |
The following macros are provided to manipulate the `nmsgsfds` parameter and the return value from `pselect()` and `select()`:

### Macro Description

- **_SET_FDS_MSGS(nmsgsfds, nmsgs, nfds)**
  
  Sets the high-order halfword of `nmsgsfds` to `nmsgs`, and sets the low-order halfword of `nmsgsfds` to `nfds`.

- **_NFDS(n)**
  If the return value `n` from `pselect()` or `select()` is nonnegative, returns the number of descriptors that meet the read, write, and exception criteria. A descriptor may be counted multiple times if it meets more than one given criterion.

- **_NMSGS(n)**
  If the return value `n` from `pselect()` or `select()` is nonnegative, returns the number of message queues that meet the read, write, and exception criteria. A message queue may be counted multiple times if it meets more than one given criterion.

A socket is ready for reading when incoming data is buffered for it or when a connection request is pending. To test whether any sockets are ready for reading, use either `FD_ZERO()` or `memset()`, if the function was dynamically allocated, to initialize the fdset bit set in `readlist` and invoke `FD_SET()` for each socket to test.

A socket is ready for writing if there is buffer space for outgoing data. A socket is ready for reading if there is data on the socket to be received. For a nonblocking stream socket in the process of connecting the `connect()` will return with a -1. The program needs to check the `errno`. If the `errno` is `EINPROGRESS`, the socket is selected for write when the `connect()` completes. In the situation where the `errno` is not `EINPROGRESS`, the socket will still be selected for write which indicates that there is a pending error on the socket. A call to `write()`, `send()`, or `sendto()` does not block provided that the amount of data is less than the amount of buffer space. If a socket is selected for write, the amount of available buffer space is guaranteed to be at least as large as the size returned from using `SO_SNDBUF` with `getsockopt()`. To test whether any sockets are ready for writing, initialize the fdset bit set in `writelist` with either `FD_ZERO()` or `memset()`, if dynamically allocated, and use `FD_SET()` for each socket to test.

A message queue is ready for reading when any time it has a message on it. It is considered ready for writing when any time it is not full. A message queue is full when it has either reached its number of messages limit or its number of bytes limit. An exception condition exists when a message queue is deleted while a `select()` caller is waiting on the queue.

The programmer can pass NULL for any of the `readlist`, `writelist`, and `exceptlist` parameters. However, when they are not NULL, they must all point to the same type of structures. For example, suppose the `readlist` points to a sellist. If the `writelist` is not NULL, it must point to a sellist also. Now, let us say the `writelist` is not NULL. If the programmer wants to check a set of file descriptors for read status only, the appropriate bits in the bit set in the sellist structure pointed to by the `writelist` must be set to 0. If the programmer wants to check a set of message queues for write status only, the appropriate elements in the array in the sellist structure pointed to by the `readlist` must be set to -1. Regular files are always ready for reading and writing.

Because the sets of sockets passed to `pselect()` and `select()` are bit sets, the `pselect()` and `select()` call must test each bit in each bit set before polling the socket.
for its status. The pselect() and select() call tests only sockets in the range 0 to n-1 (where n = the value of the second halfword of nmsgsfds).

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

The value −1 indicates the error code should be checked for an error. The value zero indicates an expired time limit.

When the return value is greater than 0, then it is similar to nmsgsfds in that the high-order 16 bits give the number of message queues, and the low-order 16 bits give the number of descriptors. These values indicate the sum total that meet each of the read, write, and exception criteria. Note that a descriptor or a message queue may be counted multiple times if it meets more than one given criterion. Should the return value for message queues exceed the value 32767, only 32767 will be reported. This is to ensure that the return value does not appear to be negative. Should the return value for file/socket descriptors be greater than 65535, only 65535 will be reported.

If the return value is greater than 0, the files/socket s that are ready in each bit set are set to 1. Files/Sockets in each bit set that are not ready are set to zero. Use the macro FD_ISSET() with each file/socket to test its status. For those message queues that do not meet the conditions their identifiers in the msgsid arrays will be replaced with a value of -1.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>One of the bit sets specified an invalid socket or a message queue identifier is invalid. FD_ZERO() was probably not called to clear the bit set before the sockets were set.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>One of the parameters contained an invalid address.</td>
</tr>
<tr>
<td>EINTR</td>
<td>The pselect() or select() function was interrupted before any of the selected events occurred and before the timeout interval expired.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>One of the fields in the timeval structure or timespec structure is invalid, or there was an invalid nmsgsfds value.</td>
</tr>
<tr>
<td>EIO</td>
<td>One of the descriptors in the select mask has become inoperative and it is being repeatedly included in a select even though other operations against this descriptor have been failing with EIO. A socket descriptor, for example, can become inoperative if TCP/IP is shut down. When a descriptor fails a failure from select could not tell you which descriptor had failed so generally select will succeed and these descriptors will be reported to you as being ready for whatever events were specified on the select. Subsequently when the descriptor is used on a receive or other operation you will receive the EIO failure then and can react to the problem with the individual descriptor. In general you would close() the descriptor and remove it from the next select mask. If the individual descriptor's failing return code is ignored though and an inoperative descriptor is repeatedly selected on and used, even though each time it is used that call fails with EIO, eventually the select call itself will fail with EIO.</td>
</tr>
</tbody>
</table>
Note: The pselect() function can also return errno's set by the sigprocmask() function.

Example

In the following example, select() is used to poll sockets for reading (socket sr), writing (socket sw), and exception (socket se) conditions, and to check message queue ids mr, mw, and me.

```c
#define _XOPEN_SOURCE_EXTENDED 1
#define _OPEN_MSGQ_EXT

#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>

struct sellist {
  FD_set fdset;
  int msgids[2];
};

int sock_msg_stats(int sr, int sw, int se, int mr, int mw, int me)
{
  struct sellist *reading, *writing, *excepting;
  struct sellist read, write, except;
  struct timeval timeout;
  int rc, max_sock, sock_size, nmsgsfds;
  int msgids[1]; /* we only check 1 message queue */
  /* What's the maximum socket number? */
  max_sock = MAX( sr, sw);
  max_sock = MAX( max_sock, se);
  /* initialize the static bit sets */
  FD_ZERO( &read.fdset ); reading = &read;
  FD_ZERO( &write.fdset ); writing = &write;
  FD_ZERO( &except.fdset ); excepting = &except;
  /* add sr, sw, and se to the appropriate bit set */
  FD_SET( sr, &reading->fdset );
  FD_SET( sw, &writing->fdset );
  FD_SET( se, &excepting->fdset );
  /* initialize the message id arrays */
  reading->msgids[0] = mr;
  writing->msgids[0] = mw;
  excepting->msgids[0] = me;
  /* set the nmsgsfds parameter */
  _SET_FDS_MSGS( nmsgsfds, 1, max_sock+1 );
  /* make select poll by sending a 0 timeval */
  memset( &timeout, 0, sizeof(timeout) );
  /* poll */
  rc = select( nmsgsfds, reading, writing, excepting, &timeout);
  if ( rc < 0 ) { /* an error occurred during the SELECT() */
    perror( "select" );
  } else if ( rc == 0 ) {
```
/* no sockets or messages were ready in our little poll */
printf("nobody is home.\n");
} else
if (_NFDS(rc) > 0) {
    /* at least one of the sockets is ready */
    printf("sr is %s\n",
        FD_ISSET(sr,&reading->fdset) ? "READY" : "NOT READY");
    printf("sw is %s\n",
        FD_ISSET(sw,&writing->fdset) ? "READY" : "NOT READY");
    printf("se is %s\n",

selectex() — Monitor activity on files or sockets and message queues

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#define _ALL_SOURCE
#define _OPEN_MSGQ_EXT
#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>

int selectex(int nmsgsfds, fd_set *readlist, 
              fd_set *writelist, 
              fd_set *exceptlist, 
              struct timeval *timeout, int *ecbptr);
```

Berkeley sockets:

```c
#define _OE_SOCKETS
#define _ALL_SOURCE
#define _OPEN_MSGQ_EXT
#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>

int selectex(int nmsgsfds, fd_set *readlist, 
              fd_set *writelist, 
              fd_set *exceptlist, 
              struct timeval *timeout, int *ecbptr);
```

_OPEN_MSGQ_EXT must be defined if message queues are to be monitored (X/Open sockets only).

General description

The selectex() function provides an extension to the select() call by allowing you to use an ECB that defines an event not described by `readlist`, `writelist`, or `exceptlist`.

The selectex() call monitors activity on a set of files/sockets and message queues until a timeout occurs, or until the ECB is posted, to see if any of the files/sockets and message queues have read, write, or exception processing conditions pending.

When the storage key of the first (or only) ECB matches the caller's PSW key, the kernel performs the wait in the caller's PSW key; otherwise, the kernel performs the wait in the TCB key (TCBPFK). However, if the caller is running in key 0, then the kernel performs the wait in key 0, regardless of the storage key.

See select() for more information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nmsgsfds</td>
<td>The number of message queues and the number of file or socket descriptors to check. (Refer to select() for a full description of this and other parameters below.)</td>
</tr>
</tbody>
</table>
selectex

**Note:** This function is limited to descriptor numbers less than or equal to 65535.

`readlist`  
A pointer to an `fd_set` type, array of message queue identifiers, or `sellist` structure specifying descriptors and message queues to check for reading.

`writelist`  
A pointer to an `fd_set` type, array of message queue identifiers, or `sellist` structure specifying descriptors and message queues to check for writing.

`exceptlist`  
A pointer to an `fd_set` type, array of message queue identifiers, or `sellist` structure specifying descriptors and message queues to be checked for exceptional pending conditions.

`timeout`  
The pointer to the time to wait for the selectex() call to complete.

`ecbptr`  
This variable can contain one of the following values:

1. A pointer to a user event control block. To specify this usage of `ecbptr`, the high-order bit must be set to `'0'B`.
2. A pointer to a list of ECBs. To specify this usage of `ecbptr`, the high-order bit must be set to `'1'B`. The list can contain the pointers for up to 1013 ECBs. The high-order bit of the last pointer in the list must be set to `'1'B`.
3. A NULL pointer. This indicates no ECBs are specified.

**Special behavior for C++:** To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

**Returned value**

The value −1 indicates the error code should be checked for an error. The value 0 indicates an expired time limit or that the ECB is posted.

When the return value is greater than 0, then it is similar to `nmsgsfds` in that the high-order 16 bits give the number of message queues, and the low-order 16 bits give the number of descriptors. These values indicate the sum total that meet each of the read, write, and exception criteria. Note that a descriptor or a message queue may be counted multiple times if it meets more than one requested criterion. Should the return value for message queues exceed the value 32767, only 32767 will be reported. This is to ensure that the return value does not appear to be negative. Should the return value for file/socket descriptors be greater than 65535, only 65535 will be reported.

If the return value is greater than 0, the files/sockets that are ready in each bit set are set to 1. Files/Sockets in each bit set that are not ready are set to zero. Use the macro `FD_ISSET()` with each bit set to test its status. For those message queues that do not meet the conditions their identifiers in the `msgsid` array will be replaced with a value of -1.

**Error Code**  
**Description**

EBADF  
one of the descriptor sets specified an incorrect descriptor or a message queue identifier is invalid.

EFAULT  
one of the parameters contained an invalid address.

EINTR  
selectex() was interrupted before any of the selected events occurred and before the timeout interval expired.
selectex

EINVAL One of the fields in the timeval structure is incorrect.

EIO One of the descriptors in the select mask has become inoperative and it is being repeatedly included in a select even though other operations against this descriptor have been failing with EIO. A socket descriptor, for example, can become inoperative if TCP/IP is shut down. A failure from select can not tell you which descriptor has failed so generally select will succeed and these descriptors will be reported to you as being ready for whatever event they were being selected for. Subsequently when the descriptor is used on a receive or other operation you will receive the EIO failure and can react to the problem with the individual descriptor. In general you would close() the descriptor and remove it from the next select mask. If the individual descriptor's failing return code is ignored though and an inoperative descriptor is repeatedly selected on and used, even though each time it is used that call fails with EIO, eventually the select call itself will fail with EIO.

</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <sys/sem.h>

int semctl(int semid, int semnum, int cmd, ...);
```

General description

The semctl() function performs control operations in semaphore set `semid` as specified by the argument `cmd`.

Depending on the value of argument `cmd`, argument `semnum` may be ignored or identify one specific semaphore number.

The fourth argument is optional and depends upon the operation requested. If required, it is of type `union semun`, which the application program must explicitly declare:

```c
union semun {
    int val;
    struct semid_ds *buf;
    unsigned short *array;
} arg;
```

Each semaphore in the semaphore set is represented by the following anonymous data structure:

```c
unsigned short int semval  Semaphore value
pid_t sempid Process ID of last operation
unsigned sort int semcnt Number of processes waiting for `semval` to become greater than current value
unsigned short int semzcnt Number of processes waiting for `semval` to become zero
```

When semctl() is used to identify one specific semaphore number for commands GETVAL, SETVAL, GETPID, GETNCNT, and GETZCNT, then references are made to this anonymous data structure for the semaphore `semnum`.

The following semaphore control operations as specified by argument `cmd` may be specified. The level of permission required for each operation is shown with each command. These symbolic constants are defined by the `<sys/sem.h>` header:

- **GETVAL**
  Returns the value of `semval`, if the current process has read permission.

- **SETVAL**
  Sets the value of `semval` to `arg.val`, where `arg` is the value of the fourth argument to semctl(). When this command is successfully
executed, the semadj value corresponding to the specified semaphore in all processes is cleared. This command requires alter permission. For an __IPC_BINSEM semaphore set the only values that may be set are zero and one.

GETPID Returns the most recent process to update the semaphore (sempid), if the current process has read permission.

GETNCNT Returns the number of threads waiting on the semaphore to become greater than the current value, if the current process has read permission.

GETZCNT Returns the number of threads waiting on the semaphore to become zero, if the current process has read permission. For an __IPC_BINSEM semaphore set this operation will always return a zero; threads are not allowed to wait for the semaphore to become zero in this type of semaphore set.

GETALL Stores semvals for each semaphore in the semaphore set and place into the array pointed to by arg.array, where arg is the fourth argument to semctl(). GETALL requires read permission. It is the caller's responsibility to ensure that the storage allocated is large enough to hold the number of semaphore elements. The number of semaphore values stored is sem_nsems, which may be obtained using the IPC_STAT command.

SETALL Sets semval values for each semaphore in the semaphore set according to the array pointed to by arg.array, where arg is the fourth argument to semctl(). SETALL requires alter permission. Each semval value must be zero or positive. When this command is successfully executed, the semadj values corresponding to each specified semaphore in all processes are cleared. It is the caller's responsibility to ensure that the storage allocated is large enough to hold the number of semaphore elements. The number of semaphore values set is sem_nsems, which may be obtained using the IPC_STAT command. If __IPC_BINSEM was specified on the semget, this option should not be used while there is the possibility of other threads performing semaphore operations on this semaphore, as there may be no serialization while updating the semaphore values; therefore a SETALL will not be allowed after a semop has been done to the __IPC_BINSEM semaphore set. Also, for the __IPC_BINSEM semaphore set, the only values that may be set are zero and one.

IPC_STAT This command obtains status information for the semaphore identifier specified by semid. This requires read permission. This information is stored in the address specified by the fourth argument defined by data structure semid_ds.

IPC_SET Set the value of the sem_perm.uid, sem_perm.gid, and sem_perm.mode in semid_ds data structure for the semaphore identifier specified by semid. These values are set to the values found in semid_ds structure pointed to by the fourth argument. Any value for sem_perm.uid and semperm.gid may be set.

This command can only be executed by a process that has an effective user ID equal to either that of a process with appropriate
semctl

privileges or to the value of sem_perm.cuid or sem_perm.uid in the semid_ds structure associated with semid.

IPC_RMID Remove the semaphore identifier specified by argument semid from the system and free the storage for the set of semaphores in the semid_ds structure.

This command can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of sem_perm.cuid or sem_perm.uid in the semid_ds structure associated with semid. For an __IPC_BINSEM semaphore set, it is recommended that all use of semop should be completed before removing the semaphore ID.

Returned value

If successful, the value returned by semctl() depends on the value of the argument cmd as follows:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETVAL</td>
<td>value of semval is returned</td>
</tr>
<tr>
<td>GETPID</td>
<td>value of sempid is returned</td>
</tr>
<tr>
<td>GETNCNT</td>
<td>value of semncnt is returned</td>
</tr>
<tr>
<td>GETZCNT</td>
<td>value of semzcnt is returned</td>
</tr>
<tr>
<td>All others</td>
<td>value of zero is returned</td>
</tr>
</tbody>
</table>

If unsuccessful, semctl() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Operation permission (read or write) is denied to the calling process.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of argument semid is not a valid semaphore identifier, or the value of semnum is less than zero or greater than or equal to the number of semaphores in the set, or the argument cmd is not a valid command, or the bits specified for sem_perm.mode are undefined. Note that the valid range of semnum is 0 to (number of semaphores in the set minus 1).</td>
</tr>
<tr>
<td>EPERM</td>
<td>The argument cmd has a value of IPC_RMID or IPC_SET and the effective user ID of the caller is not that of a process with appropriate privileges and is not the value of sem_perm.cuid or sem_perm.uid in the semid_ds data structure associated with semid.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The argument cmd has a value of SETVAL or SETALL and the semval value to be set exceeds the system limit as defined in &lt;sys/sem.h&gt;.</td>
</tr>
</tbody>
</table>

Format

```
#define _XOPEN_SOURCE
#include <sys/sem.h>

int semget(key_t key, int nsems, int semflg);
```

General description

The semget() function returns the semaphore identifier associated with key.

A semaphore identifier is created with a semid_ds data structure, see <sys/sem.h>, associated with nsems semaphores when any of the following is true:

- Argument key has a value of IPC_PRIVATE
- Argument key is not associated with a semaphore ID and (semflg & IPC_CREAT) is non zero.

Valid values for the field semflg include any combination of the following defined in <sys/ipc.h> and <sys/modes.h>:

- `IPC_CREAT` Creates a semaphore if the key specified does not already have an associated ID. IPC_CREATE is ignored when IPC_PRIVATE is specified.
- `IPC_EXCL` Causes the semget() function to fail if the key specified has an associated ID. IPC_EXCL is ignored when IPC_CREAT is not specified or IPC_PRIVATE is specified.
- `__IPC_BINSEM` Binary semaphore - semaphore must behave in a binary manner: number of semaphore operations must be 1 and the semop must be 1 with a semval of 0 or the semop must be -1 with a semval of 0 or 1. SEM_UNDO is now allowed on a semop() with this option. The use of this flag will cause improved performance if the PLO instruction is available on the hardware. See [z/OS XL C/C++ Programming Guide](#) for further information on semaphore performance.
- `__IPC_SHORTHOLD` This flag states that it is known that the application will only hold the resource being serialized for extremely short time intervals. When this flag is combined with the __IPC_BINSEM flag, the default first-in-first-out (FIFO) ordering of semaphore obtain requesters will be bypassed, to allow short duration requesters to successfully obtain the semaphore (and hopefully release it) within the interval it normally takes to dispatch the next pending waiter for that semaphore.
S_IRUSR    Permits read access when the effective user ID of the caller matches either sem_perm.cuid or sem_perm.uid.

S_IWUSR    Permits write access when the effective user ID of the caller matches either sem_perm.cuid or sem_perm.uid.

S_IRGRP    Permits read access when the effective group ID of the caller matches either sem_perm.cgid or sem_perm.gid.

S_IWGRP    Permits write access when the effective group ID of the caller matches either sem_perm.cgid or sem_perm.gid.

S_IROTH    Permits others read access

S_IWOTH    Permits others write access

When a semaphore set associated with argument key already exists, setting IPC_EXCL and IPC_CREAT in argument semflg will force semget() to fail.

When a semid_ds data structure is created the following anonymous data structure is created for each semaphore in the set:

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>unsigned short int</td>
<td>semval</td>
<td>Semaphore value</td>
</tr>
<tr>
<td>pid_t</td>
<td>sempid</td>
<td>Process ID of last operation</td>
</tr>
<tr>
<td>unsigned short int</td>
<td>semcnt</td>
<td>Number of processes waiting for semval to become greater than current value</td>
</tr>
<tr>
<td>unsigned short int</td>
<td>semzcnt</td>
<td>Number of processes waiting for semval to become zero</td>
</tr>
</tbody>
</table>

The following fields are initialized when a semid_ds data structure is created:

- The fields sem_perm.cuid and sem_perm.uid are set equal to the effective user ID of the calling process.
- The fields sem_perm.cgid and sem_perm.gid are set equal to effective group ID of the calling process.
- The low-order 9 bits of sem_perm.mode are set to the value in the low-order 9 bits of semflg.
- The field sem_nsems is set to the value of nsems.
- The field sem_otime is set to 0.
- The field sem_ctime is set to the current time.
- The anonymous data structure containing semval for each semaphore is not initialized. semctl() commands SETVAL and SETALL should be used to initialize each semaphore's semval value.

Usage notes

1. Semaphores created with __IPC_BINSEM will show this bit and may show the IPC_PLOINUSE bit in the S_MODE byte returned with w_getipc.

Returned value

If successful, semget() returns a nonnegative semaphore identifier.

If unsuccessful, semget() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Error code 1</td>
</tr>
<tr>
<td>2</td>
<td>Error code 2</td>
</tr>
</tbody>
</table>
**semget**

**EACCES**  A semaphore identifier exists for the argument `key`, but access
permission as specified by the low-order 9 bits of `semflg` could not
be granted.

**EEXIST**  A semaphore identifier exists for the argument `key` and both
`IPC_CREAT` and `IPC_EXCL` are specified in `semflg`.

**EINVAL**  The value of `nsems` is either less than zero or greater than the
system limit. A semaphore identifier associated with `key` does not
exist and the `nsems` is zero. A semaphore identifier associated with
`key` already exists and the `nsems` value specified on `semget()` when
the semaphore identifier was created is less than the `nsems` value
on the current `semget()`. The `semflg` argument specified flags not
currently supported.

**ENOENT**  A semaphore identifier does not exist for the argument `key` and
`IPC_CREAT` is not specified.

**ENOSPC**  A system limit of number of semaphore identifiers has been
reached.

When `semflg` equals 0, the following applies:

- If a semaphore identifier has already been created with `key` earlier, and the
calling process of this `semget()` has read and/or write permissions to it, then
`semget()` returns the associated semaphore identifier.

- If a semaphore identifier has already been created with `key` earlier, and the
calling process of this `semget()` does not have read and/or write permissions to it,
then `semget()` returns -1 and sets `errno` to EACCES.

- If a semaphore identifier has not been created with `key` earlier, then `semget()`
returns -1 and sets `errno` to ENOENT.

Format

```c
#define _XOPEN_SOURCE
#include <sys/sem.h>

int semop(int semid, struct sembuf *sops, size_t nsops);
```

General description

The semop() function performs semaphore operations atomically on a set of semaphores associated with argument `semid`. The argument `sops` is a pointer to an array of `sembuf` data structures. The argument `nsops` is the number of `sembuf` structures in the array.

The structure `sembuf` is defined as follows:

```c
struct sembuf {
  short sem_num; /* Semaphore number in the range 0 to (nsems - 1) */
  short sem_op; /* Semaphore operation */
  short sem_flg; /* Operation flags */
};
```

Each semaphore in the semaphore set, identified by `sem_num`, is represented by the following anonymous data structure. This data structure for all semaphores is updated atomically when semop() returns successfully:

```c
typedef struct {
  unsigned short int semval;  /* Semaphore value */
  pid_t sempid;               /* Process ID of last operation */
  unsigned short int semcnt;  /* Number of processes waiting for semval to become greater than current value */
  unsigned short int semzcnt; /* Number of processes waiting for semval to become zero */
} sem_t;
```

Each semaphore operation specified by `sem_op` is performed on the corresponding semaphore specified by `semid` and `sem_num`.

The variable `sem_op` specifies one of three semaphore operations:

1. If `sem_op` is a negative integer and the calling process has alter permission, one of the following will occur:
   - If `semval`, see `<sys/sem.h>`, is greater than or equal to the absolute value of `sem_op`, the absolute value of `sem_op` is subtracted from `semval`.
   - If `semval` is less than the absolute value of `sem_op` and `sem_flg` & `IPC_NOWAIT` is nonzero, semop() will return immediately.
semop

- If semval is less than the absolute value of sem_op and (sem_flg & IPC_NOWAIT) is zero, semop() will increment the semncnt associated with the specified semaphore and suspend execution of the calling process until one of the following conditions occurs:
  - The value of semval becomes greater than or equal to the absolute value of sem_op. When this occurs, the value of semncnt associated with the specified semaphore is decremented, the absolute value of sem_op is subtracted from semval.
  - The semid for which the calling process is awaiting action is removed from the system. When this occurs, errno is set equal to EIDRM and -1 is returned.
  - The calling process receives a signal that is to be caught. When this occurs, the value of semncnt associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in sigaction().

2. If sem_op is a positive integer and the calling process has alter permission, the value of sem_op is added to semval.

3. If sem_op is zero and the calling process has read permission, one of the following will occur:
   - If semval is zero, semop() will return immediately.
   - If semval is nonzero and (sem_flg & IPC_NOWAIT) is nonzero, semop() will return immediately.
   - If semval is nonzero and (sem_flg & IPC_NOWAIT) is 0, semop() will increment the semzcnt associated with the specified semaphore and suspend execution of the calling thread until one of the following occurs:
     - The value of semval becomes 0, at which time the value of semzcnt associated with the specified semaphore is decremented.
     - The semid for which the calling process is awaiting action is removed from the system. When this occurs, errno is set equal to EIDRM and -1 is returned.
     - The calling process receives a signal that is to be caught. When this occurs, the value of semzcnt associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in sigaction().
   - Upon successful completion, the value of sempid for each semaphore specified in the array pointed to by sops is set equal to the process ID of the calling process.

sem_flg contains the IPC_NOWAIT and SEM_UNDO flags described as follows:

IPC_NOWAIT Will cause semop() to return EAGAIN rather than place the thread into wait state.

SEM_UNDO Will result in semadj adjustment values being maintained for each semaphore on a per process basis. If sem_op value is not equal to zero and SEM_UNDO is specified, then sem_op value is subtracted from the current process's semadj value for that semaphore. When the current process is terminated, see exit(), the semadj value(s) will be added to the semval for each semaphore. The semctl() command SETALL may be used to clear all semadj values in all processes. If __IPC_BINSEM was specified on semget for this semaphore, the Sem_UNDO flag will cause an error to be returned.
A semaphore set created with the __IPC_BINSEM flag must behave in the following manner: number of semaphore operations must be 1 and the semop must be +1 with a semval of 0 or the semop must be -1 with a semval of 0 or 1. SEM_UNDO is not allowed on a semop() with this option. The use of this flag will cause improved performance if the PLO instruction is available on the hardware.

Returned value

If successful, semop() returns 0. Also the semid parameter value for each semaphore that is operated upon is set to the process ID of the calling process.

If unsuccessful, semop() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>

Format

```c
#define _OPEN_SYS_TIMED_EXT 1
#include <time.h>
#include <sys/sem.h>

int __semop_timed(int semid, struct sembuf *sops, size_t nsops, 
                   struct timespec *set)
```

General description

Performs semaphore operations atomically on a set of semaphores associated with argument `semid`. The argument `sops` is a pointer to an array of `sembuf` data structures. The argument `nsops` is the number of `sembuf` structures in the array. The argument `set` the structure timespec with the timeout values.

The structure `sembuf` is defined as follows:

- `short sem_num`: Semaphore number in the range 0 to (nsems - 1)
- `short sem_op`: Semaphore operation
- `short sem_flg`: Operation flags

Each semaphore in the semaphore set, identified by `sem_num`, is represented by the following anonymous data structure. This data structure for all semaphores is updated automatically when semop() returns successfully:

- `unsigned short int semval`: Semaphore value
- `pid_t sempid`: Process ID of last operation
- `unsigned sort int semcnt`: Number of processes waiting for `semval` to become greater than current value
- `unsigned short int semzcnt`: Number of processes waiting for `semval` to become zero

Each semaphore operation specified by `sem_op` is performed on the corresponding semaphore specified by `semid` and `sem_num`.

The variable `sem_op` specifies one of three semaphore operations:

1. If `sem_op` is a negative integer and the calling process has alter permission, one of the following will occur:
   - If `semval`, see `<sys/semm.h>`, is greater than or equal to the absolute value of `sem_op`, the absolute value of `sem_op` is subtracted from `semval`.
   - If `semval` is less than the absolute value of `sem_op` and (`sem_flg` & `IPC_NOWAIT`) is nonzero, semop() will return immediately.
If `semval` is less than the absolute value of `sem_op` and (`sem_flg & IPC_NOWAIT`) is zero, semop() will increment the `semncnt` associated with the specified semaphore and suspend execution of the calling process until one of the following conditions occurs:

- The value of `semval` becomes greater than or equal to the absolute value of `sem_op`. When this occurs, the value of `semncnt` associated with the specified semaphore is decremented, the absolute value of `sem_op` is subtracted from `semval`.
- The `semid` for which the calling process is awaiting action is removed from the system. When this occurs, `errno` is set equal to EIDRM and -1 is returned.
- The calling process receives a signal that is to be caught. When this occurs, the value of `semncnt` associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in `sigaction()`.

2. If `sem_op` is a positive integer and the calling process has alter permission, the value of `sem_op` is added to `semval`.

3. If `sem_op` is zero and the calling process has read permission, one of the following will occur:
   - If `semval` is zero, semop() will return immediately.
   - If `semval` is nonzero and (`sem_flg & IPC_NOWAIT`) is nonzero, semop() will return immediately.
   - If `semval` is nonzero and (`sem_flg & IPC_NOWAIT`) is 0, semop() will increment the `semzcnt` associated with the specified semaphore and suspend execution of the calling thread until one of the following occurs:
     - The value of `semval` becomes 0, at which time the value of `semzcnt` associated with the specified semaphore is decremented.
     - The `semid` for which the calling process is awaiting action is removed from the system. When this occurs, `errno` is set equal to EIDRM and -1 is returned.
     - The calling process receives a signal that is to be caught. When this occurs, the value of `semzcnt` associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in `sigaction()`.
     - Upon successful completion, the value of `semid` for each semaphore specified in the array pointed to by `sops` is set equal to the process ID of the calling process.

The variable, `set`, gives the timeout specification.

- If the __semop_timed() function finds that none of the semaphores specified by `semid` are received, it waits for the time interval specified in the `timespec` structure referenced by `set`. If the `timespec` structure pointed to by `set` is zero-valued and if none of the semaphores specified by `semid` are received, then __semop_timed() returns immediately with EAGAIN. A `timespec` with the `tv_sec` field set with `INT_MAX`, as defined in `<limits.h>`, will cause the __semop_timed() service to wait until a semaphore is received. If `set` is the NULL pointer, it will be treated the same as when `timespec` structure was supplied with the `tv_sec` field set with `INT_MAX`.

**Returned value**

If successful, __semop_timed() returns 0. Also the `semid` parameter value for each semaphore that is operated upon is set to the process ID of the calling process.
__semop_timed

If unsuccessful, __semop_timed() returns −1 and sets errno to one of the following values:

<table>

- **MSG_OOB**

  Sends out-of-band data on sockets that support this notion. Only SOCK_STREAM sockets support out-of-band data. The out-of-band data is a single byte.

  Before out-of-band data can be sent between two programs, there must be some coordination of effort. If the data is intended to not be read inline, the recipient of the out-of-band data must specify the recipient of the SIGURG signal that is generated when the out-of-band data is sent. If no recipient is set, no signal is sent. The recipient is set up by using F_SETOWN operand of the `fcntl` command, specifying either a pid or gid. For more information on this operand, refer to the `fcntl` command.

  The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the SO_OOBINLINE option of...
setsockopt(). For more information on receiving out-of-band data, refer to the setsockopt(), recv(), recvfrom() and recvmsg() commands.

**MSG_DONTROUTE**

The SO_DONTROUTE option is turned on for the duration of the operation. This is usually used only by diagnostic or routing programs.

If there is not enough available buffer space to hold the socket data to be transmitted, and the socket is in blocking mode, send() blocks the caller until additional buffer space becomes available. If the socket is in nonblocking mode, send() returns -1 and sets the error code to EWOULDBLOCK. See "fcntl() — Control open file descriptors" on page 539 or "ioctl() — Control device" on page 1002 for a description of how to set nonblocking mode.

For datagram sockets, this call sends the entire datagram, provided that the datagram fits into the TCP/IP buffers. Stream sockets act like streams of information with no boundaries separating data. For example, if an application wishes to send 1000 bytes, each call to this function can send 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been sent.

**Special behavior for C++:** To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

**Returned value**

If successful, send() returns 0 or greater indicating the number of bytes sent. However, this does not assure that data delivery was complete. A connection can be dropped by a peer socket and a SIGPIPE signal generated at a later time if data delivery is not complete.

If unsuccessful, send() returns -1 indicating locally detected errors and sets errno to one of the following values. No indication of failure to deliver is implicit in a send() routine.

**Error Code**  
**Description**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><em>socket</em> is not a valid socket descriptor.</td>
</tr>
<tr>
<td>ECONNRESET</td>
<td>A connection was forcibly closed by a peer.</td>
</tr>
<tr>
<td>EDESTADDRREQ</td>
<td>The socket is not connection-oriented and no peer address is set.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using the <em>msg</em> and <em>length</em> parameters would result in an attempt to access storage outside the caller’s address space.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>A signal interrupted send() before any data was transmitted.</td>
</tr>
<tr>
<td>EIO</td>
<td>There has been a network or transport failure.</td>
</tr>
<tr>
<td>EMSGSIZE</td>
<td>The message was too big to be sent as a single datagram.</td>
</tr>
<tr>
<td>ENOBUFS</td>
<td>Buffer space is not available to send the message.</td>
</tr>
<tr>
<td>ENOTCONN</td>
<td>The socket is not connected.</td>
</tr>
<tr>
<td>ENOTSOCK</td>
<td>The descriptor is for a file, not for a socket.</td>
</tr>
</tbody>
</table>
The socket argument is associated with a socket that does not support one or more of the values set in flags.

For a connected stream socket the connection to the peer socket has been lost. A SIGPIPE signal is sent to the calling process.

socket is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.

Format

```c
#define _OPEN_SYS_SOCK_EXT2
#include <sys/socket.h>

int send_file(int *socket_ptr, struct sf_parms *sf_struct, int options);
```

General description

The `send_file()` function sends data from the file associated with the open file handle over the connection associated with the socket.

The function takes the following arguments:

- `socket_ptr`  A pointer to a socket file descriptor.
- `sf_struct`   A pointer to a structure that contains variables needed by sendfile - header information, file information, trailer information and results of operation. See below for details.
- `options`     Specifies one of the following options:
  - `SF_CLOSE`: Close the connection after the data has been successfully sent or queued for transmission.
  - `SF_REUSE`: Prepare the socket for reuse after the data has been successfully sent or queued for transmission and the existing connection closed.

Send_File Structure - `sf_parms`

Argument `sf_struct` points to a struct `sf_parms` that contains the file descriptor, a header data buffer, and a trailer data buffer.

The struct `sf_parms` is defined in `<sys/sockets.h>` and contains the following elements:

- `header_data`  Pointer to a buffer that contains header data which is to be sent before the file data. It may be a NULL pointer if `header_length` is zero.
- `header_length`  Specifies the number of bytes in the `header_data`. It must be set to zero to indicate that header data is not to be sent.
- `file_descriptor`  File descriptor for a file that has been opened for read. This is the descriptor for the file that contains the data to be transmitted.
- `file_size`  The size, in bytes, of the file associated with `file_descriptor`. This field is filled in by the system.
- `file_offset`  Specifies the byte offset into the file from which to start sending data.
- `file_bytes`  Specifies the number of bytes from the file to be transmitted.
Setting `file_bytes` to −1 will transmit the entire file from the `offset`. In this case the system will replace the −1 with (actual file size - `file_offset`). Setting `file_bytes` to 0 will result in no file data being transmitted and `file_descriptor` is ignored. If `file_descriptor` is not a regular file it may be necessary to supply a specific value for `file_bytes` unless a normal End Of File (EOF) indication is expected from `file_descriptor` during this operation or you simply want the operation to run forever transferring bytes as they arrive.

`trailer_data` Pointer to a buffer that contains trailer data which is to be sent after the file data.

`trailer_length` Specifies the number of bytes in the `trailer_data`.

`bytes_sent` Number of bytes that were sent in this call to `send_file()`. If it takes multiple calls to `send_file()` to send all the data (due to signal-handling) then this field contains the value for the last call to `send_file()`, it is not a running total. This field is set by the system.

The `send_file()` function attempts to write `header_length` bytes from the buffer pointed to by `header_data`, followed by `file_bytes` from the file associated with `file_descriptor`, followed by `trailer_length` bytes from the buffer pointed to by `trailer_data`, over the connection associated with the socket pointed to by `socket_ptr`.

As data is sent, the system will update elements in `sf_struct` so that if the `send_file()` function is interrupted by a signal, the application simply needs to reissue `send_file()`.

If the application sets `file_offset` > the actual file size, or `file_bytes` > (the actual file size - `file_offset`), the return value will be −1 and errno set to `EINVAL`.

If O_NONBLOCK is set on the socket file descriptor, the function may return −1 with errno set to EWOULDBLOCK or EAGAIN, or it may complete before all the data is sent. If O_NONBLOCK is not set, `send_file()` blocks until the requested data can be sent.

`SF_CLOSE` and `SF_REUSE` will only be effective after all the data has been sent successfully.

If `options = SF_REUSE`, and socket reuse is not supported, the system will close the socket and set the socket pointed to by `socket_ptr` to −1. See [Application usage](#) for details.

**Application usage**

`send_file()` is designed to work with `accept_and_recv()` to provide an efficient file transfer capability for a connection oriented server with short connection times and high connection rates.

On the first call to `accept_and_recv()`, it is recommended that the application set the socket pointed to by `accept_socket` to −1. This will cause the system to assign the accepting socket. On the call to `send_file()`, if the application requests socket reuse (`options = SF_REUSE`) and the system does not support it, the system will close the socket pointed to by `socket_ptr` and will set the socket pointed to by `socket_ptr` to −1. The application then passes this value onto the next call to `accept_and_recv()` (by setting `accept_socket = *socket_ptr`).
send_file

To take full advantage of the performance improvements offered by the accept_and_recv() and send_file() functions, a process/thread model different from the one where a parent accepts in a loop and spins off child process threads is needed. The parent/process thread is eliminated. Multiple worker processes/threads are created, and each worker process/thread then executes the accept_and_recv() and send_file() functions in a loop. The performance benefits of accept_and_recv() and send_file() include fewer buffer copies, recycled sockets, and optimal scheduling.

Returned value

If successful, send_file() returns 0.

send_file() returns 1 if the request was interrupted by a signal, or because a nonblocking descriptor would have blocked, while sending data. Since the sf_parms structure is updated by the system to account for the data that has been sent you can continue the operation from where is was interrupted by recalling send_file() without changing the sf_parms structure.

If unsuccessful, send_file() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The calling process does not have the appropriate privileges.</td>
</tr>
<tr>
<td>EAGAIN</td>
<td>socket_ptr is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.</td>
</tr>
</tbody>
</table>
| EBADF      | One of the following occurred:  
1. socket_ptr is not a valid descriptor or was not open for writing.  
2. file_descriptor is not a valid descriptor or was not open for reading. |
| ECONNABORTED | A connection has been aborted. |
| ECONNRESET | A connection has been forcibly closed by a peer. |
| EFAULT     | The data buffer pointed to by socket_ptr, file_size, header_data, or trailer_data was not valid. |
| EINVAL     | send_file() was interrupted by a signal that was caught before any data was sent. |
| EIO         | The value specified by options is not valid. |
| ENFILE      | An I/O error occurred. |
| EMSGSIZE    | The message is too large to be sent all at once, as the socket requires. |
| ENETDOWN    | The local interface to reach the destination is unknown. |
| ENETUNREACH | No route to the destination is present. |
| ENOBUFS     | No buffer space is available. |
| ENOMEM      | There was insufficient memory available to complete the operation. |
| ENOSR       | There were insufficient STREAMS resources available for the operation to complete. |
ENOSYS  This function is not supported in the current environment.
ENOTCONN  The socket is not connected.
ENOTSOCK  The file descriptor pointed to by the socket_ptr argument does not refer to a socket.
EPIPE  The socket is shutdown for writing, or the socket is in connection mode and is no longer connected.
EWOULDBLOCK  socket_ptr is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.

- MSG_OOB Sends out-of-band data on the socket. Only SOCK_STREAM sockets support out-of-band data. The out-of-band data is a single byte.

Before out-of-band data can be sent between two programs, there must be some coordination of effort. If the data is intended to not be read inline, the recipient of the out-of-band data must specify the recipient of the SIGURG signal that is generated when the out-of-band data is sent. If no recipient is set, no signal is sent. The recipient is set by setting the action parameter of the fcntl() function to F_SETOWN and specifying either a PID or GID. For more information on setting a recipient for out-of-band data, see "fcntl() — Control open file descriptors" on page 539.

The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the SO_OOBINLINE socket option using the setsockopt() function. For more information on receiving out-of-band data, see "setsockopt() — Set socket options" on page 589.
MSG_DONTROUTE
The SO_DONTROUTE socket option is turned on for the duration of the operation. This flag is typically used by diagnostic or routing programs.

A message header is defined by the msghdr structure, which can be found in the sys/socket.h header file and contains the following elements:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg_iov</td>
<td>An array of iovec buffers containing the message.</td>
</tr>
<tr>
<td>msg_iovlen</td>
<td>The number of elements in the msg_iov array.</td>
</tr>
<tr>
<td>msg_name</td>
<td>An optional pointer to the buffer containing the recipient's address.</td>
</tr>
<tr>

<tr>
<td>msg_flags</td>
<td>Flags on received message.</td>
</tr>
</tbody>
</table>

Ancillary data consists of a sequence of pairs, each consisting of a cmsghdr structure followed by a data array. The data array contains the ancillary data message and the cmsghdr structure contains descriptive information that allows an application to correctly parse the data.

The sys/socket.h header file defines the cmsghdr structure that includes at least the following elements:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmsg_len</td>
<td>Data byte count, including header.</td>
</tr>
<tr>
<td>cmsg_level</td>
<td>Originating protocol.</td>
</tr>
<tr>
<td>cmsg_type</td>
<td>Protocol-specific type.</td>
</tr>
</tbody>
</table>

The following ancillary data are available at the IPv4 level:

<table>
<thead>
<tr>
<th>Ancillary data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_PKTINFO</td>
<td>(RAW and UDP) Specifies the interface packets are sent over and the IP address used as the packet source IP. The data is passed in an in_pktinfo structure as defined in netinet/in.h.</td>
</tr>
</tbody>
</table>
The following ancillary data are available at the IPv6 level:

<table>
<thead>
<tr>
<th>Ancillary data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPV6_HOPLIMIT</td>
<td>(RAW, TCP, and UDP) Specifies the maximum hop limit for an outgoing packet. The data is passed in a structure as defined in netinet/in.h.</td>
</tr>
<tr>
<td>IPV6_PATHMTU</td>
<td>(RAW and UDP) Specifies the path MTU value for the destination of a connected socket. The data is passed in a structure as defined in netinet/in.h.</td>
</tr>
<tr>
<td>IPV6_PKTINFO</td>
<td>(RAW and UDP) Specifies the interface packets are sent over and the IP address used as the packet source IP. The data is passed in an in6_pktinfo structure as defined in netinet/in.h.</td>
</tr>
</tbody>
</table>

The following ancillary data are available at the socket level:

<table>
<thead>
<tr>
<th>Ancillary data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCM_RIGHTS</td>
<td>Specifies the data array that contains the access rights to be sent or received. This ancillary data is valid only for the AF_UNIX domain. The data is passed in a structure as defined in sys/socket.h.</td>
</tr>
</tbody>
</table>

The sys/socket.h header file defines the following macros to gain access to the data arrays in the ancillary data associated with a message header:

- **CMSG_DATA(cmsg)**
  - If the argument is a pointer to a cmsghdr structure, this macro returns an unsigned character pointer to the data array associated with the cmsghdr structure.

- **CMSG_NXTHDR(mhdr,cmsg)**
  - If the first argument is a pointer to a msghdr structure and the second argument is a pointer to a cmsghdr structure in the ancillary data (pointed to by the msg_control field of that msghdr structure), this macro returns a pointer to the next cmsghdr structure or a NULL pointer if this structure is the last cmsghdr structure in the ancillary data.

- **CMSG_FIRSTHDR(mhdr)**
  - If the argument is a pointer to a msghdr structure, this macro returns a pointer to the first cmsghdr structure in the ancillary data associated with this msghdr structure, or a NULL pointer if there is no ancillary data associated with the msghdr structure.

The sendmsg() call applies to sockets regardless of whether they are in the connected state.

This call returns the length of the data sent. If there is not enough available buffer space to hold the socket data to be transmitted, and the socket is in blocking mode, sendmsg() blocks the caller until additional buffer space becomes available. If the socket is in nonblocking mode, sendmsg() returns -1 and sets the error code to EWOULDBLOCK. See "fcntl() — Control open file descriptors" on page 539 or "ioctl() — Control device" on page 1002 for a description of how to set nonblocking mode.
sendmsg

For datagram sockets, this call sends the entire datagram, provided that the datagram fits into the TCP/IP buffers. Stream sockets act like streams of information with no boundaries separating data. For example, if an application wishes to send 1000 bytes, each call to this function can send 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been sent.

Socket address structure for IPv6: For an AF_INET6 socket, if msg_name is specified then the address should be in a sockaddr_in6 address structure. The sockaddr_in6 structure is defined in the header file netinet/in.h.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The sendmsg() function has a dependency on the level of the Enhanced ASCII Extensions. See Enhanced ASCII support on page 2543 for details.

Returned value

If successful, sendmsg() returns the length of the message in bytes.

A value of 0 or greater indicates the number of bytes sent, however, this does not assure that data delivery was complete. A connection can be dropped by a peer socket and a SIGPIPE signal generated at a later time if data delivery is not complete.

If unsuccessful, sendmsg() returns −1 and sets errno to one of the following values:

**Error Code**     **Description**
EADDRNOTAVAIL
     The *ipi6_addr* is not available for use on the *ipi6_ifindex* interface.
EAFNOSUPPORT
     The address family is not supported (it is not AF_UNIX, AF_INET, or AF_INET6).
EBADF
     *socket* is not a valid socket descriptor.
ECONNREFUSED
     The attempt to connect was rejected.
ECONNRESET
     A connection was forcibly closed by a peer.
EFAULT
     Using *msg* would result in an attempt to access storage outside the caller's address space.
EHOSTUNREACH
     No route to the destination exists over the interface specified by *ifi6_index*.
EINTR
     A signal interrupted sendmsg() before any data was transmitted.
EINVAL
     *msg_namelength* is not the size of a valid address for the specified address family.
EIO
     There has been a network or transport failure.
EMSGSIZE
     The message was too big to be sent as a single datagram. The default is large-envelope-size. (Envelopes are used to hold datagrams and fragments during TCP/IP processing. Large
sendmsg

envelopes hold UDP datagrams greater than 2KB while they are processed for output, and when they are waiting for an application program to receive them on input.

ENETDOWN The interface specified by *ipi6_ifindex* is not enabled for IPv6 use.
ENOBUFF Buffer space is not available to send the message.
ENOTCONN The socket is not connected.
ENOTSOCK The descriptor is for a file, not for a socket.
ENXIO The interface specified by *ipi6_ifindex* does not exist.
EOPNOTSUPP The *socket* argument is associated with a socket that does not support one or more of the values set in *flags*.
EPipe For a connected stream socket the connection to the peer socket has been lost. A SIGPIPE signal is sent to the calling process.
EWOULDBLOCK The *socket* is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.

The following are for AF_UNIX only:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Search permission is denied for a component of the path prefix, or write access to the named socket is denied.</td>
</tr>
<tr>
<td>EIO</td>
<td>An I/O error occurred while reading from or writing to the file system.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>Too many symbolic links were encountered in translating the pathname in the socket address.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>A component of a pathname exceeded <strong>NAME_MAX</strong> characters, or an entire pathname exceeded <strong>PATH_MAX</strong> characters.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>A component of the pathname does not name an existing file or the pathname is an empty string.</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>A component of the path prefix of the pathname in the socket address is not a directory.</td>
</tr>
</tbody>
</table>

</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

ssize_t sendto(int socket, const void *buffer, size_t length, int flags,
                const struct sockaddr *address, size_t address_len);
```

Berkeley sockets:

```c
#define _OE_SOCKETS
#include <sys/socket.h>

int sendto(int socket, char *buffer, int length, int flags,
            struct sockaddr *address, int address_len);
```

General description

The `sendto()` function sends data on the socket with descriptor `socket`. The `sendto()` call applies to either connected or unconnected sockets.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>socket</code></td>
<td>The socket descriptor.</td>
</tr>
<tr>
<td><code>buffer</code></td>
<td>The pointer to the buffer containing the message to transmit.</td>
</tr>
<tr>
<td><code>length</code></td>
<td>The length of the message in the buffer pointed to by the <code>msg</code> parameter.</td>
</tr>
<tr>
<td><code>flags</code></td>
<td>Setting these flags is not supported in the AF_UNIX domain. The following flags are available:</td>
</tr>
<tr>
<td></td>
<td>MSG_OOB Sends out-of-band data on the socket. Only SOCK_STREAM sockets support out-of-band data. The out-of-band data is a single byte.</td>
</tr>
</tbody>
</table>

Before out-of-band data can be sent between two programs, there must be some coordination of effort. If the data is intended to not be read inline, the recipient of the out-of-band data must specify the recipient of the SIGURG signal that is generated when the out-of-band data is sent. If no recipient is set, no signal is sent. The recipient is set up by using F_SETOWN operand of the `fcntl()` command, specifying either a pid or gid. For more information on this operand, refer to the `fcntl()` command.

The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the SO_OOBINLINE option of...
Sendto

setsockopt(). For more information on receiving out-of-band data, refer to the setsockopt(), recv(), recvfrom() and recvmsg() commands.

MSG_DONTROUTE
The SO_DONTROUTE option is turned on for the duration of the operation. This is usually used only by diagnostic or routing programs.

address The address of the target.
addr_len The size of the address pointed to by address.

If there is not enough available buffer space to hold the socket data to be transmitted, and the socket is in blocking mode, sendto() blocks the caller until additional buffer space becomes available. If the socket is in nonblocking mode, sendto() returns -1 and sets the error code to EWOULDBLOCK. See "fcntl() — Control open file descriptors" on page 539 or "ioctl() — Control device" on page 1002 for a description of how to set nonblocking mode.

For datagram sockets, this call sends the entire datagram, provided that the datagram fits into the TCP/IP buffers. Stream sockets act like streams of information with no boundaries separating data. For example, if an application wishes to send 1000 bytes, each call to this function can send 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been sent.

Socket address structure for IPv6: The sockaddr_in6 structure is added to the netinit/in.h header. It is used to pass IPv6 specific addresses between applications and the system.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The sendto() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2543 for details.

Returned value
If successful, sendto() returns the number of characters sent.

A value of 0 or greater indicates the number of bytes sent, however, this does not assure that data delivery was complete. A connection can be dropped by a peer socket and a SIGPIPE signal generated at a later time if data delivery is not complete.

No indication of failure to deliver is implied in the return value of this call when used with datagram sockets.

If unsuccessful, sendto() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAFNOSUPPORT</td>
<td>The address family is not supported (it is not AF_UNIX or AF_INET).</td>
</tr>
<tr>
<td>EBADF</td>
<td>socket is not a valid socket descriptor.</td>
</tr>
</tbody>
</table>
The following are for AF_UNIX only:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCESS</td>
<td>Search permission is denied for a component of the path prefix, or write access to the named socket is denied.</td>
</tr>
<tr>
<td>EIO</td>
<td>An I/O error occurred while reading from or writing to the file system.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>Too many symbolic links were encountered in translating the path name in the socket address.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>A component of a path name exceeded NAME_MAX characters, or an entire path name exceeded PATH_MAX characters.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>A component of the path name does not name an existing file or the path name is an empty string.</td>
</tr>
</tbody>
</table>
ENOTDIR  A component of the path prefix of the path name in the socket address is not a directory.

__server_classify

__server_classify() — Set classify area field

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/server.h>

int __server_classify(server_classify_t handle,
                       server_classify_field_t field,
                       const char *value);
```

General description

The __server_classify() function sets fields in a classify data area. The 'classify data area' is created and initialized by invoking the __server_classify_create() function. This 'classify data area' is subsequently used with the __server_pwu() function to interface with WorkLoad Manager (WLM).

The `handle` argument is a 'classify data area' created on a previous invocation of the __server_classify_create() function.

The `field` argument must be one of the following values:

__SERVER_CLASSIFY_ACCTINFO
Set the accounting information. When specified, value contains a NULL-terminated character string of up to 143 characters containing the account information for the work unit to be created.

__SERVER_CLASSIFY_COLLECTION
Set the customer defined name for a group of associated packages. When specified, value contains a NULL-terminated character string of up to 18 characters containing the collection name associated with the work unit to be created.

__SERVER_CLASSIFY_CONNECTION
Set the name associated with the environment creating the work unit. When specified, value contains a NULL-terminated character string of up to 8 characters containing the connection name associated with the environment creating the work unit.

__SERVER_CLASSIFY_CONNTKN
Set the connection token that was returned on a call to __ConnectWorkMgr() or __ConnectServerMgr(). When specified, value contains a integer value representing the connection token returned on a call to __ConnectWorkMgr() or __ConnectServerMgr().

__SERVER_CLASSIFY_CORRELATION
Set the name associated with the user/program creating the work unit. When specified, value contains a NULL-terminated character string of up to 12 characters that contains the name associated with the user/program creating the work unit.

__SERVER_CLASSIFY_LUNAME
Set the local LU name associated with the requester. When
_server_classify

specified, value contains a NULL-terminated character string of up to 8 characters containing the local LU name associated with the requester.

_SERVER_CLASSIFY_NETID
Set the network ID associated with the requester. When specified, value contains a NULL-terminated character string of up to 8 characters containing the network ID associated with the requester.

_SERVER_CLASSIFY_PACKAGE
Set the package name for a set of associated SQL statements. When specified, value contains a NULL-terminated character string of up to 8 characters containing the package name associated with the work unit to be created.

_SERVER_CLASSIFY_PERFORM
Set the performance group number (PGN) associated with the work unit. When specified, value contains a NULL-terminated character string of up to 8 characters containing the PGN associated with the work unit to be created.

_SERVER_CLASSIFY_PLAN
Set the access plan name for a set of associated SQL statements. When specified, value contains a NULL-terminated character string of up to 8 characters containing the access plan name associated with the work unit to be created.

_SERVER_CLASSIFY_PRCNAME
Set the DB2® stored SQL procedure name associated with the work unit. When specified, value contains a NULL-terminated character string of up to 18 characters containing the DB2 stored SQL procedure name associated with the work unit to be created.

_SERVER_CLASSIFY_PRIORITY
Set the priority associated with the work unit to be created. When specified, value contains an integer value representing the priority of the work unit to be created.

_SERVER_CLASSIFY_RPTCLSNM@
Set the pointer to an 8 character buffer to receive the output report class name for the work unit to be created. When specified, value contains the pointer to an 8 character buffer to receive the output report class name for the work unit to be created.

_SERVER_CLASSIFY_SCHEDENV
Set the scheduling environment information. When specified, value contains a NULL-terminated character string of up to 16 characters containing the scheduling environment name associated with the work unit.

_SERVER_CLASSIFY_SERVCLS@
Set the pointer to an integer field to receive the output service class for the work unit to be created. When specified, value contains the pointer to an integer field to receive the output service class for the work unit to be created.

_SERVER_CLASSIFY_SERVCLSNM@
Set the pointer to an 8 character buffer to receive the output service class name for the work unit to be created. When specified, value contains the pointer to an 8 character buffer to receive the output service class name for the work unit to be created.
__server_classify

__SERVER_CLASSIFY_SOURCELU
Set the source LU name associated with the requester. When specified, value contains a NULL-terminated character string of up to 17 characters containing the source LU name associated with the requester.

__SERVER_CLASSIFY_SUBCOLN
Set the subsystem collection name. When specified, the value contains a NULL-terminated character string of up to 8 characters, containing the subsystem collection name associated with the work unit.

__SERVER_CLASSIFY_SUBSYSTEM_PARM
Set the transaction subsystem parameter. When specified, value contains a NULL-terminated character string of up to 255 characters containing the subsystem parameter being used for the __server_pwu() call.

__SERVER_CLASSIFY_TRANSACTION_CLASS
Set the transaction class. When specified, value contains a NULL-terminated character string of up to 8 characters containing the name of the transaction class for the __server_pwu() call.

__SERVER_CLASSIFY_TRANSACTION_NAME
Set the transaction name. When specified, value contains a NULL-terminated character string of up to 8 characters containing the name of the transaction for the __server_pwu() call.

__SERVER_CLASSIFY_USERID
Set the user ID. When specified, value contains a NULL-terminated character string of up to 8 characters containing the name of the user for the __server_pwu() call.

The value argument is the value that the specified 'classify data area' field is to be set to. (For valid values, refer to z/OS MVS Programming: Workload Management Services, SA22-7619.)

The classify area is specific to the calling thread. The __server_classify() function call must be done on the same thread of execution as the __server_classify_create(). Use of the classify area by another thread can lead to unpredictable results.

Returned value
If successful, __server_classify() returns 0.

If unsuccessful, __server_classify() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2BIG</td>
<td>The character string specified for a classify field is too large.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The classify field symbolic is not valid.</td>
</tr>
</tbody>
</table>

__server_classify_create

__server_classify_create() — Create a classify area

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <sys/server.h>

server_classify_t __server_classify_create(void);

General description

The __server_classify_create() function creates a classify data area to be used on a subsequent __server_pwu() or CreateWorkUnit() call. The resulting classify data area can be filled in by calls to the __server_classify() function. The information in the classify area is used to establish the Transaction class, Transaction Name, user ID, and subsystem parameters for the __server_pwu() call or to establish the classification rules for the CreateWorkUnit() call.

The resulting classify area is specific to the calling thread. Use of the classify area by another thread can lead to unpredictable results.

Returned value

If successful, __server_classify_create() returns a classify_t which is a handle to the classify area.

If unsuccessful, __server_classify_create() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>Not enough storage is available.</td>
</tr>
</tbody>
</table>

Related information

The classify data area created by this function can be used without serialization only by the creating thread. In addition, storage for this structure is automatically freed at thread termination.

<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/server.h>

void __server_classify_reset(server_classify_t area);
```

General description

The __server_classify_reset() function resets a classify data area to its initial state. This is equivalent to destroying the classify area and creating another, and is intended to be a higher performance path for applications which must repeatedly change parameters in a classify area. The `area` parameter specifies the handle of the classify area to be reset, and was previously obtained by a __server_classify() call. This function must be executed by the same thread that created the classify area.

Returned value

__server_classify_reset() returns no values.

#include <sys/server.h>

int __server_init(int *managertype, const char *subsstype,
                   const char *subsysname, const char *applenv, int paralleleu);
```

General description

The __server_init() function provides the ability for a server address space to connect to WorkLoad Manager (WLM) for the purpose of queueing and servicing work requests.

The parameters supported are:

* `*managertype` Points to one or more of the following values that indicate the type of WLM manager the caller is requesting to become. The following are the supported values:
  
  **SRV_WORKMGR**
  Indicates that WLM work management services be made available to the calling address space. This value can be combined with the SRV_QUEUEEMGR and SRV_SERVERMGR values.

  **SRV_QUEUEMGR**
  Indicates that WLM queue management services be made available to the calling address space. This value can be combined with the SRV_WORKMGR and SRV_SERVERMGR values.

  **SRV_SERVERMGR**
  Indicates that WLM server management services be made available to the calling address space. This value can be combined with the SRV_WORKMGR and SRV_QUEUEMGR values.

  **SRV_SERVERMGRDYNAMIC**
  Indicates that WLM work management is to track the number of threads this address space will need. It prepares the address space to support the __service_thread_query() function. For SRV_SERVERMGRDYNAMIC the paralleleu parameter has the same effect as it does for SRV_SERVERMGR, in that, it indicates the maximum number of parallel work units that the server can create. The server would initially create some number of threads less than this maximum. The dynamic capability then allows the server to tap
__server_init

into WLM to tell the server when to increase or decrease the number of threads in the address space.

*subsystype Points to a NULL-terminated character string containing the generic subsystem type (CICS, IMS, WEB, etc.). When SRV_WORKMGR is specified for the managertype parameter this is the primary category under which WLM classification rules are grouped. The character string can be up to 4 bytes in length.

*subsysname Points to a NULL-terminated character string containing the subsystem name used for classifying work requests when SRV_WORKMGR is specified for the managertype parameter. When SRV_SERVERMGR is specified for the managertype parameter the subsystem name should match the subsystem name specified on the corresponding call to __server_init() for a work manager (SRV_WORKMGR managertype). The character string can be up to 8 bytes in length. When SRV_QUEUEMGR is specified for the managertype parameter the combination of the subsystype and subsysname parameter values must be unique to a single MVS system.

*applenv Points to a NULL-terminated character string that contains the name of the application environment under which work requests are served. The character string can be up to 32 bytes in length. This parameter is only valid when SRV_SERVERMGR is specified for the managertype parameter. It should be NULL for all other managertype values.

paralleleu Specifies the maximum number of tasks within the address space which will be created to process concurrent work requests. This parameter is valid when both or either SRV_SERVERMGR and SRV_SERVERMGRDYNAMIC are specified for the managertype parameter. It is ignored for all other managertype values.

A successful call to __server_init() results in the calling address space being connected to WLM for the WLM management services requested. Additionally, for a successful server manager WLM connection call (SRV_SERVERMGR managertype), the calling process is made a child of, and is placed in the session and process group of the corresponding work manager. The corresponding work manager is the process that called server_init() for the managertype combination SRV_WORKMGR+SRV_QUEUEMGR with the same subsystype and subsysname values specified as the server manager process. This parent/child relationship allows the server manager and the work manager to use signals to communicate with each other.

Returned value

If successful, __server_init() returns 0.

If unsuccessful, __server_init() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The managertype parameter contains a value that is not correct.</td>
</tr>
<tr>
<td>EMVSSAF2ERR</td>
<td>An error occurred in the security product.</td>
</tr>
</tbody>
</table>
EMVSWLMERROR  A WLM service failed. Use __errno2() to obtain the
WLM service reason code for the failure.

EPERM       The calling thread's address space is not permitted
to the BPX.WLMSERVER Facility class. The caller's
address space must be permitted to the
BPX.WLMSERVER Facility class, if the
BPX.WLMSERVER is defined. If
BPX.WLMSERVER is not defined, the calling
process is not defined as a superuser (UID=0).

Format

```c
#include <sys/server.h>

int __server_pwu(int fcncode, const char *transclass,
                  const char *applenv, server_classify_t classify,
                  int *appldatalen, void **appldata,
                  struct __srv_fd_list **fdlstruc);
```

General description

The __server_pwu() function provides a general purpose interface for managing and processing work using WorkLoad Manager (WLM) services. The capabilities this service provides include the ability to put work requests onto the WLM work queues, obtain work from the WLM work queues, transfer work to other WLM work servers, end units of work, delete WLM enclaves and refresh WLM work servers.

The parameters supported are:

- **fcncode** Contains one or more of the following values that indicate the function that is requested:
  - **SRV_PUT_NEWWRK** Indicates that a new work request be put onto the work queue for an application environment server identified by the `applenv` parameter as part of a newly created WLM enclave. This value cannot be combined with any other `fcncode` value.
  - **SRV_PUT_SUBWRK** Indicates that a new work request be put onto the work queue for an application environment server identified by the `applenv` parameter as part of the WLM enclave associated with the calling thread. This value can be combined with the `SRV_END_WRK` `fcncode` value.
  - **SRV_TRANSFER_WRK** Indicates that the last work request obtained by the calling thread be transferred to the work queue of the target application environment server. As part of the transfer, the calling thread is disassociated from its WLM enclave. This value cannot be combined with any other `fcncode` value.
  - **SRV_GET_WRK** Indicates that a new work request be obtained from the WLM work queue for the calling application environment server. The `SRV_GET_WRK` `fcncode` also results in the calling thread being associated with the WLM enclave of the work request. If the
calling thread is already associated with a WLM enclave due to a prior call to __server_pwu() for SRV_GET_WRK, it is disassociated from the prior WLM enclave, as well as associated with the obtained work request. When the calling thread goes thru task termination or when its process is terminated the work request is ended and the associated WLM enclave is deleted if it is owned by the terminating task or process. The SRV_GET_WRK caller owns the enclave, if the work was queued using the SRV_PUT_NEWWRK or SRV_TRANSFER_WRK functions. If the caller is a thread created using pthread_create (pthread), the thread task owns the enclave. If the caller is not a pthread, the process owns the enclave. This value can be combined with the SRV_END_WRK and SRV_DEL_ENC fcncode values.

SRV_REFRESH_WRK
Indicates that the servers associated with the application environments managed by the calling work and queue manager are to be refreshed. This will cause all servers to complete existing work requests and then terminate. New servers will then be started to process new work. This value cannot be combined with any other fcncode value.

SRV_END_WRK
Indicates that the calling thread is to be disassociated from its WLM enclave. This value can be combined with the SRV_DEL_ENC, SRV_PUT_SUBWRK and SRV_GET_WRK fcncode values.

SRV_DEL_ENC
Indicates that the WLM enclave associated with the calling thread is to be deleted. This value can be combined with the SRV_GET_WRK and SRV_END_WRK fcncode values.

SRV_DISCONNECT
Indicates that the calling server's connection to WLM is to be severed. Once a server is disconnected from WLM, it can no longer use this service to process more requests for the application environment it had been connected to (using a call to the server_init() function). If a SRV_DISCONNECT is performed by a work and queue manager, all related server managers implicitly lose their connection to WLM. This also results in the related server managers losing their ability to process more requests using this service.

SRV_DISCONNECT_COND
Indicates that the calling server's connection to WLM is to be severed only if the caller has no more WLM enclaves that it is still managing. A work and queue manager is still managing an enclave if it
has yet to be serviced by a server manager. Once a server is disconnected from WLM, it can no longer use this service to process more requests for the application environment it had been connected to (using a call to the server_init() function). If a SRV_DISCONNECT_COND is performed by a work and queue manager, all related server managers implicitly lose their connection to WLM. This also results in the related server managers losing their ability to process more requests using this service.

*transclass Points to a NULL-terminated character string that represents the name of the transaction class to be associated with the work request. This parameter is only valid when the SRV_PUT_NEWWRK fcncode parameter value is specified. It should be NULL for the other fcncode parameter values. The character string can be up to 8 bytes in length.

*applenv Points to a NULL-terminated character string that contains the name of the application environment under which work requests are served. This parameter is valid for the set of SRV_PUT fcncode values, the SRV_TRANSFER_WRK fcncode value and the SRV_REFRESH_WRK fcncode value. It should be NULL for the other fcncode parameter values. The character string can be up to 32 bytes in length.

*classify Points to a character string that contains the classification information for the work request macro.

*appldatalen When one of the SRV_PUT or SRV_TRANSFER fcncode parameter values is specified this is a supplied parameter that points to an integer containing the length of the application data specified by the **appldata parameter. When the SRV_GET_WRK fcncode value is specified, this is an output parameter where the __server_pwu() function is to return the length of the application data associated with the obtained work request. *appldatalen is only valid when one of the SRV_PUT, SRV_GET_WRK or SRV_TRANSFER fcncode parameter values is specified, it is ignored otherwise. The maximum length supported for the application data is 10 megabytes.

**appldata When one of the SRV_PUT or SRV_TRANSFER fcncode parameter values is specified this is a supplied parameter that points to the application data string. This application data allows the caller to uniquely identify the specific work the caller is requesting. When the SRV_GET_WRK fcncode value is specified, this is an output parameter where the __server_pwu() function is to return a pointer to the application data associated with the obtained work request. The returned data area will be an identical copy of the data area that was supplied on the corresponding __server_pwu() call to put the work request on a WLM work queue. **appldata is only valid when one of the SRV_PUT, SRV_GET_WRK or SRV_TRANSFER fcncode parameter values is specified, it is ignored otherwise.

**fdlstruct When one of the SRV_PUT or SRV_TRANSFER fcncode parameter values is specified this is an input parameter that contains a pointer to a __srv_fd_list structure. The __srv_fd_list structure contains the following members:
__server_pwu

```c
int fdcount /* count of file descriptors */
int flags /* flag SRV_FDCLOSE */
int fd(SRV_FDS) /* file descriptor list */
```

The supplied __srv_fd_list structure contains the count of file descriptors to be propagated, followed by the list of file descriptors that are to be propagated to the process that calls server_pwu() to obtain the work request created by the call to this service. If the SRV_FDCLOSE flag is turned on in the flags field of the __srv_fd_list structure, all file descriptors in the list are closed in the calling process. If a NULL pointer is specified, no file descriptors are propagated. When the **fdlstruc parameter is used to propagate file descriptors, the caller must ensure that all of the file descriptors in the list are valid open file descriptors in the caller's process, and are not being closed during the processing of this service. If this is not the case, then this function cannot guarantee the proper propagation of the specified file descriptors. When the SRV_GET_WRK fcncode parameter value is specified the **fdlstruc parameter is an output parameter where the __server_pwu() function returns a pointer to the __srv_fd_list structure associated with the obtained work request. The returned __srv_fd_list structure will contain the count of file descriptors in the returned structure, followed by the list of remapped file descriptor values in the calling process of the file descriptors that were supplied in the __srv_fd_list structure on the corresponding __server_pwu() call to put the work request on a WLM work queue. The flags field in the returned __srv_fd_list structure will be NULL. The **fdlstruc parameter is only valid when one of the SRV_PUT, SRV_TRANSFER or SRV_GET_WRK fcncode parameter values are specified. It is ignored otherwise. The maximum number of file descriptors supported in the file descriptor list structure is 64.

A successful call to __server_pwu() for the SRV_PUT_NEWWRK fcncode not only creates a work request that is placed onto a WLM work queue, but it also creates a new WLM enclave for that work to run in when the work request is obtained. By comparison, the SRV_PUT_SUBWRK and SRV_TRANSFER_WRK fcncodes, queue work requests that are part of the existing WLM enclave of the calling thread.

A successful call to __server_pwu() for the SRV_GET_WRK fcncode not only results in the caller obtaining a work request from a WLM work queue associated with the caller's application environment, but also results in the calling thread being associated with the WLM enclave associated with the obtained work request.

Usage of the server_pwu function requires the calling address space to have successfully issued a call to the __server_init() function.

For the SRV_PUT_NEWWRK function to run successfully, the caller must have successfully issued a call to the __server_init() service for one of the following managertype parameter combinations:
- SRV_WORKMGR + SRV_QUEUEMGR
- SRV_WORKMGR + SRV_QUEUEMGR + SRV_SERVERMGR

For the SRV_PUT_SUBWRK and SRV_TRANSFER_WRK functions to run successfully, the caller must have successfully issued a call to the __server_init() service for one of the following managertype parameter combinations:
- SRV_WORKMGR + SRV_QUEUEMGR SRV_SERVERMGR
__server_pwu

- SRV_SERVERMGR

For the SRV_GET_WRK, SRV_END_WRK and SRV_DEL_ENC functions to run successfully, the caller must have successfully issued a call to the __server_init() service for one of the following `managertype` parameter combinations:
- SRV_WORKMGR + SRV_QUEUEMGR SRV_SERVERMGR
- SRV_SERVERMGR

For the SRV_REFRESH_WRK function to run successfully, the caller must have successfully issued a call to the __server_init() service for any of the following `managertype` parameter combinations:
- SRV_WORK_MGR + SRV_QUEUE_MGR
- SRV_WORK_MGR + SRV_QUEUE_MGR + SRV_SERVER_MGR

Returned value

If successful, __server_pwu() returns 0.

If unsuccessful, __server_pwu() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The requested service could not be performed at the current time. Use __errno2() to obtain the reason code for the failure.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>An argument of this service contained an address that was not accessible to the caller.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The <code>managertype</code> parameter contains a value that is not correct.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>A MVS environmental or internal error has occurred. Use __errno2() to obtain the exact reason for the failure.</td>
</tr>
<tr>
<td>EMVSWLMERROR</td>
<td>A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.</td>
</tr>
</tbody>
</table>

<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R10</td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/server.h>

int __server_threads_query(int *threads);
```

General description

Provides information about the number of threads a server should be using for this server environment. After a successful query, `threads` will contain the number of threads that the WorkLoad Manager (WLM) recommends for this address space.

Usage notes

This service is a privileged service that requires the caller to be authorized in one of the following ways:
- Have read access to the BPX.WLMSERVER FACILTY class profile
- Have a UID=0 when the BPX.WLMSERVER FACILTY class profile is not defined

Returned value

If successful, `__server_threads_query()` returns 0.

If unsuccessful, `__server_threads_query()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINTR</td>
<td>The wait was interrupted by an unblocked, caught signal. No further waiting will occur for this call. <code>__server_threads_query()</code> can be reissued to begin waiting again.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The caller is not permitted to perform the specified operation.</td>
</tr>
</tbody>
</table>

<td></td>
</tr>
<tr>
<td>C99</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

void setbuf(FILE *restrict stream, char *restrict buffer);
```

General description

Controls buffering for the specified `stream`. The `stream` pointer must refer to an open file, and `setbuf()` must be the first operation on the stream.

If the `buffer` argument is NULL, the `stream` is unbuffered. If not, the buffering mode will be full buffer and the `buffer` must point to a character array of length at least `BUFSIZ`, which is the buffer size defined in the `stdio.h` header file. I/O functions use the `buffer`, which you specify here, for input/output buffering instead of the default system-allocated buffer for the given `stream`. If the `buffer` does not meet the requirements of the z/OS XL C/C++ product, the buffer is not used.

The `setvbuf()` function is more flexible than `setbuf()`, because you can specify the type of buffering and size of buffer.

**Note:** If you use `setvbuf()` or `setbuf()` to define your own buffer for a stream, you must ensure that the buffer is available the whole time that the stream associated with the buffer is in use.

For example, if the buffer is an automatic array (block scope) and is associated with the stream `s`, leaving the block causes the storage to be deallocated. I/O operations of stream `s` are prevented from using deallocated storage. Any operation on `s` would fail because the operation would attempt to access the nonexistent storage.

To ensure that the buffer is available throughout the life of a program, make the buffer a variable allocated at file scope. This can be achieved by using an identifier of type `array` declared at file scope, or by allocating storage (with `malloc()` or `calloc()`) and assigning the storage address to a pointer declared at file scope.

VSAM file types do not support unbuffered I/O, causing requests for unbuffered I/O to fail.

Returned value

`setbuf()` returns no values.

For details about `errno` values, and about buffers you may have set, see discussions about buffering in [z/OS XL C/C++ Programming Guide](https://www.ibm.com/support/docdisplay?rs=3008&uid=swg21069684&loc=en_US&cs=swg2).
Example

CELEBS01

/* CELEBS01

This example opens the file myfile.dat for writing.
It then calls the &setbuf. function to establish a buffer of
length BUFSIZ.
When string is written to the stream, the buffer buf is used
and contains the string before it is flushed to the file.

*/
#include <stdio.h>

int main(void)
{
    char buf[BUFSIZ];
    char string[] = "hello world";
    FILE *stream;

    stream = fopen("myfile.dat", "wb, recfm=f");
    setbuf(stream, buf); /* set up buffer */
    fwrite(string, sizeof(string), 1, stream);
    printf("%s\n", buf); /* string is found in buf now */
    fclose(stream); /* buffer is flushed out to myfile.dat */
}

setcontext() — Restore user context

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ucontext.h>

int setcontext(const ucontext_t *ucp);
```

General description

The `setcontext()` function restores the user context pointed to by `ucp`. A successful call to `setcontext()` does not return; program execution resumes at the point specified by the `ucp` argument passed to `setcontext()`. The `ucp` argument should be created either by a prior call to `getcontext()`, or by being passed as an argument to a signal handler. If the `ucp` argument was created with `getcontext()`, program execution continues as if the corresponding call of `getcontext()` had just returned. If the `ucp` argument was modified with `makecontext()`, program execution continues with the function passed to `makecontext()`. When that function returns, the process continues as if after a call to `setcontext()` with the context pointed to by the `ucmlink` member of the `ucontext_t` structure if it is not equal to 0. If the `ucmlink` member of the `ucontext_t` structure pointed to by the `ucp` argument is equal to 0, then this context is the main context, and the process will exit when this context returns. The effects of passing a `ucp` argument obtained from any other source are undefined.

`setcontext()` is similar in some respects to `siglongjmp()` (and `longjmp()` and `_longjmp()`). The `getcontext()`—`setcontext()` pair, the `sigsetjmp()`—`siglongjmp()` pair, the `setjmp()`—`longjmp()` pair, and the `setjmp()`—`_longjmp()` pair cannot be intermixed. A context saved by `getcontext()` should be restored only by `setcontext()`.

Notes:

1. Some compatibility exists with `siglongjmp()`, so it is possible to use `siglongjmp()` from a signal handler to restore a context created with `getcontext()`, but it is not recommended.
2. If the `ucontext` that is input to `setcontext()` has not been modified by `makecontext()`, you must ensure that the function that calls `getcontext()` does not return before you call the corresponding `setcontext()` function. Calling `setcontext()` after the function calling `getcontext()` returns causes unpredictable program behavior.
3. If `setcontext()` is used to jump back into an XPLINK routine, any `alloca()` requests issued by the XPLINK routine after the earlier `getcontext()` was called and before `setcontext()` is called are backed out. All storage obtained by these `alloca()` requests is freed before the XPLINK routine is resumed.
4. If `setcontext()` is used to jump back into a non-XPLINK routine, `alloca()` requests made after `getcontext()` and before `setcontext()` are not backed out.

This function is supported only in a POSIX program.
The `<ucontext.h>` header file defines the `ucontext_t` type as a structure that includes the following members:

- `mcontext_t uc_mcontext`: A machine-specific representation of the saved context.
- `ucontext_t *uc_link`: Pointer to the context that will be resumed when this context returns.
- `sigset_t uc_sigmask`: The set of signals that are blocked when this context is active.
- `stack_t uc_stack`: The stack used by this context.

**Special behavior for C++:** If `getcontext()` and `setcontext()` are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic objects is undefined. This applies to both z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of `getcontext()` and `setcontext()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Do not issue `getcontext()` in a C++ constructor or destructor, since the saved context would not be usable in a subsequent `setcontext()` or `swapcontext()` after the constructor or destructor returns.

**Special behavior for XPLINK-compiled C/C++:** Restrictions concerning `setjmp.h` and `ucontext.h`:

**Notes:**

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the `jmp_buf`, `sigjmp_buf` or `ucontext_t` types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define `jmp_buf`, `sigjmp_buf` or `ucontext_t` data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger `jmp_buf`, `sigjmp_buf` or `ucontext_t` area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from a XPLINK routine. If `__XPLINK__` is not defined, the Language Environment V2R10 and later headers define a shorter `jmp_buf`, `sigjmp_buf` or `ucontext_t` area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If a XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short `jmp_buf`, `sigjmp_buf` or `ucontext_t` area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

**Returned value**

- If successful, `setcontext()` does not return.
- If unsuccessful, `setcontext()` returns `-1`.

There are no `errno` values defined.

**Example**

This example saves the context in main with the `getcontext()` statement. It then returns to that statement from the function `func` using the `setcontext()` statement. Since `getcontext()` always returns 0 if successful, the program uses the variable `x` to determine if `getcontext()` returns as a result of `setcontext()` or not.
setcontext

/* This example shows the usage of getcontext() and setcontext(). */

#define _XOPEN_SOURCE_EXTENDED 1
#include <stdio.h>
#include <ucontext.h>

void func(void);

int x = 0;
ucontext_t context, *cp = &context;

int main(void) {
    getcontext(cp);
    if (!x) {
        printf("getcontext has been called\n");
        func();
    }
    else {
        printf("setcontext has been called\n");
    }
}

void func(void) {
    x++;
    setcontext(cp);
}

Output
getcontext has been called
setcontext has been called

#define _POSIX1_SOURCE 2
#include <unistd.h>

int setegid(gid_t gid);
```

General description

Sets the effective group ID (GID) of a process to `gid`, if `gid` is equal to the real GID or the saved set GID of the calling process, or if the process has appropriate privileges. The real GID, the saved set GID, and any supplementary GIDs are not changed.

Returned value

If successful, setegid() returns 0.

If unsuccessful, setegid() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified for <code>gid</code> is incorrect and is not supported by the implementation.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The process does not have appropriate privileges, and <code>gid</code> does not match the real GID or the saved set GID.</td>
</tr>
</tbody>
</table>

Example

```
CELEBS02

/* CELEBS02 */

   /* This example changes your effective GID. */

   #define _POSIX1_SOURCE 2
   #include <unistd.h>
   #include <stdio.h>

   main() {
       printf("your effective group id is %d\n", (int) getegid());
       if (setegid(500) != 0)
           perror("setegid() error");
       else
           printf("your effective group id was changed to %d\n", (int) getegid());
   }

Output

your effective group id is 512
your effective group id was changed to 500
```
setegid

setenv() — Add, delete, and change environment variables

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1a</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Language Environment</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

POSIX - C only:
#define _POSIX1_SOURCE 2
#include <env.h>

int setenv(const char *var_name, const char *new_value, int change_flag)

Single UNIX Specification, Version 3:
#define _UNIX03_SOURCE
#include <stdlib.h>

int setenv(const char *var_name, const char *new_value, int change_flag)

Non-POSIX:
#include <stdlib.h>

int setenv(const char *var_name, const char *new_value, int change_flag)

General description

Adds, changes, and deletes environment variables.

To avoid infringing on the user's name space, the non-POSIX version of this function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

var_name is a pointer to a character string that contains the name of the environment variable to be added, changed, or deleted. If setenv() is called with var_name containing an equal sign ('='), setenv() will fail, and errno will be set to indicate that an invalid argument was passed to the function.

new_value is a pointer to a character string that contains the value of the environment variable named in var_name. If new_value is a NULL pointer, it indicates that all occurrences of the environment variable named in var_name be deleted.

change_flag is a flag that can take any integer value:
Nonzero Change the existing entry. If var_name has already been defined
setenv

and exists in the environment variable table, its value will be updated with new_value. If var_name was previously undefined, it will be appended to the table.

0 Do not change the existing entry.

If var_name has already been defined and exists in the environment variable table, its value will not be updated with new_value. However, if var_name was previously undefined, it will be appended to the table.

Notes:
1. The value of the change_flag is irrelevant if new_value=_NULL.
2. You should not define environment variables that begin with '_BPXK_' since they might conflict with variable names defined by z/OS UNIX services. setenv() uses the BPX1ENV callable service to pass environment variables that begin with '_BPXK_' to the kernel.
   Also, do not use '_EDC_' and '_CEE_'. They are used by the run-time library and the Language Environment.

Environment variables set with the setenv() function will only exist for the life of the program, and are not saved before program termination. Other ways to set environment variables are found in “Using Environment Variables” in z/OS XL C/C++ Programming Guide.

Special behavior for POSIX C: Under POSIX, setenv() is available if one of the following is true:
- Code is compiled with the compiler option LANGLV(ANSI), uses #include <env.h>, and has the POSIX feature tests turned on.
- Code is compiled with LONGNAME and prelinked with the OMVS option.

Returned value

If successful, setenv() returns 0.

If unsuccessful, setenv() returns −1 and sets errno to indicate the type of failure that occurred.

Error Code
   Description
EINVAL
   The name argument is a null pointer, points to an empty string, or points to a string containing an ‘=’ character.

   Note: Starting with z/OS V1.9, environment variable _EDC_SUSV3 can be used to control the behavior of setenv() with respect to setting EINVAL when var_name is a null pointer, points to an empty string or points to a string containing an ‘=’ character. By default, setenv() will not set EINVAL for these conditions. When _EDC_SUSV3 is set to 1, setenv() will set errno to EINVAL if one of these conditions is true.

ENOMEM
   Insufficient memory was available to add a variable or its value to the environment.
Example

CELEBS03
/* CELEBS03 */

This example (program 1) sets the environment variable _EDC_ANSI_OPEN_DEFAULT.
A child program (program 2) is then initiated via a system call.
The example illustrates that environment variables are propagated forward to a child program, but not backward to the parent.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    char *x;
    /* set environment variable _EDC_ANSI_OPEN_DEFAULT to "Y" */
    setenv("_EDC_ANSI_OPEN_DEFAULT","Y",1);
    /* set x to the current value of the _EDC_ANSI_OPEN_DEFAULT */
    x = getenv("_EDC_ANSI_OPEN_DEFAULT");
    printf("program1 _EDC_ANSI_OPEN_DEFAULT = %s
", (x != NULL) ? x : "undefined");
    /* call the child program */
    system("program2");
    /* set x to the current value of the _EDC_ANSI_OPEN_DEFAULT */
    x = getenv("_EDC_ANSI_OPEN_DEFAULT");
    printf("program1 _EDC_ANSI_OPEN_DEFAULT = %s
", (x != NULL) ? x : "undefined");
}

CELEBS04
/* CELEBS04 */

Program 2:
A child program of CELEBS03, which is initiated via a system call.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    char *x;
    /* set x to the current value of the _EDC_ANSI_OPEN_DEFAULT */
    x = getenv("_EDC_ANSI_OPEN_DEFAULT");
    printf("program2 _EDC_ANSI_OPEN_DEFAULT = %s
", (x != NULL) ? x : "undefined");
    /* clear the Environment Variables Table */
    setenv("_EDC_ANSI_OPEN_DEFAULT", NULL, 1);
    /* set x to the current value of the _EDC_ANSI_OPEN_DEFAULT */
    x = getenv("_EDC_ANSI_OPEN_DEFAULT");
printf("program2 _EDC_ANSI_OPEN_DEFAULT = %s\n", 
    (x != NULL) ? x : "undefined");
}

Output
program1 _EDC_ANSI_OPEN_DEFAULT = Y
program2 _EDC_ANSI_OPEN_DEFAULT = Y
program2 _EDC_ANSI_OPEN_DEFAULT = undefined
program1 _EDC_ANSI_OPEN_DEFAULT = Y

seteuid() — Set the effective user ID

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1a Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX1_SOURCE 2
#include <unistd.h>

int seteuid(uid_t uid);
```

General description

Sets the effective user ID (UID) to `uid` if `uid` is equal to the real UID or the saved set user ID of the calling process, or if the process has appropriate privileges. The real UID and the saved set UID are not changed.

The seteuid() function is not supported from an address space running multiple processes, since it would cause all processes in the address space to have their security environment changed unexpectedly.

seteuid() can be used by daemon processes to change the identity of a process in order for the process to be used to run work on behalf of a user. In z/OS UNIX, changing the identity of a process is done by changing the real and effectiveUIDs and the auxiliary groups. In order to change the identity of the process on MVS completely, it is necessary to also change the MVS security environment. The identity change will only occur if the EUID value is specified, changing just the real UID will have no effect on the MVS environment.

The seteuid() function invokes MVS SAF services to change the MVS identity of the address space. The MVS identity that is used is determined as follows:

- If an MVS user ID is already known by the kernel from a previous call to a kernel function (for example, getpwnam()) and the UID for this user ID matches the UID specified on the seteuid() call, then this user ID is used.
- For nonzero target UIDs, if there is no saved user ID or the UID for the saved user ID does not match the UID requested on the seteuid() call, the seteuid() function queries the security database (for example, using getpwnam) to retrieve a user ID. The retrieved user ID is then used.
- If the target UID=0 and a user ID is not known, the seteuid() function always sets the MVS user ID to BPXROOT or the value specified on the SUPERUSER parm in sysparms. BPXROOT is set up during system initialization as a superuser with a UID=0. The BPXROOT user ID is not defined to the BPX.DAEMON FACILITY class profile. This special processing is necessary to prevent a superuser from gaining daemon authority.
- A nondaemon superuser that attempts to set a user ID to a daemon superuser UID fails with an EPERM.

When the MVS identity is changed, the auxiliary list of groups is also set to the list of groups for the new user ID.
seteuid

If the seteuid() function is issued from multiple tasks within one address space, use synchronization to ensure that the seteuid() functions are not performed concurrently. The execution of seteuid() function concurrently within one address space can yield unpredictable results.

Returned value

If successful, seteuid() returns 0.

If unsuccessful, seteuid() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified for uid is incorrect and is not supported by the implementation.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The process does not have appropriate privileges, and uid does not match the real UID or the saved set UID.</td>
</tr>
</tbody>
</table>

Example

CELEBS05

/* CELEBS05

   This example changes the effective UID.

*/
#define _POSIX1_SOURCE 2
#include <unistd.h>
#include <stdio.h>

main() {
    printf("your effective user id is %d\n", (int) geteuid());
    if (seteuid(25) != 0)
        perror("seteuid() error");
    else
        printf("your effective user id was changed to %d\n", (int) geteuid());
}

Output

your effective user id is 0
your effective user id was changed to 25

__set_exception_handler

__set_exception_handler() — Register an exception handler routine

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <le_api.h>

int __set_exception_handler( void(*exception_handler) (struct __cib *, void *),
                            void *user_data);
```

General description

**Restriction:** This function is only valid for AMODE 64.

A nonstandard function that registers an 'Exception Handler' function for the current stack frame. Exception Handlers are used to process 'exceptions' at the thread level (unlike signal catchers which process signals at the process level).

**Parameter Description**

- **exception_handle**
  - Address of a function descriptor that is associated with an 'Exception Handler' function.

- **user_data**
  - A user definable token that will be passed to the 'Exception Handler' function.

Exception Handlers are invoked for the following conditions:

**Table 43. Invoked Exception Handlers**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Feedback Code</th>
<th>Message Number</th>
<th>Resulting Signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation</td>
<td>CEE341</td>
<td>CEE3201S</td>
<td>SIGILL</td>
</tr>
<tr>
<td>Privileged-operation</td>

<td>CEE3207S</td>
<td>SIGFPE</td>
</tr>
<tr>
<td>Fixed-point overflow</td>
<td>CEE348</td>
<td>CEE3208S</td>
<td>SIGFPE</td>
</tr>
</tbody>
</table>

**Note:** Not processed in a C/C++ application.

- Fixed-point divide by zero
- Decimal overflow exception
- Decimal divide by zero
- Exponent overflow

Chapter 3. Library functions
When one of the exceptions listed above occurs, on a specific thread with a registered Exception Handler, Language Environment will invoke the handler function with the following syntax:

```c
void exception_handler(struct __cib * cib, void * user_data);
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cib</td>
<td>Address of the Language Environment Condition Information Block (CIB).</td>
</tr>
<tr>
<td>user_data</td>
<td>A user definable token that was specified when the Exception Handler was registered.</td>
</tr>
</tbody>
</table>

An Exception Handler function should never return to Language Environment. It should terminate the thread with `pthread_exit()`, terminate the process with `exit()`, or
resume execution at a predefined point with setjmp() and longjmp(). If the Exception Handler returns to Language Environment, the thread will be abnormally terminated.

- In a Posix environment only the thread is abnormally terminated, and the thread exit status is set to -1. Equivalent to:
  ```c
  pthread_exit((void*) -1);
  ```
- In a non-Posix environment the entire Language Environment (process as well as thread) is abnormally terminated. Equivalent to:
  ```c
  exit(-1);
  ```

**Returned value**

If successful, __set_exception_handler() returns 0. Otherwise, -1 is returned and errno is set to indicate the error. The following is a possible value for errno:
-EINVAL — The Exception Handler is invalid.

**Application usage**

1. Multiple Exception Handlers may not be registered for a single stack frame. Only the last one registered is honored.
2. Exception Handlers may be nested, but they must be on different stack frames.
3. Once an Exception Handler is registered, it remains active across calls to nested functions, and will be automatically unregistered once the flow returns from the stack frame in which the call to __set_exception_handler() was invoked.
4. If an Exception Handler is registered, it remains active across subsequence function calls (nested function calls), unless one of the nested functions registers another exception handler. In which case the first exception handler is suspended.
5. Exception Handlers are automatically unregistered when a longjmp() returns to a stack frame earlier on the stack then the frame on which the Exception Handler was registered. All Exception Handlers that are associated with stack frames that are traversed as a result of a longjmp() are automatically unregistered.
6. When an Exception Handler is given control, it is disabled. Any other Exception Handler (that may have been previously registered) is not set active. In other words, when the Exception Handler is given control there is no Exception Handler active. It is suspended.
   - Any exception that occurs while the Exception Handler is executing, will be processed in the same way that Language Environment processes exceptions when no Exception Handlers are present.
   - If the Exception Handler needs to be able to handle exceptions that occur during the execution of the Exception Handler, the handler must invoke __set_exception_handler() to register another (or re-register the same) Exception Handler.
7. One and only one, Exception Handler will be invoked for a condition (the Handler that is active for the stack frame on which the condition (or exception) occurred).
8. If an Exception Handler exists and the condition is one of those listed above, all of the standard Language Environment condition processing is bypassed (including, when POSIX(ON), the mapping of the exception into a signal). Instead, the one active Exception Handler is given control, and it has one opportunity to 'handle' the exception. If it does not handle the exception then abnormal termination will occur.
9. Functions used to affect the processing of signals, have no impact on the processing of Exception Handlers. That is, blocking or ignoring SIGABND, SIGFPE, SIGILL, or SIGSEGV will not prevent Exception Handlers from getting control.

10. In order for Exception Handlers to work, the Language Environment 'TRAP' run-time option must be set on (i.e., TRAP(ON) or TRAP(ON, NOSPIE)).

</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX1_SOURCE 2
#include <unistd.h>

int setgid(gid_t gid);
```

General description

Sets one or more of the group IDs (GIDs) for the current process to `gid`.

If `gid` is the same as the process's real GID or the saved set-group-ID, `setgid()` always succeeds and sets the effective GID to `gid`.

If `gid` is not the same as the process's real GID, `setgid()` succeeds only if the process has appropriate privileges. If the process has such privileges, `setgid()` sets the real GID, the effective GID, and saved set GID to `gid`.

`setgid()` does not change any supplementary GIDs of the calling process.

Returned value

If successful, `setgid()` returns 0.

If unsuccessful, `setgid()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of <code>gid</code> is incorrect.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The process does not have appropriate privileges to set the GID.</td>
</tr>
</tbody>
</table>

Example

```c
CELEBS06
/* CELEBS06

    This example sets your GID.

*/
#define _POSIX_SOURCE 1
#include <unistd.h>
#include <stdio.h>

main() {
    printf("your group id is %d\n", (int) getgid());
    if (setgid(500) != 0)
        perror("setgid() error");
```
setgid

```c
else
    printf("your group id was changed to %d\n", (int) getgid());
}

Output
your group id is 512
your group id was changed to 500

setgroups

setgroups() — Set the supplementary group ID list for the process

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS
#include <sys/types.h>
#include <grp.h>

int setgroups(const int size, const gid_t list[]);
```

General description

`setgroups()` sets the supplementary group IDs for the process to the list provided in the `list` array. The argument `size` gives the number of `gid_t` elements in `list` array. The maximum number of supplementary groups for a strictly conforming program is `NGROUPS_MAX`, as defined in `<limits.h>` or refer to `sysconf()` (see “sysconf() — Determine system configuration options” on page 2142) for information on dynamically determining the number of supplementary groups allowed.

The caller of this function must be a superuser.

Returned value

If successful, `setgroups()` returns 0.

If unsuccessful, `setgroups()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>The <code>list</code> and <code>size</code> specify an array that is partially or completely outside of addressable storage for the process.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The <code>size</code> parameter is greater than the maximum allowed.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>An MVS environmental or internal error occurred.</td>
</tr>
<tr>
<td>EMVSSAF2ERR</td>
<td>The Security Authorization Facility (SAF) had an error.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The caller is not authorized, only authorized users are allowed to alter the supplementary group IDs list.</td>
</tr>
</tbody>
</table>

Format

X/Open:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void sethostent(int stayopen);
```

Berkeley sockets:

```c
#define _OE_SOCKETS
#include <netdb.h>

void sethostent(int stayopen);
```

General description

The sethostent() function opens and rewinds the local host tables. If the `stayopen` flag is nonzero, the local host tables remain open after each call.

You can use the X_SITE environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization.

**Note:** For more information on these local host tables or the environment variables, see [z/OS Communications Server: IP Configuration Guide, SC31-8775](https://www.ibm.com/servers/resourcelink/pac slips/nds/nt/tcpipv4/0000000006313595.prl).

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

sethostent() returns no values.

setibmopt() — Set IBM TCP/IP image

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int setibmopt(int cmd, struct ibm_tcpimage *bfrp);
```

General description

The setibmopt() function call is used to set TCP/IP options. Currently, the only supported command is IBMTCP_IMAGE which allows the setibmopt() to choose the active TCP/IP image stack the application will connect to.

To reset ibm_tcpimage to nothing chosen, set the name to all blanks.

The chosen transport is inherited over fork() and preserved over exec(). If this is not desired, the child process should call setibmopt() with a blank name to reset the TCP/IP image for the child.

Parameter Description

- `cmd`: The value in `cmd` must be set to the command to be performed. Currently, only IBMTCP_IMAGE is supported and must be paired with the `bfrp` parameter as described.
- `bfrp`: The pointer to a ibm_tcpimage structure.

To set the TCP/IP image for a socket, the application should set values in the ibm_tcpimage structure as follows:

Element Description

- `status`: 0 means is not known and need not be checked. Currently, this is the only value with meaning.
- `version`: 0 means the version is to be set on return if known.
- `name`: The name must be left justified, uppercase, padded with blanks, and be the name of an active TCP stack.

Returned value

If successful, setibmopt() returns 0.

If unsuccessful, setibmopt() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>Using the <code>bfrp</code> supplied would result in access of a storage location that is inaccessible.</td>
</tr>
<tr>
<td>EIBMBADTCPNAME</td>
<td>A name of a PFS was specified that either is not configured or is not a Sockets PFS.</td>
</tr>
</tbody>
</table>
setibmopt

EOPNOTSUPP The *cmd* is a function that is not supported.

ENXIO The name that was specified did not match an AF_INET socket stack, but Common Inet is not configured on this system. Because this system does not have multiple AF_INET socket transports configured, there is already a natural affinity to one single stack, and this failure may not be a problem for the application.

setibmsockopt

setibmsockopt() — Set IBM specific options associated with a socket

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int setibmsockopt(int s, int level, int optname, char *optval, size_t optlen);
```

General description

These options are only valid on IBM systems and can be specified to allow improved processing of requests on sockets.

Parameter Description

- **s**: The socket descriptor.
- **level**: The level for which the option is set.
- **optname**: The name of a specified socket option. The socket option currently available is:
  - SO_EioIfNewTP
- **optval**: The pointer to option data.
- **optlen**: The length of the option data.

Usage notes

The SO_EioIfNewTP option allows a socket application that has bound INADDRANY to be notified if a new common inet transport provider was activated after the socket was created. In order to activate this option, the option data should have a value of 1. To deactivate this option, supply a value of 0 for the option data. This option can be useful to a server that is listening - waiting for requests to come in from a number of sources. When a new transport provider is activated while this option is in effect, the application program will receive an EIO on the next accept, select or read request. Once this happens, the application should close the current socket and create a new one - thus enabling the socket to communicate with the new transport provider.

Returned value

If successful, setibmsockopt() returns 0.

If unsuccessful, setibmsockopt() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The s parameter is not a valid socket descriptor.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using optval and optlen parameters would result in an attempt to access storage outside the caller's address space.</td>
</tr>
</tbody>
</table>
ENOPROTOOPT

The "optname" parameter is unrecognized. The "level" parameter is not
SOL_SOCKET. The domain of the socket descriptor is not
AF_INET. The socket descriptor is not a datagram type socket.

setipv4sourcefilter

setipv4sourcefilter() — Set source filter

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3678</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>

int setipv4sourcefilter(int s, struct in_addr interface, struct in_addr group,
                        uint32_t fmode, uint32_t numsrc, struct in_addr *slist);
```

General description

This function allows applications to set and replace the current multicast filtering state for a tuple consisting of socket, interface, and multicast group values.

A multicast filter is described by a filter mode, which is MCAST_INCLUDE or MCAST_EXCLUDE, and a list of source addresses which are filtered.

This function is IPv4-specific, must be used only on AF_INET sockets with an open socket of type SOCK_DGRAM or SOCK_RAW.

If the function is unable to obtain the required storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

Argument

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
</tr>
<tr>
<td>interface</td>
</tr>
<tr>
<td>group</td>
</tr>
<tr>
<td>fmode</td>
</tr>
<tr>
<td>numsrc</td>
</tr>
<tr>
<td>slist</td>
</tr>
</tbody>
</table>

Description

- `s`: Identifies the socket.
- `interface`: Holds the local IP address of the interface.
- `group`: Holds the IP multicast address of the group.
- `fmode`: Identifies the filter mode. The value of this field must be either MCAST_INCLUDE or MCAST_EXCLUDE, which are likewise defined in <netinet/in.h>.
- `numsrc`: Holds the number of source addresses in the slist array.
- `slist`: Points to an array of IP addresses of sources to include or exclude depending on the filter mode.

Returned value

If successful, the function returns 0. Otherwise, it returns -1 and sets errno to one of the following values.

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errno</td>
</tr>
</tbody>
</table>

Description

- EADDRNOTAVAIL: The specified interface address is incorrect for this host, or the specified interface address is not multicast capable.
setipv4sourcefilter

EBADF
   s is not a valid socket descriptor.

EINVAL
   Interface or group is not a valid IPv4 address, or the socket s has already
   requested multicast setsockopt options.

ENOBUFFS
   The number of the source addresses exceeds the allowed limit.

EPROTOTYPE
   The socket s is not of type SOCK_DGRAM or SOCK_RAW.

setitimer() — Set value of an interval timer

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/time.h>

int setitimer(int which, struct itimerval *value, struct itimerval *ovalue);
```

General description

`setitimer()` sets the value of an interval timer. An interval timer is a timer which sends a signal after each repetition (interval) of time.

The `which` argument indicates what kind of time is being controlled. Values for `which` are:

- **ITIMER_REAL**
  - This timer is marking real (clock) time. A SIGALRM signal is generated after each interval of time.
  - **Note:** `alarm()` also sets the real interval timer.

- **ITIMER_VIRTUAL**
  - This timer is marking process virtual time. Process virtual time is the amount of time spent while executing in the process, and can be thought of as a CPU timer. A SIGVTALRM signal is generated after each interval of time.

- **ITIMER_PROF**
  - This timer is marking process virtual time plus time spent while the system is running on behalf of the process. A SIGPROF signal is generated after each interval of time.

  **Note:** In a multithreaded environment, each of the above timers is specific to a thread of execution for both the generation of the time interval and the measurement of time. For example, an a ITIMER_VIRTUAL timer will mark execution time for just the thread, not the entire process.

The `value` argument points to an `itimerval` structure containing the timer value to be set. The structure contains:

- **it_interval**
  - timer interval
  - When `it_interval` is nonzero, it is used as the value which `it_value` is initialized to after each timer expiration. If `it_interval` is zero, the timer is disabled after the next expiration, subject to the value in `it_value`.

- **it_value**
  - current timer value to be set
  - When `it_value` is nonzero, it is used as the initial value to establish the timer with, that is, the time to the next timer expiration. If `it_value` is zero, the timer is immediately disabled.
setitimer

The \textit{ovalue} argument points to an \textit{itimerval} structure in which the current value of the timer is returned. If \textit{ovalue} is a NULL pointer, the current timer value is not returned. The structure contains:

\begin{verbatim}
  it_interval    current timer interval
  it_value       current timer value
\end{verbatim}

For both \textit{itimerval} structures, each of the fields (\textit{it_interval} and \textit{it_value}) is a \textit{timeval} structure, and contains:

\begin{verbatim}
  tv_sec          seconds since January 1, 1970 Coordinated Universal Time (UTC)
  tv_usec         microseconds
\end{verbatim}

\textbf{Returned value}

If successful, setitimer() returns 0, and if \textit{ovalue} was non-NULL, \textit{ovalue} points to the \textit{itimerval} structure containing the old timer values.

If unsuccessful, setitimer() returns \texttt{-1} and sets \texttt{errno} to one of the following values:

\begin{itemize}
  \item \texttt{EINVAL} \textit{which} is not a valid timer type, or the \textit{value} argument has an incorrect (noncanonical) form. The \texttt{tv_seconds} field must be a nonnegative integer, and the \texttt{tv_usec} field must be a nonnegative integer in the range of 0-1,000,000.
\end{itemize}

Usage of the ITIMER_PROF timer generates a SIGPROF signal which may interrupt an in-progress function. Thus, programs using this timer may need to be able to restart an interrupted function.

</tbody>
</table>

Format

```c
#include <setjmp.h>

int setjmp(jmp_buf env);
```

General description

Saves a stack environment that can subsequently be restored by longjmp(). The `setjmp()` and `longjmp()` functions provide a way to perform a nonlocal `goto`. They are often used in signal handlers.

A call to `setjmp()` causes it to save the current stack environment in `env`. A subsequent call to `longjmp()` restores the saved environment and returns control to a point corresponding to the `setjmp()` call. The values of all variables, except register variables and nonvolatile automatic variables, accessible to the function receiving control, contain the values they had when `longjmp()` was called. The values of register variables are unpredictable. Nonvolatile `auto` variables that are changed between calls to `setjmp()` and `longjmp()` are also unpredictable.

An invocation of `setjmp()` must appear in one of the following contexts only:

- The entire controlling expression of a selection or iteration statement.
- One operand of a relational or equality operator with the other operand an integral constant expression, with the resulting expression being the entire controlling expression of a selection or iteration statement.
- The operand of a unary “!” operator with the resulting expression being the entire controlling expression of a selection or iteration.
- The entire expression of an expression statement (possibly cast to void).

**Note:** Ensure that the function that calls `setjmp()` does not return before you call the corresponding `longjmp()` function. Calling `longjmp()` after the function calling `setjmp()` returns causes unpredictable program behavior.

**Special behavior for POSIX C:** To save and restore a stack environment that includes a signal mask, use `sigsetjmp()` and `siglongjmp()`, instead of `setjmp()`.

The `sigsetjmp()`—`siglongjmp()` pair, the `setjmp()`—`longjmp()` pair, the `_setjmp()`—`_longjmp()` pair, and the `getcontext()`—`setcontext()` pair cannot be intermixed. A stack environment saved by `setjmp()` can only be restored by `longjmp()`.

**Special behavior for C++:** If `setjmp()` and `longjmp()` are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic
setjmp

objects is undefined. This applies both to z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of setjmp() and longjmp() in conjunction with try(), catch(), and throw() is also undefined.

Special behavior for XPG4.2: In a program that was compiled with the feature test macro _XOPEN_SOURCE_EXTENDED defined, another pair of functions, _setjmp()—_longjmp(), are available. On this implementation, these calls are functionally identical to setjmp()—longjmp(). Therefore it is possible, but not recommended, to intermix the setjmp()—longjmp() pair with the _setjmp()—_longjmp() pair.

Special behavior for XPLINK-compiled C++: Restrictions concerning setjmp.h and ucontext.h:

Notes:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the jmp_buf, sigjmp_buf or ucontext_t types must not be compiled with C headers from Language Environment V2R9 or earlier.

2. Non-XPLINK functions compiled with any level of Language Environment headers must not define jmp_buf, sigjmp_buf or ucontext_t data items and pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(), setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.

3. When __XPLINK__ is defined, the Language Environment V2R10 and later headers define a larger jmp_buf, sigjmp_buf or ucontext_t area that is required by setjmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Language Environment V2R10 and later headers define a shorter jmp_buf, sigjmp_buf or ucontext_t area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls setjmp(), getcontext() or similar functions with a short jmp_buf, sigjmp_buf or ucontext_t area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

setjmp() returns 0 after saving the stack environment.

If setjmp() returns as a result of a longjmp() call, it returns the value argument of longjmp(), or the value 1 if the value argument of longjmp() is equal to 0.

Example

This example stores the stack environment at the statement:

```c
if(setjmp(mark) != 0) ...
```

When the system first performs the if statement, it saves the environment in mark and sets the condition to FALSE because setjmp() returns 0 when it saves the environment. The program prints the message: set jmp has been called.

The subsequent call to function p tests for a local error condition, which can cause it to perform the longjmp() function. Then control returns to the original setjmp() function using the environment saved in mark. This time the condition is TRUE because −1 is the returned value from the longjmp() function. The program then performs the statements in the block and prints: long jmp has been called. Finally, the program calls the recover function and exits.
/* This example shows the effect of having set the stack environment. */
#include <stdio.h>
#include <setjmp.h>

jmp_buf mark;

void p(void);
void recover(void);

int main(void)
{
  if (setjmp(mark) != 0) {
    printf("longjmp has been called\n");
    recover();
    exit(1);
  }
  printf("setjmp has been called\n");
  p();
}

void p(void)
{
  int error = 0;
  ...
  error = 9;
  ...
  if (error != 0)
    longjmp(mark, -1);
  ...
}

void recover(void)
{
  ...
}

<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <setjmp.h>

int _setjmp(jmp_buf env);
```

General description

The _setjmp() function saves a stack environment that can subsequently be restored by _longjmp(). The _setjmp() and _longjmp() functions provide a way to perform a nonlocal goto. They are often used in signal handlers.

A call to _setjmp() causes it to save the current stack environment in `env`. A subsequent call to _longjmp() restores the saved environment and returns control to a point corresponding to the _setjmp() call. The values of all variables, except register variables, and except nonvolatile automatic variables, accessible to the function receiving control contain the values they had when _longjmp() was called. The values of register variables are unpredictable. Nonvolatile `auto` variables that are changed between calls to _setjmp() and _longjmp() are also unpredictable.

An invocation of _setjmp() must appear in one of the following contexts only:

1. The entire controlling expression of a selection or iteration statement.
2. One operand of a relational or equality operator with the other operand an integral constant expression, with the resulting expression being the entire controlling expression of a selection or iteration statement.
3. The operand of a unary "!" operator with the resulting expression being the entire controlling expression of a selection or iteration.
4. The entire expression of an expression statement (possibly cast to void).

The X/Open standard states that _setjmp() and _longjmp() are functionally identical to longjmp() and setjmp(), respectively, with the addition restriction that _setjmp() and _longjmp() do not manipulate the signal mask. However, on this implementation longjmp() and setjmp() do not manipulate the signal mask. So on this implementation _setjmp() and _longjmp() are literally identical to longjmp() and setjmp(), respectively.

To save and restore a stack environment, including the current signal mask, use sigsetjmp() and siglongjmp() instead of _setjmp() and _longjmp(), or setjmp() and longjmp().

The _setjmp()—_longjmp() pair, the setjmp()—longjmp() pair, the sigsetjmp()—siglongjmp() pair, and the getcontext()—setcontext() pair cannot be intermixed. A stack environment saved by _setjmp() can be restored only by _longjmp().
**_setjmp**

**Notes:**

1. However, on this implementation, since the _setjmp()—_longjmp() pair are functionally identical to the set jmp()—longjmp() pair it is possible to intermix them, but it is not recommended.

2. Ensure that the function that calls _setjmp() does not return before you call the corresponding _longjmp() function. Calling _longjmp() after the function calling _setjmp() returns causes unpredictable program behavior.

**Special behavior for C++:** If _setjmp() and _longjmp() are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic objects is undefined. This applies both to z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of _setjmp() and _longjmp() in conjunction with try(), catch(), and throw() is also undefined.

**Special behavior for XPLINK-compiled C++:** Restrictions concerning setjmp.h and ucontext.h:

**Notes:**

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the jmp buf, sigjmp_buf or ucontext_t types must not be compiled with C headers from Language Environment V2R9 or earlier.

2. Non-XPLINK functions compiled with any level of Language Environment headers must not define jmp buf, sigjmp_buf or ucontext_t data items and pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(), setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.

3. When __XPLINK__ is defined, the Language Environment V2R10 and later headers define a larger jmp buf, sigjmp_buf or ucontext_t area that is required by set jmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Language Environment V2R10 and later headers define a shorter jmp buf, sigjmp_buf or ucontext_t area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls set jmp(), getcontext() or similar functions with a short jmp buf, sigjmp_buf or ucontext_t area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

**Returned value**

_setjmp() returns 0 after saving the stack environment.

If _setjmp() returns as a result of a _longjmp() call, it returns the value argument of _longjmp(), or 1 if the value argument of _longjmp() was 0.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdlib.h>

void setkey(const char *key);
```

General description

The setkey() function transforms the `key` argument array into data encryption keys which are used by the encrypt() function to encode blocks of data.

The `key` argument of setkey() is an array of length 64 bytes containing only the bytes with numerical value of 0 and 1. If this 64 byte array is divided into groups of 8, the low-order byte of each group is ignored. The setkey() function transforms the remaining 56 bytes, each with values 0 or 1, into 16 48-bit keys according to the Data Encryption Standard (DES) key algorithm.

**Special behavior for z/OS UNIX Services:** When setkey() is called from a thread, the array of 16 bit-bit keys produced by setkey() is unique to the thread. Thus, for each thread from which the encrypt() function is called by a threaded application, the setkey() function must first be called from each thread.

Returned value

setkey() returns no values.

**Special behavior for z/OS UNIX Services:** The setkey() function will fail if:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>64 byte input array contains bytes with values other than 0x00 or 0x01.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Unable to allocate storage for DES keys on thread from which setkey() invoked.</td>
</tr>
</tbody>
</table>

**Note:** Because setkey() returns no values, applications wishing to check for errors should set errno to 0, call setkey(), then test errno and, if it is nonzero, assume an error has occurred.

Format

#include <locale.h>

char *setlocale(int category, const char *locale);

General description

Sets, changes, or queries locale categories or groups of categories. It does this action according to values of the locale and category arguments.

A locale is the complete definition of the part of a user's program that depends on language and cultural conventions. You can accept the default value of locale, or you can set it to one of the supplied locales listed in the appendix, "Supplied Locales", in z/OS XL C/C++ Programming Guide. Some examples of the supplied locales are: "C", "POSIX", "SAA", "S370", "Fr_BE.IBM-1047", "En_GB.IBM-285", "En_US.IBM_1047", "Fr_BE.IBM-1148@euro", and "Fr_BE.IBM-1148".

Note that non-POSIX programs may exploit the POSIX style of locale support. This use of environment variables also applies to non-POSIX programs that use POSIX locale support.

Effect of setlocale() on Language Environment: The current locale set with the setlocale() function affects only some C library functions. (See Table 44). It does not affect the CEE locale set and query functions available under Language Environment and described in the IBM Language Environment Programming Reference.

The category argument

The category argument may be set to one of these values:

Table 44. Values for Category Arguments of setlocale()

<table>
<thead>
<tr>
<th>Category</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>LC_ALL</td>
<td>Specifies all categories associated with the program's locale.</td>
</tr>
<tr>
<td>Category</td>
<td>Purpose</td>
</tr>
<tr>
<td>-----------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LC_COLLATE</td>
<td>Defines the collation sequence, that is, the relative order of collation elements (characters and multicharacter collation elements) in the program's locale. The collation sequence definition is used by regular expression, pattern matching, and sorting functions. These string functions are affected by the defined collation sequence: strcoll(), strxfrm(), wcscoll(), and wcsxfrm(). LC_CTYPE, LC_COLLATE, and LC_SYNTAX should refer to the same locale. Changing just one of them may invalidate another.</td>
</tr>
<tr>
<td>LC_CTYPE</td>
<td>Defines character classification and case conversion for characters in the program's locale. Affects the behavior of character-handling functions defined in the ctype.h header file: csid(), isalnum(), isalpha(), isblank(), isblank(), iscntrl(), isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace(), isupper(), iswalnum(), iswalpha(), iswcntrl(), iswctype(), iswdigit(), iswgraph(), iswlower(), iswprint(), iswpunct(), iswspace(), iswupper(), iswxdigit(), isxdigit(), tolower(), toupper(), towlower(), towupper(), wcsid(), and wctype(). Affects behavior of the printf() and scanf() families of functions: fprintf(), printf(), sprintf(), fscanf(), scanf(), and sscanf(). Affects the behavior of wide-character input/output functions: fgetwc(), fgetws(), getwc(), getwchar(), fputwc(), fputws(), putwc(), putwchar(), and ungetwc(). Affects the behavior of multibyte and wide-character functions: mblen(), mbtowc(), mbstowcs(), wcstomb(), wcstombs(), mbtowc(), mbstowcs(), wcrtomb(), wcsrtombs(), wcwidth(), wcstod(), wcstol(), and wcstoul(). LC_CTYPE, LC_COLLATE, and LC_SYNTAX should refer to the same locale. Changing just one of them may invalidate another.</td>
</tr>
<tr>
<td>LC_MESSAGES</td>
<td>Under z/OS XL C/C++ support, it affects the messages returned by the nl_langinfo() function and it also has an effect on rpmatch(). The LC_MESSAGES category will not affect the messages for the following functions: perror(), strerror(), and regerror(). In the locale of a C program running with POSIX(ON), it defines affirmative and negative response patterns.</td>
</tr>
<tr>
<td>LC_MONETARY</td>
<td>Affects monetary information returned by localeconv() and the strfmon() function. It defines the rules and symbols used to format monetary numeric information in the program's locale. The formatting rules and symbols are strings. localeconv() returns pointers to these strings with names found in the locale.h header file.</td>
</tr>
</tbody>
</table>
**setlocale**

<table>
<thead>
<tr>
<th>Category</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| LC_NUMERIC    | Affects the decimal-point character for the formatted input/output and string conversion functions, and the non-monetary formatting information returned by the localeconv() function, specifically:  
- The printf() family of functions  
- The scanf() family of functions  
- strtod()  
- atof()  

The formatting rules and symbols are strings. localeconv() returns pointers to the strings with names found in the locale.h header file. |
| LC_TIME       | Defines time and date format information in the program's locale used by the strftime(), strptime(), and wcsftime() functions.         |
| LC_SYNTAX     | Affects the behavior of functions that use encoded values to format characters:  
- printf() family of functions  
- scanf() family of functions  
- regcomp()  
- strfmon()  

LC_SYNTAX also affects values that may be retrieved using the getsyntx() function.  
LC_TYPE, LC_COLLATE, and LC_SYNTAX should refer to the same locale. Changing just one of them may invalidate another. |
| LC_TOD        | Affects the behavior of the functions related to time zone and Daylight Savings Time information in the program's locale, when time zone and Daylight Savings Time information is not defined by the TZ environment variable. This information is used by ctime(), localtime(), mktime(), and strftime(). |

For a POSIX program, the functions ctime(), localtime(), mktime(), setlocale(), and strftime() call the tzset() function to override LC_TOD category information when TZ is defined and valid.

**The locale argument**

Identifies the locale. For a list of locales provided by IBM, see the topic about supplied locales in [z/OS XL C/C++ Programming Guide](#).

If the value of an environment variable is used, it must be a valid locale name. If this is the case, setlocale() sets the specified category to the named locale, and returns a string giving the name of the locale. Otherwise, setlocale() does not change the program's locale and returns a NULL pointer. Valid *category* names include names of locales provided by IBM. Also, names of locales, which are created using the z/OS XL C/C++ locale definition mechanism, are valid.

**The null-string (""") locale value:** If "" is specified, the locale-related environment variables are checked. If the locale name is not defined by the environment variables, the default is "S370" when running POSIX(OFF) and "C" when running POSIX(ON).

For both C and C++ languages, and whether you are using POSIX or not, if a program using POSIX-style locale support specifies "" for the value of locale, then setlocale() interrogates locale-related environment variables in the program's
setlocale

environment to find a locale name or names to use. The locale name is chosen according to the first of the following conditions that applies:
1. If the environment variable LC_ALL is defined and is not NULL, the value of LC_ALL is used. That value is applied to all categories.
2. If individual environmental variables are defined, then their values are used for the categories.
3. If the environment variable LANG is defined and is not NULL, the value of LANG is used.
4. If no non-NULL environment variable is present to supply a value, "C" is used.

If a program using POSIX-style locale support specifies LC_ALL for the value of category and "" for the value of locale, setlocale() searches environment variables in the way just described to obtain a locale name for each category. If all the locale names obtained identify valid locales, setlocale() sets each category to the appropriate locale and returns a string naming the locale associated with each category. Otherwise, setlocale() does not change the program's locale and returns a NULL pointer.

Default locale: The relationship between the POSIX C and SAA C locales is as follows.

Using C or C++ languages with the run-time option POSIX(OFF):
1. The SAA C locale definition is the default. "C", "SAA", and "S370" are synonyms for the SAA C locale definition, which is prebuilt into the library.
   The source file EDC$SAA C LOCALE is provided for reference, but cannot be used to alter the definition of this prebuilt locale.
2. Issuing setlocale(category, "") has the following effect:
   • Locale-related environment variables are checked to find the name of locales) to use to set the category specified. Querying the locale with setlocale(category, NULL) returns the name of the locales specified by the appropriate environment variables.
   • If no non-NULL environment variable is present, it is the equivalent of having issued setlocale(category, "S370"). That is, the locale chosen is the SAA C locale definition, and querying the locale with setlocale(category, NULL), returns "S370" as the locale name.
3. If no setlocale() function is issued or setlocale(LC_ALL, "C") is used, then the locale chosen is the prebuilt SAA C locale, and querying the locale with setlocale(category, NULL), returns "C" as the locale name.
4. For setlocale(LC_ALL,"SAA"), the locale chosen is the prebuilt SAA C locale, and querying the locale with setlocale(category, NULL), returns "SAA" as the locale name.
5. For setlocale(LC_ALL,"S370"), the locale chosen is the prebuilt SAA C locale, and querying the locale with setlocale(category, NULL), returns "S370" as the locale name.
6. For setlocale(LC_ALL,"POSIX"), the locale chosen is the prebuilt POSIX C locale, and querying the locale with setlocale(category, NULL), returns "POSIX" as the locale name.

Using z/OS XL C with the run-time option POSIX(ON):
1. The POSIX C locale definition is the default. "C" and "POSIX" are synonyms for the POSIX C locale definition, which is prebuilt into the library.
setlocale

The source file EDC$POSX LOCALE is provided for reference, but cannot be used to alter the definition of this prebuilt locale.

2. Issuing `setlocale(category, "")` has the following effect:
   - Locale-related environment variables are checked to find the name of locales that can set the `category` specified. Querying the locale with `setlocale(category, NULL)` returns the name of the locale specified by the appropriate environment variables.
   - If no non-NULL environment variable is present, the result is equivalent to having issued `setlocale(category, "C")`. That is, the locale chosen is the POSIX C locale definition, and querying the locale with `setlocale(category, NULL)`, returns "C" as the locale name.

3. If no `setlocale()` function is issued or if `setlocale(LC_ALL, "C")` is used, the locale chosen is the prebuilt POSIX C locale. Querying the locale with `setlocale(category, NULL)` returns "C" as the locale name.

4. For `setlocale(LC_ALL,"POSIX")` the locale chosen is the prebuilt POSIX C locale. Querying the locale with `setlocale(category, NULL)` returns "POSIX" as the locale name.

5. For `setlocale(LC_ALL,"SAA")` the locale chosen is the prebuilt SAA C locale. Querying the locale with `setlocale(category, NULL)` returns "SAA" as the locale name.

6. For `setlocale(LC_ALL,"S370")` the locale chosen is the prebuilt SAA C locale. Querying the locale with `setlocale(category, NULL)` returns "S370" as the locale name.

   The `setlocale()` function supports locales built by using the localedef utility, as well as locales built using the assembler language source and produced by the EDCLOC macro. Find more information about old format locales in "Internationalization: Locales and Character Sets", in z/OS XL C/C++ Programming Guide.

**Special behavior for z/OS UNIX Services**

The LOCPATH environment variable specifies a colon separated list of HFS directories. If LOCPATH is defined, `setlocale()` searches HFS directories in the order specified by LOCPATH for locale object files it requires. Locale object files in the HFS are produced by the localedef utility running under z/OS UNIX. If LOCPATH is not defined and `setlocale()` is called by a POSIX program, `setlocale()` looks in the default HFS locale directory, /usr/lib/nls/locale, for locale object files it requires. If `setlocale()` does not find a locale object it requires in the HFS, it converts the locale name to a PDS member name as described in z/OS XL C/C++ Programming Guide and searches locale PDS load libraries associated with the program calling `setlocale()`.

Locale names may be file names, relative path names, or absolute path names. LOCPATH is used if file name rather than path name is specified. Also, // preceding a file name tells `setlocale()` to skip HFS search and to convert the name to a load module name of the form EDC$xxxx, and to search MVS load libraries for a member to load with this name. Also, // preceding a file name tells `setlocale()` to skip HFS search, to convert the name to a load module PDS name. XPLINK locale object PDS names begin with EDC. Non-XPLINK locale object load module names begin with CEH. See z/OS XL C/C++ Programming Guide section titled Locale Naming Conventions for further information regarding locale object names.

All locales supplied by IBM come in two versions: non-XPLINK and XPLINK. The HFS-resident XPLINK locale objects are distinguished from their non-XPLINK
versions by an ".xplink" suffix on the HFS path name. PDS-resident XPLINK locale objects are distinguished from their non-XPLINK versions by a "CEH" prefix. The non-XPLINK PDS-resident locale objects have a prefix of "EDC".

It is the convention to specify locales using the locale descriptive names as they are listed in Appendix D of the [z/OS XL C/C++ Programming Guide](#). The run-time loads the non-XPLINK or XPLINK locale as appropriate.

It is also possible to specify a locale's relative or full path name on the setlocale call. However, the run-time does nothing to ensure the locale is the appropriate version. Setlocale uses the locale object exactly as specified if it is a relative or fully qualified path name. For example, setlocale() will fail if it is given an XPLINK locale full path name but the application is a non-XPLINK application. Similarly, setlocale() will fail if it is given a non-XPLINK locale full path name but the application is an XPLINK application. These problems are avoided if the locale names are the descriptive locale names.

**Invocation sequence for setlocale()**

In all three variations of the setlocale() function call, a pointer to a string that represents the locale value is returned. Also, in all variations, if the value for either category or locale is invalid, setlocale() returns a NULL pointer and the operating environment is not changed.

Each variation causes a different function to be performed:

1. `setlocale(category, locale);`
   
   When an explicit locale is named, the category named in the call is set according to the named locale.

2. `setlocale(category, "");`
   
   When the locale argument of the setlocale() function is given as a NULL string (""), the setlocale() function sets the locale environment according to the environment variables. If these are not set, the default locale "S370" is used. This locale may be customized when the z/OS XL C/C++ product is installed. See "Using Environment Variables" in [z/OS XL C/C++ Programming Guide](#).

   The environment variables are not currently supported under all z/OS XL C/C++ environments. The processing above will allow the setlocale() function to use the environment variables if they are available, and to use the "S370" locale otherwise.

3. `setlocale(category, (char *) 0);`
   
   When a NULL pointer is given as a locale, a pointer to a string that represents the current locale for the specified category is returned. The string has the property that if it were specified as the locale of a subsequent setlocale() call of the same category, the current locale would be restored. For example, the following sequence is effectively a no-op:

   ```c
   setlocale(category, setlocale(category, (char *) 0));
   ```

   When called with a NULL string (for example, `setlocale(LC_ALL,"")`, setlocale() determines the locale to be set, using the environment variables, and checking them in this order:

   1. `LC_ALL`. If set, it specifies the name for all categories; it can override the values in the other environmental variables.
   2. `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_MONETARY`, `LC_NUMERIC`, `LC_TIME`, `LC_SYNTAX`, and `LC_TOD`. If set, these variables specify the locale name for the given category.
3. LANG.

The setlocale() function uses the getenv() function to retrieve the environment variables if the system supports the getenv() function. Under CICS it is not supported.

Querying the locale

When locale is set to a NULL pointer, setlocale() returns a string indicating the program's locale without changing it. This provides a means to query the program's current locale. To query the locale, give a NULL pointer as the second parameter. For example, to query all the categories of your locale, use a statement like the following:

char *string = setlocale(LC_ALL, NULL);

Returned value

If successful, setlocale() returns a pointer to the string associated with the specified category for the new locale. The string can be used on a subsequent call to restore that part of the program's locale.

Note: Because the string that a successful call to setlocale() points to may be overwritten by subsequent calls to the setlocale() function, you should copy the string if you plan to use it later.

If unsuccessful, setlocale() returns a NULL pointer and the program's locale is not changed.

If successful, setlocale() returns a string whose contents depend on the values of the category and locale arguments as shown in the following table.

<table>
<thead>
<tr>
<th>Category Value</th>
<th>Locale Value</th>
<th>Return String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specific category</td>
<td>NULL pointer</td>
<td>current-locale-name for category</td>
</tr>
<tr>
<td></td>
<td>new-locale-name</td>
<td>new-locale-name for category</td>
</tr>
<tr>
<td>&quot;&quot;</td>
<td>(Null string)</td>
<td>If the environmental variables are set, new-locale-name: environment-variable-value or C.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If the environmental variables are not set, and if non-POSIX Program, then S370 or SAA.</td>
</tr>
<tr>
<td>LC_ALL</td>
<td>NULL pointer</td>
<td>One of these:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• locale-name</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• locale-name-list: locale-name1, locale-name2, ..., if different names for one or more categories.</td>
</tr>
<tr>
<td></td>
<td>new-locale-name</td>
<td>new-locale-name (same for all categories)</td>
</tr>
</tbody>
</table>
### Table 45. Return String as Determined by Category and Locale Values (continued)

<table>
<thead>
<tr>
<th>Category Value</th>
<th>Locale Value</th>
<th>Return String</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;&quot;</td>
<td>(Null string)</td>
<td>One of these:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- new-locale-name: environment-variable-value or C</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- locale-name-list: environment-variable-value-list if different names for one or more categories.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If environmental variables are not set, and if non-POSIX program, then S370 (same for all categories).</td>
</tr>
</tbody>
</table>

If the string returned contains a locale name list, the names have the following order:
1. LC_COLLATE locale-name
2. LC_CTYPE locale-name
3. LC_MONETARY locale-name
4. LC_NUMERIC locale-name
5. LC_TIME locale-name
6. LC_TOD locale-name
7. LC_MESSAGES locale-name
8. LC_SYNTAX locale-name

If unsuccessful, `setlocale()` returns a NULL pointer and does not change the program's locale. Failure can result if:
- An incorrect category value is used.
- An incorrect locale value is used.
- The value of the environment variable used by `setlocale()` when the value of `locale` is "" is an undefined or incorrect locale name.

**Note:** If `setlocale()` is called and an application has called `pthread_create()` to create another thread, `setlocale()` returns a NULL pointer and does not change the current locale.

### Example

**CELEBS07**

```c
/* CELEBS07

This example sets the locale of the program to be Fr_FR.IBM-1047 and prints the string that is associated with the locale.

*/
#include <stdio.h>
#include <locale.h>

char *string;

int main(void)
{
    string = setlocale(LC_ALL, "Fr_FR.IBM-1047");
    if (string != NULL)
        printf(" %s \n",string);
}
```
CELEBS08

/* CELEBS08

This example uses &setenv. to set the value of the environment variable LC_TIME to FRAN, calls &setloc. to set all categories to default values, uses &setloc. to query all categories, and uses &printf. to print results.

*/
#include <stdio.h>
#include <stdlib.h>
#include <env.h>
#include <locale.h>

int main(void)
{
    char *string;
    setenv("LC_TIME", "FRAN", 1);
    setlocale(LC_ALL, "");
    string = setlocale(LC_ALL, NULL);
    printf("string = %s \n", string);
}

Output

If the example is run with POSIX(OFF), the result of printf() is:
string = "S370,S370,S370,S370,FRAN,S370,S370,S370"

If the example is run with POSIX(ON), the result of printf() is:

Example

The following example shows euro currency support:

/* EUROSAMP

This example sets the locale of the program to be Fr_BE.IBM-1148 and Fr_BE.IBM-1148@euro and prints the string associated with each locale.

*/
#include <stdio.h>
#include <locale.h>

int main(void)
{
    char *string;
    string = setlocale(LC_ALL,"Fr_BE.IBM-1148");
    if (string != NULL)
        printf("String = %s \n",string);
    string = setlocale(LC_ALL,"Fr_BE.IBM-1148@euro");
    if (string != NULL)
        printf("String = %s \n",string);
}

Output

String = Fr_BE.IBM-1148
String = Fr_BE.IBM-1148@euro

setlogmask

setlogmask() — Set the mask for the control log

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <syslog.h>

int setlogmask(int maskpri);
```

General description

The setlogmask() function sets the log priority mask for the current process to `maskpri` and returns the previous mask. If the `maskpri` argument is 0 (zero), the current log mask is not modified. Calls by the current process to the `syslog()` function with a priority not set in `maskpri` are rejected. The mask for an individual priority `pri` is calculated by the macro `LOG_MASK(pri)`; the mask for all priorities up to and including `toppri` is given by the macro `LOG_UPTO(toppri)` The default log mask allows all priorities to be logged.

Returned value

If successful, setlogmask() returns the value of the previous mask setting.

No errors are defined.

**setnetent() — Open the network information data set**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

**X/Open:**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void setnetent(int stayopen);
```

**Berkeley sockets:**

```c
#define _OE_SOCKETS
#include <netdb.h>

void setnetent(int stayopen);
```

**General description**

The `setnetent()` function opens and rewinds the `tcpip.HOSTS.ADDRINFO` data set, which contains information about known networks. If the `stayopen` flag is nonzero, the `tcpip.HOSTS.ADDRINFO` remains open after each call to `setnetent()`. You can use the `X_ADDR` environment variable to specify a data set other than `tcpip.HOSTS.ADDRINFO`.

**Note:** For more information on these data sets and environment variables, `tcpip.HOSTS.ADDRINFO`, see the [z/OS Communications Server: IP Configuration Guide](https://www.ibm.com/support/knowledgecenter/SC31-8775), SC31-8775.

**Special behavior for C++:** To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

**Returned value**

`setnetent()` returns no values.

**Related information**

- "netdb.h" on page 48
- "endhostent() — Close the host information data set" on page 476
- "endnetent() — Close network information data sets" on page 477

set_new_handler

set_new_handler() — Register a function for set_new_handler()

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO/ANSI C++</td>
<td>C++ only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <new>

new_handler set_new_handler(new_handler ph) throw();
```

General description

The set_new_handler() function is part of the z/OS XL C++ error handling mechanism. If you have registered a new-handler function with set_new_handler(), that new-handler function will be called by the new operator if it is unable to allocate storage. If you have not registered a new-handler function, the default behavior is for the new operator to return NULL.

The argument supplied to set_new_handler() is of type new_handler as defined in the header <new> (that is, a pointer to a function with a void return type and no arguments).

For C++ applications that are compiled NOXPLINK, the variable containing the address of the new handler function is statically bound with the executable. This means that each executable has its own new handler function which is shared only by the other functions that are linked edited as part of that executable. This is true even if multiple threads are using that same executable. This means that you cannot issue a set_new_handler() from within a non-XPLINK DLL if the new handler function is to be invoked outside of that DLL.

For C++ applications that are compiled XPLINK, the new handler function is truly global, so the DLL restriction is lifted. In a multithreaded environment consisting of XPLINK executables, the new handler function created by a call to set_new_handler() still applies to all threads in the (POSIX) process.

The required behavior of a new handler is to perform one of the following operations:

- Make more storage available for allocation and then return.
- Call either abort() or exit(int).
- Throw an object of type bad_alloc.

Returned value

Returns a value of type new_handler. The function pointed to is the function that was previously called by the set_new_handler() function, or NULL if a new handler function was not established.

Refer to z/OS XL C/C++ Language Reference for more information about z/OS XL C++ error handling, including the new operator and the set_new_handler() functions.

setpeer

setpeer() — Preset the socket peer address

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

**X/Open:**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int setpeer(int socket, struct sockaddr *address, int length, char *name);
```

**Berkeley sockets:**

```c
#define _OE_SOCKETS
#include <sys/socket.h>

int setpeer(int socket, struct sockaddr *address, int length, char *name);
```

General description

The setpeer() function presets the peer address associated with a socket.

**Note:** Neither AF_INET, AF_UNIX, nor AF_INET6 support this function.

**Parameter** | **Description**
---|---
socket | The socket descriptor.
address | The address of the socket peer.
length | The length of the socket address.
name | The name of a field indicating the conditions of the peer request.

**Special behavior for C++:** To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

setpeer() always returns −1.

**Error Code** | **Description**
---|---
EINVAL | The request is invalid or not supported.

setpgid() — Set process group ID for job control

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

int setpgid(pid_t pid, pid_t pgid);
```

General description

Sets the process group ID (PGID) of a process within the session of the calling process, so you can reassign a process to a different process group, or start a new process group with the specified process as its group leader.

`pid_t pid` is the process ID (PID) of the process whose PGID you want to change. This must either be the caller of setpgid() or one of its children, and it must be in the caller's session. It cannot be the PID of a session leader. If `pid` is zero, the system uses the PID of the process calling setpgid().

`pid_t pgid` is the new PGID you want to assign to the process identified by `pid`. If `pgid` indicates an existing process group, it must be in the caller's session. If `pgid` is zero, the system uses the PID of the process indicated by `pid` as the ID for the new process group. The new group is created in the caller's session.

Returned value

If successful, setpgid() returns 0.

If unsuccessful, setpgid() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The value of <code>pid</code> matches the PID of a child of the calling process, but the child has successfully run one of the EXEC functions.</td>
</tr>
<tr>
<td>EINVAL</td>
<td><code>pgid</code> is less than zero or has some other unsupported value.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The caller cannot change the PGID of the specified process. Some possible reasons are:</td>
</tr>
<tr>
<td></td>
<td>- The specified process is a session leader.</td>
</tr>
<tr>
<td></td>
<td>- <code>pid</code> matches the PID of a child of the calling process, but the child is not in the same session as the caller.</td>
</tr>
<tr>
<td></td>
<td>- <code>pgid</code> does not match the PID of the process specified by <code>pid</code>, and it does not match the PGID of any other process in the caller's session.</td>
</tr>
<tr>
<td>ESRCH</td>
<td><code>pid</code> does not match the PID of the calling process or any of its children.</td>
</tr>
</tbody>
</table>
Example

CELEBS09
/* CELEBS09
This example sets the PGID.
*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <sys/types.h>
#include <stdio.h>
main() {
    pid_t pid;
    int p1[2], p2[2];
    char c='?';
    if (pipe(p1) != 0)
        perror("pipe() #1 error");
    else if (pipe(p2) != 0)
        perror("pipe() #2 error");
    else
        if ((pid = fork()) == 0) {
            printf("child's process group id is %d\n", (int) getpgrp());
            write(p2[1], &c, 1);
            puts("child is waiting for parent to complete task");
            read(p1[0], &c, 1);
            printf("child's process group id is now %d\n", (int) getpgrp());
            exit(0);
        }
        else {
            printf("parent's process group id is %d\n", (int) getpgrp());
            read(p2[0], &c, 1);
            printf("parent is performing setpgid() on pid %d\n", (int) pid);
            if (setpgid(pid, 0) != 0)
                perror("setpgid() error");
            write(p1[1], &c, 1);
            printf("parent's process group id is now %d\n", (int) getpgrp());
            sleep(5);
        }
    }
}

Output
parent's process group id is 5767174
child's process group id is 5767174
parent is performing setpgid() on pid 131084
parent's process group id is now 5767174
child is waiting for parent to complete task
child's process group id is now 131084

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

pid_t setpgrp(void);
```

General description

If the calling process is not already a session leader, setpgrp() sets the process group ID of the calling process to the process ID of the calling process. If a new process group is created, it is created within the session of the calling process.

Returned value

If successful, setpgrp() returns the new process group ID.

If unsuccessful, setpgrp() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPERM</td>
<td>The calling process is a session leader.</td>

setpriority

setpriority() — Set process scheduling priority

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int setpriority(int which, id_t who, int priority);
```

General description

setpriority() sets the scheduling priority of a process, process group or user.

Processes are specified by the values of the `which` and `who` arguments. The `which` argument may be any one of the following set of symbols defined in the `sys/resource.h` include file:

- `PRIO_PROCESS` indicates that the `who` argument is to be interpreted as a process ID
- `PRIO_PGRP` indicates that the `who` argument is to be interpreted as a process group ID
- `PRIO_USER` indicates that the `who` argument is to be interpreted as a user ID

The `who` argument specifies the ID (process, process group, or user). A 0 (zero) value for the `who` argument specifies the current process, process group or user ID.

The `priority` argument specifies the scheduling priority. It is specified as a signed integer in the range, -20 to 19. Negative priorities cause more favorable scheduling. The default priority is 0. If the value specified to `setrlimit()` is less than the system's lowest supported priority value, the system's lowest supported value is used; if it is greater than the system's highest supported value, the system's highest supported value is used. The setting of a process's scheduling priority value has the equivalent effect on a process's nice value, since they both represent the process's relative CPU priority. For example, setting one's scheduling priority value to its maximum value (19) has the equivalent effect of increasing one's nice value to its maximum value ($(2^\text{NZERO})-1$), and will be reflected on the `nice()`, `getpriority()` and `setpriority()` functions.

If more than one process is specified, `setpriority()` sets the priorities of all of the specified processes to the specified value.

Only a process with appropriate privilege can lower its priority.

Returned value

If successful, `setpriority()` returns 0.

If unsuccessful, `setpriority()` returns -1 and sets `errno` to one of the following values:
## setpriority

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>

</tbody>
</table>

Format

X/Open:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void setprotoent(int stayopen);
```

Berkeley sockets:

```c
#define _OE_SOCKETS
#include <netdb.h>

void setprotoent(int stayopen);
```

General description

The setprotoent() function opens and rewinds the `/etc/protocol` or the `tcpip.ETC.PROTO` data set. If the `stayopen` flag is nonzero, the `/etc/protocol` or the `tcpip.ETC.PROTO` data set remains open after each call.

Special behavior for C++

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

`setprotoent()` returns no values.

**setregid() — Set real and effective group IDs**

## Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

## Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int setregid(gid_t rgid, gid_t egid);
```

## General description

The `setregid()` function sets the real and/or effective GIDs for the calling process to the values specified by the input real and effective GID values. If a specified value is equal to -1, the corresponding real or effective GID of the calling process is left unchanged.

A process with appropriate privileges can set the real and effective GID to any valid GID value. An unprivileged process can only set the effective GID if the EGID argument is equal to either the real, effective, or saved GID of the process. An unprivileged process can only set the real GID if the RGID argument is equal to either the real, effective, or saved GID of the process.

If the `setregid()` function is issued from multiple tasks within one address space, use synchronization to ensure that the `setregid()` functions are not performed concurrently. The execution of `setregid()` function concurrently within one address space can yield unpredictable results.

The `setregid()` function does not change any supplementary GIDs of the calling process.

## Returned value

If successful, `setregid()` returns 0.

If unsuccessful, neither of the group IDs will be changed, `setregid()` returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of the <code>rgid</code> or <code>egid</code> argument is invalid or out-of-range.</td>
</tr>

<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int setreuid(uid_t ruid, uid_t euid);
```

General description

The setreuid() function sets the real and/or effective UIDs for the calling process to the values specified by the input real and effective UID values. If a specified value is equal to -1, the corresponding real or effective UID of the calling process is left unchanged.

A process with appropriate privileges can set the real and effective UID to any valid UID value. An unprivileged process can only set the effective UID if the EUID argument is equal to either the real, effective, or saved UID of the process. An unprivileged process can only set the real UID if the RUID argument is equal to either the real, effective, or saved UID of the process.

The setreuid() function is not supported from an address space running multiple processes, since it would cause all processes in the address space to have their security environment changed unexpectedly.

setreuid() can be used by daemon processes to change the identity of a process in order for the process to be used to run work on behalf of a user. In z/OS UNIX, changing the identity of a process is done by changing the real and effective UIDs and the auxiliary groups. In order to change the identity of the process on MVS completely, it is necessary to also change the MVS security environment. The identity change will only occur if the EUID value is specified, changing just the real UID will have no effect on the MVS environment.

The setreuid() function invokes MVS SAF services to change the MVS identity of the address space. The MVS identity that is used is determined as follows:

- If an MVS user ID is already known by the kernel from a previous call to a kernel function (for example, getpwnam()) and the UID for this user ID matches the UID specified on the setreuid() call, then this user ID is used.
- For nonzero target UIDs, if there is no saved user ID or the UID for the saved user ID does not match the UID requested on the setreuid() call, the setreuid() function queries the security database (for example, using getpwnam()) to retrieve a user ID. The retrieved user ID is then used.
- If the target UID=0 and a user ID is not known, the setreuid() function always sets the MVS user ID to BPXROOT or the value specified on the SUPERUSER parm in sysparms. BPXROOT is set up during system initialization as a superuser with a UID=0. The BPXROOT user ID is not defined to the BPX.DAEMON FACILITY class profile. This special processing is necessary to prevent a superuser from gaining daemon authority.
setreuid

- A non-daemon superuser that attempts to set a user ID to a daemon superuser UID fails with an EPERM.

When the MVS identity is changed, the auxiliary list of groups is also set to the list of groups for the new user ID.

If the setreuid() function is issued from multiple tasks within one address space, use synchronization to ensure that the setreuid() functions are not performed concurrently. The execution of setreuid() function concurrently within one address space can yield unpredictable results.

**Returned value**

If successful, setreuid() returns 0.

If unsuccessful, neither of the group IDs will be changed, setreuid() returns -1, and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>

setrlimit() — Control maximum resource consumption

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int setrlimit(int resource, const struct rlimit *rlp);
```

General description

The `setrlimit()` function sets resource limits for the calling process. A resource limit is a pair of values; one specifying the current (soft) limit, the other a maximum (hard) limit.

The soft limit may be modified to any value that is less than or equal to the hard limit. For certain resource values, (RLIMIT_CPU, RLIMIT_NOFILE, RLIMIT_AS), the soft limit cannot be set lower than the existing usage.

The hard limit may be lowered to any value that is greater than or equal to the soft limit. The hard limit can be raised only by a process which has superuser authority. Both the soft limit and hard limit can be changed by a single call to `setrlimit()`.

The value RLIM_INFINITY defined in `<sys/resource.h>`, is considered to be larger than any other limit value. If a call to `getrlimit()` returns RLIM_INFINITY for a resource, it means the implementation does not enforce limits on that resource. Specifying RLIM_INFINITY as any resource limit values on a successful call to `setrlimit()` inhibits enforcement of that resource limit.

The `resource` argument specifies which resource to set the hard and/or soft limits for, and may be one of the following values:

- **RLIMIT_CORE**
  - The maximum size of a dump of memory (in bytes) allowed for the process. A value of 0 (zero) prevents file creation. Dump file creation will stop at this limit.

- **RLIMIT_CPU**
  - The maximum amount of CPU time (in seconds) allowed for the process. If the limit is exceeded, a SIGXCPU signal is sent to the process and the process is granted a small CPU time extension to allow for signal generation and delivery. If the extension is used up, the process is terminated with a SIGKILL signal. An attempt to set the CPU limit lower than that already used will result in an EINVAL errno.

- **RLIMIT_DATA**
  - The maximum size of the break value for the process, in bytes. In this implementation, this resource always has a hard and soft limit value of RLIM_INFINITY. A call to `setrlimit()` to set this resource to any value other than RLIM_INFINITY will fail with an errno of EINVAL.
The maximum file size (in bytes) allowed for the process. A value of 0 (zero) prevents file creation. If the size is exceeded, a SIGXFSZ signal is sent to the process. If the process is blocking, catching, or ignoring SIGXFSZ, continued attempts to increase the size of a file beyond the limit will fail with an errno of EFBIG.

The maximum amount of usable storage above the 2 gigabyte bar (in 1 megabyte segments) that can be allocated. Any attempt to extend the usable amount of virtual storage above the 2 gigabyte bar fails.

The maximum number of open file descriptors allowed for the process. This number is one greater than the maximum value that may be assigned to a newly created descriptor. (That is, it is one-based.) Any function that attempts to create a new file descriptor beyond the limit will fail with an EMFILE errno. An attempt to set the open file descriptors limit lower than that already used will result in an EINVAL errno.

Restrictions: This value may not exceed 524288.

The maximum size of the stack for a process, in bytes. Note that in z/OS UNIX services, the stack is a per-thread resource. In this implementation, this resource always has a hard and soft limit value of RLIM_INFINITY. A call to setrlimit() to set this resource to any value other than RLIM_INFINITY will fail with an errno of EINVAL.

The maximum address space size for the process, in bytes. If the limit is exceeded, malloc() and mmap() functions will fail with an errno of ENOMEM. Also, automatic stack growth will fail.

The rlp argument points to a rlimit structure. This structure contains the following members:

- rlim_cur: The current (soft) limit
- rlim_max: The maximum (hard) limit

Refer to the <sys/resource.h> header for more detail.

The resource limit values are propagated across exec and fork.

Special behavior for z/OS UNIX Services: An exception exists for exec processing in conjunction with daemon support. If a daemon process invokes exec and it had previously invoked setuid() before exec, the RLIMIT_CPU, RLIMIT_AS, RLIMIT_CORE, RLIMIT_FSIZE, and RLIMIT_NOFILE limit values are set based on the limit values specified in the kernel parmlib member BPXPRMxx.

For processes which are not the only process within an address space, the RLIMIT_CPU and RLIMIT_AS limits are shared with all the processes within the address space. For RLIMIT_CPU, when the soft limit is exceeded, action will be taken on the first process within the address space. If the action is termination, all processes within the address space will be terminated.
setrlimit

In addition to the RLIMIT_CORE limit values, the dump file defaults are set by SYSMDUMP defaults. Refer to z/OS MVS Initialization and Tuning Reference for more information on setting up SYSMDUMP defaults using the IEADMR00 parmlib member.

Dumps of memory are taken in 4160 byte increments. Therefore, RLIMIT_CORE values affect the size of memory dumps in 4160 byte increments. For example, if the RLIMIT_CORE soft limit value is 4000, the dump will contain no data. If the RLIMIT_CORE soft limit value is 8000, the maximum size of a memory dump is 4160 bytes.

When setting RLIMIT_NOFILE, the hard limit cannot exceed the system defined limit of 524288.

Large file support for z/OS UNIX files:

Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLEVEL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If successful, setrlimit() returns 0.

If unsuccessful, setrlimit() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>An invalid resource was specified, or the soft limit to set exceeds the hard limit to set, the soft limit to set is below the current usage, or the resource does not allow any value other than RLIM_INFINITY.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The limit specified to setrlimit() would have raised the maximum limit value, and the calling process does not have appropriate privileges.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _POSIX_SOURCE
#include <unistd.h>

pid_t setsid(void);
```

**General description**

Creates a new session with the calling process as its session leader. The caller becomes the process group leader of a new process group. The calling process must not be a process group leader already. The caller does not have a controlling terminal.

The process group ID (PGID) of the new process group is equal to the process ID (PID) of the caller. The caller starts as the only process in the new process group and in the new session.

**Returned value**

If successful, setsid() returns the value of the caller's new PGID.

If unsuccessful, setsid() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPERM</td>
<td>One of the following error conditions exists:</td>
</tr>
<tr>
<td></td>
<td>• The caller is already a process group leader.</td>
</tr>
<tr>
<td></td>
<td>• The caller's PID matches the PGID of some other process.</td>
</tr>
</tbody>
</table>

**Example**

```c
CELEBS10
/* CELEBS10

  This example creates a new session.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <sys/types.h>
#include <stdio.h>

int main() {
    pid_t pid;
    int p[2];
    char c='?';

    if (pipe(p) != 0)
        perror("pipe() error");
    return 0;
}
```
else
  if ((pid = fork()) == 0) {
    printf("child's process group id is %d\n", (int) getpgrp());
    write(p[1], &c, 1);
    setsid();
    printf("child's process group id is now %d\n", (int) getpgrp());
    exit(0);
  } else {
    printf("parent's process group id is %d\n", (int) getpgrp());
    read(p[0], &c, 1);
    sleep(5);
  }

Output
child's process group id is 262152
child's process group id is now 262150
parent's process group id is 262152

#include <sys/socket.h>

int setsockopt(int socket, int level, int option_name,
               char *option_value, int *option_length);
```

IPv6: To include support for IPv6 socket options, add the following code:

```c
#define _OPEN_SYS_SOCK_IPV6 1
#include <netinet/in.h>
```

**ip_mreq structure:** To include the ip_mreq structure in your program, add the following code:

```c
#define _XOPEN_SOURCE 500
#include <netinet/in.h>

or
```

```c
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>
```

**group_req structure:** To include the group_req structure in your program, add the following code:

```c
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>
```

**group_source_req structure:** To include the group_source_req structure in your program, add the following code:

```c
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>
```

**ipv6_mreq structure:** To include the ipv6_mreq structure in your program, add the following code:

```c
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>
```

**icmp6_filter structure:** To include the icmp6_filter structure in your program, add the following code:
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/icmp6.h>

General description

The `setsockopt()` function sets options associated with a socket. Options can exist at multiple protocol levels.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>socket</td>
<td>The socket descriptor.</td>
</tr>
<tr>
<td>level</td>
<td>The level for which the option is being set.</td>
</tr>
<tr>
<td>option_name</td>
<td>The name of a specified socket option.</td>
</tr>
<tr>
<td>option_value</td>
<td>The pointer to option data.</td>
</tr>
<tr>
<td>option_length</td>
<td>The length of the option data.</td>
</tr>
</tbody>
</table>

When manipulating socket options, you must specify the level at which the option resides and the name of the option. To manipulate options at the socket level, the `level` parameter must be set to SOL_SOCKET as defined in `sys/socket.h`. To manipulate options at the IPv4 or IPv6 level, the `level` parameter must be set to IPPROTO_IP as defined in `sys/socket.h` or IPPROTO_IPV6 as defined in `netinet/in.h`. To manipulate options at any other level, such as the TCP level, supply the appropriate protocol number for the protocol controlling the option. The `getprotobyname()` call can be used to return the protocol number for a named protocol.

The `option_value` and `option_length` parameters are used to pass data used by the particular set command. The `option_value` parameter points to a buffer containing the data needed by the set command. The `option_value` parameter is optional and can be set to the NULL pointer, if data is not needed by the command. The `option_length` parameter must be set to the size of the data pointed to by `option_value`.

All of the socket-level options except SO_LINGER, SO_RCVTIMEO and SO_SNDTIMEO, expect `option_value` to point to an integer and `option_length` to be set to the size of an integer. When the integer is nonzero, the option is enabled. When it is zero, the option is disabled. The SO_LINGER option expects `option_value` to point to a `linger` structure, as defined in `sys/socket.h`. This structure is defined in the following example:

```c
struct linger
{
    int l_onoff;  /* option on/off */
    int l_linger; /* linger time */
};
```

The `l_onoff` field is set to 0 if the SO_LINGER option is begin disabled. A nonzero value enables the option. The `l_linger` field specifies the amount of time to linger on close. The units of `l_linger` are seconds.

The following options are recognized at the IPv4 level:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_ADD_MEMBERSHIP</td>
<td>(RAW and UDP) This option is used to join a multicast group on a specific interface (an interface has to be specified with this option).</td>
</tr>
</tbody>
</table>
Only applications that want to receive multicast datagrams need to join multicast groups. Applications that only transmit will not need to do so.

The multicast IP address and the interface IP address will be passed in the following structure available in netinet/in.h:

```c
struct ip_mreq
{
  struct in_addr imr_multiaddr; /* IP multicast addr of group */
  struct in_addr imr_interface; /* local IP addr of interface */
};
```

If INADDR_ANY is specified on the interface address of the mreq structure passed a default interface will be chosen as follows:
- If the group address specified in the mreq structure was specified on a GATEWAY statement use that interface.
- If 224.0.0.0 was specified on GATEWAY statement use that interface.
- If DEFAULTNET was specified and is multicast capable use that interface.

**IP_ADD_SOURCE_MEMBERSHIP**
(raw and UDP) This option is used to join a source-specific multicast group specified by the ip_mreq_source structure. The ip_mreq_source structure is defined in netinet/in.h.

**IP_BLOCK_SOURCE**
(raw and UDP) This option is used to block from a given source to a given multicast group (e.g., if the user "mutes" that source). The source multicast group is specified by the ip_mreq_source structure which is defined in netinet/in.h.

**IP_DROP_MEMBERSHIP**
(raw and UDP) This option is used to leave a multicast group.

The multicast IP address and the interface IP address will be passed in the following structure available in netinet/in.h:

```c
struct ip_mreq
{
  struct in_addr imr_multiaddr; /* IP multicast addr of group */
  struct in_addr imr_interface; /* local IP addr of interface */
};
```

If INADDR_ANY is specified on the interface address of the mreq structure passed the system will drop the first group that matches the group (class D) address without regard to the interface.

**IP_DROP_SOURCE_MEMBERSHIP**
(raw and UDP) This option is used to leave a source-specific multicast group specified by the ip_mreq_source structure. The ip_mreq_source structure is defined in netinet/in.h.

**IP_MULTICAST_IF**
(raw and UDP) Sets the interface for sending outbound multicast datagrams from this socket application. Multicast datagrams will be transmitted only on one interface at a time. An IP address is passed in an in_addr structure.

If INADDR_ANY is specified for the interface address passed a default interface will be chosen as follows:
- If 224.0.0.0 was specified on GATEWAY statement use that interface.
If DEFAULTNET was specified and is multicast capable use that interface.

**IP_MULTICAST_LOOP**
(RAW and UDP) Enables or disables loopback of outgoing multicast datagrams. Default is enable. When it is enabled, multicast applications that have joined the outgoing multicast group can receive a copy of the multicast datagrams destined for that address/port pair. The loopback indicator is passed as an u_char. The value 0 is specified to disable loopback. The value 1 is specified to enable loopback.

**IP_MULTICAST_TTL**
(RAW and UDP) Sets the IP time-to-live of outgoing multicast datagrams. Default value is 1 (that is, multicast only to the local subnet). The TTL value is passed as an u_char.

**IP_RECVPKINFO**
(RAW and UDP) Enables or disables returning the destination IP address of an incoming packet and the interface over which the packet was received as IP_PKTINFO ancillary data on recvmsg() function calls. The option value is specified as an int. A nonzero value enables the option; 0 disables the option.

This option is protected by the _OPEN_SYS_SOCK_EXT4 feature test macro.

**IP_UNBLOCK_SOURCE**
(RAW and UDP) This option is used to undo the operation performed with the IP_BLOCKSOURCE option (e.g., if the user "mutes" that source). The source group is specified by the ip_mreq_source structure which is defined in netinet/in.h.

**MCAST_BLOCK_SOURCE**
(RAW and UDP) This option is used to block data from a given source to a given group (e.g., if the user "mutes" that source). The source is specified by the group_source_req structure which is defined in netinet/in.h.

**MCAST_JOIN_GROUP**
(RAW and UDP) This option is used to join an any-source group. The group is specified by the group_req structure. The group_req structure is defined in netinet/in.h.

**MCAST_JOIN_SOURCE_GROUP**
(RAW and UDP) This option is used to join a source-specific group. The source is specified by the group_source_req structure which is defined in netinet/in.h.

**MCAST_LEAVE_GROUP**
(RAW and UDP) This option is used to leave an any-source group. The group is specified by the group_req structure. The group_req structure is defined in netinet/in.h.

**MCAST_LEAVE_SOURCE_GROUP**
(RAW and UDP) This option is used to leave a source-specific group. The source is specified by the group_source_req structure which is defined in netinet/in.h.

**MCAST_UNBLOCK_SOURCE**
(RAW and UDP) This option is used to undo the operation
performed with the MCAST_BLOCK_SOURCE option (e.g., if the user then "unmutes" the source). The source is specified by the group_source_req structure which is defined in netinet/in.h.

The following options are recognized at IPv6 level:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPV6_ADDR_PREFERENCES</td>
<td>(TCP and UDP) Used to set the source address selection preference flags for a given socket. The socket option value (optval) is a 32-bit unsigned integer argument. The argument consists of a number of flags where each flag indicates a source address selection preference. These flags indicate the application's preferences for a source address, but will be ignored by the TCP stack if an IP address with the preferred address attributes is not available. For example, a preference flag of IPV6_PREFER_SRC_TMP tells the stack that the application would prefer to use a temporary IPv6 source address rather than a public source address. You can combine multiple flags with logical OR to express multiple preferences as long as the flags are not contradictory. The constants for the flag bit values are defined in netinet/in.h.</td>
</tr>
<tr>
<td>IPV6_CHECKSUM</td>
<td>(RAW) For a RAW (non-ICMPv6) socket, this option instructs the kernel to compute and store a checksum for output and verifies the received checksum on input. This prevents applications from having to perform source address selection on the packets sent. This option specifies an integer value into the user data where the checksum is located. This option can be disabled by specifying an option value of -1.</td>
</tr>
<tr>
<td>IPV6_DONTFRAG</td>
<td>(RAW and UDP) This option turns off the automatic inserting of a fragment header in the packet for UDP and raw sockets.</td>
</tr>
<tr>
<td>IPV6_DSTOPTS</td>
<td>(RAW and UDP) The application can remove any sticky destination options header by calling setsockopt() for this option with a zero option length.</td>
</tr>
<tr>
<td>IPV6_HOPOPTS</td>
<td>(RAW and UDP) The application can remove any sticky hop-by-hop options header by calling setsockopt() for this option with a zero option length.</td>
</tr>
<tr>
<td>IPV6_JOIN_GROUP</td>
<td>(RAW and UDP) Controls the receipt of multicast packets by joining the multicast group specified by the ipv6_mreq structure that is passed. The ipv6_mreq structure is defined in netinet/in.h.</td>
</tr>
<tr>
<td>IPV6_LEAVE_GROUP</td>
<td>(RAW and UDP) Controls the receipt of multicast packets by leaving the multicast group specified by the ipv6_mreq structure that is passed. The ipv6_mreq structure is defined in netinet/in.h.</td>
</tr>
<tr>
<td>IPV6_MULTICAST_HOPS</td>
<td>(RAW and UDP) Sets the hop limit for outgoing multicast packets. The hop limit value is passed as an int.</td>
</tr>
</tbody>
</table>
**IPV6_MULTICAST_IF**
(RAW and UDP) Sets the interface for outgoing multicast packets. An interface index is used to specify the interface. It is passed as an u_int.

**IPV6_MULTICAST_LOOP**
(RAW and UDP) If a multicast datagram is sent to a group to which the sending host itself belongs (on the outgoing interface), a copy of the datagram is looped back by the IP layer for local delivery if this option is set to one. If this option is set to zero, a copy is not looped back. Other option values return an errno of EINVAL. The default is one (loopback). The option value is passed as an int.

**IPV6_NEXTHOP**
(RAW and UDP) Specifies the next hop for the datagram as a socket address structure.

**IPV6_RECV_DST_OPTS**
(RAW and UDP) To receive destination options header this option must be enabled.

**IPV6_RECV_HOPLIMIT**
(RAW, TCP, and UDP) When this option is enabled, the received hop limit from an incoming packet will be returned as IPV6_HOPLIMIT ancillary data on recvmsg() function calls. The option value is specified as an int. A nonzero value enables the option, zero disables the option.

**IPV6_RECV_HOPOPTS**
(RAW and UDP) To receive a hop-by-hop options header this option must be enabled.

**IPV6_RECV_PATHMTU**
(RAW and UDP) Enables the receipt of IPV6_PATHMTU ancillary data on recvmsg() function calls.

**IPV6_RECV_PKTINFO**
(RAW and UDP) Enables or disables returning the destination IP address of an incoming packet and the interface over which the packet was received as IPV6_PKTINFO ancillary data on recvmsg() function calls. The option value is specified as an int. A nonzero value enables the option; 0 disables the option.

**IPV6_RECV_RTHDR**
(RAW and UDP) To receive a routing header this option must be enabled.

**IPV6_RECV_TCLASS**
(RAW, TCP, and UDP) To receive the traffic class this option must be enabled.

**IPV6_RTHDR**
(RAW and UDP) The application can remove any sticky routing header by calling setsockopt() for this option with a zero option length.

**IPV6_RTHDR_DST_OPTS**
(RAW and UDP) The application can remove any sticky destination options header by calling setsockopt() for this option with a zero option length.

**IPV6_TCLASS**
(RAW, TCP, and UDP) To specify the traffic class value this option must be enabled.
IPV6_UNICAST_HOPS
(RAW and UDP) Used to control hop limit in outgoing unicast IPv6 packets. The hop limit value is passed as an int.

IPV6_USE_MIN_MTU
(RAW, TCP, and UDP) Indicates whether the IP layer will use the minimum MTU size (1280) for sending packets, bypassing path MTU discovery. The option value is passed as an int. A value of -1 causes the default values for unicast (disabled) and multicast (enabled) destinations to be used. A value of 0 disables this option for unicast and multicast destinations. A value of 1 enables this option for unicast and multicast destinations and the minimum MTU size will be used.

IPV6_V6ONLY (RAW, TCP, and UDP) Used to determine whether a socket is restricted to IPv6 communications only. The default setting is off. The option value is passed as an int. A non-zero value means the option is enabled (socket can only be used for IPv6 communications). 0 means the option is disabled.

**Note:** To use these options, you must use the feature test macro `#define _OPEN_SYS_SOCK_IPV6`.

The following options are recognized at the ICMPv6 level:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP6_FILTER</td>
<td>(RAW) Used to filter ICMPv6 messages. The option value is passed as an icmp6_filter structure. The icmp6_filter structure is defined in netinet/icmp6.h.</td>
</tr>
</tbody>
</table>

The following options are recognized at the socket level:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SO_BROADCAST</td>
<td>Toggles the ability to broadcast messages. If enabled, this option allows the application program to send broadcast messages over socket, if the interface specified in the destination supports broadcasting of packets. This option has no meaning for stream sockets.</td>
</tr>
<tr>
<td>SO_DEBUG</td>
<td>Turns on recording of debugging information. This option enables or disables debugging in the underlying protocol modules. This option takes an int value.</td>
</tr>
<tr>
<td>SO_KEEPALIVE</td>
<td>Toggles the TCP keep-alive mechanism for a stream socket. When activated, the keep-alive mechanism periodically sends a packet on an otherwise idle connection. If the remote TCP does not respond to the packet or to retransmissions of the packet, the connection is terminated with the error ETIMEDOUT.</td>
</tr>
<tr>
<td>SO_LINGER</td>
<td>Lingers on close if data is present. When this option is enabled and there is unsent data present when close() is called, the calling application program is blocked during the close() call, until the data is transmitted or the connection has timed out. If this option is disabled, the TCP/IP address space waits to try to send the data. Although the data transfer is usually successful, it cannot be</td>
</tr>
</tbody>
</table>
guaranteed, because the TCP/IP address space waits only a finite amount of time trying to send the data. The close() call returns without blocking the caller. This option has meaning only for stream sockets.

SO_OOBINLINE
Toggles the reception of out-of-band data. When this option is enabled, it causes out-of-band data to be placed in the normal data input queue as it is received, making it available to recv(), recvfrom(), and recvmsg() without having to specify the MSG_OOB flag in those calls. When this option is disabled, it causes out-of-band data to be placed in the priority data input queue as it is received, making it available to recv(), recvfrom(), and recvmsg() only by specifying the MSG_OOB flag in those calls. This option has meaning only for stream sockets.

_SO_PROPAGATEUSERID
Toggles propagating a user ID (UID) over an AF_UNIX stream socket. When enabled, user (UID) information is extracted from the system when the connect() function is invoked. Then, when the accept() function is invoked, the accepter assumes the identity of the connecter until the accepted socket is closed.

SO_RCVBUF
Sets receive buffer size. This option takes an int value. The value cannot be set after the socket is connected.

SO_RCVTIMEO
Sets the timeout specifying the maximum amount of time an input function waits until it completes.

It accepts a timeval structure with the number of seconds and microseconds specifying the limit on how long to wait for an input operation to complete. The timeval structure contains the number of seconds and microseconds specified as fullword binary numbers. The seconds can be a value in the range from 0 to 2,678,400 (equal to 31 days), and the microseconds can be a value in the range from 0 to 1,000,000 (equal to 1 second). While the timeval structure can be specified using microsecond granularity, the internal TCP/IP timers used to implement this function have a granularity of approximately 100 milliseconds.

If a receive operation has blocked for this much time without receiving additional data, it returns with a partial count or errno set to EWOULDBLOCK if no data is received. The default for this option is zero, which indicates that a receive operation does not time out.

SO_REUSEADDR
Toggles local address reuse. When enabled, this option allows local addresses that are already in use to be bound. This alters the normal algorithm used in the bind() call.

The system checks at connect time to ensure that the local address and port do not have the same foreign address and port. The error EADDRINUSE is returned if the association already exists.

After the SO_REUSEADDR option is active, the following situation is supported:
setsockopt

A server can bind() the same port multiple times as long as every invocation uses a different local IP address and the wildcard address INADDR_ANY is used only one time per port.

SO_SNDBUF
Sets send buffer size. This option takes an int value. The value cannot be set after the socket is connected.

SO_SNDTIMEO
Sets the timeout value specifying the amount of time that an output function blocks due to flow control preventing data from being sent. It accepts a timeval structure with the number of seconds and microseconds specifying the limit on how long to wait for an input operation to complete. The timeval structure contains the number of seconds and microseconds specified as fullword binary numbers. The seconds can be a value in the range from 0 to 2,678,400 (equal to 31 days), and the microseconds can be a value in the range from 0 to 1,000,000 (equal to 1 second). While the timeval structure can be specified using microsecond granularity, the internal TCP/IP timers used to implement this function have a granularity of approximately 100 milliseconds.

If a send operation has blocked for this time, it returns with a partial count or with errno set to EWOULDBLOCK if no data is sent. The default for this option is zero, which indicates that a send operation does not time out.

SO_SECINFO
Toggles receiving security information. When enabled on an AF_UNIX UDP socket, the recvmsg() function will return security information about the sender of each datagram as ancillary data. This information contains the sender's user ID, UID, GID, and job name and it is mapped by the secsinfo structure in sys/socket.h.

Note: To use these options, you must use the Feature Test Macro #define _OPEN_SYS_SOCK_IPV6.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, setsockopt() returns 0.

If unsuccessful, setsockopt() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EADDRNOTAVAIL</td>
<td>The ipi6_addr is not available for use on the ipi6_ifindex interface or the tuple consisting of socket, interface, and multicast group values does not exist.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The socket parameter is not a valid socket descriptor.</td>
</tr>
<tr>
<td>EDOM</td>
<td>The send or receive timeout values exceed 31 days.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using option_value and option_length parameters would result in an attempt to access storage outside the caller's address space.</td>
</tr>
</tbody>
</table>
EHOSTUNREACH
No route to the destination exists over the interface specified by ifi6_ifindex.

EINVAL
The specified option is invalid at the specified socket level or the socket has been shut down.

ENETDOWN
The interface specified by ipi6_ifindex is not enabled for IPv6 use.

ENOBUFFS
Insufficient system resources are available to complete the call or a maximum of 64 source filters can be specified per multicast group, interface pair.

ENOPROTOOPT
The option_name parameter is unrecognized, or the level parameter is not SOL_SOCKET.

ENOSYS
The function is not implemented. You attempted to use a function that is not yet available.

ENOTSOCK
The descriptor is for a file, not for a socket.

ENXIO
The interface specified by ipi6_ifindex does not exist.

Example
The following are examples of the setsockopt() call. See setsockopt() — Get the options associated with a socket" on page 882 for examples of how the setsockopt() options set are queried.

```c
int rc;
int s;
int option_value;
struct linger l;
int setsockopt(int s, int level, int option_name, char *option_value,
  int option_len);

/* I want out of band data in the normal input queue */
option_value = 1;
rc = setsockopt(s, SOL_SOCKET, SO_OOBINLINE, (char *) &option_value, sizeof(int));

/* I want to linger on close */
l.l_onoff = 1;
l.l_linger = 100;
rc = setsockopt(s, SOL_SOCKET, SO_LINGER, (char *) &l, sizeof(l));
```

setsourcefilter

**setsourcefilter() — Set source filter**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC3678</td>
<td>both</td>
<td>z/OS V1.9</td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SYS_SOCK_EXT3
#include <netinet/in.h>

int setsourcefilter(int s, uint32_t interface, struct sockaddr *group,
socklen_t grouplen, uint32_t fmode, uint32_t numsrc,
struct sockaddr_storage *slist);
```

**General description**

This function allows applications to set and replace the current multicast filtering state for a tuple consisting of socket, interface, and multicast group values.

A multicast filter is described by a filter mode, which is MCAST_INCLUDE or MCAST_EXCLUDE, and a list of source addresses which are filtered.

This function is protocol-independent. It can be on either AF_INET or AF_INET6 sockets of the type SOCK_DGRAM or SOCK_RAW.

If the function is unable to obtain the required storage, control will not return to the caller. Instead, the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

**Argument**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
</tr>
<tr>
<td>interface</td>
</tr>
<tr>
<td>group</td>
</tr>
<tr>
<td>grouplen</td>
</tr>
<tr>
<td>fmode</td>
</tr>
<tr>
<td>numsrc</td>
</tr>
<tr>
<td>slist</td>
</tr>
</tbody>
</table>

**Returned value**

If successful, the function returns 0. Otherwise, it returns -1 and sets errno to one of the following values.
errno Description

EBADF
  s is not a valid socket descriptor.

EAFNOSUPPORT
  The address family of the input sockaddr is not AF_INET or AF_INET6.

EPROTOTYPE
  The socket s is not of type SOCK_DGRAM or SOCK_RAW.

EINVAL
  Interface or group is not a valid address, or the socket s has already requested multicast setsockopt options (refer to z/OS Communications Server: IP Sockets Application Programming Interface Guide and Reference for details.) Or if the group address family is AF_INET and grouplen is not at least size of sockaddr_in or if the group address family is AF_INET6 and grouplen is not at least size of sockaddr_in6 or if grouplen is not at least size of sockaddr_in.

ENOBUFFS
  The number of the source addresses exceeds the allowed limit.

setstate

setstate() — Change generator for random()

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *setstate(const char *state);
```

General description

The setstate() function allows switching between state arrays used by the random() function once a state has been initialized. The array defined by the `state` argument is used for further random-number generation by the calling thread until initstate() is called or setstate() is called again. The setstate() function returns a pointer to the previous state array.

After initialization, a state array can be restarted at a different point by calling setstate() with the desired state, followed by srandom() with the desired seed.

Returned value

If successful, setstate() returns a pointer to the previous state array.

If unsuccessful, setstate() returns a NULL pointer. The function will fail and write a message to standard error if it detects that the state information has been damaged.

set_terminate() — Register a function for terminate()

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANSI/ISO C++</td>
<td>C++ only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <exception>

terminate_handler set_terminate(terminate_handler ph) throw();
```

General description

The set_terminate() function is part of the z/OS XL C++ error handling mechanism. The argument supplied to set_terminate() is of type terminate_handler as defined in the header <exception> (that is, a pointer to a function with a void return type and no arguments). The function specified will be called by the terminate() function.

Note that the function registered for terminate() must terminate execution of the program without returning to its caller(). If set_terminate() has not yet been called, then terminate() calls a system-defined default terminate handler, which calls abort().

In a multithreaded environment, the terminate function created by the issuance of a set_terminate() call applies to all threads in the (POSIX) process. If a thread throws an exception which is not caught by that thread of execution, then terminate() is called. The default terminate() action calls abort() which by default cause a SIGABRT signal. If there is no signal handler, then SIGABRT terminates the process. You can override this with a thread-level termination by supplying a function which invokes pthread_exit() as a terminate function. This terminates the thread but not the process.

Returned value

set_terminate() returns the address of the previous terminate_handler.

Refer to [z/OS XL C/C++ Language Reference](#) for more information about z/OS XL C++ exception handling, including the set_terminate() function.

**_SET_THLIIPADDR**

**_SET_THLIIPADDR() — Set the client's IP address**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <sys/__ussos.h>

int _SET_THLIIPADDR(ln, ipaddr);
```

**General description**

The _SET_THLIIPADDR() macro provides a way for daemons to set a client's IP address.

_SET_THLIIPADDR() takes the following arguments:

- `ln`: The length of the IP address as specified by `ipaddr`. The IP address length can be between 1 and 16 inclusive. The argument is specified as an unsigned int.
- `ipaddr`: Pointer to the IP address.

**Usage notes**

The intent of the _SET_THLIIPADDR() macro is to provide a way for daemons to set the IP address of a client for Security Authorization Facility (SAF) exits when performing security related functions.

**Restrictions**

Results are unpredictable if _SET_THLIIPADDR() is issued outside of the z/OS UNIX environment.

**Returned value**

If the client's IP address is set, _SET_THLIIPADDR() returns nonzero.

_SET_THLIIPADDR() returns 0 and does not set the IP address of the client when:
- The base level of z/OS UNIX is not OS/390 R5.
- The setting of the IP address is not supported.
- The length of the IP address is less than 1 or greater than 16.

<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

int setuid(uid_t uid);
```

General description

Sets the real, effective, or saved set user IDs (UIDs) for the current process to `uid`.

If `uid` is the same as the real UID or the saved set-user-ID of the process, `setuid()` always succeeds and sets the effective UID. The real user ID and saved set-user-ID will remain unchanged.

The `setuid()` function will not affect the supplementary group list in any way.

If `uid` is not the same as the real UID of the process, `setuid()` succeeds only if the process has appropriate privileges. If the process has such privileges, `setuid()` sets the real group ID (UID), effective UID, and saved set UID to `uid`.

The `setuid()` function is not supported from an address space running multiple processes, since it would cause all processes in the address space to have their security environment changed unexpectedly.

`setuid()` can be used by daemon processes to change the identity of a process in order for the process to be used to run work on behalf of a user. In z/OS UNIX, changing the identity of a process is done by changing the real and effective UIDs and the auxiliary groups. In order to change the identity of the process on MVS completely, it is necessary to also change the MVS security environment. The identity change will only occur if the EUID value is specified, changing just the real UID will have no effect on the MVS environment.

The `setuid()` function invokes MVS SAF services to change the MVS identity of the address space. The MVS identity that is used is determined as follows:

- If an MVS user ID is already known by the kernel from a previous call to a kernel function (for example, `getpwnam()`) and the UID for this user ID matches the UID specified on the `setuid()` call, then this user ID is used.
- For nonzero target UIDs, if there is no saved user ID or the UID for the saved user ID does not match the UID requested on the `setuid()` call, the `setuid()` function queries the security database (for example, using `getpwnam()`) to retrieve a user ID. The retrieved user ID is then used.
- If the target UID is 0 and a user ID is not known, the `setuid()` function always sets the MVS user ID to BPXROOT or the value specified on the SUPERUSER parm in sysparms. BPXROOT is set up during system initialization as a...
superuser with a UID=0. The BPXROOT user ID is not defined to the BPX.DAEMON FACILITY class profile. This special processing is necessary to prevent a superuser from gaining daemon authority.

**Note:** When running under UID=0, some servers will issue setuid(0) in order to test whether they are running UID=0. The problem with this is that the setuid function will change the userid to BPXROOT which will likely cause the daemon to fail on subsequent function requests.

- When changing from a nonzero UID to a UID=0, the MVS user ID is not changed. When using the su shell command without specifying user name to become a superuser, the new shell retains the original MVS user ID.
- A non daemon superuser that attempts to set a user ID to a daemon superuser UID fails with an EPERM.

When the MVS identity is changed, the daemon must make a call to initgroups() to set the auxiliary list of groups to the list of groups for the new user ID.

If the setuid() function is issued from multiple tasks within one address space, use synchronization to ensure that the setuid() functions are not performed concurrently. The execution of setuid() function concurrently within one address space can yield unpredictable results.

**Returned value**

If successful, setuid() returns 0.

If unsuccessful, setuid() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>The process is currently not able to change UIDs.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of uid is incorrect.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The process does not have appropriate privileges to set the UID to uid.</td>
</tr>
</tbody>
</table>

**Example**

**CELEBS11**

```c
/* CELEBS11 */

#define _POSIX_SOURCE
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>

main() {
    printf("prior to setuid(), uid=%d, effective uid=%d\n", (int) getuid(), (int) geteuid());
    if (setuid(25) != 0)
        perror("setuid() error");
    else
        printf("after setuid(), uid=%d, effective uid=%d\n", (int) getuid(), (int) geteuid());
}
```

**Output**

`1886 z/OS V1R13.0 XL C/C++ Run-Time Library Reference`
before setuid(), uid=0, effective uid=0
after setuid(), uid=25, effective uid=25

set_unexpected

set_unexpected() — Register a function for unexpected()

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANSI/ISO C++</td>
<td>C++ only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <exception>

unexpected_handler set_unexpected(unexpected_handler ph) throw();
```

General description

The set_unexpected() function is part of the z/OS XL C++ error handling mechanism. The argument supplied to set_unexpected() is of type unexpected_handler as defined in the header <exception> (that is, a pointer to a function with a void return type and no arguments). The function specified will be called by the unexpected() function.

Note that the function registered for unexpected() must not return to its caller. It may terminate execution by:

- Throwing an object of a type listed in the exception specification (or an object of any type if the unexpected handler is called directly by the program).
- Throwing an object of type bad_exception.
- Calling terminate(), abort(), or exit(int).

If set_unexpected() has not yet been called, then unexpected() calls terminate().

In a multithreaded environment, the unexpected() function created by the issuance of a set_unexpected() call applies to all threads in the (POSIX) process.

Returned value

set_unexpected() returns the address of the previous unexpected_handler.

Refer to [z/OS XL C/C++ Language Reference](#) for more information about z/OS XL C++ exception handling, including the set_unexpected() function.

setuxent() — Reset to start of utmpx database

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

void setuxent(void);
```

General description

The setuxent() function resets the input to the beginning of the utmpx database opened by previous calls to getutxid(), getutxent(), getutxline(), or pututxline() calls from the current thread. This should be done before each getutxid() and getutxline() search for a new entry if it is desired that the entire database be examined.

Because the setuxent() function processes thread-specific data the setuxent() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

Returned value

setuxent() returns no values.

<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int setvbuf(FILE * __restrict__ stream, char * __restrict__ buf, int type, size_t size);
```

General description

Controls the buffering strategy and buffer size for a specified stream. The `stream` pointer must refer to an open file, and `setvbuf()` must be the first operation on the file.

To provide an ASCII input/output format for applications using this function, define the feature test macro `__LIBASCII` as described in topic 2.1.

The location pointed to by `buf` designates an area that you provide that the z/OS XL C/C++ Run-Time Library may choose to use as a buffer for the stream. A `buf` value of NULL indicates that no such area is supplied and that the z/OS XL C/C++ Run-Time Library is to assume responsibility for managing its own buffers for the stream. If you supply a buffer, it must exist until the stream is closed.

If `type` is `_IONBF` or `_IOLBF`, `size` is the size of the supplied buffer. If `buf` is NULL, the C library will take `size` as the suggested size for its own buffer. If `type` is `_IONBF`, both `buf` and `size` are ignored. Unbuffered I/O is allowed for memory files and hierarchical file system (HFS) files. However, it is not permitted for Hiperspace memory files. If the size of the supplied buffer for hiperspace memory files is greater than 4k, only the first 4k of the buffer will be used.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>_IONBF</td>
<td>No buffer is used.</td>
</tr>
<tr>
<td>_IOLBF</td>
<td>Line buffering is used for text stream I/O and terminal I/O. The buffer is flushed when a newline character is used (text stream), when the buffer is full, or when input is requested (terminal). The value for size must be greater than 0.</td>
</tr>
<tr>
<td>_IOFBF</td>
<td>Full buffering is used for input and output. Use <code>buf</code> as the buffer and <code>size</code> as the size of the buffer.</td>
</tr>
</tbody>
</table>

The value for `size` must be greater than 0.

Note: If you use `setvbuf()` or `setbuf()` to define your own buffer for a stream, you must ensure that either the buffer is available after program termination, or...
the stream is closed or flushed, before you call exit(). This can be done by defining the array with file scope or by dynamically allocating the storage for the array using malloc().

For example, if the buffer is declared within the scope of a function block, the stream must be closed before the function is terminated. This prevents the storage allocated to the buffer from being freed.

**Returned value**

If successful, even if it chooses not to use your buffer. setvbuf() returns 0.

If an invalid value was specified in the parameter list, or if the request cannot be performed, setvbuf() returns nonzero.

**Example**

```c
/* This example sets up a buffer of buf for stream1 and specifies that input from stream2 is to be unbuffered. */
#include <stdio.h>
#define BUF_SIZE 1024
char buf[BUF_SIZE];
int main(void)
{
    FILE *stream1, *stream2;
    stream1 = fopen("myfile1.dat", "r");
    stream2 = fopen("myfile2.dat", "r");
    /* stream1 uses a user-assigned buffer of BUF_SIZE bytes */
    if (setvbuf(stream1, buf, _IOFBF, sizeof(buf)) != 0)
        printf("Incorrect type or size of buffer 1");
    /* stream2 is unbuffered */
    if (setvbuf(stream2, NULL, _IONBF, 0) != 0)
        printf("Incorrect type or size of buffer 2");
    
    printf("\n");
}
```

shmat

shmat() — Shared memory attach operation

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _XOPEN_SOURCE
#include <sys/shm.h>

void *shmat(int shmid, const void *shmaddr, int shmflg);
```

General description

The shmat() function attaches the shared memory segment associated with the shared memory identifier, shmid, to the address space of the calling process. The segment is attached at the address specified by one of the following criteria:

- If shmaddr is a NULL pointer, the segment is attached at the first available address as selected by the system.
- If shmaddr is not a NULL pointer, and the flag, SHM_RND was specified, the segment is attached at the address given by \((shmaddr-(\text{prtdiff}_t)\text{shmaddr} \mod \text{SHMLBA})\) where \% is the 'C' language remainder operator.
- If shmaddr is not a NULL pointer, and the flag, SHM_RND was not specified, the segment is attached at the address given by shmaddr.
- The segment is attached for reading if the flag, SHM_RDONLY, is specified with shmflg and the calling process has read permission. If the flag is not set and the process has both read and write permission, the segment is attached for reading and writing.

The first attach of newly created __IPC_MEGA segment, as well as subsequent attaches, will have write access to the segment, regardless of the SHM_RDONLY option.

- All attaches to an __IPC_MEGA shared memory segment have the same Write or Read access authority. If a segment is enabled for writes then all attaches have the ability to read and write to the segment. If the segment is disabled for writes, then all attaches have the ability to read from the segment and cannot write to the segment.

The first attach of newly created __IPC_MEGA segment, as well as subsequent attaches, will have write access to the segment, regardless of the SHM_RDONLY option. Write/Read access can be changed by the shmctl() function, Shared Memory Control Operations.

An __IPC_MEGA shared memory segment is attached as follows:

- If shmaddr is zero and __IPC_MEGA segment, then the segment will be attached at the first available address selected by the system on a segment boundary.
- If shmaddr is not zero and SHM_RND is specified and __IPC_MEGA segment, the segment address will be truncated to the segment boundary (last 20 bits zero).
- If shmaddr is not zero and SHM_RND is not specified and __IPC_MEGA segment, the segment address must be a megabyte multiple (segment boundary).
**shmat**

**Returned value**

If successful, shmat() increments the value of shm_nattach in the data structure associated with the shared memory ID of the attached shared memory segment and returns the segment's starting address.

If unsuccessful, shmat() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Operation permission is denied to the calling process.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of shmid is not a valid shared memory identifier; the shmaddr is not a NULL pointer and the value of (shmaddr−((ptrdiff_t)shmaddr%SHMLBA)) is an illegal address for attaching shared memory segments; or the shmaddr is not a NULL pointer, SHM_RND was specified, and the value of shmaddr is an illegal address for attaching shared memory segments. The shared memory address, *shmaddr, is not zero, is not on a megabyte boundary, and SHM_RND was not specified.</td>
</tr>
<tr>
<td>EMFILE</td>
<td>The number of shared memory segments attached to the calling process would exceed the system-imposed limit.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>The available data space is not large enough to accommodate the shared memory segment.</td>
</tr>
</tbody>
</table>

shmctl

shmctl() — Shared memory control operations

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <sys/shm.h>

int shmctl(int shmid, int cmd, struct shmid_ds *buf);
```

General description

The `shmctl()` function provides a variety of shared memory control operations on the shared memory segment identified by the argument, `shmid`.

The argument `cmd` specifies the shared memory control operation and may be any of the following values:

**IPC_STAT**

This command obtains status information for the shared memory segment specified by the shared memory identifier, `shmid`. It places the current value of each member of the `shmid_ds` data structure associated with `shmid` into the structure pointed to by `buf`. The contents of this structure is defined in `<sys/shm.h>`. This command requires read permission.

**IPC_SET**

Set the value of the following members of the `shmid_ds` data structure associated with `shmid` to the corresponding value in the structure pointed to by `buf`:

- `shm_perm.uid`
- `shm_perm.gid`
- `shm_perm.mode` (only the low-order 9 bits)

This command can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of `shm_perm.cuid` or `shm_perm.uid` in the `shmid_ds` data structure associated with `shmid`.

Using the `IPC_SET` function to change the IPC_MODE for an __IPC_MEGA shared memory segment will have an immediate effect on all attaches to the target segment. That is, the read and write access of all current attachers is immediately affected by the permissions specified in the new IPC_MODE. To determine how the new mode affects access, you must consider the effect of all three parts of the mode field (the owner permissions, group permissions and other permissions). If all three read and all three write permissions in the new mode are set off, then the access for all attachors is changed to read. If any of the three read permission bits is set on but the corresponding write permission bit is off, then the access for all attachors is changed to read. Otherwise, the access of all attachors is changed to write.
shmctl

IPC_RMID  Remove the shared memory identified specified by *shmid* from the system and destroy the shared memory segment and *shmid_ds* data structure associated with *shmid*. This command can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of *shm_perm.cuid* or *shm_perm.uid* in the *shmid_ds* data structure associated with *shmid*. The remove will be completed asynchronous to the return from the shmctl() function, when the last attachment is detached. When **IPC_RMID** is processed, no further attaches will be allowed.

The IPC_STAT option of shmctl() returns a structure named *shmid_ds* (mapped in shm.h). *shmid_ds* contains status information for the requested shared memory segment.

As part of its own dump priority support, the USS Kernel will be adding a new field to *shmid_ds*. This field will contain the dump priority of the requested shared memory segment. The new field will be added to the *shmid_ds* structure in shm.h.

**Returned value**

If successful, shmctl() returns 0.

If unsuccessful, shmctl() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The argument <em>cmd</em> is equal to <strong>IPC_STAT</strong> but the calling process does not have read permission.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of <em>shmid</em> is not a valid shared memory identifier or the value of <em>cmd</em> is not a valid command.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The argument <em>cmd</em> is equal to either <strong>IPC_RMID</strong> or <strong>IPC_SET</strong> and the effective user ID of the calling process is not equal to that of a process with appropriate privileges and it is not equal to the value of <em>shm_perm.cuid</em> or <em>shm_perm.uid</em> in the data structure associated with <em>shmid</em>.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define __XOPEN_SOURCE
#include <sys/shm.h>

int shmdt(const void *shmaddr);
```

General description

The shmdt() function detaches from the calling process's address space the shared memory segment located at the address specified by the argument `shmaddr`.

Storage in the user address space for a segment with the `__IPC_SHAREAS` attribute is not cleaned up unless the segment is no longer attached to by other processes in the address space.

Returned value

If successful, shmdt() decrements the value of `shm_nattach` in the data structure associated with the shared memory ID of the attached shared memory segment and returns 0.

If unsuccessful, shmdt() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of <code>shmaddr</code> is not the data segment start address of a shared memory segment.</td>
</tr>

</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define __XOPEN_SOURCE
#include <sys/shm.h>

int shmget(key_t key, size_t size, int shmflg);
```

General description

The shmget() function returns the shared memory identifier associated with `key`.

A shared memory identifier, associated data structure and shared memory segment of at least `size` bytes, see `<sys/shm.h>`, are created for `key` if one of the following is true:
1. Argument `key` has a value of `IPC_PRIVATE`
2. Argument `key` does not already have a shared memory identifier associated with it and the flag `IPC_CREAT` was specified

Specify `__IPC_MEGA` to request segment level sharing. The resulting shared memory segment will be allocated in units of segments instead of units of pages. The shared memory size parameter still reflects the number of bytes required but must be in megabyte multiples. A shared memory size parameter of 0 or one which is not a megabyte multiple will result in the request failing.

The first `shmget` to define the shared memory segment determines whether the segment has the `__IPC_MEGA` attribute or not. Subsequent `shmget`s, those that use existing shared memory segments, will use the `__IPC_MEGA` attribute defined by that segment. The `__IPC_MEGA` option will have no effect for these `shmget`s and will be ignored.

Specification of the `__IPC_MEGA` option for large segments will result in significant real storage savings and reduced ESQA usage, especially as the number of shares increases.

Valid values for the argument `shmflg` include any combination of the following constants defined in `<sys/ipc.h>` and `<sys/modes.h>`:

- `__IPC_SHAREAS`
  This flag enables the sharing of the same storage area from multiple processes in the same address space. When specified by an AMODE 31 application, this flag is only honored when `__IPC_MEGA` is also specified, otherwise it is ignored. When specified by an AMODE 64 application, this flag is honored for any type of shared memory segment that is obtained above the bar.

- `__IPC_BELOWBAR`
  Forces the memory object to be allocated from below the 2
shmget

gigabyte address range. This can be used to allow AMODE 64 applications to share objects with non-AMODE 64 applications. This option is mutually exclusive with the __IPC_GIGA option. If a 31-bit application specifies this option, then the request will be failed with EINVAL.

IPC_CREAT Create a shared memory segment if the key specified does not already have an associated ID. IPC_CREAT is ignored when IPC_PRIVATE is specified.

IPC_EXCL Causes the shmget() function to fail if the key specified has an associated ID. IPC_EXCL is ignored when IPC_CREAT is not specified or IPC_PRIVATE is specified.

__IPC_GIGA Requests a shared memory segment with a size in gigabyte multiples. Use of this option requires that the size parameter be specified as a gigabyte multiple. Failure to use a gigabyte multiple will result in a failure. [EINVAL] This option is mutually exclusive with the __IPC_BELOWBAR and __IPC_MEGA options.

__IPC_MEGA Requests a shared memory segment with the size in megabyte multiples. Use of this option requires that the size parameter, size_t, be in a megabyte multiple. The __IPC_MEGA option is required to create the shared memory segment but the __IPC_MEGA option is not required to acquire access to a previously defined/created shared memory segment that has the __IPC_MEGA attribute. When specified by an AMODE 64 application, option __IPC_BELOWBAR is implied and megaroo sharing will be in effect. This option is mutually exclusive with the __IPC_GIGA option.

S_IRGRP Permits read access when the effective group ID of the caller matches either shm_perm.cgid or shm_perm.gid.

S_IROTH Permits other read access.

S_IRUSR Permits read access when the effective user ID of the caller matches either shm_perm.cuid or shm_perm.uid.

S_IWGRP Permits write access when the effective group ID of the caller matches either shm_perm.cgid or shm_perm.gid.

S_IWOTH Permits other write access.

S_IWUSR Permits write access when the effective user ID of the caller matches either shm_perm.cuid or shm_perm.uid.

When a shared memory segment associated with argument key already exists, setting IPC_EXCL and IPC_CREAT in argument shmflg will force shmget() to fail.

The following fields are initialized when a shmid_ds data structure is created:

- The fields shm_perm.cuid and shm_perm.uid are set equal to the effective user ID of the calling process.
- The fields shm_perm.cgid and sem_perm.gid are set equal to the effective group ID of the calling process.
- The low-order 9 bits of shm_perm.mode are set to the value in the low-order 9 bits of shmflg.
- The field shm_segsz is set equal to the value of the argument size.
- The field shm_lpid, shm_nattach, shm_atime, and shm_dtime are set equal to zero.
- The value of shm_ctime is set equal to the current time.
Usage notes

- Shared memory segments created with __IPC_MEGA will show this bit in S_MODE byte returned with w_getipc.

Special behavior for AMODE 64: Applications will not be allowed to change the address to which a shared memory segment allocated is attached, when it resides above the 2 gigabyte address range. The size parameter is rounded up to a megabyte multiple for AMODE 64 users.

Returned value

If successful, shmget() returns a nonnegative integer, namely a shared memory identifier.

If unsuccessful, shmget() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>A shared memory identifier exists for the argument key, but operation permission as specified by the low-order 9 bits of shmflg could not be granted.</td>
</tr>
<tr>
<td>EEXIST</td>
<td>A shared memory identifier exists for the argument key and both IPC_CREAT and IPC_EXCL are specified in shmflg.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>A shared memory identifier does not exist for the argument key specified and the value of argument size is less than the system-imposed minimum or greater than the system-imposed maximum. OR a shared memory identifier exists for the argument key, but the size of the segment associated with it is less that specified by argument size. OR __IPC_MEGA is specified and the segment size, size_t, is not in megabyte multiples.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>A shared memory identifier does not exist for the argument, key, and IPC_CREAT is not specified.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>A shared memory identifier and associated shared memory segment are to be created but the amount of available system storage was insufficient to fill the request.</td>
</tr>
<tr>
<td>ENOSPC</td>
<td>A shared memory identifier is to be created but the system-imposed limit on the maximum number of allocated shared memory identifiers, system-wide, would be exceeded.</td>
</tr>
</tbody>
</table>

When shmflg equals 0, the following applies:

- If a shared memory identifier has already been created with key earlier, and the calling process of this shmget() has read and/or write permissions to it, then shmget() returns the associated shared memory identifier.
- If a shared memory identifier has already been created with key earlier, and the calling process of this shmget() does not have read and/or write permissions to it, then shmget() returns -1 and sets errno to EACCES.
- If a shared memory identifier has not been created with key earlier, then shmget() returns -1 and sets errno to ENOENT.
shmget

shutdown() — Shut down all or part of a duplex connection

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int shutdown(int socket, int how);
```

Berkeley sockets:

```c
#define _OE_SOCKETS
#include <sys/socket.h>

long shutdown(int *s, int how);
```

General description

The shutdown() function shuts down all or part of a duplex connection.

Parameter Description

- **socket**: The socket descriptor.
- **how**: The condition of the shutdown. The values 0, 1, or 2 set the condition. **how** sets the condition for shutting down the connection to the socket indicated by **socket**.

  **how** can have a value of:
  - **SHUT_RD**, which ends communication from the socket indicated by **socket**.
  - **SHUT_WR**, which ends communication to the socket indicated by **socket**.
  - **SHUT_RDWR**, which ends communication both to and from the socket indicated by **socket**.

Note: You should issue a shutdown() call before you issue a close() call for a socket.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, shutdown() returns 0.

If unsuccessful, shutdown() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><strong>socket</strong> is not a valid socket descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The <strong>how</strong> parameter was not set to one of the valid values.</td>
</tr>
</tbody>
</table>
shutdown

ENOBUFS    Insufficient system resources are available to complete the call.
ENOTCONN   The socket is not connected.
ENOTSOCK   The descriptor is for a file, not for a socket.

__shutdown_registration() — Register OMVS shutdown options

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R3</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS
#include <signal.h>

int __shutdown_registration(int regtype, int regscope, int regoptions);
```

General description

The __shutdown_registration() function is used to register OMVS Shutdown characteristics for the process. The process can be registered as one of the following:

- a shutdown blocking process
- a permanent process
- a shutdown notification process

These types are mutually exclusive. A shutdown blocking process will prevent OMVS shutdown from proceeding until it either de-registers as a blocking process or ends. A permanent process will survive across an OMVS shutdown. Most OMVS process attributes will be checkpointed during the shutdown and restored during the Restart. A shutdown notification process will be informed when an OMVS shutdown is initiated. It neither blocks Shutdown nor survives shutdown. Blocking and permanent processes can also register to be informed when OMVS shutdown is initiated. For more information on OMVS shutdown see [z/OS UNIX System Services Planning, GA22-7800](#).

Registration can be done for the invoking process only, or for all of the tasks in the job. The process can also modify the behavior of OMVS requests issued by permanent processes while OMVS shutdown and restart is in progress.

Checkpointed permanent process attributes include the following:

- process user and group identity
- process, session and process group identities
- process file mode creation mask
- zombie child processes
- signal registration, signal actions, signal mask data and pending signals
- current working directory
- open file and socket descriptors

Zombie child process ending status is checkpointed so that the permanent process can retrieve it after the restart.

If the current working directory path name cannot be resolved after restart, then the current working directory is set to a dummy root which will cause relative path name lookup to fail.
All of the checkpointed file descriptors will be marked invalid after restart, and any I/O requests other than close() will cause EIO errors.

Timer events are not checkpointed. Timer events which expire before the restart completes are lost. Timer events which have not expired after restart is complete will still be in effect.

Non-checkpointable permanent process attributes include the following:
- semaphores
- shared library programs
- __map() shared memory blocks
- message queues
- memory mapped files
- all other UNIX System Services resources

If any non-checkpointable resources are being used by a permanent process, the shutdown request will fail.

Registration is at the process level, not the thread level. For multithreaded applications, the SIGDANGER signal is sent to the process and not to any particular thread.

If a process is registered as a blocking process or a permanent process, the process must de-register before attempting to register with a different registration type. For example, a blocking process must de-register as a blocking process before attempting to register as a permanent process.

Registration remains in effect for the life of the process, or until the process de-registers. Registration remains in place across an exec() syscall because the new program image runs in the same process. Registration does not propagate to child processes as a result of fork() and spawn() syscalls.

`regtype` defines the type of registration. The possible values are listed below. These values are all mutually exclusive.

<table>
<thead>
<tr>
<th><code>regtype</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_SDR_BLOCKING</td>
<td>The process will prevent OMVS Shutdown from proceeding for as long as it the process remains registered as a blocking process. If the process exits or de-registers as a blocking process then OMVS Shutdown can proceed.</td>
</tr>
<tr>
<td>_SDR_PERMANENT</td>
<td>The process will not be terminated during OMVS Shutdown and Restart processing.</td>
</tr>
<tr>
<td>_SDR_NOBLOCKING</td>
<td>The process will no longer block an OMVS Shutdown.</td>
</tr>
<tr>
<td>_SDR_NOPERMANENT</td>
<td>The process will no longer be a permanent process.</td>
</tr>
<tr>
<td>_SDR_NOTIFY</td>
<td>The process will be notified by SIGDANGER signal delivery once OMVS Shutdown is initiated.</td>
</tr>
<tr>
<td>_SDR_NONOTIFY</td>
<td>The process will no longer be notified by SIGDANGER signal delivery if OMVS Shutdown is initiated.</td>
</tr>
</tbody>
</table>
__shutdown_registration()

The _SDR_BLOCKING and _SDR_PERMANENT registrations are restricted. The invoker must meet one of the following criteria in order for these two registration types to succeed:

- The calling address space is a system started task address space.
- The caller is running authorized (APF Authorized, System Key (0-7) or Supervisor State).
- The caller is a privileged UNIX process. It must either have a superuser identity or have read permission to BPX.SHUTDOWN.

regscope defines the registration scope. The possible values are listed below. The two values are mutually exclusive.

<table>
<thead>
<tr>
<th>regscope</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>_SDR_REGJOB</td>
<td>All the processes in the Job are registered.</td>
</tr>
<tr>
<td>_SDR_REGPROCESS</td>
<td>Only the calling process is registered.</td>
</tr>
</tbody>
</table>

regoptions defines various options for the registered process. The possible values are listed below. Multiple options may be specified by or'ing the values together. The default behavior for kernel calls issued by permanent processes while z/OS UNIX is not up is to fail the request with errno set to EMVSERR and the reason code (__errno2() value) set to JrKernelReady. Those kernel calls which which do not return a return code will end with an EC6 abend and reason code xxxx8039.

<table>
<thead>
<tr>
<th>regoptions</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>_SDR_NOOPTIONS</td>
<td>No options are requested. This request code is not valid for _SDR_NOTIFY registration.</td>
</tr>
<tr>
<td>_SDR_BLOCKSYSCALLS</td>
<td>Kernel calls issued from permanent processes while OMVS is not up will hang, and return to the caller once z/OS UNIX System Services is back up. This request is mutually exclusive with _SDR_ABENDSYSCALLS, and is valid only for permanent process registration.</td>
</tr>
<tr>
<td>_SDR_ABENDSYSCALLS</td>
<td>Kernel calls issued from permanent processes while OMVS is not up will ABEND. This request is mutually exclusive with _SDR_BLOCKSYSCALLS, and is valid only for permanent process registration.</td>
</tr>
<tr>
<td>_SDR_SENDSIGDANGER</td>
<td>Kernel sends SIGDANGER signal to the process when OMVS Shutdown is initiated. This option MUST be specified on _SDR_NOTIFY registration. This option may be specified for _SDR_BLOCKING and _SDR_PERMANENT registration. It may be combined with either _SDR_BLOCK_SYSCALLS or _SDR_ABENDSYSCALLS on _SDR_PERMANENT registration.</td>
</tr>
</tbody>
</table>

**Returned value**

If successful, __shutdown_registration() returns zero. the service completes without error, otherwise it returns

There are no documented errnos for this function.
__shutdown_registration()

If unsuccessful, __shutdown_registration() returns -1 and sets errno and __errno2() to indicate the cause of the failure. The __errno2() values are documented as reason codes in z/OS UNIX System Services Messages and Codes.

The values of errno are:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>Failed for one of the following reasons:</td>
</tr>
<tr>
<td></td>
<td>• The callable service is rejected because the job step process must be registered before registering a lower process of the job step process.</td>
</tr>
<tr>
<td></td>
<td>• The request to register a blocking process or job, or a request to register a permanent process or job cannot be performed as a shutdown is currently in progress.</td>
</tr>
<tr>
<td></td>
<td>• The request to register a blocking process or job, or a request to register a permanent process or job cannot be performed as the job can not be de-registered while a lower process is still registered.</td>
</tr>
<tr>
<td></td>
<td>• The request to deregister a blocking process or job, or a request to deregister a permanent process or job cannot be performed because the job or the current process is not registered.</td>
</tr>
<tr>
<td></td>
<td>• One of the parameters was invalid.</td>
</tr>
<tr>
<td>EPERM</td>
<td>Failed for one of the following reasons:</td>
</tr>
<tr>
<td></td>
<td>• Invoker does not have superuser or equivalent authority.</td>
</tr>
<tr>
<td></td>
<td>• Caller must be given read permission to BPX.SHUTDOWN facility class profile in order to use __shutdown_registration() successfully.</td>
</tr>
</tbody>
</table>

EMVSSAF2ERR

Internal Security product error. Hexadecimal Reason code value contains the two byte security product return code xx and reason code yy.

Example

```c
/*
Register the process as a blocking process and request notification of shutdown initiation by way of SIGDANGER signal.
*/
#define _OPEN_SYS
#include <signal.h>
...
if (-1 == (rc = __shutdown_registration(_SDR_BLOCKING, _SDR_REGPROCESS, _SDR_SENDSIGDANGER)))
    printf("Error during __shutdown_registration errno=%d, errno2=0x%08x\n", errno, __errno2())

/*
Register the process as a permanent process and don't ask for SIGDANGER signals.
*/
#define _OPEN_SYS
#include <sys>
if (-1 == (rc = __shutdown_registration(_SDR_PERMANENT, _SDR_REGPROCESS, _SDR_NOOPTIONS)))
    printf("Error during __shutdown_registration errno=%d, errno2=0x%08x\n", errno, __errno2())
```

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _POSIX_SOURCE
#include <signal.h>

int sigaction(int sig, const struct sigaction *__restrict__ new,
               struct sigaction *__restrict__ old);
```

**General description**

Examines and changes the action associated with a specific signal.

int *sig* is the number of a recognized signal. *sigaction()* examines and sets the action to be associated with this signal. See Table 46 for the values of *sig*, as well as the signals supported by z/OS UNIX services. The *sig* argument must be one of the macros defined in the signal.h header file.

const struct sigaction *new may be a NULL pointer. If so, *sigaction()* merely determines the action currently defined to handle *sig*. It does not change this action. If new is not NULL, it should point to a sigaction structure. The action specified in this structure becomes the new action associated with *sig*.

struct sigaction *old points to a memory location where *sigaction()* can store a sigaction structure. *sigaction()* uses this memory location to store a sigaction structure describing the action currently associated with *sig*. old can also be a NULL pointer, in which case *sigaction()* does not store this information.

This function is supported only in a POSIX program.

**Special behavior for C++:**

- The behavior when mixing signal-handling with C++ exception handling is undefined. Also, the use of signal-handling with constructors and destructors is undefined.
- C++ and C language linkage conventions are incompatible, and therefore *sigaction()* cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to *sigaction()* , the compiler will flag it as an error. Therefore, to use the *sigaction()* function in the C++ language, you must ensure that signal handler routines established have C linkage, by declaring them as extern "C".

**Signals:** Table 46 lists signal values and their default action and meaning.

</tbody>
</table>
Table 46. Signal values and signals supported by z/OS UNIX services (continued)

<table>
<thead>
<tr>
<th>Value</th>
<th>Default Action</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGCONT</td>
<td>4</td>
<td>If stopped, continue.</td>
</tr>
</tbody>
</table>

The Default Actions in Table 46 on page 1908 are:

1. Normal termination of the process.
2. Ignore the signal.
3. Stop the process.
4. Continue the process if it is currently stopped. Otherwise, ignore the signal.

If the main program abends in a way that is not caught or handled by the operating system or application, z/OS UNIX terminates the running application with a KILL -9.

If z/OS UNIX gets control in EOT or EOM and the terminating status has not been set, z/OS UNIX sets it to appear as if a KILL -9 occurred.

If a signal catcher for a SIGABND, SIGFPE, SIGILL or SIGSEGV signal runs as a result of a program check or an ABEND, and the signal catcher executes a RETURN statement, the process will be terminated.

**sigaction structure**: The sigaction structure is defined as follows:

```c
struct sigaction {
    void (*sa_handler)(int);
    sigset_t sa_mask;
    int sa_flags;
    void (*sa_sigaction)(int, siginfo_t *, void *);
};
```

The following are members of the structure:

- `void (*)(int) sa_handler`
  - A pointer to the function assigned to handle the signal. The value of this member can also be SIG_DFL (indicating the default action) or SIG_IGN (indicating that the signal is to be ignored).

  **Special behavior for XPG4.2**: This member and sa_sigaction are mutually exclusive of each other. When the SA_SINFO flag is set in sa_flags then sa_sigaction is used. Otherwise, sa_handler is used.

- `sigset_t sa_mask`
  - A signal set identifies a set of signals that are to be added to the signal mask of the calling process before the signal-handling function sa_handler or sa_sigaction (in XPG4.2) is invoked. For more on signal sets, see "sigemptyset() — Initialize a signal mask to exclude all signals" on page 1933. You cannot use this mechanism to block SIGKILL, SIGSTOP, or SIGTRACE. If sa_mask includes these signals, they will simply be ignored; sigaction() will not return an error.
  
  sa_mask must be set by using one or more of the signal set manipulation functions: sigemptyset(), sigfillset(), sigaddset(), or sigdelset()

- `int sa_flags`
  - A collection of flag bits that affect the behavior of signals. The following flag bits can be set in sa_flags:
_SA_IGNORE
This bit is output only and cannot be specified by the application. The handler value will be saved and returned on subsequent calls, but the signal is ignored.

SA_NOCLDSTOP
Tells the system not to issue a SIGCHLD signal when child processes stop. This is relevant only when the sig argument of sigaction() is SIGCHLD.

SA_NOCLDWAIT
Tells the system not to create 'zombie' processes when a child process dies. This is relevant only when the sig argument of sigaction() is SIGCHLD. If the calling process subsequently waits for its children, and the process has no unwaited for children that were transformed into zombie processes, it will block until all of its children terminate. The wait(), waitid(), or waitpid() will fail and set errno to ECHILD.

SA_NODEFER
Tells the system to bypass automatically blocking this signal when invoking a signal handler function.

_SA_OLD_STYLE
Tells the C run-time library to use ANSI signal delivery rules, instead of POSIX rules. It is supported for compatibility with applications that use signal() to set signal action. (See [signal() — Handle interrupts on page 1945](https://www.ibm.com/support/knowledgecenter/SSY5KG_8.2.0/com.ibm.zos.v8r2.C-languageסיכלן español_v8.2.doc/doc/books/zzz瑚eפגש_Signals%20%26%20Error%20Handling%20Guide.html) for a description of ANSI and POSIX.1 signal delivery rules, and “Handling Error Conditions and Signals” in [z/OS XL C/C++ Programming Guide](https://www.ibm.com/support/knowledgecenter/SSY5KG_8.2.0/com.ibm.zos.v8r2.c.doc/books/zzz珊瑚eפגש_Signals%20%26%20Error%20Handling%20Guide.html).)

SA_ONSTACK
Tells the system to use the alternate signal stack when invoking a signal handler function. If an alternate signal stack has not been declared, the signal handler function will be invoked with the current stack.

SA_RESETHAND
Tells the system to reset the signal’s action to SIG_DFL and clear the SA_SIGINFO flag before invoking a signal handler function. (Note: SIGILL and SIGTRAP cannot be automatically reset when delivered. However, no error will be generated should this situation exist). Otherwise, the disposition of the signal will not be modified on entry to the signal handler.

In addition, if this flag is set, sigaction() behaves as if the SA_NODEFER flag were also set.

SA_RESTART
Tells the system to restart certain library functions if they should be interrupted by a signal. The functions that this restartability applies to are all of those that are defined as interruptible by signals and set errno to EINTR (except pause(), sigpause(), and sigsuspend()).

Table 47 lists functions that are restartable if interrupted by a signal.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Restartable</th>
</tr>
</thead>
<tbody>
<tr>
<td>accept()</td>
<td></td>
<td></td>

**SA_SIGINFO**

Tells the system to use the signal action specified by `sa_sigaction` instead of `sa_handler`.

When this flag is off and the action is to catch the signal, the signal handler function specified by `sa_handler` is invoked as:

```c
void function(int signo);
```

Where `signo` is the only argument to the signal handler and it specifies the type of signal that has caused the signal handler function to be invoked.

When this flag is on and the action is to catch the signal, the signal handler function specified by `sa_sigaction` is invoked as:

```c
void function(int signo, siginfo_t *info, void *context);
```

Where two additional arguments are passed to the signal handler function. If the second argument is not a NULL pointer, it will point to an object of type `siginfo_t` which provides additional information about the source of the signal. A `siginfo_t` object is a structure contains the following members:

- `si_signo`  
  Contains the system-generated signal number

- `si_errno`  
  Contains the implementation-specific error information (it is not used on this implementation)

- `si_code`  
  Contains a code identifying the cause of the signal (refer to...
the `<signal.h>` include file for a list of these codes and for their meanings, see Table 48 on page 1947.

If `si_signo` contains SIGPOLL then `si_code` can be set to SI_ASYNCIO. Otherwise, if the value of `si_code` is less than or equal to zero then the signal was generated by another process and the `si_pid` and `si_uid` members respectively indicate the process ID and the real user ID of the sender of this signal.

If the value of `si_code` is less than or equal to zero, then the signal was generated by another process and the `si_pid` and `si_uid` members respectively indicate the process ID and the real user ID of the sender of this signal.

`si_pid` If the value of `si_code` is less than or equal to zero, then this member will indicate the process ID of the sender of this signal. Otherwise, this member is meaningless.

`si_uid` If the value of `si_code` is less than or equal to zero, then this member will indicate the real user ID of the sender of this signal. Otherwise, this member is meaningless.

`si_value` If `si_code` is SI_ASYNCIO the `si_value` contains the application specified value. Otherwise, the contents of `si_value` are undefined.

The third argument will point to an object of type `ucontext_t` (refer to the `<ucontext.h>` include file for a description of the contents of this object).

Note: The remaining flag bits are reserved for system use. There is no guarantee that the integer value of "int sa_flags" will be the same upon return from sigaction(). However, all flag bits defined above will remain unchanged.

```c
void (*)(int, siginfo_t *, void *) sa_sigaction
```

A pointer to the function assigned to handle the signal, or SIG_DFL, or SIG_IGN. This function will be invoked passing three parameters. The first is of type 'int' that contains the signal type for which this function is being invoked. The second is of type 'pointer to siginfo_t' where the siginfo_t contain additional information about the source of the signal. The third is of type 'pointer to void' but will actually point to a ucontext_t containing the context information at the time of the signal interrupt.

Notes:
1. The user must cast SIG_IGN or SIG_DFL to match the sa_sigaction definition. (indicating that the signal is to be ignored).
2. Special behavior for XPG4.2: This member and sa_handler are mutually exclusive of each other. When the SA_SIGINFO flag is set in sa_flags then sa_sigaction is used. Otherwise, sa_handler is used.

When a signal handler installed by sigaction(), with the _SA_OLD_STYLE flag set off, catches a signal, the system calculates a new signal mask by taking the union of the current signal mask, the signals specified by sa_mask, and the signal that was just caught (if the SA_NODEFER flag is not set). This new mask stays in effect...
until the signal handler returns, or sigprocmask(), sigsuspend(), siglongjmp(),
sighold(), sigpause(), or sigrelse() is called. When the signal handler ends, the
original signal mask is restored.

After an action has been specified for a particular signal, using sigaction() or
signal(), it remains installed until it is explicitly changed with another call to
going() or signal(), one of the exec functions, bsd_signal(), sigignore(), sigset(), or
until the SA_RESETHAND flag causes it to be reset to SIG_DFL.

After an action has been specified for a particular signal, using sigaction() with the
_SA_OLD_STYLE flag not set, it remains installed until it is explicitly changed with
another call to sigaction(), signal(), or one of the exec functions.

After an action has been specified for a particular signal, using sigaction() with the
_SA_OLD_STYLE flag set or using signal(), it remains installed until it is explicitly
changed with another call to sigaction(), signal(), or one of the exec functions, or a
signal catcher is driven, where it will be reset to SIG_DFL.

Successful setting of signal action to SIG_IGN for a signal that is pending causes
the pending signal to be discarded, whether or not it is blocked. This provides the
ability to discard signals that are found to be blocked and pending by sigpending().

**Special behavior for XPG4.2:**

- If a process sets the action of the SIGCHLD signal to SIG_IGN, child processes
  of the calling process will not be transformed into 'zombie' processes when they
  terminate. If the calling process subsequently waits for its children, and the
  process has no unwaited for children that were transformed into 'zombie'
  processes, it will block until all of its children terminate. The wait(), waitid(), or
  waitpid() function will fail and set errno to ECHILD.

- If the SA_SIGINFO flag is set, the signal-catching function specified by
  sa_sigaction is invoked as:

  ```
  void function(int signo, siginfo_t *info, void *context);
  ```

  Where function is the specified signal-catching function, signo is the signal
  number of the signal being delivered, info points to an object of type siginfo_t
  associated with the signal being delivered, and context points to an object of type
  ucontext_t.

**Considerations for asynchronous signal-catching functions:** Some of the
functions have been restricted to be serially reusable with respect to asynchronous
signals. That is, the library will not allow an asynchronous signal to interrupt the
execution of one of these functions until it has completed.

This restriction needs to be taken into consideration when a signal-catching function
is invoked asynchronously because it causes the behavior of some of the library
functions to become unpredictable.

Thus, when you are producing a strictly compliant POSIX C or X/Open application,
only the following functions should be assumed to be reentrant with respect to
asynchronous signals. Use only these functions in your signal-catching functions:

- access()
- alarm()
- cfgetispeed()
- cfgetospeed()
- chdir()
- chmod()
- chown()
sigaction

</tbody>
</table>

**Special behavior for XPG4.2:** Adds the following functions to the list of functions above that may be used in signal-catching functions in strictly compliant X/Open applications:

- _fpathconf_()
- _raise_()
- _signal_()

The macro versions of `getc()` and `putc()` are not reentrant, even though the library versions of these functions are.

For nonportable POSIX applications, most of the library functions can be used in a signal-catching function. However, do not use the following functions:

- _getenv_()
- _getgrent_()
- _getgid_()
- _getgrgid_()
- _getgrnam_()
- _getpwent_()
- _getpwnam_()
- _getpwuid_()
- _ttname_()

**Special behavior for XPLINK-compiled C++:** Restrictions concerning `setjmp.h` and `ucontext.h`:

**Notes:**

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the `jmp_buf`, `sigjmp_buf` or `ucontext_t` types must not be compiled with C headers from Language Environment V2R9 or earlier.

2. Non-XPLINK functions compiled with any level of Language Environment headers must not define `jmp_buf`, `sigjmp_buf` or `ucontext_t` data items and
pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(),
setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these
passed-in data items.

3. When __XPLINK__ is defined, the Language Environment V2R10 and later
headers define a larger jmp_buf, sigjmp_buf or ucontext_t area that is
required by setjmp(), getcontext(), and related functions when they are called
from an XPLINK routine. If __XPLINK__ is not defined, the Language
Environment V2R10 and later headers define a shorter jmp_buf, sigjmp_buf or
ucontext_t area. The Language Environment headers before V2R10 also
define the shorter version of these data areas. If an XPLINK function calls
setjmp(), getcontext() or similar functions with a short jmp_buf, sigjmp_buf or
ucontext_t area, a storage overlay or program check may occur when the C
library tries to store past the end of the passed-in (too short) data area.

4. The sigaction() function supersedes the signal() interface, and should be the
preferred usage. In particular, sigaction() and signal() must not be used in the
same process to control the same signal.

Usage notes

The use of the SIGTSTOP and SIGTCONT signal is not supported with this function.

Returned value

If successful, sigaction() returns 0.

If unsuccessful, no new signal handler is installed, sigaction() returns -1, and sets
errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>
| EINVAL     | The value of sig is not a valid signal for one of the following reasons:
|            | • The sig is not recognized.  
|            | • The process tried to ignore a signal that cannot be ignored.  
|            | • The process tried to catch a signal that cannot be caught. |

The default action for SIGCHILD and SIGIO is for the signal to be ignored. A
sigaction() to set the action to SIG_IGN for SIGIO will result in an error, with errno
equal to EINVAL.

Example

**CELEBS13**

/* CELEBS13

The first part of this example determines whether the SIGCHLD
signal is currently being ignored.
With a NULL pointer for the new argument, the current signal
handler action is not changed.

*/
#define _POSIX_SOURCE
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdio.h>
#include <signal.h>

void main(void) {
    struct sigaction info;
    if (sigaction(SIGCHLD,NULL,&info) != -1)
        if (info.sa_handler == SIG_IGN)
...
```c
CELEBS14
/* CELEBS14

This fragment initializes a sigaction structure to specify
mysig as a signal handler and then sets the signal handler
for SIGCHLD.
Information on the previous signal handler for SIGCHLD is
stored in info.

*/
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>
#include <stdio.h>
void mysig(int a) { printf("In mysig\n"); }
void main(void) {
    struct sigaction info, newhandler;
    if (sigaction(SIGCHLD,NULL,&info) != −1)
        if (info.sa_handler == SIG_IGN)
            printf("SIGCHLD being ignored.\n");
        else if(info.sa_handler == SIG_DFL)
            printf("SIGCHLD being defaulted.\n");
    newhandler.sa_handler = &mysig;
    sigemptyset(&(newhandler.sa_mask));
    newhandler.sa_flags = 0;
    if (sigaction(SIGCHLD,&newhandler,&info) != −1)
        printf("New handler set.\n");
}
```

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int __sigactionset(size_t newct, const __sigactionset_t new[],
                    size_t *oldct, __sigactionset_t old[],
                    int options);
```

General description

Examines and changes the actions associated with one or more signals. This function is equivalent to using sigaction() one or more times.

The parameters are:

- `size_t newct`: newct is the number of __sigactionset_t structures to be processed in the new array. The value of newct must be from 0 to 64. If this parameter is 0, the new parameter is ignored, and may be NULL. If the newct parameter is not 0, new must be an array containing at least newct __sigactionset_t structures.

- `const __sigactionset_t new[]`: new is an optional array of __sigactionset_t structures. When newct is 0, new may be NULL, and no signal actions will be changed.

When newct is not 0, the data in the new array of __sigactionset_t structures will cause the actions associated with one or more signals to be changed. The system will change the signal actions as if sigaction() were called multiple times. The first newct __sigactionset_t structures in the new array are processed in order, and may cause the actions for one or more signals to be set. For each array entry, the effect is the same as calling sigaction() once for each signal whose bit is on in the __sa_signals signal set. The fields __sa_handler, __sa_mask, __sa_flags, and __sa_sigaction correspond to the sa_handler, sa_mask, sa_flags, and sa_sigaction fields in the sigaction structure for sigaction().

If a signal appears in more than one __sa_signals signal set in the new array, the last action specified for that signal will be in effect when __sigactionset() returns. If all bits in all __sa_signals signal sets in the new parameter are off, no signal actions will be changed.

- `size_t*oldct`: oldct is both an input and output parameter. It points to a word containing the number of output entries allowed, used, or needed in the old array.

When __sigactionset() is called, *oldct is the maximum number of __sigactionset_t structures in the old array that the system can fill.
in. The value of *oldct must be from 0 to 64. If this parameter is 0, the old parameter is ignored, and may be NULL. If the *oldct parameter is not 0, old must be an array of __sigactionset_t structures that the system can fill in. The number of array entries in old must be at least *oldct. If not 0, *oldct must be large enough to allow the system to pass back all the unique actions currently associated with all signals. If *oldct is not large enough, __sigactionset() will fail and the errno will be set to ENOMEM.

If __sigactionset() returns with no error and *oldct was not 0, *oldct is set to the number of __sigactionset_t array entries in old that are filled in. If *oldct was too small, causing an ENOMEM error, *oldct is set to the number of __sigactionset_t structures the system would need in order to fill in all the distinct current signal actions. If *oldct was 0 when __sigactionset() was called, it is not updated.

__sigactionset_t old[]
old is an optional array of __sigactionset_t structures.

When *oldct is not 0, the structures in the old array will be filled in with the signal actions currently in effect before any changes are made. The __sigactionset_t structure entries in old are filled in with all the distinct signal actions currently in effect, starting with the first array entry. Each __sigactionset_t structure in the array will contain information about one or more signals. Bits in the __sa_signals signal set in each array entry will indicate which signals that entry applies to. The system will try to use as few array entries as possible when passing back the different signal actions. The signal actions for SIGKILL, SIGSTOP, or SIGTRACE will not be returned.

The output information in each array entry is similar to that returned from sigaction(). In the __sigactionset_t structure, the fields __sa_handler, __sa_mask, __sa_flags, and __sa_sigaction correspond to the sa_handler, sa_mask, sa_flags, and sa_sigaction fields in the sigaction structure filled in by sigaction(). The signal action as described by these fields applies to all signals whose bits are on in the __sa_signals signal set in the array entry.

If old is not large enough to contain information about all distinct signal actions currently in effect, __sigactionset() fails, and ENOMEM is returned. There is no way to obtain the current signal actions for a specified subset of signals.

When old is NULL, the system does not return any information about the current signal actions.

int options
options is a collection of flag bits that affects the operation __sigactionset(). The following flag bit can be set in options:

__SIGACTIONSET_IGN_INVALID
Tells the system to ignore invalid bits in the __sa_signals field in all __sigactionset_t array entries in the new parameter. Also, the system will ignore attempts to set SIGKILL, SIGSTOP or SIGTRACE to an action other than SIG_DFL, or SIGIO to SIG_IGN.

If this option bit is off, the system will fail the __sigactionset() request if any invalid bits are found
The __sigactionset() function is supported only in a POSIX(ON) program.

Special behavior for C++: The behavior when mixing signal-handling with C++ exception handling is undefined. Also, the use of signal-handling with constructors and destructors is undefined.

C++ and C language linkage conventions are incompatible, and therefore __sigactionset() cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to __sigactionset(), the compiler will flag it as an error. Therefore to use the __sigactionset() function in the C++ language, you must ensure that signal handler routines have C linkage, by declaring them as extern "C".

Special behavior for XPLINK-compiled C++: Restrictions concerning setjmp.h and ucontext.h:

Notes:
1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the jmp_buf, sigjmp_buf or ucontext_t types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define jmp_buf, sigjmp_buf or ucontext_t data items and pass them to XPLINK functions that call getcontext(), longjmp(), __longjmp(), setjmp(), __setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.
3. When __XPLINK__ is defined, the Language Environment V2R10 and later headers define a larger jmp_buf, sigjmp_buf or ucontext_t area that is required by setjmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Language Environment V2R10 and later headers define a shorter jmp_buf, sigjmp_buf or ucontext_t area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls setjmp(), getcontext() or similar functions with a short jmp_buf, sigjmp_buf or ucontext_t area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Usage note

The use of the SIGTSTOP and SIGTCONT signal is not supported with this function.

__sigactionset_t type

The __sigactionset_t type is defined as follows:

```c
typedef struct __sigactionset_s
{
    sigset_t __sa_signals;
    int __sa_flags;
    void (*__sa_handler)(int);
    sigset_t __sa_mask;
    void (*__sa_sigaction)(int, siginfo_t *, void *);
} __sigactionset_t;
```
The following are members of the structure:

`sigset_t __sa_signals`
This is a signal set. It contains the signals whose actions are described by the other members in this structure. For more information on signal sets, see "sigemptyset() — Initialize a signal mask to exclude all signals" on page 1933.

In the new array of `__sigactionset_t` structures, the caller sets bits in this signal set. The signal action for each signal in the signal set will be set as described by the other members of the structure.

`__sa_signals` must be set using one or more of the signal set manipulation functions: `sigaddset()`, `sigdelset()`, `sigemptyset()`, or `sigfillset()`.

In the old array of `__sigactionset_t` structures, the system sets the bits in the `__sa_signals` field. The current signal action for each member of the signal set is described by the other members of the structure. All signals in the set have the same signal action.

`int __sa_flags`
A collection of flag bits that affect the behavior of the specified signal.

The flag bits in the `__sa_flags` field are the same as those in the `sa_flags` member of the `sigaction` structure. See "sigaction() — Examine or change a signal action" on page 1908 for a detailed description of these flag bits.

`void (* __sa_handler)(int)`
A pointer to the function assigned to handle the signals in the `__sa_signals` signal set. This function will be invoked passing one parameter of type `int` that contains the signal type for which this function is being invoked. The value of this member can also be `SIG_DFL` (indicating the default action) or `SIG_IGN` (indicating that the signal is to be ignored).

**Note:** This member and `__sa_sigaction` are mutually exclusive. When the `SA_SIGINFO` flag is set in `__sa_flags`, `__sa_sigaction` is used. Otherwise, `__sa_handler` is used.

`sigset_t __sa_mask`
This signal set identifies a set of signals that are to be added to the signal mask of the calling thread before the signal-handling function `__sa_handler` or `__sa_sigaction` is invoked. For more information on signal sets, see "sigemptyset() — Initialize a signal mask to exclude all signals" on page 1933. You cannot use this mechanism to block `SIGKILL`, `SIGSTOP`, or `SIGTRACE`. If `__sa_mask` includes these signals, they will simply be ignored; `__sigactionset()` will not return an error.

`__sa_mask` must be set by using one or more of the signal set manipulation functions: `sigaddset()`, `sigdelset()`, `sigemptyset()`, or `sigfillset()`.
__sigactionset

```c
void (*_sa_sigaction)(int, siginfo_t *, void *)
```

A pointer to the function assigned to handle the signal, or SIG_DFL, or SIG_IGN. This function will be invoked passing three parameters. The first is of type `int` that contains the signal type for which this function is being invoked. The second is of type `siginfo_t` where the `siginfo_t` contain additional information about the source of the signal. The third is of type `void`* but will actually point to a `ucontext_t` containing the context information at the time the signal interrupt.

**Notes:**

1. The user must cast `SIG_DFL` or `SIG_IGN` to match the __sa_sigaction definition.
2. This member and sa_handler are mutually exclusive. When the SA_SIGINFO flag is set in __sa_flags, __sa_sigaction is used. Otherwise, __sa_handler is used.

When a signal handler installed by __sigactionset(), with the _SA_OLD_STYLE flag set off, catches a signal, the system calculates a new signal mask by taking the union of the current signal mask at the time of the signal interrupt, the signals specified by __sa_mask, and the signal that was just caught (if the SA_NODEFER flag is not set). This new mask stays in effect until the signal handler returns, or sigprocmask(), sigsuspend(), siglongjmp(), sighold(), sigpause(), or sigrelse() is called. When the signal handler ends, the original signal mask is restored.

After an action has been specified for a particular signal, using __sigactionset() with the _SA_OLD_STYLE flag not set, it remains installed until it is explicitly changed with another call to __sigactionset(), sigaction(), signal(), bsd_signal(), sigset(), sigignore(), one of the exec functions, or until the SA_RESETHAND flag causes it to be reset to SIG_DFL.

After an action has been specified for a particular signal, using __sigactionset() with the _SA_OLD_STYLE flag set or using signal(), it remains installed until it is explicitly changed with another call to __sigactionset(), sigaction(), signal(), bsd_signal(), sigset(), sigignore(), one of the exec functions, or a signal catcher is driven, where it will be reset to SIG_DFL.

Successful setting of a signal action to SIG_IGN for a signal that is pending causes the pending signal to be discarded, whether or not it is blocked. This provides the ability to discard signals that are found to be blocked and pending by sigpending(). A signal is discarded across a call to __sigactionset() if any __sigactionset_t structure in the new array causes the action for that signal to be set to SIG_IGN. This happens even if a later __sigactionset_t structure in the new array sets the signal action to something other than SIG_IGN before __sigactionset() returns.

If a process sets the action of the SIGCHLD signal to SIG_IGN, child processes of the calling process will not be transformed into zombie processes when they terminate. If the calling process subsequently waits for its children, and the process has no unwaited from children that were transformed into zombie processes, it will block until all of its children terminate. The wait(), waitid(), or waitpid() function will fail and set errno to ECHILD.
If the SA_SIGINFO flag is set, the signal catching function specified by
__sa_sigaction is invoked as:

```c
void function(int signo, siginfo_t *info, void *context);
```

where `function` is the specified signal-catching function, `signo` is the signal number
of the signal being delivered, `info` points to an object of type `siginfo_t` associated
with the signal being delivered, and `context` points to an object of type `ucontext_t`.

For a signal catcher that has been loaded by `fetch()` or `fetchep()`, the address
returned by __sigactionset() in the __sa_handler or __sa_sigaction fields may be
different than the value originally passed in to `sigaction()` or __sigactionset() (when
the signal action was first set). This signal catcher address can be passed in again
to `sigaction()` or __sigactionset() to reestablish the same signal catcher. The effect
will be similar to passing in the original catcher address obtained from `fetch()` or
`fetchep()`. However, this address should not be used for any other purpose, such as
directly calling the signal catcher. Always use the original address obtained from
fetch() or fetchep() when calling the catcher directly.

**Considerations for asynchronous signal-catching functions**

Some of the functions have been restricted to be serially reusable with respect to
asynchronous signals. For more information on these functions, see “sigaction() —
Examine or change a signal action” on page 1908.

**Returned value**

If successful, __sigactionset() returns 0.

If unsuccessful, no signal actions are changed, __sigactionset() returns -1 and sets
`errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>
| EINVAL     | This error can occur if:
  * An unsupported signal bit was on in the __sa_signals signal set in the `new` parameter. This error will not be reported if the __SSET_IGNINVAL flag is set in `options`. To obtain more information in this case, use __errno2().
  * An attempt was made to set the signal action for SIGSTOP, SIGKILL, or SIGTRACE to something other than SIG_DFL. This error will not be reported if the __SSET_IGNINVAL flag is set in `options`. To obtain more information in this case, use __errno2().
  * The `newct` or `oldct` parameters are not in the range from 0 to 64.
  * `newct` was not 0 and `new` was NULL.
  * `oldct` was not 0 and `old` was NULL. |
| EMVSERR    | An MVS environmental or internal error has occurred. Use __errno2() to obtain more information about this error. |
| ENOMEM     | The input value in `oldct` was not 0, and was too small to let the system pass back all distinct current signal actions. When __sigactionset() returns, `oldct` will be set to the number of array entries needed by the system. |
Example

```c
/*
 * Note: This is just a code fragment
 */

void catch_sigchld(int, siginfo_t *, void *);

...

__sigactionset_t new[2], old[64];
int options;
int rc;
size_t oldct = 64;

/*
 * Set SIGUSR1 and SIGUSR2 to SIG_IGN
 * Set SIGCHLD to new-style catcher catch_sigchld()
 * Save original signal setup in variable old
 */

bzero(new, sizeof new);

(void)sigemptyset(&(new[0].__sa_signals));
(void)sigaddset (&(new[0].__sa_signals), SIGUSR1);
(void)sigaddset (&(new[0].__sa_signals), SIGUSR2);

(void)sigemptyset(&(new[1].__sa_signals));
(void)sigaddset (&(new[1].__sa_signals), SIGCHLD);

new[0].__sa_handler = SIG_IGN;
new[1].__sa_sigaction = &catch_sigchld;
new[1].__sa_flags = SA_SIGINFO;

rc = __sigactionset((size_t)2, new, &oldct, old, __SSET_IGNVALID);
```

<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <signal.h>

int sigaddset(sigset_t *set, int signal);
```

General description

 Adds a signal to the set of signals already recorded in `set`.

`sigaddset()` is part of a family of functions that manipulate signal sets. Signal sets are data objects that let a process keep track of groups of signals. For example, a process can create one signal set to record which signals it is blocking, and another signal set to record which signals are pending. In general, signal sets are used to manipulate groups of signals used by other functions (such as `sigprocmask()`) or to examine signal sets returned by other functions (such as `sigpending()`).

Applications should call either `sigemptyset()` or `sigfillset()` at least once for each object of type `sigset_t` prior to any other use of that object. If such an object is not initialized in this way, but is nonetheless supplied as an argument to any of `pthread_sigmask()`, `sigaction()`, `sigaddset()`, `sigdelset()`, `sigismember()`, `sigpending()`, `sigprocmask()`, `sigsuspend()`, `sigtimedwait()`, `signal()`, or `sigwaitinfo()`, the results are undefined.

Usage note

The use of the SIGTSTOP and SIGTCONT signal is not supported with this function.

Returned value

If the signal is successfully added to the signal set, `sigaddset()` returns 0.

If `signal` is not supported, `sigaddset()` returns −1 and sets `errno` to EINVAL.

Example

```c
CELEBS15
/* CELEBS15

   This example adds a set of signals.

   */
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <unistd.h>

void catcher(int signum) {
```
main() {
    struct sigaction sact;
    sigset_t sigset;

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGUSR1, &sact, NULL);

    puts("before first kill()"acades);
    kill(getpid(), SIGUSR1);
    puts("before second kill()"acades);

    sigemptyset(&sigset);
    sigaddset(&sigset, SIGUSR1);
    sigprocmask(SIG_SETMASK, &sigset, NULL);

    kill(getpid(), SIGUSR1);
    puts("after second kill()"acades);
}

Output
before first kill()
catcher() has gained control
before second kill()
after second kill()

</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int sigaltstack(const stack_t *__restrict__ ss, stack_t *__restrict__ oss);
```

General description

The `sigaltstack()` function allows a thread to define and examine the state of an alternate stack for signal handlers. Signals that have been explicitly declared to execute on the alternate stack will be delivered on the alternate stack.

**Note:** To explicitly declare that a signal catcher is to run on the alternate signal stack, the `SA_ONSTACK` flag must be set in the `sa_flags` when the signal action is set using `sigaction()`.

If `ss` is not a NULL pointer, it points to a `stack_t` structure that specifies the alternate signal stack that will take effect upon return from `sigaltstack()`. The `ss_flags` member specifies the new stack state. If it is set to `SS_DISABLE`, the stack is disabled and `ss_sp` and `ss_size` are ignored. Otherwise the stack will be enabled, and the `ss_sp` and `ss_size` members specify the new address and size of the stack.

**AMODE 64 considerations:** Storage for this stack must be above the 2GB bar. It may not be storage acquired with the `__malloc24()` or `__malloc31()` functions.

The range of addresses starting at `ss_sp`, up to but not including `ss_sp + ss_size`, is available to the implementation for use as the stack. This interface makes no assumptions regarding which end is the stack base and in which direction the stack grows as items are pushed.

If `oss` is not a NULL pointer, on successful completion it will point to a `stack_t` structure that specifies the alternate signal stack that was in effect before the call to `sigaltstack()`. The `ss_sp` and `ss_size` members specify the address and size of that stack. The `ss_flags` member specifies the stack’s state, and may contain one of the following values:

- **SS_ONSTACK** The thread is currently executing on the alternate signal stack. Attempts to modify the alternate signal stack while the thread is executing on it fails. This flag must not be modified by threads.

- **SS_DISABLE** The alternate signal stack is currently disabled.

The value `SIGSTKSZ` is a system default specifying the number of bytes that would be used to cover the usual case when manually allocating an alternate stack area. The value `MINSIGSTKSZ` is defined to be the minimum stack size for a signal handler.
In computing an alternate signal stack size, a program should add that amount to its stack requirements to allow for the system implementation overhead. The constants SS_ONSTACK, SS_DISABLE, SIGSTKSZ, and MINSIGSTKSZ are defined in <signal.h>.

After a successful call to one of the exec functions, there are no alternate signal stacks in the new process image.

Notes:
1. If a signal handler is enabled to run on an alternate stack, then all functions called by that signal handler must be compiled with the same linkage. For example, if the signal handler is compiled with XPLINK, then all functions it calls must also be compiled XPLINK. Since only one alternate stack can be supplied, no mixing of linkages (which would require both upward and downward-growing alternate stacks) is allowed. The type of stack created will be based on the attributes of the signal handler to be given control. If the signal handler has been compiled with XPLINK, then a downward-growing stack will be created in the alternate stack, including, in AMODE 31, using enough storage in the user stack to create a 4k read-only guard page (aligned on a 4k boundary).
2. If a new signal is received while a signal handler is running on an alternate stack, and that new signal specified a signal handler that also runs on the alternate stack, then both signal handlers must have been compiled with the same linkage (XPLINK versus non-XPLINK).

Returned value

If successful, sigaltstack() returns 0.

If unsuccessful, sigaltstack() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>ss argument is not a NULL pointer, and the ss_flags member pointed to by ss contains flags other than SS_DISABLE.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>The size of the alternate stack area is less than MINSIGSTKSZ.</td>
</tr>
<tr>
<td>EPERM</td>
<td>An attempt was made to modify an active stack.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <signal.h>

int sigdelset(sigset_t *set, int signal);
```

General description

Removes the specified `signal` from the list of signals recorded in `set`.

The sigdelset() function is part of a family of functions that manipulate signal sets. Signal sets are data objects that let a process keep track of groups of signals. For example, a process can create one signal set to record which signals it is blocking, and another signal set to record which signals are pending. In general, signal sets are used to manipulate groups of signals used by other functions (such as sigprocmask()) or to examine signal sets returned by other functions (such as sigpending()).

Applications should call either sigemptyset() or sigfillset() at least once for each object of type sigset_t prior to any other use of that object. If such an object is not initialized in this way, but is nonetheless supplied as an argument to any of pthread_sigmask(), sigaction(), sigaddset(), sigdelset(), sigismember(), sigpending(), sigprocmask(), sigsuspend(), sigtimedwait(), sigwait(), or sigwaitinfo(), the results are undefined.

Usage note

The use of the SIGTSTOP and SIGTCONT signal is not supported with this function.

Returned value

If the signal is successfully deleted from the signal set, sigdelset() returns 0.

If `signal` is not supported, sigdelset() returns −1 and sets errno to EINVAL.

Example

```c
CELEBS16
/* CELEBS16
   This example deletes specific signals.
*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <unistd.h>
```
void catcher(int signum) {
    puts("catcher() has gained control");
}

main() {
    struct sigaction sact;
    sigset_t sigset;

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGUSR1, &sact, NULL);

    sigfillset(&sigset);
    sigprocmask(SIG_SETMASK, &sigset, NULL);

    puts("before kill()");
    kill(getpid(), SIGUSR1);

    puts("before unblocking SIGUSR1");
    sigdelset(&sigset, SIGUSR1);
    sigprocmask(SIG_SETMASK, &sigset, NULL);
    puts("after unblocking SIGUSR1");
}

Output
before kill()
before unblocking SIGUSR1
catcher() has gained control
after unblocking SIGUSR1

</table>

Format

```c
#define _POSIX_SOURCE
#include <signal.h>

int sigemptyset(sigset_t *set);
```

General description

Initializes a signal set `set` to the empty set. All recognized signals are excluded.

sigemptyset() is part of a family of functions that manipulate signal sets. *Signal sets* are data objects that let a process keep track of groups of signals. For example, a process can create one signal set to record which signals it is blocking, and another signal set to record which signals are pending. Signal sets are used to manipulate groups of signals used by other functions (such as sigprocmask()) or to examine signal sets returned by other functions (such as sigpending()).

Returned value

If successful, sigemptyset() returns 0.

There are no documented errno values.

Example

**CELEBS17**

```c
/* CELEBS17

   This example initializes a set of signals to an empty set.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <unistd.h>

main() {
    struct sigaction sact;
    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = SIG_IGN;
    sigaction(SIGUSR2, &sact, NULL);
    puts("before kill()");
    kill(getpid(), SIGUSR2);
    puts("after kill()");
}
```
sigemptyset

Output
before kill()
after kill()

</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <signal.h>

int sigfillset(sigset_t *set);
```

General description

Initializes a signal set `set` to the complete set of supported signals.

`sigfillset()` is part of a family of functions that manipulate signal sets. **Signal sets** are data objects that let a process keep track of groups of signals. For example, a process can create one signal set to record which signals it is blocking, and another signal set to record which signals are pending. Signal sets are used to manipulate groups of signals used by other functions (such as `sigprocmask()`) or to examine signal sets returned by other functions (such as `sigpending()`).

Returned value

If successful, `sigfillset()` returns 0.

There are no documented `errno` values.

Example

```c
CELEBS18
/* CELEBS18
   This example initializes a set of signals to a complete set.
*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <unistd.h>

main() {
    sigset_t sigset;
    sigfillset(&sigset);
    sigprocmask(SIG_SETMASK, &sigset, NULL);
    puts("before kill()");
    kill(getpid(), SIGSEGV);
    puts("after kill()");
}
```

Output
sigfillset

before kill()
after kill()

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int sigignore(int sig);
```

General description

The sigignore() function provides a simplified method for setting the signal action of the signal specified by the argument `sig` to `SIG_IGN`.

Usage note

The use of the `SIGTSTOP` and `SIGTCONT` signal is not supported with this function.

Returned value

If successful, sigignore() returns 0.

If unsuccessful, sigignore() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of the argument <code>sig</code> is not a valid signal type or it is SIGKILL, SIGSTOP, or SIGTRACE.</td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int siginterrupt(int sig, int flag);
```

General description

The siginterrupt() function provides a simplified method for changing the restart behavior when a function is interrupted by the signal specified in the argument `sig`.

The argument `flag` serves as a binary switch to enable or disable restart behavior. When `flag` is nonzero, restart behavior will be disabled. Otherwise it is enabled.

Returned value

If successful, siginterrupt() returns 0.

If unsuccessful, siginterrupt() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of the argument <code>sig</code> is not a valid signal type.</td>

<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _POSIX_SOURCE
#include <signal.h>

int sigismember(const sigset_t *set, int signal);
```

**General description**

Tests whether a specified signal number `signal` is a member of a signal set `set`.

sigismember() is part of a family of functions that manipulate signal sets. `Signal sets` are data objects that let a process keep track of groups of signals. For example, a process can create one signal set to record which signals it is blocking, and another signal set to record which signals are pending. Signal sets are used to manipulate groups of signals used by other functions (such as sigprocmask()) or to examine signal sets returned by other functions (such as sigpending()).

Applications should call either sigemptyset() or sigfillset() at least once for each object of type sigset_t prior to any other use of that object. If such an object is not initialized in this way, but is nonetheless supplied as an argument to any of pthread_sigmask(), sigaction(), sigaddset(), sigdelset(), sigismember(), sigpending(), sigprocmask(), sigsuspend(), sigtimedwait(), sigwait(), or sigwaitinfo(), the results are undefined.

**Usage note**

The use of the SIGTHSTOP and SIGTCHCONT signal is not supported with this function.

**Returned value**

sigismember() returns 1 if `signal` is in `set`, and it returns 0 if it is not.

If unsuccessful, sigismember() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of <code>signal</code> is not one of the supported signals.</td>
</tr>
</tbody>
</table>

**Example**

```c
CELEBS19

/* CELEBS19

   This example tests signals.

*/
#define _POSIX_SOURCE
```
`#include <stdio.h>
#include <signal.h>

void check(sigset_t set, int signum, char *signame) {
   printf("%8s is ", signame);
   if (!sigismember(&set, signum))
      printf("not ");
   puts(" in the set");
}

main() {
   sigset_t sigset;

   sigemptyset(&sigset);
   sigaddset(&sigset, SIGUSR1);
   sigaddset(&sigset, SIGKILL);
   sigaddset(&sigset, SIGCHLD);

   check(sigset, SIGUSR1, "SIGUSR1");
   check(sigset, SIGUSR2, "SIGUSR2");
   check(sigset, SIGFPE, "SIGFPE");
   check(sigset, SIGKILL, "SIGKILL");
}

Output
SIGUSR1 is in the set
SIGUSR2 is not in the set
SIGFPE is not in the set
SIGKILL is in the set

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <setjmp.h>

void siglongjmp(sigjmp_buf env, int val);
```

General description

For a stack environment previously saved in `env` by `sigsetjmp()`, the `siglongjmp()` function restores all the stack environment and, optionally, the signal mask, depending on whether it was saved by `sigsetjmp()`. The `sigsetjmp()` and `siglongjmp()` functions provide a way to perform a nonlocal goto.

`env` is an address for a `sigjmp_buf` structure.

`val` is the return value from `siglongjmp()`.

`siglongjmp()` is similar to `longjmp()`, except for the optional capability of restoring the signal mask. The `sigsetjmp()`—`siglongjmp()` pair, the `setjmp()`—`longjmp()` pair, the `__setjmp()`—`__longjmp()` pair, and the `getcontext()`—`setcontext()` pair cannot be intermixed. A stack environment and signal mask saved by `sigsetjmp()` can be restored only by `siglongjmp()`.

A call to `sigsetjmp()` causes the current stack environment including, optionally, the signal mask to be saved in `env`. A subsequent call to `siglongjmp()` restores the saved environment and signal mask (if saved by `sigsetjmp()` and returns control to a point in the program corresponding to the `sigsetjmp()` call. Execution resumes as if the `sigsetjmp()` call had just returned the given `value`. All variables (except register variables) that are accessible to the function that receives control contain the values they had when you called `siglongjmp()`. The values of register variables are unpredictable. Nonvolatile auto variables that are changed between calls to `sigsetjmp()` and `siglongjmp()` are also unpredictable.

Notes:

1. If you call `siglongjmp()`, the function in which the corresponding call to `sigsetjmp()` was made must not have returned first. After the function calling `sigsetjmp()` returns, calling `siglongjmp()` causes unpredictable program behavior.
2. If `siglongjmp()` is used to jump back into an XPLINK routine, any `alloca()` requests issued by the XPLINK routine after the earlier `sigsetjmp()` (or `getcontext()`, and so on.) was called and before `siglongjmp()` is called are backed out. All storage obtained by these `alloca()` requests is freed before the XPLINK routine is resumed.
3. If `siglongjmp()` is used to jump back into a non-XPLINK routine, `alloca()` requests made after `sigsetjmp()` and before `siglongjmp()` are not backed out.
siglongjmp

The value argument passed to siglongjmp() must be nonzero. If you give a zero argument for value, siglongjmp() substitutes the value 1 in its place.

siglongjmp() does not use the normal function call and return mechanisms. siglongjmp() restores the saved signal mask only if the env parameter was initialized by a call to sigsetjmp() with a nonzero savemask argument.

Special behavior for C++: If sigsetjmp() and siglongjmp() are used to transfer control in a z/OS XL C++ program, the behavior is undefined in terms of the destruction of automatic objects. Additionally, if any automatic objects would be destroyed by a thrown exception transferring control to another (destination) point in the program, then a call to siglongjmp() at the throw point that transfers control to the same (destination) point has undefined behavior. This applies to both z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of sigsetjmp() and siglongjmp() in conjunction with try(), catch(), and throw() is also undefined.

Special behavior for XPLINK-compiled C++: Restrictions concerning setjmp.h and ucontext.h:

Notes:
1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the jmp_buf, sigjmp_buf or ucontext_t types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define jmp_buf, sigjmp_buf or ucontext_t data items and pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(), setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.
3. When __XPLINK__ is defined, the Language Environment V2R10 and later headers define a larger jmp_buf, sigjmp_buf or ucontext_t area that is required by setjmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Language Environment V2R10 and later headers define a shorter jmp_buf, sigjmp_buf or ucontext_t area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls setjmp(), getcontext() or similar functions with a short jmp_buf, sigjmp_buf or ucontext_t area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

siglongjmp() returns no values.

There are no documented errno values.

Example

This example saves the stack environment and signal mask at the statement:
if(sigsetjmp(mark,1) != 0) ...

When the system first performs the if statement, it saves the environment and signal mask in mark and sets the condition to false, because sigsetjmp() returns 0 when it saves the environment. The program prints the message: sigsetjmp() has been called
The subsequent call to function p() tests for a local error condition, which can cause it to perform siglongjmp(). Then control returns to the original sigsetjmp() function using the environment saved in mark and restores the signal mask. This time the condition is true because −1 is the return value from siglongjmp(). The example then performs the statements in the block and prints: siglongjmp() has been called. Then it performs your recover() function and leaves the program.

```c
#define _POSIX_SOURCE  
#include <stdio.h>   
#include <setjmp.h>  
sigjmp_buf mark;  
void p(void);      
void recover(void); 

int main(void)  
{  
  if (sigsetjmp(mark) != 0)  
    {  
      printf("siglongjmp() has been called\n");  
      recover();  
      exit(1);  
    }  
  printf("sigsetjmp() has been called\n");  
  ...  
  p();  
  ...  
}  

void p(void) {  
  int error = 0;  
  ...  
  error = 9;  
  ...  
  if (error != 0)  
    siglongjmp(mark, -1);  
  ...  
}  

void recover(void) {  
  ...  
}
```

</tr>
</tbody>
</table>

Format

```c
#include <signal.h>

void(*signal(int sig, void(*func)(int)))(int);
```

General description

Allows a process to choose one of several ways to handle an interrupt signal `sig` from the operating system or from the `raise()` function.

The `sig` argument must be one of the macros defined in the `signal.h` header file. See Table 48 on page 1947

The `func` argument must be one of the macros, SIG_DFL or SIG_IGN, defined in the `signal.h` header file, or a function address.

If the value of `func` is SIG_DFL, default handling for that signal will occur. If the value of `func` is SIG_IGN, the signal will be ignored. Otherwise, `func` points to a function to be called when that signal occurs. Such a function is called a signal handler.

When a signal occurs, if `func` points to a function:
1. First the equivalent of `signal(sig, SIG_DFL);` is executed or an implementation-defined blocking of the system is performed. (If the value of `sig` is SIGILL, the occurrence of the reset to SIG_DFL is implementation-defined.)
2. Next, the equivalent of `(*func)(sig);` is executed. The function `func` may terminate by executing a return statement or by calling the `abort()`, `exit()`, or `longjmp()` function. If `func` executes a return statement and the value of `sig` was SIGFPE or any other implementation-defined value corresponding to a computational exception, the behavior is undefined. Otherwise, the program will resume execution at the point it was interrupted.

If a signal occurs for a reason other than having called the `abort()` or `raise()` function, the behavior is undefined if the signal handler calls any function in the standard library other than the `signal()` function itself (with a first argument of the signal number corresponding to the signal that caused the invocation of the handler). Behavior is also undefined if the signal handler refers to any object with static storage duration other than by assigning a value to a static storage duration variable of type `volatile sig_atomic_t`. Furthermore, if such a call to the `signal()` function returns SIG_ERR, the value of `errno` is indeterminate.
At program startup, the equivalent of `signal(sig, SIG_IGN);` may be executed for some selected signals. The equivalent of `signal(sig, SIG_DFL);` is executed for all other signals.

The action taken when the interrupt signal is received depends on the value of `func`.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIG_DFL</td>
<td>Default handling for the signal will occur.</td>
</tr>
<tr>
<td>SIG_IGN</td>
<td>The signal is to be ignored.</td>
</tr>
</tbody>
</table>

As of Language Environment Release 3, the defaults for SIGUSR1, SIGUSR2, SIGINT, and SIGTERM are changed from the signal being ignored to abnormal termination. To compensate for this change, you would explicitly register that the signal is to be ignored, using a call sequence such as:

```c
signal(SIGUSR1, SIG_IGN);
signal(SIGUSR2, SIG_IGN);
signal(SIGINT, SIG_IGN);
signal(SIGTERM, SIG_IGN);
```

These calls may be made either in the source or they can be made from the HLL user exit CEEBINT, which will require a re-link.

**Special behavior for POSIX:** For a z/OS UNIX C application running POSIX(ON), the interrupt signal can also come from kill() or from another process. A program can use `sigaction()` to establish a signal handler; `sigaction()` blocks the signal while the signal handler has control. If you use `signal()` to establish a signal handler, the signal reverts back to the default action. If you want the signal handler to get control for the next signal of this type, you must reissue `signal()`.

The `signal(sig, func)` is equivalent to `sigaction(sig, &act, NULL)`, where `act` points to a `sigaction` structure containing an `sa_action` of `func`, an `sa_mask` by `sigemptyset()`, and an `sa_flags` containing `_SA_OLD_STYLE`.

**Note:** The `sigaction()` function supersedes the `signal()` interface, and should be the preferred usage. In particular, `sigaction()` and `signal()` must not be used in the same process to control the same signal.

For a list of considerations for coding signal-catching functions that will support asynchronous signals, refer to "sigaction() — Examine or change a signal action" on page 1908.

The `sig` argument must be one of the macros defined in the `signal.h` header file.

**Special behavior for C++:**
- The behavior when mixing signal-handling with C++ exception handling is undefined. Also, the use of signal-handling with constructors and destructors is undefined.
- C++ and C language linkage conventions are incompatible, and therefore `signal()` cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to `signal()`, the compiler will flag it as an error. Therefore, to use the `signal()` function in the C++ language, you must ensure that signal handler routines established have C linkage, by declaring them as extern "C".

The signals supported are listed below.
Table 48. Signals Supported by C or C++ — POSIX(OFF)

<table>
<thead>
<tr>
<th>Value</th>
<th>Default Action</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGABND</td>
<td>1</td>
<td>Abend</td>
</tr>
<tr>
<td>SIGABRT</td>
<td>1</td>
<td>Abnormal termination (sent by abort())</td>
</tr>
<tr>
<td>SIGFPE</td>
<td>1</td>
<td>Arithmetic exceptions that are not masked, for example, overflow, division by zero, and incorrect operation</td>
</tr>
<tr>
<td>SIGILL</td>
<td>1</td>
<td>Detection of an incorrect function image</td>
</tr>
<tr>
<td>SIGINT</td>
<td>1</td>
<td>Interactive attention</td>
</tr>
<tr>
<td>SIGSEGV</td>
<td>1</td>
<td>Incorrect access to memory</td>
</tr>
<tr>
<td>SIGTERM</td>
<td>1</td>
<td>Termination request sent to the program</td>
</tr>
<tr>
<td>SIGUSR1</td>
<td>1</td>
<td>Intended for use by user applications</td>
</tr>
<tr>
<td>SIGUSR2</td>
<td>1</td>
<td>Intended for use by user applications</td>
</tr>
<tr>
<td>SIGIOERR</td>
<td>2</td>
<td>A serious I/O error was detected.</td>
</tr>
</tbody>
</table>

In Table 48, the Default Actions are:

1  Normal termination of the process.
2  Ignore the signal.

When the runtime option POSIX(ON) is specified, if a signal catcher for a SIGABND, SIGFPE, SIGILL or SIGSEGV signal runs as a result of a program check or an ABEND, and the signal catcher executes a RETURN statement, the process will be terminated.

Returned value

If successful, signal() returns the most recent value of func.

If unsuccessful, signal() returns a value of SIG_ERR and a positive value in errno.

There are no documented errno values. If an error occurs, issue perror() using the errno value.

Example

CELEBS20

/* CELEBS20 */

This example shows you how to establish a signal handler.

/*
 #include <signal.h>
 #include <stdio.h>
 #include <stdlib.h>
 #define ONE_K 1024
 #define OUT_OF_STORAGE (SIGUSR1)

 /* The SIGNAL macro does a signal() checking the return code */
 #define SIGNAL(handler, StrCln) { 
    if (signal((handler), (StrCln)) == SIG_ERR) { 
        perror("Could not signal user signal"); 
        abort(); 
    } 
} */
```c
#ifdef __cplusplus
/* the __cplusplus macro */
extern "C" void StrCln(int); /* is automatically defined */
#else /* by the C++/MVS compiler */
void StrCln(int);
#endif

void DoWork(char **buffer, int);

int main(int argc, char *argv[]) {  
  int size;
  char *buffer;

  signal(OUT_OF_STORAGE, StrCln);

  if (argc != 2) {  
    printf("Syntax: %s size \n", argv[0]);
    return(-1);
  }

  size = atoi(argv[1]);
  DoWork(&buffer, size);
  return(0);
}

void StrCln(int SIG_TYPE) {
  printf("Failed trying to malloc storage\n");
  signal(SIG_TYPE, SIG_DFL);
  exit(0);
}

void DoWork(char **buffer, int size) {
  int rc;

  while (*buffer != NULL)
    *buffer = (char *)malloc(size*ONE_K);
  if (*buffer == NULL) {
    if (raise(OUT_OF_STORAGE)) {
      perror("Could not raise user signal");
      abort();
    }
  }
  return;
}
```

<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R8</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <math.h>

int signbit(real-floating x);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int signbit(real-floating x); /* C only */
int signbit(decimal-floating x); /* C only */
bool signbit(real-floating x); /* C++ only */
bool signbit(decimal-floating x); /* C++ only */

#define _TR1_C99
#include <math.h>

bool signbit(real-floating x); /* C++ only */
```

General description

The signbit() macro or function template determines whether the sign of its argument value is negative.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>signbit</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Notes:
1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The signbit() macro returns 1 if the sign of its argument value is negative, else returns 0. The C++ function template returns true if the sign of its argument value is negative, else returns false.

__signgam() — Return signgam reference

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <math.h>

int *__signgam(void);
#define signgam (*__signgam())
```

General description

The __signgam() function returns the address of the calling thread's storage for the `signgam` external variable used by the `gamma()` and `lgamma()` functions. This extended mechanism is necessary for multithreaded processes which use either of these two functions, since each thread has its own instance of `signgam`. The `<math.h>` header defines `signgam` to an invocation of __signgam(), so generally, all references to `signgam` will be mapped to calls to __signgam(). If the user eliminates this definition, either by not including the header, or by using #undef, then references to `signgam` will refer to the actual `signgam` external variable, which contains the `signgam` value for the IPT only. In the absence of the definition of `signgam` to a call to __signgam(), `signgam` values in threads other than the IPT are inaccessible.

Returned value

__signgam() is always successful.

```

General description

The sigpause() function provides a simplified method for removing a signal, specified by the argument `sig`, from the calling thread's signal mask and suspending this thread until a signal is received whose action is either to execute a signal catcher function or to terminate the process.

Usage notes

The use of the SIGTSTOP and SIGTCONT signal is not supported with this function.

Returned value

If successful, sigpause() returns −1 and sets errno to EINTR.

If unsuccessful, sigpause() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of the argument <code>sig</code> is not a valid signal type or it is SIGKILL, or SIGTRACE.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <signal.h>

int sigpending(sigset_t *set);
```

General description

Returns the union of the set of signals that are blocked from delivery and pending for the calling thread and the set that are pending for the process. If there is only one thread, it does the same for the calling process. This information is represented as a signal set stored in `set`. For more information on examining the signal set pointed to by `set`, see "sigismember() — Test if a signal is in a signal mask" on page 1940.

Usage notes

The use of the SIGTSTOP and SIGTCONT signal is not supported with this function.

Returned value

If successful, sigpending() returns 0.

If unsuccessful, sigpending() returns −1.

There are no documented errno values.

Example

```c
CELEBS22
/* CELEBS22
   This example returns blocked or pending signals.
*/
#define _POSIX_SOURCE
#include <signal.h>
#include <stdio.h>
#include <unistd.h>

void catcher(int signum) {
    puts("inside catcher!");
}

void check_pending(int signum, char *signame) {
    sigset_t sigset;
    if (sigpending(&sigset) != 0)
        perror("sigpending() error");
```
else if (sigismember(&sigset, signum))
    printf("a %s signal is pending\n", signame);
else
    printf("no %s signals are pending\n", signame);
}

main() {
    struct sigaction sigact;
    sigset_t sigset;
    sigemptyset(&sigact.sa_mask);
    sigact.sa_flags = 0;
    sigact.sa_handler = catcher;
    if (sigaction(SIGUSR1, &sigact, NULL) !- 0)
        perror("sigaction() error");
    else {
        sigemptyset(&sigset);
        sigaddset(&sigset, SIGUSR1);
        if (sigprocmask(SIG_SETMASK, &sigset, NULL) !- 0)
            perror("sigprocmask() error");
        else {
            puts("SIGUSR1 signals are now blocked");
            kill(getpid(), SIGUSR1);
            printf("after kill: ");
            check_pending(SIGUSR1, "SIGUSR1");
            sigemptyset(&sigset);
            sigprocmask(SIG_SETMASK, &sigset, NULL);
            puts("SIGUSR1 signals are no longer blocked");
            check_pending(SIGUSR1, "SIGUSR1");
        }
    }
}

Output
SIGUSR1 signals are now blocked
after kill: a SIGUSR1 signal is pending
inside catcher!
SIGUSR1 signals are no longer blocked
no SIGUSR1 signals are pending

Format

```
#define _POSIX_SOURCE
#include <signal.h>

int sigprocmask(int option, const sigset_t *__restrict__ new_set,
                 sigset_t *__restrict__ old_set);
```

General description

Examines, changes, or examines and changes the signal mask of the calling thread. If there is only one thread, it does the same for the calling process.

Typically, `sigprocmask(SIG_BLOCK, ..., ...)` is used to block signals during a critical section of code. At the end of the critical section of code, `sigprocmask(SIG_SETMASK, ..., ...) is used to restore the mask to the previous value returned by `sigprocmask(SIG_BLOCK, ..., ...)`.  

`option` Indicates the way in which the existing set of blocked signals should be changed. The following are the possible values for `option`, defined in the `<signal.h>` header file:

- **SIG_BLOCK** Indicates that the set of signals given by `new_set` should be blocked, in addition to the set currently being blocked.
- **SIG_UNBLOCK** Indicates that the set of signals given by `new_set` should not be blocked. These signals are removed from the current set of signals being blocked.
- **SIG_SETMASK** Indicates that the set of signals given by `new_set` should replace the old set of signals being blocked.

`new_set` Points to a signal set giving the new signals that should be blocked or unblocked (depending on the value of `option`) or it points to the new signal mask if the option was `SIG_SETMASK`. Signal sets are described in `sigemptyset()` — Initialize a signal mask to exclude all signals” on page 1933. If `new_set` is a NULL pointer, the set of blocked signals is not changed. `sigprocmask()` determines the current set and returns this information in `old_set`. If `new_set` is NULL, the value of `option` is not significant.

The signal set manipulation functions: `sigemptyset()`, `sigfillset()`, `sigaddset()`, and `sigdelset()` must be used to establish the new signal set pointed to by `new_set`.

`old_set` Points to a memory location where `sigprocmask()` can store a signal
**sigprocmask**

set. If `new_set` is NULL, `old_set` returns the current set of signals being blocked. When `new_set` is not NULL, the set of signals pointed to by `old_set` is the previous set.

If there are any pending unblocked signals, either at the process level or at the current thread’s level after sigprocmask() has changed the signal mask, then at least one of those signals is delivered to the thread before sigprocmask() returns.

The signals SIGKILL, SIGSTOP, or SIGTRACE cannot be blocked. If you attempt to use sigprocmask() to block these signals, the attempt is simply ignored. sigprocmask() does not return an error status.

SIGFPE, SIGILL, and SIGSEGV signals that are not artificially generated by kill(), killpg(), raise(), sigqueue(), or pthread_kill() (that is, were generated by the system as a result of a hardware or software exception) will not be blocked.

If an artificially raised SIGFPE, SIGILL, or SIGSEGV signal is pending and blocked when an exception causes another SIGFPE, SIGILL, or SIGSEGV signal, both the artificial and exception-caused signals may be delivered to the application.

If sigprocmask() fails, the signal mask of the thread is not changed.

**Usage notes**

The use of the SIGTHTSTOP and SIGTHTCONT signal is not supported with this function.

** Returned value**

If successful, sigprocmask() returns 0.

If unsuccessful, sigprocmask() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>option does not have one of the recognized values.</td>
</tr>
</tbody>
</table>

**Example**

CELEBS23

```c
/* CELEBS23

  This example changes the signal mask.

*/
#define _POSIX_SOURCE
#include <signal.h>
#include <stdio.h>
#include <time.h>
#include <unistd.h>

void catcher(int signum) {
  puts("inside catcher");
}

main() {
  time_t start, finish;
  struct sigaction sact;
  sigset_t new_set, old_set;
  double diff;
  sigemptyset(&sact.sa_mask);
```
sact.sa_flags = 0;
sact.sa_handler = catcher;
if (sigaction(SIGALRM, &sact, NULL) != 0)
    perror("sigaction() error");
else {
    sigemptyset(&new_set);
    sigaddset(&new_set, SIGALRM);
    if (sigprocmask(SIG_BLOCK, &new_set, &old_set) != 0)
        perror("1st sigprocmask() error");
    else {
        time(&start);
        printf("SIGALRM signals blocked at %s", ctime(&start));
        alarm(1);

        do {
            time(&finish);
            diff = difftime(finish, start);
        } while (diff < 10);
        if (sigprocmask(SIG_SETMASK, &old_set, NULL) != 0)
            perror("2nd sigprocmask() error");
        else
            printf("SIGALRM signals unblocked at %s", ctime(&finish));
    }
}
}

Output
SIGALRM signals blocked at Fri Jun 16 12:24:19 2001
inside catcher
SIGALRM signals unblocked at Fri Jun 16 12:24:29 2001

</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R9</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <signal.h>

int sigqueue(pid_t pid, int signo, const union sigval value);
```

General description

Causes the signal specified by `signo` to be sent with the value specified by `value` to the process specified by `pid`. If `signo` is zero (the null signal), error checking is performed but no signal is actually sent. The null signal can be used to check the validity of `pid`. The conditions required for a process to have permission to queue a signal to another process are the same as for the `kill()` function.

The `sigqueue()` function returns immediately. If the resources were available to queue the signal, the signal is queued and sent to the receiving process. The fact that `SA_SIGINFO` is not set for `signo` does not affect this processing and queueing of the signal.

If the value of `pid` causes `signo` to be generated for the sending process, and if `signo` is not blocked for the calling thread and if no other thread has `signo` unblocked or is waiting in a `sigwait()` function for `signo`, either `signo` or at least the pending, unblocked signal will be delivered to the calling thread before `sigqueue()` returns.

Usage notes

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

Since in AMODE 64 programs, `sigval` is 64 bits long, and in AMODE 31 programs `sigval` is only 32 bits long, when passing `sigval` data between an AMODE 31 and AMODE 64 process, there are the following restrictions:

- In AMODE 64, the `sival_int` field covers only the first 4 bytes of the `sigval` field -- only the `sival_ptr` field can access all 8 bytes of the `sigval` field.
- When an AMODE 64 program passes a `sival_ptr` value to an AMODE 31 program, the AMODE 31 program receives only the low 32 bits of the original `sival_ptr`.
- When an AMODE 31 program passes a `sival_ptr` value to an AMODE 64 program, the original `sival_ptr` value is received in the low 32 bits of the AMODE 64 `sival_ptr`.
- When an AMODE 64 program tries to pass a value to an AMODE 31 program using the `sival_int` field, the AMODE 31 program will receive 0 in `sigval`.
- When an AMODE 31 program sends a value to an AMODE 64 program using `sival_int`, the AMODE 64 program will receive a 0 value in `sival_int`, but it can access the original value as the low 32 bits of the AMODE 64 `sival_ptr` field.
Returned value

If successful, sigqueue() returns 0.

If unsuccessful, sigqueue() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>No resources available to queue the signal or the system-wide resource limit, defined by MAXQUEUEDSIGS, has been exceeded.</td>

</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

void (*sigset(int sig, void (*disp)(int))(int);
```

**General description**

The `sigset()` function provides a simplified method for changing the action associated with a specific signal and unblock the signal, or to block this signal.

- **sig**: The number of a recognized signal. `sigset()` sets the action associated with this signal and unblock this signal, or adds this signal to the calling thread's signal mask (thus blocking this signal). Refer to Table 46 on page 1908 for a list of the supported values of `sig`.

  The value of `sig` can be any valid signal type except SIGKILL, SIGSTOP, or SIGTRACE.

- **disp**: There are four possible values that `disp` can have. Three are actions that can be associated with the signal, `sig`: SIG_DFL, SIG_IGN, or a pointer to a function. The fourth value is not a signal action, but a flag to `sigset()` that affects whether the signal action is changed.

  The values that `disp` is permitted to have are:

  - **SIG_DFL**: Set the signal action to the signal-specific default.
    - The default actions for each signal is shown in Table 46 on page 1908.
    - If `disp` is set to SIG_DFL, `sigset()` will change the signal action associated with `sig` and remove this signal from the calling thread's signal mask (thus unblocking this signal).
    - If the default action is to stop the process, the execution of that process is temporarily suspended. When a process stops, a SIGCHLD signal will be generated for its parent process, unless the parent process has set the **SA_NOCLDSTOP** flag. While a process is stopped, any additional signals that are sent to the process will not be delivered until the process is continued, except SIGKILL which always terminates the receiving process. A process that is a member of an orphaned process group will not be allowed to stop in response to the SIGTSTP, SIGTTIN, or SIGTTOU signals. In cases where delivery of one of these signals would stop such a process, the signal will be discarded.
    - Setting a signal action to SIG_DFL for a signal that is pending, and whose default action is to ignore the signal (for example SIGCHLD), will cause the pending signal to be discarded.

  - **SIG_IGN**: Set the signal action to ignore the signal.
sigset

- Delivery of the signal will have no effect on the process.
- If disp is set to SIG_IGN, sigset() will change the signal action associated with sig and remove this signal from the calling thread's signal mask (thus unblocking this signal).
- Setting a signal action to SIG_IGN for a signal that is pending will cause the pending signal to be discarded. This provides the ability to discard signals that are found to be blocked and pending by sigpending().
- If sig is SIGCHLD, child processes of the calling process will not be transformed into 'zombie' processes when they terminate. If the calling process subsequently waits for its children, and the process has no unwaited from children that were transformed into 'zombie' processes, it will block until all of its children terminate. The wait(), waitid(), or waitpid() function will fail and set errno to ECHILD.

SIG_HOLD  Set the calling thread's signal mask to block signal, sig.
- The signal action associated with sig is not changed.

Pointer to function
Set the signal action to catch the signal.
- sigset() will change the signal action associated with sig and remove this signal from the calling thread's signal mask (thus unblocking this signal).
- On delivery of the signal, the receiving process is to execute the signal-catching function at the specified address. After returning from the signal-catching function, the receiving process will resume execution at the point at which it was interrupted.
- The signal-catching function specified by disp is invoked as:

  void function(int signo);

  Where function is the specified signal-catching function and signo is the signal number of the signal being delivered.

After an action has been specified for a particular signal, using sigset(), it remains installed until it is explicitly changed with another call to sigset(), sigaction(), signal(), one of the exec functions, bsd_signal(), or sigignore().

Special behavior for C++:
- The behavior when mixing signal-handling with C++ exception handling is undefined. Also, the use of signal-handling with constructors and destructors is undefined.
- C++ and C language linkage conventions are incompatible, and therefore sigaction() cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to sigaction(), the compiler will flag it as an error. Therefore, to use the sigaction() function in the C++ language, you must ensure that signal handler routines established have C linkage, by declaring them as extern "C".

Usage notes
The use of the SIGSTOP and SIGCONT signal is not supported with this function.
Returned value

If successful, sigset() returns SIG_HOLD if the signal had been blocked and the signal's previous action if it had not been blocked.

If unsuccessful, sigset() returns SIG_ERR and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of the argument <em>sig</em> was not a valid signal type, or it was SIGKILL, SIGSTOP, or SIGTRACE.</td>
</tr>
</tbody>

</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _POSIX_SOURCE
#include <setjmp.h>

int sigsetjmp(sigjmp_buf env, int savemask);
```

**General description**

Saves the current stack environment including, optionally, the current signal mask. The stack environment and signal mask saved by sigsetjmp() can subsequently be restored by siglongjmp().

`env` is an address for a `sigjmp_buf` structure. `savemask` is a flag used to determine if the signal mask is to be saved. If it has a value of 0, the current signal mask is not to be saved or restored as part of the environment. Any other value means the current signal mask is saved and restored.

sigsetjmp() is similar to setjmp() and _setjmp(), except for the optional capability of saving the signal mask. Like setjmp() and longjmp(), the sigsetjmp() and siglongjmp() functions provide a way to perform a nonlocal goto.

The sigsetjmp()—siglongjmp() pair, the setjmp()—longjmp() pair, the _setjmp()—_longjmp() pair and the getcontext()—setcontext() pair cannot be intermixed. A stack environment and signal mask saved by sigsetjmp() can be restored only by siglongjmp().

A call to sigsetjmp() causes it to save the current stack environment in `env`. If the value of the `savemask` parameter is nonzero, it will also save the current signal mask in `env`. A subsequent call to siglongjmp() restores the saved environment and signal mask (if saved by sigsetjmp()), and returns control to a point corresponding to the sigsetjmp() call. The values of all variables (except register variables) accessible to the function receiving control contain the values they had when siglongjmp() was called. The values of register variables are unpredictable. Nonvolatile auto variables that are changed between calls to sigsetjmp() and siglongjmp() are also unpredictable.

**Note:** Ensure that the function that calls sigsetjmp() does not return before you call the corresponding siglongjmp() function. Calling siglongjmp() after the function calling sigsetjmp() returns causes unpredictable program behavior.

**Special behavior for C++:** If sigsetjmp() and siglongjmp() are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic objects is undefined. This applies to both z/OS XL C++ and z/OS XL C/C++ ILC modules. The use of sigsetjmp() and siglongjmp() in conjunction with try(), catch(), and throw() is also undefined.
Special behavior for XPLINK-compiled C++: Restrictions concerning setjmp.h and ucontext.h:

Notes:
1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the jmp_buf, sigjmp_buf or ucontext_t types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define jmp_buf, sigjmp_buf or ucontext_t data items and pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(), setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.
3. When __XPLINK__ is defined, the Language Environment V2R10 and later headers define a larger jmp_buf, sigjmp_buf or ucontext_t area that is required by setjmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Language Environment V2R10 and later headers define a shorter jmp_buf, sigjmp_buf or ucontext_t area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls setjmp(), getcontext() or similar functions with a short jmp_buf, sigjmp_buf or ucontext_t area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

sigsetjmp() returns 0 when it is invoked to save the stack environment and signal mask.

sigsetjmp() returns the value val, specified on siglongjmp() (or 1 if the value of val is zero), when siglongjmp() causes control to be transferred to the place in the user's program where sigsetjmp() was issued.

There are no documented errno values.

Example

The following saves the stack environment and signal mask at the statement:

```c
if(sigsetjmp(mark,1) != 0) ...
```

When the system first performs the if statement, it saves the environment and signal mask in mark and sets the condition to false because sigsetjmp() returns 0 when it saves the environment. The program prints the message:

```
sigsetjmp() has been called
```

The subsequent call to function p() tests for a local error condition, which can cause it to perform siglongjmp(). Then control returns to the original sigsetjmp() function using the environment saved in mark and the restored signal mask. This time the condition is true because −1 is the return value from siglongjmp(). The program then performs the statements in the block and prints:

```
siglongjmp() has been called
```

Then the program performs the sample recover() function and exits.

```c
#define _POSIX_SOURCE
#include <stdio.h>
#include <setjmp.h>
```
sigsetjmp

sigjmp_buf mark;

void p(void); 
void recover(void);

int main(void)
{
if (sigsetjmp(mark,1) != 0) {
    printf("siglongjmp() has been called\n");
    recover();
    exit(1);
}
printf("sigsetjmp() has been called\n");
...

</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int sigstack(struct sigstack *ss, struct sigstack *oss);
```

General description

The sigstack() function allows the calling thread to indicate, to the system, an area of its address space to be used for processing signals received by this thread.

**Note:** To explicitly declare that a signal catcher is to run on the alternate signal stack, the SA_ONSTACK flag must be set in the sa_flags when the signal action is set using sigaction().

If the `ss` argument is not a NULL pointer, it must point to a `sigstack` structure. The length of the application-supplied stack must be at least SIGSTKSZ bytes. If the alternate signal stack overflows, the resulting behavior is undefined.

- The value of the `ss_onstack` member indicates whether the thread wants the system to use an alternate signal stack when delivering signals.
- The value of the `ss_sp` member indicates the desired location of the alternate signal stack area in the process's address space.

**AMODE 64:** Storage for this stack must be above the 2GB bar. It may not be storage acquired with the `__malloc24()` or `__malloc31()` functions.

- If the `ss` argument is a NULL pointer, the current alternate signal stack context is not changed.

If the `oss` argument is not a NULL pointer, it must point to a `sigstack` structure into which the current alternate signal stack context is placed. The value stored in the `ss_onstack` member of this `sigstack` structure will be nonzero if the thread is currently executing on the alternate signal stack. If the `oss` argument is a NULL pointer, the current alternate signal stack context is not returned.

When a signal's action indicates its handler should execute on the alternate signal stack (specified by calling sigaction()), the implementation checks to see if the thread is currently executing on the alternate signal stack. If it is not, the system will switch to the alternate signal stack for the duration of the signal handler's execution.

After a successful call to one of the exec functions, there are no alternate signal stacks in the new process image.

**Notes:**

1. If a signal handler is enabled to run on an alternate stack, then all functions called by that signal handler must be compiled with the same linkage. For example, if the signal handler is compiled with XPLINK, then all functions it calls must also be compiled XPLINK. Since only one alternate stack can be supplied,
no mixing of linkages (which would require both upward and downward-growing alternate stacks) is allowed. The type of stack created will be based on the attributes of the signal handler to be given control. If the signal handler has been compiled with XPLINK, then a downward-growing stack will be created in the alternate stack, including, in AMODE 31, using enough storage in the user stack to create a 4k read-only guard page (aligned on a 4k boundary).

2. If a new signal is received while a signal handler is running on an alternate stack, and that new signal specified a signal handler that also runs on the alternate stack, then both signal handlers must have been compiled with the same linkage (XPLINK versus non-XPLINK).

3. This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use sigaltstack() instead of sigstack().

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, sigstack() returns 0.

If unsuccessful, sigstack() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPERM</td>
<td>An attempt was made to modify an active stack.</td>
</tr>

<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <signal.h>

int sigsuspend(const sigset_t *mask);
```

General description

Replaces the current signal mask of a thread with the signal set given by `mask` and then suspends execution of the calling thread. The thread does not resume running until a signal is delivered whose action is either to execute a signal-handling function or to end the process. (Signal sets are described in more detail in "sigemptyset() — Initialize a signal mask to exclude all signals" on page 1933.)

The signal mask indicates a set of signals that should be blocked. Such signals do not “wake up” the suspended function. The signals SIGKILL, SIGSTOP, or SIGTRACE cannot be blocked or ignored; they are delivered to the thread no matter what the `mask` argument specifies.

If an incoming unblocked signal ends the thread, sigsuspend() never returns to the caller. If an incoming signal is handled by a signal-handling function, sigsuspend() returns after the signal-handling function returns. The signal mask of the thread is restored to whatever it was before sigsuspend() was called, unless the signal-handling functions explicitly changed the mask.

This function is supported only in a POSIX program.

Usage notes

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If sigsuspend() returns, it always returns -1.

If unsuccessful, sigsuspend() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINTR</td>
<td>A signal was received and handled successfully.</td>
</tr>
</tbody>
</table>

Example

CELEBS25
This example replaces the signal mask and then suspends execution.

```c
/* CELEBS25

This example replaces the signal mask and then suspends execution.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <time.h>
#include <unistd.h>

void catcher(int signum) {
    switch (signum) {
        case SIGUSR1: puts("catcher caught SIGUSR1");
                       break;
        case SIGUSR2: puts("catcher caught SIGUSR2");
                       break;
        default: printf("catcher caught unexpected signal %d\n", signum);
    }
}

int main() {
    sigset_t sigset;
    struct sigaction sact;
    time_t t;
    if (fork() == 0) {
        sleep(10);
        puts("child is sending SIGUSR2 signal − which should be blocked");
        kill(getppid(), SIGUSR2);
        sleep(5);
        puts("child is sending SIGUSR1 signal − which should be caught");
        kill(getppid(), SIGUSR1);
        exit(0);
    }
    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    if (sigaction(SIGUSR1, &sact, NULL) != 0)
        perror("1st sigaction() error");
    else if (sigaction(SIGUSR2, &sact, NULL) != 0)
        perror("2nd sigaction() error");
    else {
        sigfillset(&sigset);
        sigdelset(&sigset, SIGUSR1);
        time(&t);
        printf("parent is waiting for child to send SIGUSR1 at %s", ctime(&t));
        if (sigsuspend(&sigset) == -1)
            perror("sigsuspend() returned -1 as expected");
        time(&t);
        printf("sigsuspend is over at %s", ctime(&t));
    }
    return 0;
}
```

**Output**

```
parent is waiting for child to send SIGUSR1 at Fri Jun 16 12:30:57 2001
child is sending SIGUSR2 signal - which should be blocked
child is sending SIGUSR1 signal - which should be caught
catcher caught SIGUSR2
```
catcher caught SIGUSR1
sigsuspend() returned −1 as expected: Interrupted function call
sigsuspend is over at Fri Jun 16 12:31:12 2001

sigtimedwait

sigtimedwait() — Wait for queued signals

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <signal.h>

int sigtimedwait(const sigset_t *set, siginfo_t *info
                 const struct timespec *timeout);
```

General description

The sigtimedwait() function selects a pending signal from the sigset_t object (signal set) pointed to by set, automatically clearing it from the system’s set of pending signals, and returning that signal number. If there are multiple pending signals, the lowest numbered signal will be selected.

If no signal in the signal set is pending at the time of the call to sigtimedwait(), the thread is suspended until one or more of the signals specified in the signal set become pending or until it is interrupted by an unblocked, caught signal. The signals defined in the sigset_t object (signal set) pointed to by set may be unblocked during the call to this routine and will be blocked when the thread returns from the call unless some other thread is currently waiting for one of those signals.

If more than one thread is using sigtimedwait() to wait for the same signal, only one of these threads will return from this routine with the signal number, until a second signal of the same type is received.

The function sigtimedwait() behaves the same as the sigwait() function if the info argument is NULL. If the info argument is not NULL, then in addition to behaving the same as sigwait(), sigtimedwait() places the selected signal number in the si_signo member, places the cause of the signal in the si_code member, and, if any value is queued to the selected signal, sigtimedwait() will place it in the si_value member of info. However, if there is no value queued for the selected signal then the content of si_value is undefined.

If the sigtimedwait() function finds that none of the signals specified by set are pending, it waits for the time interval specified in the timespec structure referenced by timeout. If the timespec structure pointed to by timeout is zero-valued and if none of the signals specified by set are pending, then sigtimedwait() returns immediately with an error. A timespec with the tv_sec field set with INT_MAX, as defined in <limits.h>, will cause the sigtimedwait() service to wait until a signal is received. If timeout is the NULL pointer, the behavior is not necessarily the same on all platforms but for this platform it will be treated the same as when timespec structure was supplied with the tv_sec field set with INT_MAX.

Usage notes

The use of the SIGTSTOP and SIGTCONT signal is not supported with this function.
Returned value

If successful, sigtimedwait() returns the signal number.

If unsuccessful, sigtimedwait() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>No signal specified by set was generated within the specified time out period.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>set points to a sigset_t that contains a signal number that is either not valid or not supported.</td>
</tr>
<tr>
<td>EINTR</td>
<td>The wait was interrupted by an unblocked, caught signal. No further waiting will occur for this call. sigtimedwait() can be reissued to begin waiting again.</td>
</tr>
</tbody>
</table>

### sigwait

**sigwait() — Wait for an asynchronous signal**

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#define _OPEN_THREADS
#include <signal.h>

int sigwait(sigset_t *set);
```

**SUSV3:**

```c
#define _POSIX_C_SOURCE 200112L
#include <signal.h>
int sigwait(const sigset_t *__restrict__ set, int *__restrict__ sig);
```

#### General description

Causes a thread to wait for an asynchronous signal by choosing a pending signal from `set`, automatically clearing it from the system's set of pending signals, and returning that signal number in the return code.

If no signal in `set` is pending at the time of the call, the thread is suspended until one or more of the signals in `set` become pending. The signals defined by `set` may be unblocked during the call to this routine, and will be blocked when the thread returns from the call unless some other thread is currently waiting for one of those signals.

If more than one thread is using this routine to wait for the same signal, only one of these threads will return from this routine with the signal number.

**Special behavior for SUSV3:** The `sigwait()` function selects a pending signal from `set`, atomically clear it from the system's set of pending signals, and return that signal number in the location referenced by `sig`.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sig</td>
<td>location reference where the signal number is stored</td>
</tr>
</tbody>
</table>

#### Usage notes

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

#### Returned value

If successful, `sigwait()` returns the signal number.

If unsuccessful, `sigwait()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The <code>set</code> argument contains an invalid or unsupported signal number.</td>
</tr>
</tbody>
</table>
Special behavior for SUSV3: Upon successful completion, sigwait() stores the signal number of the received signal at the location referenced by sig and return zero. Otherwise, an error number is returned to indicate the error.

Example

CELEBS26
/* CELEBS26 */
#define _OPEN_THREADS
#include <stdio.h>
#include <errno.h>
#include <signal.h>
#include <pthread.h>
#include <unistd.h>

void  *threadfunc(void *parm)
{
    int    threadnum;
    int   *tnum;
    sigset_t  set;

    tnum = parm;
    threadnum = *tnum;

    printf("Thread %d executing\n", threadnum);
    sigemptyset(&set);
    if(sigaddset(&set, SIGUSR1) == -1) {
        perror("Sigaddset error");
        pthread_exit((void *)1);
    }

    if(sigwait(&set) != SIGUSR1) {
        perror("Sigwait error");
        pthread_exit((void *)2);
    }

    pthread_exit((void *)0);
}

main() {
    int     status;
    int     threadparm = 1;
    pthread_t  threadid;
    int     thread_stat;

    status = pthread_create( &threadid, NULL,
       threadfunc,
        (void *)&threadparm);
    if ( status < 0) {
        perror("pthread_create failed");
        exit(1);
    }

    sleep(5);

    status = pthread_kill( threadid, SIGUSR1);
    if ( status < 0)
        perror("pthread_kill failed");

    status = pthread_join( threadid, (void *)&thread_stat);
    if ( status < 0)
CELEBP73
/* CELEBS73
This example demonstrates the use of the sigwait() function.
The program will wait until a SIGINT signal is received from the
command line.
Expected output:
SIGINT was received
*/
#define _POSIX_C_SOURCE 200112L
#include <signal.h>
#include <stdio.h>
#include <errno.h>

void main()
{
    sigset_t set;
    int sig;
    int *sigptr = &sig;
    int ret_val;
    sigemptyset(&set);
    sigaddset(&set, SIGINT);
    sigprocmask( SIG_BLOCK, &set, NULL );
    printf("Waiting for a SIGINT signal\n");
    ret_val = sigwait(&set,sigptr);
    if(ret_val == −1)
        perror("sigwait failed\n");
    else {
        if(*sigptr == 2)
            printf("SIGINT was received\n");
        else
            printf("sigwait returned with sig: %d\n", *sigptr);
    }
}
sigwaitinfo() — Wait for queued signals

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <signal.h>

int sigwaitinfo(const sigset_t *set, siginfo_t *info);
```

General description

The sigwaitinfo() function selects a pending signal from the `sigset_t` object (signal set) pointed to by `set`, automatically clearing it from the system's set of pending signals, and returning that signal number. If there are multiple pending signals, the lowest numbered signal will be selected.

If no signal in the signal set is pending at the time of the call to sigwaitinfo(), the thread is suspended until one or more of the signals specified in the signal set become pending or until it is interrupted by an unblocked, caught signal. The signals defined in the `sigset_t` object (signal set) pointed to by `set` may be unblocked during the call to this routine and will be blocked when the thread returns from the call unless some other thread is currently waiting for one of those signals.

If more than one thread is using sigwaitinfo() to wait for the same signal, only one of these threads will return from this routine with the signal number, until a second signal of the same type is received.

The function sigwaitinfo() behaves the same as the sigwait() function if the `info` argument is NULL. If the `info` argument is not NULL, then in addition to behaving the same as sigwait(), sigwaitinfo() places the selected signal number in the `si_signo` member, places the cause of the signal in the `si_code` member, and, if any value is queued to the selected signal, sigwaitinfo() will place it in the `si_value` member of `info`. However, if there is no value queued for the selected signal then the content of `si_value` is undefined.

Usage notes

The use of the SIGTSTOP and SIGTCONT signal is not supported with this function.

Returned value

If successful, sigwaitinfo() returns the signal number.

If unsuccessful, sigwaitinfo() returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINTR</td>
<td>The wait was interrupted by an unblocked, caught signal. No further waiting will occur for this call. sigwaitinfo() can be reissued to begin waiting again.</td>
</tr>
</tbody>
</table>
sigwaitinfo

EINVAL set points to a sigset_t that contains a signal number that is either not valid or not supported.

General description

Calculates the sine of x, with x expressed in radians.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, the function returns the calculated value, expressed as a _Decimal32, _Decimal64, or _Decimal128.

If x is outside prescribed limits, the value is not calculated. Instead, the function returns 0 and sets errno to EDOM.

Example

```c
/* CELEBS69

    This example illustrates the sind32() function.

*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal32 pi, x, y;
    pi = 3.141593DF;
    x = pi/2.0DF;
    y = sind32(x);
    printf("sind32(%.Hf) = %.Hf\n", x, y);
}
sind32, sind64, sind128

Format

```c
#include <math.h>

double sinh(double x);
float sinhf(float x); /* C++ only */
long double sinhl(long double x); /* C++ only */
float sinh(float x);
long double sinhl(long double x);
```

General description

Calculates the hyperbolic sine of x, with x expressed in radians.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “IEEE binary floating-point” on page 94 for more information about IEEE Binary Floating-Point.

Returned value

If successful, the function returns the calculated value.

Otherwise, if the result is too large, the function sets errno to ERANGE and returns ±HUGE_VAL, depending on the value of x. If the value underflows, the function returns 0 and sets errno to ERANGE.

**Special behavior for IEEE:** If successful, the function returns the hyperbolic sine of x with x expressed in radians.

If the result would overflow, the function returns ±HUGE_VAL, according to the value of x, and sets errno to ERANGE. No other errors can occur.

Example

```c
CELEBS28
/* CELEBS28

   This example computes y as the hyperbolic sine of &pi;&aslr.2.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
```
### sinh, sinhf, sinhl

double pi, x, y;
pi = 3.1415926535;
x = pi/2;
y = sinh(x);

printf("sinh( %lf ) = %lf\n", x, y);
}

**Output**

\[
\text{sinh( 1.570796 ) = 2.301299}
\]

```

General description

Calculates the hyperbolic sine of `x`, with `x` expressed in radians.

**Note:** These functions work in IEEE decimal floating-point format. See [IEEE decimal floating-point](#) for more information.

Returned value

If successful, the function returns the hyperbolic sine of `x` with `x` expressed in radians.

If the result would overflow, the function returns ±HUGE_VAL_D32, ±HUGE_VAL_D64, or ±HUGE_VAL_D128 according to the value of `x`, and sets `errno` to ERANGE. No other errors can occur.

Example

```c
CELEBS75
/* CELEBS75
   This example illustrates the sinh64() function.
*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 pi, x, y;
    pi = 3.1415926535DD;
    x = pi/2.0DD;
```
sinhd

y = sinhd64(x);

printf("sinhd64( %Df ) = %Df\n", x, y);
}

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

unsigned int sleep(unsigned int seconds);
```

General description

Suspends thread execution for a specified number of `seconds`. Because of processor delays, the thread can sleep slightly longer than this specified time. An unblocked signal received during this time (for which the action is to invoke a signal handler function or to end the thread) “wakes up” the thread prematurely. When that function returns, `sleep()` returns immediately even if there is sleep time remaining.

This function is supported only in a POSIX program.

Returned value

If the thread slept for the full specified time, `sleep()` returns 0.

If the thread awoke prematurely because of a signal whose action is to invoke a signal-handling function or to end the thread, `sleep()` returns the number of seconds remaining in its sleep time (that is, the value of `seconds` minus the actual number of seconds that the thread was suspended).

`sleep()` always succeeds, so there is no failure return. An abend is generated when any failures are encountered that prevent this function from completing successfully.

There are no documented `errno` values.

Example

```c
/* CELEBS29
   This example suspends execution for a specified time.
*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <time.h>
#include <unistd.h>

main() {
    unsigned int ret;
    time_t t;
    time(&t);
    printf("Starting sleep at %s", ctime(&t));
```

```
```c
ret = sleep(10);
time(&t);
printf("naptime over at %s", ctime(&t));
printf("sleep() returned %d\n", ret);
}
```

Output

starting sleep at Fri Jun 16 07:44:47 2001
naptime over at Fri Jun 16 07:44:58 2001
sleep() returned 0

__smf_record

__smf_record() — Record an SMF record

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

int __smf_record(int smf_record_type,
                 int smf_record_subtype,
                 int smf_record_length,
                 char *smf_record);
```

General description

The __smf_record() function writes an SMF record pointed to by `smf_record` of length `smf_record_length` for SMF record type `smf_record_type` and subtype `smf_record_subtype` to the SMF data set.

The service can also be used to determine if a particular type or subtype of SMF record is being recorded to avoid the overhead of data collection if the SMF record is not going to be recorded. See z/OS MVS System Management Facilities (SMF), SA22-7630 for more information on SMF record types and layout.

The caller of this service must be permitted to the BPX.SMF facility class profile or must be APF authorized. For information on creating and using this profile and the restrictions on its use, refer to z/OS UNIX System Services Planning, GA22-7800.

Returned value

If successful, __smf_record() returns 0.

If unsuccessful, __smf_record() returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value specified on the length operand was incorrect.</td>
</tr>
<tr>
<td>EMVSERR</td>
<td>The SMF service returned a nonzero return code. Use __errno2() to determine why the error occurred. The following reason codes can accompany the return code: JRSMFNotAccepting, JRSMFError, JRBadAddress, or JRIternalError.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Not enough storage.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The calling process is not permitted to the BPX.SMF facility class and the calling process is not APF authorized.</td>
</tr>
</tbody>
</table>

Related information

None.
__smf_record2() — Record an SMF record with exit control

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1.12</td>
</tr>
</tbody>
</table>

Format

```c
#include <unistd.h>

int __smf_record2 (int smf_record_type,
                   int smf_record_subtype,
                   int smf_record_length,
                   char *smf_record
                   unsigned int smf_exit );
```

General description

The __smf_record2() function writes an SMF record pointed to by `smf_record` of length `smf_record_length` for SMF record type `smf_record_type` and subtype `smf_record_subtype` to the SMF data set.

The `smf_exit` argument defines which user exit is to take control when the SMF record is written. Acceptable values for this argument are as follows:

- `_SMF_IEFU83` Cause SMF exit IEFU83 to gain control.
- `_SMF_IEFU84` Cause SMF exit IEFU84 to gain control.

and are defined in `<unistd.h>`

The service can also be used to determine if a particular type or subtype of SMF record is being recorded to avoid the overhead of data collection if the SMF record is not going to be recorded. See [z/OS MVS System Management Facilities (SMF)](https://www.ibm.com/support/docview.wss?rs=313&uid=swg21379776) for more information on SMF record types and layout.

The caller of this service must be permitted to the BPX.SMF facility class profile or must be APF authorized. For information on creating and using this profile and the restrictions on its use, See [z/OS UNIX System Services Planning](https://www.ibm.com/support/docview.wss?rs=313&uid=swg21289342).

This function is supported under CICS Transaction Server for z/OS only when run in an open transaction environment (OTE).

**Note:** To determine if a particular SMF record type or subtype is being recorded, specify NULL for the `smf_record` argument. If the return value is 0, the type or subtype is being recorded. If the return value is -1 and `errno` is EMVSERR with a reason code of JRSMFNotAccepting, SMF is not recording this type or subtype.

Returned value

If successful, __smf_record2() returns 0.

If unsuccessful, __smf_record2() returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>

EINVAL The value that was specified for an argument was incorrect.
EMVSERR The SMF service returned a nonzero return code. Use __errno2() to retrieve the reason code associated with the error. The following reason codes can accompany the return code: JRSMFNotAccepting, JRSMFError, JRBadAddress, or JRInternalError.
ENOMEM Not enough storage is available.
EPERM The calling process is not permitted to the BPX.SMF resource in the FACILITY class and the calling process is not APF authorized..

Example

Related information

snprintf() — Format and write data

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R6</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <stdio.h>

int snprintf(char *__restrict__ s, size_t n, const char *__restrict__ format, ...);
```

Note: The snprintf() function is also available under the alternate name __snprintf(). The __snprintf() function is accessible in the open name space.

```c
#include <stdio.h>

int __snprintf(char *__restrict__ s, size_t n, const char *__restrict__ format, ...);
```

General description

Equivalent to fprintf(), except that the output is written into an array (specified by argument s) rather than to a stream. If n is zero, nothing is written, and s may be a null pointer. Otherwise, output characters beyond the n-1st are discarded rather than being written to the array, and a null character is written at the end of the characters actually written into the array. If copying takes place between objects that overlap, the behavior is undefined.

Returned value

Returns the number of characters that would have been written had n been sufficiently large, not counting the terminating null character, or a negative value if an encoding error occurred. Thus, the null-terminated output has been completely written if and only if the returned value is nonnegative and less than n.

Errors

Function fails if:

- The value of n is greater than (INT_MAX) or the number of bytes needed to hold the output excluding the terminating null is greater than (INT_MAX). In this case, the function returns a negative value and sets errno to EOVERFLOW
sockatmark

sockatmark() — Determine whether a socket is at the out-of-band mark

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R9</td>
</tr>
</tbody>
</table>

Format

**SUSV3:**

```
#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>

int sockatmark(int s);
```

General description

The `sockatmark()` function determines whether the socket specified by the descriptor `s` is at the out-of-band data mark. If the protocol for the socket supports out-of-band data by marking the stream with an out-of-band data mark, the `sockatmark()` function returns 1 when all data preceding the mark has been read and the out-of-band data mark is the first element in the receive queue. The `sockatmark()` function does not remove the mark from the stream.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>s</code></td>
<td>the descriptor used to determine if the socket is at the out-of-band data mark</td>
</tr>
</tbody>
</table>

Returned value

Upon successful completion, the `sockatmark()` function returns a value indicating whether the socket is at an out-of-band data mark. If the protocol has marked the data stream and all data preceding the mark has been read, the return value is 1; if there is no mark, or if data precedes the mark in the receive queue, the `sockatmark()` function returns 0. Otherwise, it returns a value of -1 and set `errno` to indicate the error.

Error Code

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
</tr>
<tr>
<td>ENOTTY</td>
</tr>
</tbody>
</table>

Example

```

</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

void sock_do_teststor(int onoff);
```

General description

The `sock_do_teststor` call is used to check for calls that attempt to access storage outside the caller's address space.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>onoff</code></td>
<td>A parameter that can be set to zero or nonzero.</td>
</tr>
</tbody>
</table>

If `onoff` is set to a nonzero value, for either inbound or outbound sockets, both the address of the message buffer and the message buffer are checked for addressability for each bulk mode socket call. The EFAULT error condition is set if there is an addressing problem. If `onoff` is set to 0, address checking is not done by the socket library program. If an error occurs when `onoff` is 0, normal run-time error handling reports the exception condition.

To improve response time, you can disable this checking when your program has been tested.

As an alternative to calling `sock_do_teststor`, with `onoff` set to a nonzero value, you can include the statement `SOCKTESTSTOR` in the file `/etc/resolv.conf` or data set `tcpip.TCPIP.DATA`. When the process is started, all the programs using bulk mode sockets for this process will validate the storage for the caller's parameters.

Returned value

`sock_do_teststor()` returns no values.

Format

**X/Open:**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int socket(int domain, int type, int protocol);
```

**Berkeley sockets:**

```c
#define _OE_SOCKETS
#include <sys/socket.h>

int socket(int *domain, int type, int protocol);
```

General description

The `socket()` function creates an endpoint for communication and returns a socket descriptor representing the endpoint. Different types of sockets provide different communication services.

**Parameter** | **Description**
--- | ---
`domain` | The address domain requested, either AF_INET, AF_INET6, AF_UNIX, or AF_RAW.
`type` | The type of socket created, either SOCK_STREAM, SOCK_DGRAM, or SOCK_RAW.
`protocol` | The protocol requested. Some possible values are 0, IPPROTO_UDP, or IPPROTO_TCP.

The `domain` parameter specifies a communication domain within which communication is to take place. This parameter selects the address family (format of addresses within a domain) that is used. The families supported are AF_INET and AF_INET6, which is the Internet domain, and AF_UNIX, which is the local socket domain. These constants are defined in the `sys/socket.h` include file.

The `type` parameter specifies the type of socket created. The type is analogous with the semantics of the communication requested. These socket type constants are defined in the `sys/socket.h` include file. The types supported are:

**Socket Type** | **Description**
--- | ---
SOCK_DGRAM | Provides datagrams, which are connectionless messages of a fixed maximum length whose reliability is not guaranteed. Datagrams can be corrupted, received out of order, lost, or delivered multiple times. This type is supported in the AF_INET, AF_INET6, and AF_UNIX domains.
SOCK_RAW | Provides the interface to internal protocols (such as IP and ICMP).
This type is supported in the AF_INET and AF_INET6 domains. You must be a superuser to use this type.

SOCK_STREAM
Provides sequenced, two-way byte streams that are reliable and connection-oriented. They support a mechanism for out-of-band data. This type is supported in the AF_INET, AF_INET6, and AF_UNIX domains.

Understanding the socket() Parameters: The protocol parameter specifies a particular protocol to be used with the socket. In most cases, a single protocol exists to support a particular type of socket in a particular address family. If the protocol parameter is set to 0, the system selects the default protocol number for the domain and socket type requested. Protocol numbers are found in the tcpip.ETC.PROTO data set. Alternatively, the getprotobyname() call can be used to get the protocol number for a protocol with a known name.

Note: The protocol field must be set to 0, if the domain parameter is set to AF_UNIX.

SOCK_STREAM sockets model duplex-byte streams. They provide reliable, flow-controlled connections between peer application programs. Stream sockets are either active or passive. Active sockets are used by clients who start connection requests with connect(). By default, socket() creates active sockets. Passive sockets are used by servers to accept connection requests with the connect() call. You can transform an active socket into a passive socket by binding a name to the socket with the bind() call and by indicating a willingness to accept connections with the listen() call. After a socket is passive, it cannot be used to start connection requests.

In the AF_INET and AF_INET6 domains, the bind() call applied to a stream socket lets the application program specify the networks from which it is willing to accept connection requests. The application program can fully specify the network interface by setting the Internet address field in the address structure to the Internet address of a network interface. Alternatively, the application program can use a wildcard to specify that it wants to receive connection requests from any network. For AF_INET sockets, this is done by setting the Internet address field in the address structure to the constant INADDR_ANY, as defined in <netinet/in.h>. For AF_INET6 sockets, this is done by setting the Internet address field in the address structure to in6addr_any as defined in <netinet/in.h>.

After a connection has been established between stream sockets, any of the data transfer calls can be used: (read(), readv(), recv(), recvfrom(), recvmsg(), send(), sendmsg(), sendto(), write(), and writev()). Usually, the read()-write() or send()-recv() pairs are used for sending data on stream sockets. If out-of-band data is to be exchanged, the send()-recv() pair is normally used.

SOCK_DGRAM sockets model datagrams. They provide connectionless message exchange without guarantees of reliability. Messages sent have a maximum size. Datagram sockets are supported in the AF_UNIX domain.

There is no active or passive analogy to stream sockets with datagram sockets. Servers must still call bind() to name a socket and to specify from which network interfaces it wishes to receive packets. Wildcard addressing, as described for
stream sockets, applies for datagram sockets also. Because datagram sockets are connectionless, the listen() call has no meaning for them and must not be used with them.

After an application program has received a datagram socket, it can exchange datagrams using the sendto() and recvfrom(), or sendmsg() and recvmsg() calls. If the application program goes one step further by calling connect() and fully specifying the name of the peer with which all messages will be exchanged, then the other data transfer calls read(), write(), readv(), writev(), send(), and recv() can also be used. For more information on placing a socket into the connected state, see "connect() — Connect a socket" on page 329.

Datagram sockets allow messages to be broadcast to multiple recipients. Setting the destination address to be a broadcast address is network-interface-dependent (it depends on the class of address and whether subnets—logical networks divided into smaller physical networks to simplify routing—are used). The constant INADDR_BROADCAST, defined in netinet/in.h, can be used to broadcast to the primary network if the primary network configured supports broadcast.

Outgoing packets have an IP header prefixed to them. IP options can be set and inspected using the setsockopt() and getsockopt() calls, respectively. Incoming packets are received with the IP header and options intact.

Sockets are deallocated with the close() call.

Note: For AF_UNIX, when closing sockets that were bound, you should also use unlink() to delete the file created at bind() time.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value
If successful, socket() returns a nonnegative socket descriptor.

If unsuccessful, socket() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Permission to create a socket of the specified type or protocol is denied.</td>
</tr>
<tr>

</tr>
</tbody>
</table>
socket

**EPROTOTYPE**

The socket type is not supported by the protocol.

**Example**

The following are examples of the socket() call.

```c
int s;
char *name;
int socket(int domain, int type, int protocol);

/* Get stream socket in Internet domain with default protocol */
s = socket(AF_INET, SOCK_STREAM, 0);

/* Get stream socket in local socket domain with default protocol */
s = socket(AF_UNIX, SOCK_STREAM, 0);
```

<td></td>
</tr>
</tbody>
</table>

Format

X/Open:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int socketpair(int *domain, int type, int protocol, int socket_vector[2]);
```

Berkeley sockets:

```c
#define _OE_SOCKETS
#include <sys/socket.h>

int socketpair(int *domain, int type, int protocol, int sv[2]);
```

General description

The socketpair() function acquires a pair of sockets of the type specified that are unnamed and connected in the specified domain and using the specified protocol. For socket pairs in the AF_UNIX domain, the protocol must be 0.

Parameter Description

- **domain**: The domain in which to open the socket. Although socket pairs can be obtained for AF_INET domain sockets, it is recommended that AF_UNIX domain sockets be used for socket pairs.
- **type**: The type of socket created, either SOCK_STREAM, or SOCK_DGRAM.
- **protocol**: The protocol requested must be 0.
- **sv**: The descriptors used to refer to the obtained sockets.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, socketpair() returns a nonnegative socket descriptor.

If unsuccessful, socketpair() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>Permission to create a socket of the specified type or protocol is denied.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>sv is not in the writable part of the user's address space.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The request is invalid or not supported.</td>
</tr>
<tr>
<td>EMFILE</td>
<td>Too many files are open for this process.</td>
</tr>
</tbody>
</table>
socketpair

ENFILE    Too many files are open in the system.
ENOBUFFS Insufficient system resources are available to complete the call.
EOPNOSUPPORT
    The protocol does not allow for the creation of socket pairs.
EPROTONOSUPPORT
    The protocol is not supported in this domain or this protocol is not
supported for this socket type.
EPROTOTYPE
    The socket type is not supported by the protocol.

Example

The following are examples of the socketpair() call.
#include <types.h>
#include <sys/socket.h>

int sv[2];
::* Get stream socket in UNIX domain with default protocol */
if (socketpair(AF_UNIX, SOCK_STREAM, 0, sv) < 0)
    printf ("Error occurred while trying to get a socket pair.
");
else
    :

spawn(), spawnp() — Spawn a new process

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.4b</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>z/OS UNIX</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <spawn.h>

pid_t spawn(const char *
      path,
      const int fd_count,
      const int fd_map[],
      const struct inheritance *inherit,
      const char *argv[],
      const char *envp[]);

pid_t spawnp(const char *
        file,
      const int fd_count,
      const int fd_map[],
      const struct inheritance *inherit,
      const char *argv[],
      const char *envp[]);
```

General description

The spawn() and spawnp() functions create a new process from the specified process image. spawn() and spawnp() create the new process image from a regular executable file called the new process image file.

To execute a C program as a result of this call, enter the function call as follows:

```c
int main (int argc, char *argv[]);
```

Where `argc` is the argument count and `argv` is an array of character pointers to the arguments themselves. In addition, the following variable:

```c
extern char **environ;
```

is initialized as a pointer to an array of character pointers to the environment strings. The `argv` and `environ` arrays are each terminated by a NULL pointer. The NULL pointer terminating the `argv` array is not counted in `argc`.

Supported parameters are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>path</code></td>
<td>Path name used by spawn() that identifies the new process image file to execute.</td>
</tr>
<tr>
<td><code>file</code></td>
<td>Used by spawnp() to construct path name that identifies the new process image file. If the file parameter contains a slash character, spawn() uses the file parameter as a path name for the new process image file. Otherwise, spawnp() obtains the path prefix for this file by a search of the directories passed as the environment variable <code>PATH</code>.</td>
</tr>
<tr>
<td><code>fd_count</code></td>
<td>Specifies the number of file descriptors the child process inherits. It</td>
</tr>
</tbody>
</table>
may take values from zero to OPEN_MAX. Except for those file descriptors designated by SPAWN_FDCLOSED, each of the child's file descriptors, x, in the range zero to fd_count - 1 inherits descriptor fd_map[x] from the parent process.

The files from fd_count through OPEN_MAX are closed in the child process, as are any elements of fd_map designated as SPAWN_FDCLOSED.

If the fd_map parameter is NULL, fd_count and fd_map are ignored. All file descriptors except those with the FD_CLOEXEC or FD_CLOFORK attribute are inherited without reordering. File descriptors with the FD_CLOEXEC or FD_CLOFORK attribute are closed under simple inheritance.

For those file descriptors that remain open, all other attributes of the associated file descriptor object and open file description remain unchanged by this operation.

Directory streams open in the calling process are closed in the new process image.

If an element of fd_map refers to an invalid file descriptor, then the (EBADF) spawn() or spawnp() posts the error status.

The FD_CLOEXEC and FD_CLOFORK file descriptor attributes are never inherited.

The FD_CLOEXEC and FD_CLOFORK file descriptor attributes have no effect on inheritance when the fd_map parameter is not NULL.

Note: For XTI endpoints, fd_map must not map to a number greater than 65535 in the child process.

The name of a data area that contains the inheritance structure.

The 'struct inheritance' is defined as follows:

```c
struct inheritance {
    short flags; --Flags
    pid_t pgroup; --Process group
    sigset_t sigmask; --Signal mask
    sigset_t sigdefault; --Signals set to SIG_DFL
    int ctlttyfd; --Cntl tty FD for tcsetpgrp()
};
```

The inherit.flags effect spawn() and spawnp() as follows:

**SPAWN_SETGROUP**

If the SPAWN_SETGROUP flag is set in inherit.flags, then the child's process group is as specified in inherit.pgroup.

If the SPAWN_SETGROUP flag is set in inherit.flags and inherit.pgroup is set to SPAWN_NEWPGROUP, then the child is in a new process group with a process group ID equal to its process ID.

If the SPAWN_SETGROUP flag is not set in inheritflags, the new child process inherits the parent's process group ID.

**SPAWN_SETSIGMASK**

If the SPAWN_SETSIGMASK flag is set in inherit.flags,
the child process initially has the signal mask specified in inherit.sigmask.

**SPAWN_SETSIGDEF**

If the **SPAWN_SETSIGDEF** flag is set in inherit.flags, the signals specified in inherit.sigdefault are set to their default actions in the child process. Signals set to the default action in the parent process, are set to the default action in the new process.

Signals set to be caught by the calling process are set to the default action in the child process.

Signals set to be ignored by the calling process are set to be ignored by the new process, unless otherwise specified by the **SPAWN_SETSIGDEF** flag being set in inherit.flags and the signal being indicated in inherit.sigdefault.

**SPAWN_SETTCPGRP**

If the **SPAWN_SETTCPGRP** flag is set in inherit.flags, the file descriptor specified in inherit.ctlttyfd is used to set the controlling terminal file descriptor (tcsetpgrp()) for the child's foreground process group. The child's foreground process group is inherited from the parent, unless the **SPAWN_SETGROUP** flag in inherit.flags is set, indicating that the value specified in inherit.pgroup is to be used to determine the child's process group.

**SPAWN_PROCESS_INITTAB**

If this flag is set, spawn attempts to read the /etc/inittab file and process the entries found there. This processing involves the spawning of child shell processes to run each of the commands identified in the file. Only the **SPAWN_SETSIGMASK** flag can be set in combination with this flag. All other flags will be ignored. Use of this flag implies that only file descriptors 0, 1, and 2 will be initially opened in the child process. File descriptor 0 will be initially opened as /dev/null, while file descriptors 1 and 2 will initially opened as /etc/log. The fd_count and fd_map parameters will be ignored. This flag is currently restricted to the /usr/sbin/init process. See z/OS UNIX System Services Planning for more information on the /etc/inittab support.

**argv**

The value in the first element of **argv** should point to a file name that is associated with the process being started by the spawn() or spawnp() operation.

The number of bytes available for the new process's combined argument and environment lists is **ARG_MAX**.

**envp**

The value **envp** contains the list of environmental variables that is to be passed to the specified program.

If the set-user-ID mode bit of the new process image file is set, the effective user ID of the new process image is set to the owner id of the new process image file.
Similarly, if the set-group-ID mode bit of the new process image file is set, the effective group ID of the new process image is set to the group id of the new process image file. The real user ID, real group ID, and supplementary group IDs of the new process image remain the same as those of the calling process image. The effective user ID and effective group ID of the new process image are saved (as the saved set-user-ID and the saved set-group-ID) for use by the setuid() function.

The new process image inherits the following attributes from the calling process image:
- Process group ID (unless the SPAWN_SETGROUP flag is set in inherit.flags)
- Session membership
- Real user ID
- Real group ID
- Supplementary group IDs
- Priority
- Current working directory
- Root directory
- File creation mask
- Signal mask (unless the SPAWN_SETSIGMASK flag is set in inherit.flags)
- Signal actions specified as default (SIG_DFL)
- Signal actions specified as ignore (SIG_IGN) (except as modified by inherit.sigdefault and the SPAWN_SETSIGDEF flag set in inherit.flags)

The following are differences between the parent process and the child process:
- Signals set to be caught by the calling process are set to the default action (SIG_DFL).
- The process and system utilization times for the child are set to zero.
- Any file locks previously set by the parent are not inherited by the child.
- The child process has no alarms set.
- The child process has no interval timers set.
- The child has no pending signals.
- Memory mappings established by the parent are not inherited by the child.

If the process image was read from a writable file system, then upon successful completion, the spawn() or spawnp() function mark for update the st_atime field of the new process image file.

If the spawn() or spawnp() function is successful, the new child process image file is opened, with all the effects of the open() function.

**Special behavior for z/OS UNIX Services:**

**Note:** If an application spawns a shell command or utility that performs terminal I/O, the command may fail due to the fact that the shell file descriptors are not initialized. The Shell file descriptors must be defined. An example of how these can be defined in a C application are as follows:

```c
stdin = fopen(`/tmp/sys.stdin`,"r");
stdout = fopen(`/tmp/sys.stdout`,"w");
stderr = fopen(`/tmp/sys.stderr`,"w");
```

Aspects of spawn processing are controlled by environment variables. The environment variables that affect spawn processing are the ones that are passed into the spawn syscall and not the environment variables of the calling process. The environment variables of the calling process do not affect spawn processing unless they are the same as those that are passed in envp.
The _BPXK_JOBLOG environment variable can be used to specify that WTO messages are to be written to an open HFS job log file. The following are the allowable values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nn</td>
<td>Job log messages are to be written to open file descriptor nn.</td>
</tr>
<tr>
<td>STDERR</td>
<td>Job log messages are to be written to the standard error file descriptor, 2.</td>
</tr>
<tr>
<td>None</td>
<td>Job log messages are not to be written. This is the default.</td>
</tr>
</tbody>
</table>

The file that is used to capture messages can be changed at any time by calling the oe_env_np service (BPX1ENV) and specifying _BPXK_JOBLOG with a different file descriptor.

Message capturing is turned off if the specified file descriptor is marked for close on a fork or exec.

Message capturing is process-related. All threads under a given process share the same job log file. Message capturing may be initiated by any thread under that process.

Multiple processes in a single address space can each have different files active as the JOBLOG file; some or all of them can share the same file; and some processes can have message capturing active while others do not.

Only files that can be represented by file descriptors may be used as job log files; MVS data sets are not supported.

Message capturing will be propagated on a fork() or spawn(). In the case where a file descriptor was specified, the physical file must be the same for message capturing to continue in the forked or spawned process. If STDERR was specified, the file descriptor may be re-mapped to a different physical file.

Message capturing may be overridden on exec() or spawn() by specifying the _BPXK_JOBLOG environment variable as a parameter to the exec() or spawn().

Message capturing will only work in forked (BPXAS) address spaces.

**Note:** This is not true joblog support, messages that would normally go to the JESYSMSG data set are captured, but messages that go to JESMSGLG are not captured.

For more information on the use of environment variables, see [z/OS UNIX System Services Programming: Assembler Callable Services Reference, SA22-7803](http://www.ibm.com/support/docview.wss?uid=swg21272931).

Security information from the parent's address space is propagated to the child's address space, unless the _BPX_USERID environment variable specifies otherwise. As a result, the child has a security environment equivalent to that of the parent.

The TASKLIB, STEPLIB, or JOBLIB DD data set allocations that are active for the current task are propagated to the child's address space, unless the STEPLIB environment variable specifies otherwise. This causes the child address space to have the same exact MVS program search order as the calling parent task.
The accounting information of the parent's address space is propagated to the child's address space. See z/OS UNIX System Services Planning, GA22-7800.

The jobname of the parent is propagated to the child and appended with a numeric value in the range of 1-9 if the jobname is 7 characters or less. If the jobname is 8 characters, then it is propagated as-is. When a jobname is appended with a numeric value, the count wraps back to 1 when it exceeds 9.

If the calling parent task is in a WLM enclave, the child is joined to the same WLM enclave. This allows WLM to manage the parent and child as one "business unit of work" entity for system accounting and management purposes.

To allow the caller to control whether the spawned child process runs in a separate address space from the parent address space or in the same address space, the spawn service allows for the specification of the _BPX_SHAREAS environment variable. The following are the accepted values for the _BPX_SHAREAS environment variable, and the actions taken for each value:

1. _BPX_SHAREAS=YES - Indicates that the child process that is to be created is to run in the same address space as the parent. In the following circumstances, the _BPX_SHAREAS=YES value cannot be honored, and the child process is created in its own address space:
   - If the program to be run is a set-user-ID or set-group-ID program that would cause the effective user-ID or group-ID of the child process to be different from that of the parent process.
   - If the program to be run is an APF-authorized HFS or MVS program and the caller is not running APF authorized.
   - If the program to be run is an unauthorized HFS or MVS program and the caller is running APF authorized.
   - If the specified file name represents an external link or a sticky bit file. However, if the program that is to be run is a shell script and _BPX_SPAWN_SCRIPT=YES is set, the process runs in the same address space. _BPX_SPAWN_SCRIPT only has an effect while running in the z/OS shell (/bin/sh... NOT /bin/tcsh).
   - If the address space of the parent lacks the necessary resources to create another process within the address space.
   
   Note that only one local spawned process per TSO address space is supported at a given time. This is done to reduce conflict among multiple shells running in the same address space.

2. _BPX_SHAREAS=MUST - Indicates that the child process that is to be created must run in the same address space as the parent, or the spawn request will fail. In the following circumstances, the _BPX_SHAREAS=MUST value cannot be honored, and the spawn invocation fails:
   - If the program to be run is a set-user-ID or set-group-ID program that would cause the effective user ID or group ID of the child process to be different from that of the parent process.
   - If the program to be run is an APF-authorized HFS or MVS program and the caller is not running APF authorized.
   - If the program to be run is an unauthorized HFS or MVS program and the caller is running APF authorized.
   - If the address space of the parent lacks the necessary resources to create another process within the address space.

3. _BPX_SHAREAS=REUSE - Indicates that the child process to be created is to run in the same address space as the parent; also, that it will be created as a
medium-weight process. Specifying REUSE allows the caller to indicate that it wants to reuse the existing process structure for locally spawned processes. The same rules that apply to the creation of a local spawn process apply to the specification of a local spawn medium-weight process. In addition, in the following circumstances, the _BPX_SHAREAS=REUSE value cannot be honored, and the child process will be created as a non-medium weight local spawn process:

- If PTRACE is active for the process.
- If the program to execute is a REXX exec.

For performance reasons, the STEPLIB that is specified for each medium-weight process that is created for the address space should be the same.

4. _BPX_SHAREAS=NO - Indicates that the child process that is to be created is to run in a separate address space from the address space of the parent. This is the default behavior for the spawn service if the _BPX_SHAREAS environment variable is not specified, or if it contains an unsupported value.

If you specify the _BPX_USERID environment variable, then spawn() creates the new address space and image with the specified userid's identity. The invoker of spawn() must be authorized to change MVS identity. The resulting spawn() image will emerge as if a program had done a fork(), setgid(), initgroups(), setuid(), and exec.

The value of _BPX_USERID can be any 1-to-8-character XPG4 compliant username. If you specify both _BPX_USERID and _BPX_SHAREAS, then spawn() ignores _BPX_SHAREAS, and creates a new address space with the new identity.

If the caller of the spawn() function is the z/OS UNIX shell (i.e. /bin/sh), then the setting of the _BPX_SPAWN_SCRIPT= environment variable to YES is recommended. The setting of this variable to YES provides a more efficient mechanism to invoke z/OS UNIX shell scripts.

To support the creation and propagation of a STEPLIB environment to the new process image, spawn() and spawnp() allow for the specification of a STEPLIB environment variable. The following are the accepted values for the STEPLIB environment variable and the actions taken for each:

- STEPLIB=NONE. No Steplib DD is to be created for the new process image.
- STEPLIB=CURRENT. The TASKLIB, STEPLIB or JOBLIB DD data set allocations that are active for the calling task at the time of the call to spawn() and spawnp() are propagated to the new process image, if found to be cataloged. Uncataloged data sets are not propagated to the new process image.
- STEPLIB=Dsn1:Dsn2:,...DsnN. The specified data sets, Dsn1:Dsn2:,...DsnN, are built into a STEPLIB DD in the new process image.

**Note:** The actual name of the DD is not STEPLIB, but is a system-generated name that has the same effect as a STEPLIB DD.

The data sets are concatenated in the order specified. The specified data sets must follow standard MVS data set naming conventions. Data sets found to be in violation of this standard are ignored. If the data sets do follow the standard, but:

- The caller does not have the proper security access to a data set.
- A data set is uncataloged or is not in load library format.
then the data set is ignored. Because the data sets in error are ignored, the executable file may run without the proper STEPLIB environment. If a data set is in error due to improper security access a X'913' abend is generated. The dump for this abend can be suppressed by your installation.

If the STEPLIB environment variable is not specified, spawn() and spawnp() default behavior is the same as if STEPLIB=CURRENT were specified.

If the program to be invoked is a set-user-ID or set-group-ID file and the user-ID or group-ID of the file is different from that of the current process image, then the data sets to be built into the STEPLIB environment for the new process image must be found in the system sanction list for set-user-id and set-group-id programs. Only those data sets that are found in the sanction list are built into the STEPLIB environment for the new process image. For detailed information regarding the sanction list, and for information on STEPLIB performance considerations, see z/OS UNIX System Services Planning, GA22-7800.

Notes:
1. A prior loaded copy of an HFS program in the same address space is reused under the same circumstances that apply to the reuse of a prior loaded MVS unauthorized program from an unauthorized library by the MVS XCTL service with the following exceptions:
   • If the calling process is in Ptrace debug mode, a prior loaded copy is not reused.
   • If the calling process is not in Ptrace debug mode, but the only prior loaded usable copy found of the HFS program is in storage modifiable by the caller, the prior copy is not reused.

2. If the specified file name represents an external link or a sticky bit file, the program is loaded from the caller’s MVS load library search order. For an external link, the external name is only used if the name is eight characters or less, otherwise the caller receives an error from the loadhfs service. For a sticky bit program, the file name is used if it is eight characters or less. Otherwise, the program is loaded from the HFS.

3. If the calling task is in a WLM enclave, the resulting task in the new process image is joined to the same WLM enclave. This allows WLM to manage the old and new process images as one “business unit of work” entity for system accounting and management purposes.

Note: If you are expecting this function to take advantage of the z/OS UNIX magic number support, the Language Environment run-time option to POSIX(ON) must have been set when the process was initialized. Attempting to use magic number support with a process initialized with POSIX(OFF) may produce undesirable effects. See z/OS UNIX System Services Planning, GA22-7800 and z/OS UNIX System Services User’s Guide, SA22-7801 for details and uses of the z/OS UNIX magic number.

Returned value
If successful, spawn() and spawnp() return the value of the process ID of the child process to the parent process.

If unsuccessful, spawn() and spawnp() return −1, no child process is created, and they set errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>

code
spawn, spawnp

E2BIG The number of bytes used by the argument and environment list of
the new process image is greater than the system-imposed limit of
ARG_MAX bytes.

EACCES Search permission is denied for a directory in the path of the new
process image file or the new process image file denies execution
permission, or the new process image file is not a regular file and
the implementation does not support execution of files of its type.

EAGAIN The system lacked the necessary resources to create another
process or the system-imposed limit on the total number of
processes or UIDs under execution by a single user would be
exceeded.

EBADF An entry in the fd_map array refers to an invalid file descriptor or the
controlling terminal file descriptor specified in the inherit.ctlttyfd
is not valid.

EFAULT The system detected an invalid address in attempting to use a
parameter of the call.

EINVAL One or more of the following conditions were detected:
  • The username that was specified on the _BPX_USERID
    environment variable has an incorrect length.
  • An attribute that was specified in the inheritance structure
    (BPXYINHE) is not valid or contains an unsupported value.
  • The version number that was specified for the inheritance
    structure (BPXYINHE) is not valid.
  • The inheritance structure length that was specified by the
    Inherit_area_len parameter or within the inheritance structure
    does not contain a length that is appropriate for the BPXYINHE
    version.
  • The process group ID that was specified in the inheritance
    structure is less than zero or has some other unsupported value.

The following reason codes can accompany the return code: JROK,
JRUserNameLenError, JRJsRacXtr, JRInheUserid, JRInheRegion,
JRInheCPUTime, JRInheDynamber, JRInheAccountData,
JRInheCWD, JRInheSetPgrp, JRInheVersion, and JRInheLength.

ELOOP A loop exists in symbolic links encountered during resolution file
argument. This error is issued if more than 8 symbolic links are
detected in the resolution of file name.

EMVSERR An MVS internal error has occurred. This may indicate a problem
with security permissions for the user calling spawn() or spawnp().

EMVSSAF2ERR The executable file is a set-user-ID or set-group-ID file and the
file owner's UID or GID is not defined to the Security Authorization
Facility (SAF), or _BPX_USERID was specified and the specified
username was not defined to SAF with a z/OS UNIX segment.

ENAMETOOLONG The length of the path or file arguments, or an element of the
environment variable PATH prefixed to file exceeds PATH_MAX, or
a path name component is longer than NAME_MAX and
_{POSIX_NO_TRUNC} is in effect for that file.
ENOENT    One or more components of the path name of the new process image file do not exist or the path or file argument is empty.

ENOEXEC   The new process image file has the appropriate access permission but is not in the proper format.

**Note:** Reason codes further qualify the errno. For most of the reason codes, see [z/OS UNIX System Services Messages and Codes](https://www.ibm.com/support/knowledgecenter/en/SSLTBW_2.2.7/com.ibm.zos.v2r11.bms/). For ENOEXEC, the reason codes are:

<table>
<thead>
<tr>
<th>Reason Code</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'xxxx0C27'</td>
<td>The target HFS file is not in the correct format to be an executable file.</td>
</tr>
<tr>
<td>X'xxxx0C31'</td>
<td>The target HFS file is built at a level that is higher than that supported by the running system.</td>
</tr>
</tbody>
</table>

ENOMEM    The new process requires more memory than is permitted by the hardware or the operating system.

ENOTDIR   A component of the path prefix of the new process image file is not a directory.

ENOTTY    The tcsetpgrp() failed for the specified controlling terminal file descriptor in inherit.clttyfd. The failure occurred because the calling process does not have a controlling terminal, or the specified file descriptor is not associated with the controlling terminal, or the controlling terminal is no longer associated with the session of the calling process.

EPERM     The spawn failed for one of the following reasons:

- The spawned process is not a process group leader.
- The _BPX_USERID environment variable was specified, but the invoker does not have appropriate privileges to change the MVS identity.
- The invoker does not have the appropriate privileges to change one or more of the attributes specified in the inheritance structure (BPXYINHE).

The following reason codes can accompany the return code: JROK, JRNoChangIdentity, JRInheUserid, JRInheRegion, JRInheCPUTime, JRInheUmask, and JRInheCWD.

ESRCH     The process group ID specified in inherit.pgroup is not that of a process group in the session of the calling process.

**Example**

The following is an example of a parent program that uses spawn to create a child process.

```c
#include <unistd.h>
#include <spawn.h>
#include <stdio.h>
#include <errno.h>
#include <sys/types.h>

/* This program uses spawn instead of fork/exec to create a child * process and uses unnamed pipes to allow the parent and child to */```
```c
void main(int argc, char *argv[]) {
    pid_t child;
    int fd_count, fd_map[10];
    struct inheritance inherit;
    const char *c_argv[10], *c_envp[10];
    char buf[256];
    int nbytes;

    int c.stdin[2], c.stdout[2], c.stderr[2]; /* Pipes for child
    * communication */

    /* Create pipes to communicate with child via stdin/stdout/stderr */
    if(pipe(c.stdin) ||
        pipe(c.stdout) ||
        pipe(c.stderr)) {
        perror("Bad pipe");
        exit(-1);
    }

    /* Set up file descriptor map for child process */
    fd_map[0]=dup(c.stdin[0]); /* child stdin is read end of pipe */
    fd_map[1]=dup(c.stdout[1]); /* child stdout is write end of pipe */
    fd_map[2]=dup(c.stderr[1]); /* child stderr is write end of pipe */
    fd_count=3;

    /* Close unused end of pipes for the parent */
    close(c.stdin[0]); close(c.stdout[1]); close(c.stderr[1]);

    /* Build the argument structure for child arguments. */
    * [0] is the program name */
    c_argv[0]="spawnc";
    c_argv[1]="arg1";
    c_argv[2]="arg2";
    c_argv[3]=NULL;

    /* Build the environment structure which defines the child's
    * environment variables */
    c_envp[0]="TEST_ENV=YES";
    c_envp[1]="BPX_SHAREAS=NO";
    c_envp[2]=NULL;

    /* Spawn the child process */
    child=spawnp("spawnc", fd_count, fd_map, &inherit, c_argv, c_envp);
    if(child==-1) {
        perror("Error on spawn");
        exit(-1);
    } else printf("Spawned %i\n", child);

    /* Test interaction with the child process */
    printf("parent: Asking child, "what are you doing?\n\n") ;
    strcpy(buf, "child from parent: what are you doing?\n") ;
    if(write(c.stdout[1], buf, sizeof(buf))==-1) {
        perror("write stdout");
        exit(-1);
    }

    memset(buf, 0, 255); /* Just zeroing out the buffer */
    printf("parent: reading from child now\n");
    if((nbytes=read(c.stdout[0], buf, 255))==-1) {
        perror("read error:");
        exit(-1);
    }
    printf("parent: child says, \"%s\n\", buf);

    /* Cleanup pipes before exiting */
}
```
Example

The following is an example of a child program used by spawn.

```c
#include <stdlib.h>
#include <stdio.h>
/* This is a sample child program used by spawn. This program will  
 * work stand-alone as well as from spawn or fork/exec. */
extern char ** environ; /* External used to access the environment  
 * directly instead of using getenv */

void main(int argc, char *argv[]) {
    char *e, **env=environ; /* Used to step through the environment  
 * to write out to file. */
    char buf[256]={0};
    FILE *fp=fopen("spawntest.out","w");
    int i;
    /* Print out the environment variables */
    i=0;
    fprintf(fp, "Environment:\n");
    while(e=env[i++]) fprintf(fp, "%s\n", e);
    fprintf(fp, "\n\n");
    /* Just to prove getenv works */
    fprintf(fp, "TEST_ENV envvar = %s", getenv("TEST_ENV"));
    /* Print out the command line arguments */
    i=0;
    fprintf(fp,"Args:\n");
    while(e=argv[i++]) fprintf(fp,"%s\n", e);
    fprintf(fp, "\n\n");
    /* Print out what was sent on stdin */
    fprintf(fp, "Child/parent\n");
    if(!gets(buf)) {
        ferror(stdin);
        exit(-1);
    }
    fprintf(fp, "child from parent: %i bytes,[%s]\n", strlen(buf), buf);
    /* Send something to stdout */
    printf("nothing");
    fclose(fp);
    exit(0);
}
```

               const int fd_count,
               const int fd_map[],
               const struct __inheritance *inherit,
               const char *argv[],
               const char *envp[]);
```

General description

The __spawn2() and __spawnp2() functions creates a new process from the specified process image. The new process image is constructed from a regular executable file called the new process image file.

To execute a C program as a result of this call, enter the function call as follows:

```c
int main (int argc, char *argv[]);
```

Where `argc` is the argument count and `argv` is an array of character pointers to the arguments themselves. In addition, the following variable:

```c
extern char **environ;
```

is initialized as a pointer to an array of character pointers to the environment strings. The `argv` and `environ` arrays are each terminated by a NULL pointer. The NULL pointer terminating the `argv` array is not counted in `argc`.

Supported parameters are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Path name used by __spawn2() that identifies the new process image file to execute.</td>
</tr>
<tr>
<td>file</td>
<td>Used by __spawnp2() to construct a path name that identifies the new process image file. If the file parameter contains a slash character, the file parameter shall be used as a path name for the new process image file. Otherwise, the path prefix for this file shall be obtained by a search of the directories passed as the environment variable PATH.</td>
</tr>
<tr>
<td>fd-count</td>
<td>Specifies the number of file descriptors the child process shall</td>
</tr>
</tbody>
</table>
Inherit. It may take values from zero to \texttt{OPEN_MAX}. Except those file descriptors designated by \texttt{SPAWN_FDCLOSED}, each of the child's file descriptors, \(x\), in the range zero to \(fd\_count-1\) shall inherit descriptor \(fd\_map(x)\) from the parent process.

The files from \(fd\_count\) through \texttt{OPEN_MAX} are closed in the child process, as are any elements of \texttt{fd_map} designated as \texttt{SPAWN_FDCLOSED}.

\texttt{fd-map}

If the \texttt{fd_map} parameter is \texttt{NULL}, \texttt{fd_count} and \texttt{fd_map} are ignored. All file descriptors except those with the \texttt{FD_CLOEXEC} or \texttt{FD_CLOFORK} attribute are inherited without reordering. File descriptors with the \texttt{FD_CLOEXEC} or \texttt{FD_CLOFORK} attribute are closed under simple inheritance.

For those file descriptors that remain open, all other attributes of the associated file descriptor object and open file description shall remain unchanged by this operation.

Directory streams open in the calling process image shall be closed in the new process image, with the effect of the closedir() operation.

If an element of \texttt{fd_map} refers to an invalid file descriptor, then the (EBADF) error status shall be posted by \texttt{__spawn2()} or \texttt{__spawnp2()}.

The \texttt{FD_CLOEXEC} and \texttt{FD_CLOFORK} file descriptor attributes are never inherited.

The \texttt{FD_CLOEXEC} and \texttt{FD_CLOFORK} file descriptor attributes have no effect on inheritance when the \texttt{fd_map} parameter is not \texttt{NULL}.

\textbf{Note:} For XTI endpoints, \texttt{fd_map} must not map to a number greater than 65535 in the child process.

\texttt{inherit}

The name of a data area that contains the inheritance structure.

The 'struct __inheritance' is defined as follows:

\begin{verbatim}
struct __inheritance {
  short flags; -- Flags
  pid_t pgroup; -- Process group
  sigset_t sigmask; -- Signal mask
  sigset_t sigdefault; -- Signals set to SIG_DFL
  int ctlttyfd; -- Cntl tty FD for tcsetpgrp()
  char *cwdptr; -- Pointer to the users CWD
  int cwdlen; -- Length of the users CWD
  int acctdatalen; -- Length of account data area
  char *acctdataptr; -- Ptr to account data area
  int umask; -- Users UMASK
  char userid[9]; -- New A.S. user identity
  char jobname[9]; -- New A.S. jobname
  int regionsize; -- New A.S. region size
  int timelimit; -- New A.S. time limit
  union {
    #ifdef _LP64
    unsigned long memlimit;
    #define __memlimit memlimit_u.memlimit
    #endif
    #ifdef __LL
    unsigned long long memlimit_ll;
    #define __memlimit_ll memlimit_u.memlimit_ll
    #endif
    unsigned int memlimit_i[2];
    #define __memlimit_h memlimit_u.memlimit_i[0]
    }
};
\end{verbatim}
The `inherit.flags` effect spawn() and spawnp() as follows:

**SPAWN_SETGROUP**

If the `SPAWN_SETGROUP` flag is set in `inherit.flags`, then the child's process group shall be as specified in `inherit.pgroup`.

If the `SPAWN_SETGROUP` flag is set in `inherit.flags and inherit.pgroup` is set to `SPAWN_NEWPGROUP`, then the child shall be in a new process group with a process group ID equal to its process ID.

If the `SPAWN_SETGROUP` flag is not set in `inherit.flags`, the new child shall inherit the parent's process group ID.

**SPAWN_SETSIGMASK**

If the `SPAWN_SETSIGMASK` flag is set in `inherit.flags`, the child process shall initially have the signal mask specified in `inherit.sigmask`.

**SPAWN_SETSIGDEF**

If the `SPAWN_SETSIGDEF` flag is set in `inherit.flags`, the signals specified in `inherit.sigdefault` shall be set to their default actions in the child process. Signals set the default action in the parent process shall be set to the default action in the new process.

Signals set to be caught by the calling process shall be set to the default action in the child process.

Signals set to be ignored by the calling process shall be set to be ignored by the new process, unless otherwise specified by the `SPAWN_SETSIGDEF` flag being set in `inherit.flags` and the signal being indicated `inherit.sigdefault`.

**SPAWN_SETTCPGRP**

If the `SPAWN_SETTCPGRP` flag is set in `inherit.flag`, the file descriptor specified in `inherit.ctlttyfd` is used to set the controlling terminal file descriptor (tcsetattr()) for the child's foreground process group. The child's foreground process group is inherited from the parent, unless the `SPAWN_SETGROUP` flag in `inherit.flags` is set, indicating that the value specified in `inherit.pgroup` is to be used to determine the child's process group.

**argv**

The value in the first element of `argv` should point to a file name that is associated with the process being started by the spawn2() or spawnp2() operation.

The number of bytes available for the new process's combined argument and environment lists is **ARG_MAX**.
envp

The value envp contains the list of environmental variables that is to be passed to the specified program.

If the set-user-ID mode bit of the new process image file is set, the effective user ID of the new process image shall be set to the owner ID of the new process image file. Similarly, if the set-group-ID mode bit of the new process image file is set, the effective group ID of the new process image shall be set to the group ID of the new process image file. The real user ID, real group ID, and supplementary group IDs of the new process image shall remain the same as those of the calling process image. The effective user ID and effective group ID of the new process image shall be saved (as the saved set-user-ID and set-group-ID) for use by the setuid() function.

The new process image shall inherit the following attributes of the calling process image:

- Process group ID (unless the SPAWN_SETGROUP flag is set in inherit.flags).
- Session membership.
- Real user ID.
- Real group ID.
- Supplementary group IDs.
- Priority.
- Current working directory.
- File creation mask.
- Signal mask (unless the SPAWN_SETSIGNAL flag is set in inherit.flags).
- Signal actions specified as default (SIG_DFL).
- Signal actions specified as ignore (SIG_IGN) (except as modified by inherit.sigdefault and the SPAWN_SETSIGDEF flag set in inherit.flags).

The following are differences between the parent process and child:

- Signals set to be caught by the calling process shall be set to the default action (SIG_DFL).
- The process and system utilization times for the child are set to zero.
- Any file locks previously set by the parent are not inherited by the child.
- The child process has no alarms set and has no interval timers set.
- The child has no pending signals.
- Memory mappings established by the parent are not inherited by the child.

If the process image was read from a writable file system, then upon successful completion, the __spawn2() and __spawnp2() functions will mark for update the st_time field of the new process image file.

If the __spawn2() or __spawnp2() function is successful, the new child process image file shall be opened with all the effects of the open() function.

All the following inherit flags are used by __spawn2() and __spawnp2():

SPAWN_SETCWD

Specifies the Current Working Directory that the child process will run when first created. This will override the CWD that would normally be set up or propagated by the child process.

SPAWN_SETUMASK

Specifies the UMASK that the child process will run when first created. This will override the UMASK that would normally be set up in the child process. The invoker must have superuser privileges to specify UMASK.
__spawn2, __spawnp2

SPAWN_SETUSERID
When this flag is set, this attribute will be the equivalent of the
_BPX_USERID environment variable. If specified, the invoking
userid will be checked for daemon authority. If the invoker is
authorized and the userid is valid, the child process will be created
with RACF identity and POSIX permissions associated with the
input USERID. If not authorized or the userid is invalid, the
__spawn2() or __spawnp2() function will fail. If the USERID value is
specified, any value in _BPX_USERID will be ignored.

SPAWN_SETREGIONSZ
Specifies the number of megabytes the child process will have
available for private storage. The authority/ranges required will be
as per RLIMIT_AS rules. Unless the invoker has superuser
privileges, the region size range will be checked and if it exceeds
the hard limit, the __spawn2() or __spawnp2() function will fail. This
value will override RLIMIT_AS or the normal spawn propagation
rules.

SPAWN_SETTIMELIMIT
Specifies the number of seconds of CPU time that is allowed by the
child process before receiving a SIGXCPU signal. Unless the
invoker has superuser privileges, the time limit range will be
checked and if it exceeds the hard limit, the __spawn2() or
__spawnp2() function will fail. This value will override the
RLIMIT_CPU or the normal spawn propagation rules.

SPAWN_SETACCTDATA
Specifies account data of the child process. The format and length
will be as per the _BPX_ACCT_DATA environmental variable. No
special authority is needed to change account data. This will
override the target userid's default account data and any value
specified on the _BPX_ACCT_DATA will be ignored.

SPAWN_SETJOBNAME
When this flag is set, it is the equivalent of the _BPX_JOBNAME
environment variable. If specified, the invoking userid will be
checked for superuser authority. If the invoker is authorized and the
jobname is valid, the child process will be created with the specified
jobname. If not authorized or the jobname is invalid, __spawn2() or
__spawnp2() will ignore the JOBNAME attribute and continue. If the
JOBNAME value is specified, any value in _BPX_JOBNAME will be
ignored.

SPAWN_MUSTBELOCAL
When this flag is set, it is the equivalent of the
_BPX_SHAREAS=MUST environment variable. If specified, the
system will attempt a local spawn, otherwise the request will fail.

SPAWN_SETMEMLIMIT
When this flag is set and not doing a local spawn,
inherit.memlimit_u determines the maximum amount of bytes the
child address space is allowed to obtain above the 2-gigabyte bar.
If the specified value exceeds the current hard limit, the invoking
userid must have appropriate privileges, otherwise the request will
fail.

SPAWN_PROCESS_INITTAB
If this flag is set, spawn attempts to read the /etc/inittab file and
process the entries found there. This processing involves the spawning of child shell processes to run each of the commands identified in the file. Only the SPAWN_SETSIGMASK flag can be set in combination with this flag. All other flags will be ignored. Use of this flag implies that only file descriptors 0, 1, and 2 will be initially opened in the child process. File descriptor 0 will be initially opened as /dev/null, while file descriptors 1 and 2 will initially opened as /etc/log. The fd_count and fd_map parameters will be ignored. This flag is currently restricted to the /usr/sbin/init process. See z/OS UNIX System Services Planning for more information on the /etc/inittab support.

For more information on the use of inheritance structure flags, see z/OS UNIX System Services Programming: Assembler Callable Services Reference, SA22-7803.

Returned value

If successful, __spawn2() or __spawnp2() returns the process ID of the child process to the parent.

If unsuccessful, __spawn2() or __spawnp2() returns -1 to the parent process, no child is created, and they set errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2BIG</td>
<td>The number of bytes used by the argument and environment list of the new process image is greater than the system-imposed limit of ARG_MAX bytes.</td>
</tr>
<tr>
<td>EACCES</td>
<td>Search permission is denied for a directory in the path of the new process image file or the new process image file denies execution permission, or the the new process image file is not a regular file and the implementation does not support execution of files of its type.</td>
</tr>
<tr>
<td>EAGAIN</td>
<td>The system lacked the necessary resources to create another process, or the system-imposed limit on the total number of processes under execution by a single user would be exceeded. The resources required to let another process be created are not available, or you have already reached the maximum number of processes or UIDs you are allowed to create. This error will also be generated if _BPX_USERID or INHEUSERID was specified and the username was not defined to SAF with a segment.</td>
</tr>
<tr>
<td>EBADF</td>
<td>An entry in the fd_map array refers to an invalid file descriptor or the controlling terminal file descriptor specified in the __inheritance structure.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>The system detected an invalid address while attempting to use a parameter of the call.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>One or more of the following conditions were detected:</td>
</tr>
<tr>
<td></td>
<td>• The username that was specified on the _BPX_USERID environment variable has an incorrect length.</td>
</tr>
<tr>
<td></td>
<td>• An attribute that was specified in the inheritance structure (BPXYINHE) is not valid or contains an unsupported value.</td>
</tr>
<tr>
<td></td>
<td>• The version number that was specified for the inheritance structure (BPXYINHE) is not valid.</td>
</tr>
</tbody>
</table>
The inheritance structure length that was specified by the Inherit_area_len parameter or within the inheritance structure does not contain a length that is appropriate for the BPXYINHE version.

- The process group ID that was specified in the inheritance structure is less than zero or has some other unsupported value.

The following reason codes can accompany the return code: JROK, JRUserNameLenError, JRJsRacXtr, JRInheUserid, JRInheRegion, JRInheCPUTime, JRInheDynamber, JRInheAccountData, JRInheCWD, JRInheSetPgrp, JRInheVersion, and JRInheLength.

ELOOP A loop exists in symbolic links encountered during resolution of the file name argument. This error is issued if more than 8 symbolic links are detected.

EMVSERR The spawn failed for the following reason: Local spawn not allowed. Either the environment variable _BPX_SHAREAS was set to MUST (_BPX_SHAREAS=MUST), or the __inheritance structure specified SPAWN_MUSTBELOCAL.

The following reason code can accompany the return code: JRLocalSpawnNotAllowed.

EMVSSAF2ERR The executable file is a set-user-ID or set-group-ID file and the owner's UID or GID is not defined to the Security Authorization Facility (SAF).

ENAMETOOLONG The length of the path or file parameter, or an element of the environmental variable PATH prefixed to a file, exceeds PATH_MAX, or a path name component is longer than NAME_MAX and _POSIX_N_TRUNC_ is in effect for that file.

ENOENT One or more components of the path name of the new process image file do not exist or the path or file parameter is empty.

ENOEXEC The new process image file has the appropriate access permission, but is not in the proper format.

Note:

Reason codes further qualify the errno. For most of the reason codes, see z/OS UNIX System Services Messages and Codes.

For ENOEXEC, the reason codes are:

<table>
<thead>
<tr>
<th>Reason Code</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'xxxx0C27'</td>
<td>The target HFS file is not in the correct format to be an executable file.</td>
</tr>
<tr>
<td>X'xxxx0C31'</td>
<td>The target HFS file is built at a level that is higher than that supported by the running system.</td>
</tr>
</tbody>
</table>

ENOMEM The new process requires more memory than is permitted by the hardware or operating system.
__spawn2, __spawnp2

ENOTDIR A component of the path prefix of the new process image file is not a directory.

ENOTTY tcsetpgrp() failed for the specified controlling terminal file descriptor in __inheritance structure. The failure occurred because the calling process does not have a controlling terminal, or the specified file descriptor is not associated with the controlling terminal, or the controlling terminal is no longer associated with the session of the calling process.

EPERM The spawn failed for one of the following reasons:
- The spawned process is not a process group leader.
- The __BPX_USERID environment variable was specified, and the invoker does not have appropriate privileges to change the MVS identity.
- The invoker does not have the appropriate privileges to change one or more of the attributes specified in the inheritance structure (BPXYINHE).

The following reason codes can accompany the return code: JROK, JRNoChangelIdentity, JRInheUserid, JRInheRegion, JRInheCPUTime, JRInheUmask, JRInheCWD and JRInheMemLimit.

ESRCH The process group ID specified in the __inheritance structure is not that of s process group in the calling process's session.

#include <math.h>

double sqrt(double x);
float sqrtf(float x); /* C++ only */
long double sqrtl(long double x); /* C++ only */
float sqrtf(float x);
long double sqrtl(long double x);
```

General description

Calculates the square root of x.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point " on page 94 for more information about IEEE Binary Floating-Point.

Returned value

If successful, returns the square root of x.

If x is negative, the function sets errno to EDOM, and returns 0. If the correct value would cause underflow, zero is returned and the value ERANGE is stored in errno.

Special behavior for IEEE

If x < -0, the function returns NaNQ and sets errno to EDOM.

If x is a NaN, a NaN will be returned.

If x is ±0 or +INF, x will be returned.

If x is -INF, a EDOM will be set, and NaNQ will be returned.

Example

```
CELEBS30
/* CELEBS30

This example computes the square root of the quantity passed
as the first argument to main.
It prints an error message if you pass a negative value.
```

Chapter 3. Library functions  2029
**sqrt, sqrtf, sqrtl**

```c
#include <stdio.h>
#include <stdlib.h>
#include <math.h>

int main(int argc, char ** argv)
{
    char * rest;
    double value;
    if ( argc != 2 )
        printf( "Usage: %s value\n", argv[0] );
    else
    {
        value = strtod( argv[1], &rest );
        if ( value < 0.0 )
            printf( "sqrt of a negative number\n" );
        else
            printf("sqrt( %f ) = %f\n", value, sqrt( value ));
    }
}

Output

If the input is 45, then the output should be:

```
sqrt( 45.000000 ) = 6.708204
```

.Decimal32 sqrtd32(_Decimal32 x);
.Decimal64 sqrtd64(_Decimal64 x);
.Decimal128 sqrtd128(_Decimal128 x);
.Decimal32 sqrt(_Decimal32 x); /* C++ only */
.Decimal64 sqrt(_Decimal64 x); /* C++ only */
.Decimal128 sqrt(_Decimal128 x); /* C++ only */
```

General description

Calculates the square root of \(x\).

Notes:
1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, returns the square root of \(x\).

If the correct value would cause underflow, zero is returned and the value ERANGE is stored in errno.

If \(x < -0\), the function returns NaNQ and sets errno to EDOM.

If \(x\) is a NaN, a NaN will be returned.

If \(x\) is ±0 or +INF, \(x\) will be returned.

If \(x\) is -INF, the function returns NaNQ and sets errno to EDOM.

Example

```c
/* CELEBS71

This example illustrates the sqrtd32() function, along with the strtod32() function.

This example computes the square root of the quantity passed as the first argument to main.
It prints an error message if you pass a negative value.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
```

Chapter 3. Library functions 2031

srand() — Set seed for rand() function

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

void srand(unsigned int seed);
```

General description

srand() uses its argument seed as a seed for a new sequence of pseudo-random numbers to be returned by subsequent calls to rand(). If srand() is not called, the rand() seed is set as if srand(1) was called at program start. Any other value for seed sets the generator to a different starting point. The rand() function generates pseudo-random numbers.

Some people find it convenient to use the return value of the time() function as the argument to srand(), as a way to ensure random sequences of random numbers.

Returned value

srand() returns no values.

Example

```c
CELEBS31

/* CELEBS31

This example first calls srand. with a value other than 1 to initiate the random value sequence.
Then the program computes 5 random values for the array of integers called ranvals.
If you repeat this code exactly, then the same sequence of random values will be generated.

*/
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    int i, ranvals[5];
    srand(17);
    for (i = 0; i < 5; i++)
    {
        ranvals[i] = rand();
        printf("Iteration %d ranvals [%d] = %d\n", i+1, i, ranvals[i]);
    }
}
```

Output
srand

Iteration 1 ranvals [0] = 24107
Iteration 2 ranvals [1] = 16552
Iteration 3 ranvals [2] = 12125
Iteration 4 ranvals [3] = 9427
Iteration 5 ranvals [4] = 13152

</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <stdlib.h>

void srand48(long int seedval);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The lcong48(), seed48(), and srand48() functions are initialization functions, one of which should be invoked before either the drand48(), lrand48() or mrand48() function is called.

The drand48(), lrand48() and mrand48() functions generate a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

\[ X(n+1) = (aX(n) + c) \mod (2^{48}) \quad n \geq 0 \]

The initial values of X, a, and c are:

- \( X(0) = 1 \)
- \( a = 5deece66d \) (base 16)
- \( c = b \) (base 16)

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The srand48() function is used to reinitialize the most recent 48-bit value in this storage. The srand48() function replaces the high-order (leftmost) 32 bits of this storage with seedval argument value. The srand48() function replaces the low-order 16 bits of this storage with the value 330E (base 16).

The values a and c, may be changed by calling the lcong48() function. The srand48() function restores the initial values of a and c.

**Special behavior for z/OS UNIX Services:** You can make the srand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.
If thread-specific behavior is requested, calls to the drand48(), lrand48() and mrand48() functions from thread \( t \) generate a sequence of 48-bit integer values, \( X(t,i) \), according to the linear congruential formula:

\[
X(t,n+1) = (a(t)X(t,n) + c(t)) \mod(2^{48}) \quad n \geq 0
\]

C/370 provides thread-specific storage to save the most recent 48-bit integer value of the sequence, \( X(t,i) \). When the srand48() function is called from thread \( t \), it reinitializes the most recent 48-bit value in this storage. The srand48() function replaces the high-order (leftmost) 32 bits of this storage with seedval argument value. The srand48() function replaces the low-order 16 bits of this storage with the value \( 330E \) (base 16).

The values of \( a(t) \) and \( c(t) \) may be changed by calling the lcong48() function from thread \( t \). When the srand48() function is called from this thread it restores the initial values of \( a(t) \) and \( c(t) \) for the thread which are:

\[
\begin{align*}
a(t) &= 5deece66d \quad \text{(base 16)} \\
c(t) &= b \quad \text{(base 16)}
\end{align*}
\]

**Returned value**

srand48() returns no values.

srand48() returns after it has used the value of the argument seedval to reinitialize storage for the most recent 48-bit integer value in the sequence, \( X(i) \), and has restored the initial values of \( a \) and \( c \).

**Special behavior for z/OS UNIX Services:** If thread-specific behavior is requested for the drand48 family and the srand48() function is called on thread \( t \), it uses the value of the argument seedval to reinitialize storage for the most recent 48-bit integer value in the sequence, \( X(t,i) \), for the thread. It also restores the initial values of \( a(t) \) and \( c(t) \) for the thread. Then it returns.

sscanf

sscanf() — Read and format data from buffer

The information for this function is included in "fscanf(), scanf(), sscanf() — Read and format data" on page 701.
stat() — Get file information

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <sys/stat.h>

int stat(const char *__restrict__ pathname, struct stat *__restrict__ info);
```

General description

Gets status information about a specified file and places it in the area of memory pointed to by the info argument. The process does not need permissions on the file itself, but must have search permission on all directory components of the pathname. If the named file is a symbolic link, stat() resolves the symbolic link. It also returns information about the resulting file.

The information is returned as shown in the following stat structure table, as defined in the sys/stat.h header file.

Table 49. Values Returned in stat Structure

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode_t st_mode</td>
<td>A bit string indicating the permissions and privileges of the Symbols are defined in the sys/stat.h header file to refer to bits in a mode_t value; these symbols are listed in &quot;chmod() — Change the mode of a file or directory&quot; on page 284.</td>
</tr>
<tr>
<td>ino_t st_ino</td>
<td>The serial number of the file.</td>
</tr>
<tr>
<td>dev_t st_dev</td>
<td>The numeric ID of the device containing the file.</td>
</tr>
<tr>
<td>nlink_t st_nlink</td>
<td>The number of links to the file.</td>
</tr>
<tr>
<td>uid_t st_uid</td>
<td>The numeric user ID (UID) of the file's owner.</td>
</tr>
<tr>
<td>gid_t st_gid</td>
<td>The numeric group ID (GID) of the file's group.</td>
</tr>
<tr>
<td>off_t st_size</td>
<td>For regular files, the file's size in bytes. For other kinds of files, the value of this field is unspecified.</td>
</tr>
<tr>
<td>time_t st_atime</td>
<td>The most recent time the file was accessed.</td>
</tr>
<tr>
<td>time_t st_ctime</td>
<td>The most recent time the status of the file was changed.</td>
</tr>
<tr>
<td>time_t st_mtime</td>
<td>The most recent time the contents of the file were changed.</td>
</tr>
</tbody>
</table>

Values for time_t_ are given in terms of seconds since epoch.

stat() updates the time-related fields before putting information in the stat structure.

You can examine properties of a mode_t value from the st_mode field using a collection of macros defined in the sys/modes.h header file. If mode is a mode_t value, and genvalue is an unsigned int value from the stat structure, then:
stat

S_ISBLK(mode)
  Is nonzero for block special files.

S_ISCHR(mode)
  Is nonzero for character special files.

S_ISDIR(mode)
  Is nonzero for directories.

S_ISEXTL(mode,genvalue)
  Is nonzero for external links.

S_ISFIFO(mode)
  Is nonzero for pipes and FIFO special files.

S_ISLNK(mode)
  Is nonzero for symbolic links.

S_ISREG(mode)
  Is nonzero for regular files.

S_ISSOCK(mode)
  Is nonzero for sockets.

If stat() successfully determines this information, it stores it in the area indicated by the info argument. The size of the buffer determines how much information is stored; data that exceeds the size of the buffer is truncated.

Large file support for z/OS UNIX files:

Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGLEVEL(LONGLONG) and define the __LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the __LARGE_FILES feature test macro as well.

Returned value

If successful, stat() returns 0.

If unsuccessful, stat() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCESS</td>
<td>The process does not have search permission on some component of the pathname prefix.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>info is a NULL pointer.</td>
</tr>
<tr>
<td>EIO</td>
<td>Added for XPG4.2: An error occurred while reading from the file system.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links encountered during resolution of the pathname argument. This error is returned if more than POSIX_SYMLOOP (defined in the limits.h header file) symbolic links are encountered during resolution of the pathname argument.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>pathname is longer than PATH_MAX characters, or some component of pathname is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the</td>
</tr>
</tbody>
</table>
length of the path name string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined with pathconf().

ENOENT There is no file named pathname, or pathname is an empty string.

ENOTDIR A component of the pathname prefix is not a directory.

EOVERFLOW The file size in bytes or the number of blocks allocated to the file or the file serial number cannot be represented correctly in the structure pointed to by info.

Note: Environment variable _EDC_EOVERFLOW can be used to control behavior of the stat() function with respect to detecting an EOVERFLOW condition for z/OS UNIX files. By default, the stat() function will not set EOVERFLOW when the file size can not be represented correctly in structure pointed to by buf. When _EDC_EOVERFLOW is set to YES, the stat() function will check for an overflow condition.

Example

CELEBS33
/* CELEBS33

This example gets status information about a file.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <sys/stat.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <time.h>

main()
{
struct stat info;

if (stat("/", &info) != 0)
  perror("stat() error");
else {
  puts("stat() returned the following information about root f/s:");
  printf("inode: %d\n", (int) info.st_ino);
  printf("dev id: %d\n", (int) info.st_dev);
  printf("mode: %08x\n", info.st_mode);
  printf("links: %d\n", info.st_nlink);
  printf("uid: %d\n", (int) info.st_uid);
  printf("gid: %d\n", (int) info.st_gid);
  printf("created: %s", ctime(&info.st_createtime));
}
}

Output
stat() returned the following information about root f/s:
  inode: 0
  dev id: 1
  mode: 010001ed
  links: 11
  uid: 0
  gid: 500
  created: Fri Jun 16 10:07:55 2001

statvfs() — Get file system information

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/statvfs.h>

int statvfs(const char * _restrict_ pathname, struct statvfs * _restrict_ fsinfo);
```

General description

The `statvfs()` function obtains information about the file system containing the file named by `pathname` and stores it in the area of memory pointed to by the `fsinfo` argument. The process does not need permissions on the file itself, but must have search permission on all directory components of the `pathname`.

The information is returned in the following `statvfs` structure, as defined in the `sys/statvfs.h` header file.

Table 50. Values Returned in statvfs Structure

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int f_OEcblen</td>
<td>The length of the structure.</td>
</tr>
<tr>
<td>unsigned long f_bsize</td>
<td>The file system block size.</td>
</tr>
<tr>
<td>unsigned long f_blocks</td>
<td>The total number of blocks on the file system in units of f_frsize.</td>
</tr>
<tr>
<td>unsigned long f_OEusedspace</td>
<td>The allocated space in block size units.</td>
</tr>
<tr>
<td>unsigned long f_bavail</td>
<td>The number of free blocks available to non-privileged process.</td>
</tr>
<tr>
<td>unsigned long f_fsid</td>
<td>The file system ID.</td>
</tr>
<tr>
<td>unsigned long f_flag</td>
<td>A bit string indicating file system status.</td>
</tr>
<tr>
<td>int f_OEmaxfilesizehw</td>
<td>The high word of maximum file size.</td>
</tr>
<tr>
<td>unsigned long f_OEmaxfilesizelw</td>
<td>The low word of maximum file size.</td>
</tr>
<tr>
<td>unsigned long f_frsze</td>
<td>The fundamental file system block size.</td>
</tr>
<tr>
<td>unsigned long f_bfree</td>
<td>The total number of free blocks.</td>
</tr>
<tr>
<td>unsigned long f_files</td>
<td>The total number of file serial numbers.</td>
</tr>
<tr>
<td>unsigned long f_ffree</td>
<td>The total number of free file serial numbers.</td>
</tr>
<tr>
<td>unsigned long f_favail</td>
<td>The number of file serial numbers available to non-privileged process.</td>
</tr>
<tr>
<td>unsigned long f_namemax</td>
<td>The maximum file name length.</td>
</tr>
<tr>
<td>unsigned long f_OEinvarsec</td>
<td>The number of seconds the file system will remain unchanged.</td>
</tr>
</tbody>
</table>
statvfs

The following flags can be returned in the f_flag member:

- **ST_RDONLY** read-only file system
- **ST_NOSUID** setuid/setgid bits ignored by exec
- **ST_OEEXPORTED** file system is exported

If statvfs() successfully determines this information, it stores in the area indicated by the *fsinfo* argument. The size of the buffer determines how much information is stored; data that exceeds the size of the buffer is truncated.

**Returned value**

If successful, statvfs() returns 0.

If unsuccessful, statvfs() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The process does not have search permission on some component of the <em>pathname</em> prefix.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>An I/O error has occurred while reading the file system.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal was caught during the execution of the function.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links encountered during resolution of the <em>pathname</em> argument. This error is issued if more than the system-defined limit of symbolic links, 8, are detected in the resolution of <em>pathname</em>.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>The length of the <em>pathname</em> exceeds PATH_MAX or a component of <em>pathname</em> is longer than NAME_MAX.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>There is no file named <em>pathname</em>, or <em>pathname</em> is an empty string.</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>A component of the <em>pathname</em> prefix is not a directory.</td>
</tr>
</tbody>
</table>

**Example**

```c
#include <sys/statvfs.h>
#include <stdio.h>

main() {  
  int fd;
  struct statvfs buf;

  if (statvfs(".", &buf) == -1)  
    perror("statvfs() error");
  else {  
    printf("each block is %d bytes big\n", fs, buf.f_bsize);
    printf("there are %d blocks available out of a total of %d\n",  
           buf.f_bavail, buf.f_blocks);
    printf("in bytes, that's %.0f bytes free out of a total of %.0f\n          ((double)buf.f_bavail * buf.f_bsize),
           ((double)buf.f_blocks * buf.f_bsize));
  }
}
```

**Output**
each block is 4096 bytes big
there are 2089 blocks available out of a total of 2400
in bytes, that's 8556544 bytes free out of a total of 9830400

step

step() — Pattern match with regular expression

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <regexp.h>

int step(const char *string, const char *expbuf);

extern char *loc1, *loc2;
```

General description

Restriction: This function is not supported in AMODE 64.

The `step()` function attempts to match an input string of characters with the compiled regular expression which was obtained by an earlier call to `compile()`.

The first parameter `string` is a pointer to a string of characters to be checked for a match.

`expbuf` is the pointer to the regular expression which was previously obtained by a call to `compile()`.

Usage notes

1. The external variables `cirt`, `sed`, and `nbra` are reserved.
2. The application must provide the proper serialization for the `compile()`, `step()`, and `advance()` functions if they are run under a multithreaded environment.
3. The `compile()`, `step()` and `advance()` functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions `fnmatch()`, `glob()`, `regcomp()`, and `regexec()`, which provide full internationalized regular expression functionality compatible with ISO POSIX.2 standard.

Returned value

If some substring of `string` matches the regular expression in `expbuf`, `step()` returns nonzero.

If there is no match, `step()` returns 0.

If there is a match, `step()` sets two external pointers, as follows:
   • The variable `loc1` points to the first character that matched the regular expression.
   • The variable `loc2` points to the character after the last character that matched the regular expression.
For example, if the regular expression matches the entire input, loc1 will point to the first character of string and loc2 will point to the NULL at the end of string.

strcasecmp

strcasecmp() — Case-insensitive string comparison

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

int strcasecmp(const char *string1, const char *string2);
```

General description

The `strcasecmp()` function compares, while ignoring differences in case, the string pointed to by `string1` to the string pointed to by `string2`.

The string arguments to the function must contain a NULL character (\0) marking the end of the string.

The `strcasecmp()` function is locale-sensitive.

Returned value

`strcasecmp()` returns a value indicating the relationship between the strings, while ignoring case, as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td>String pointed to by <code>string1</code> is less than string pointed to by <code>string2</code>.</td>
</tr>
<tr>
<td>= 0</td>
<td>String pointed to by <code>string1</code> is equal to string pointed to by <code>string2</code>.</td>
</tr>
<tr>
<td>&gt; 0</td>
<td>String pointed to by <code>string1</code> is greater than string pointed to by <code>string2</code>.</td>
</tr>
</tbody>
</table>

There are no errno values defined.

strcat() — Concatenate strings

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>

char *strcat(char * __restrict__ string1, const char * __restrict__ string2);
```

General description

The strcat() built-in function concatenates string2 with string1 and ends the resulting string with the NULL character. In other words, strcat() appends a copy of the string pointed to by string2—including the terminating NULL byte—to the end of a string pointed to by string1, with its last byte (that is, the terminating NULL byte of string1) overwritten by the first byte of the appended string.

Do not use a literal string for a string1 value, although string2 may be a literal string.

If the storage of string1 overlaps the storage of string2, the behavior is undefined.

Returned value

Returns the value of string1, the concatenated string.

Example

```c
CELEBS34

/* CELEBS34

   This example creates the string "computer program" using strcat().

*/
#include <stdio.h>
#include <string.h>
#define SIZE 40

int main(void)
{
    char buffer1[SIZE] = "computer";
    char * ptr;
    ptr = strcat( buffer1, " program" );
    printf( "buffer1 = %s\n", buffer1 );
}
```

Output
buffer1 = computer program

## strchr() — Search for character

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Format

```c
#include <string.h>
char *strchr(const char *string, int c);
```

### General description

The `strchr()` built-in function finds the first occurrence of `c` converted to char, in the string `*string`. The character `c` can be the NULL character (`\0`); the ending NULL character of `string` is included in the search.

The `strchr()` function operates on NULL-terminated strings. The string argument to the function must contain a NULL character (`\0`) marking the end of the string.

### Returned value

If successful, `strchr()` returns a pointer to the first occurrence of `c` (converted to a character) in `string`.

If the character is not found, `strchr()` returns a NULL pointer.

### Example

```c
CELEBS35
/* CELEBS35
   This example finds the first occurrence of the character p in
   "computer program".
*/

#include <stdio.h>
#include <string.h>
#define SIZE 40
int main(void)
{
    char buffer1[SIZE] = "computer program";
    char * ptr;
    int   ch = 'p';

    ptr = strchr(buffer1, ch);
    printf( "The first occurrence of '%c' in '%s' is '%s'\n",
            ch, buffer1, ptr);
}
```

### Output

```c
```
strchr

The first occurrence of p in 'computer program' is 'puter program'

<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>

int strcmp(const char *string1, const char *string2);
```

General description

The `strcmp()` built-in function compares the string pointed to by `string1` to the string pointed to by `string2`. The string arguments to the function must contain a NULL character (\0) marking the end of the string.

The relation between the strings is determined by subtracting: `string1[i] - string2[i]`, as `i` increases from 0 to `strlen` of the smaller string. The sign of a nonzero return value is determined by the sign of the difference between the values of the first pair of bytes (both interpreted as type unsigned char) that differ in the strings being compared. This function is not locale-sensitive.

Returned value

`strcmp()` returns a value indicating the relationship between the strings, as listed below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td>String pointed to by <code>string1</code> less than string pointed to by <code>string2</code></td>
</tr>
<tr>
<td>= 0</td>
<td>String pointed to by <code>string1</code> equivalent to string pointed to by <code>string2</code></td>
</tr>
<tr>
<td>&gt; 0</td>
<td>String pointed to by <code>string1</code> greater than string pointed to by <code>string2</code></td>
</tr>
</tbody>
</table>

Example

```c
CELEBS36
/* CELEBS36

This example compares the two strings passed to main using
&strcmp..
*/

#include <stdio.h>
#include <string.h>

int main(int argc, char ** argv)
{
    int result;
    if ( argc != 3 )
    {
### strcmp

```c
#define strcmp( str1, str2 )

int strcmp( const char *str1, const char *str2 )
{
    int result;
    result = strcmp( str1, str2 );
    if ( result == 0 )
        printf( "%s is identical to %s
", str1, str2 );
    else if ( result < 0 )
        printf( "%s is less than %s
", str1, str2 );
    else
        printf( "%s is greater than %s
", str1, str2 );
}
```

**Output**

If the input is the strings "is this first?" and "is this before that one?" then the expected output is:

"is this first?" is greater than "is this before that one?"

strcoll() — Compare strings

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>

int strcoll(const char *string1, const char *string2);
```

General description

Compares the string pointed to by `string1` against the string pointed to by `string2`, both interpreted according to the information in the LC_COLLATE category of the current locale.

Returned value

`strcoll()` returns a value indicating the relationship between the strings, as listed below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td>string pointed to by <code>string1</code> less than string pointed to by <code>string2</code></td>
</tr>
<tr>
<td>= 0</td>
<td>string pointed to by <code>string1</code> equivalent to string pointed to by <code>string2</code></td>
</tr>
<tr>
<td>&gt; 0</td>
<td>string pointed to by <code>string1</code> greater than string pointed to by <code>string2</code></td>
</tr>
</tbody>
</table>

Notes:

1. The `strcoll()` function may need to allocate additional memory to perform the comparison algorithm specified in the LC_COLLATE. If the memory request cannot be satisfied (by `malloc()`), `strcoll()` fails.
2. If the locale supports double-byte characters (`MB_CUR_MAX` specified as 4), the `strcoll()` function validates the multibyte characters, whereas previously the `strcoll()` function did not validate the string. The `strcoll()` function will fail if the string contains invalid multibyte characters.
3. If `MB_CUR_MAX` is specified as 4, but the charmap file does not specify the DBCS characters, the DBCS characters will collate after the single-byte characters.

Example

```c
CELEBS37

/* CELEBS37
   This example compares the two strings passed to main.
*/

#include <stdio.h>
#include <string.h>

int main(int argc, char ** argv)
```

Chapter 3. Library functions 2055
{ int result;
    if ( argc != 3 ) {
        printf( "Usage: %s string1 string2\n", argv[0] );
    } else {
        result = strcoll( argv[1], argv[2] );
        if ( result == 0 )
            printf( "%s" is identical to "%s"\n", argv[1], argv[2] );
        else if ( result < 0 )
            printf( "%s" is less than "%s"\n", argv[1], argv[2] );
        else
            printf( "%s" is greater than "%s"\n", argv[1], argv[2] );
    }
}

Output

If the input is the strings "firststring" and "secondstring", then the expected output is:
"firststring" is less than "secondstring"

Related information

**strncpy() — Copy string**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++ Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <string.h>

char *strncpy(char * __restrict__ string1, const char * __restrict__ string2);
```

**General description**

The `strncpy()` built-in function copies `string2`, including the ending NULL character, to the location specified by `string1`. The `string2` argument to `strncpy()` must contain a NULL character (`\0`) marking the end of the string. You cannot use a literal string for a `string1` value, although `string2` may be a literal string. If the two objects overlap, the behavior is undefined.

**Returned value**

`strncpy()` returns the value of `string1`.

**Example**

```c
CELEBS38

/* CELEBS38
   This example copies the contents of source to destination.
*/

#include <stdio.h>
#include <string.h>

#define SIZE 40

int main(void)
{
    char source[ SIZE ] = "This is the source string";
    char destination[ SIZE ] = "And this is the destination string";
    char * return_string;

    printf( "destination is originally = \"%s\"\n", destination );
    return_string = strncpy( destination, source );
    printf( "After strncpy, destination becomes \"%s\"\n", destination );
}
```

**Output**

destination is originally = "And this is the destination string"
After strncpy, destination becomes "This is the source string"

strcspn() — Compare strings

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <string.h>

size_t strcspn(const char *string1, const char *string2);
```

General description

Computes the length of the initial portion of the string pointed to by string1 that contains no characters from the string pointed to by string2.

Returned value

strcspn() returns the calculated length of the initial portion found.

Example

```
CELEBS39
/* CELEBS39
   This example uses &strcspn. to find the first occurrence of any of the characters a, x, l or e in string.
*/
#include <stdio.h>
#include <string.h>
#define SIZE 40

int main(void)
{
    char string[ SIZE ] = "This is the source string";
    char * substring = "axle";

    printf( "The first %i characters in the string "%s" \\
            are not in the " %s" \n",
            strcmp(string, substring), string, substring);
    strcspn(string, substring);
}
```

Output

The first 10 characters in the string "This is the source string" are not in the string "axle"

strdup() — Duplicate a string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2 Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <string.h>

char *strdup(const char *string);
```

General description

The strdup() function creates a duplicate of the string pointed to by `string`.

Returned value

If successful, strdup() returns a pointer to a new string which is a duplicate of `string`.

Otherwise, strdup() returns a NULL pointer.

Note: The caller of strdup() should free the storage obtained for the string.

Error Code    Description
---           ---
ENOMEM        Insufficient storage space is available.

<td></td>
</tr>
<tr>
<td>C99</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#include <string.h>
char *strerror(int errnum);
```

#### General description

Maps the error number in `errnum` to an error message string. The `errnum` must be a valid `errno` value.

This function does not produce a locale-dependent error message string.

#### Returned value

`strerror()` returns a pointer to the string, which may be overwritten by a subsequent call to `strerror()`.

**Note:** Do not allow the content of this string to be modified by the program.

#### Example

```c
/* This example opens a file and prints a run-time error message if an error occurs. */
#include <stdio.h>
#include <string.h>
#include <errno.h>

int main(void)
{
    FILE *stream;
    
    if ((stream = fopen("myfile.dat", "r")) == NULL)
        printf("%s \n", strerror(errno));
}
```

#### Related information

strerror_r() — Get copy of runtime error message

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _UNIX03_SOURCE
#include <string.h>

int strerror_r(int errnum, char *strerrbuf, size_t buflen);
```

General description

strerror_r() maps the error number in `errnum` to an error message string and copies the message string into the buffer pointed to by `strerrbuf` with length `buflen`. If the length of the message string is greater than or equal to `buflen`, `strerror_r()` copies the first `buflen`-1 characters of the message string into `strerrbuf`, terminates `strerrbuf` with a null character (\0) and returns ERANGE. The error number must be a valid `errno` value.

This function does not produce a locale-dependent error message string.

Returned value

If successful, `strerror_r()` returns 0.

If unsuccessful, `strerror_r()` returns an error number to indicate the error.

- EINVAL – The value of `errnum` is not a valid error number.
- ERANGE – Insufficient storage was supplied via `strerrbuf` and `buflen` to contain the generated message string.

strfmon

strfmon() — Convert monetary value to string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _XOPEN_SOURCE
#include <monetary.h>

ssize_t strfmon(char * __restrict__ s, size_t maxsize,
    const char * __restrict__ format, ...);
```

General description

strfmon() produces a formatted monetary output string from a double argument. It has been extended to determine floating-point argument format (hexadecimal floating-point or IEEE Binary Floating-Point) using the __isBFP() function.

**Note:** In IEEE Binary Floating-Point mode, denormal, infinity and NaN argument values are out of range.

Places characters into the array pointed to by *s as controlled by the string pointed to by *format. No more than maxsize characters are placed into the array.

The character string *format* contains two types of objects: plain characters, which are copied to the output array, and directives, each of which results in the fetching of zero or more arguments that are converted and formatted. The results are undefined if there are insufficient arguments for the *format*. If the *format* is exhausted while arguments remain, the excess arguments are simply ignored. If objects pointed to by *s* and *format* overlap, the behavior is undefined.

The directive (conversion specification) consists of the following sequence:

1. A % character
2. Optional flags: =f, ^, !, then +, C, or ( 
3. Optional field width (may be preceded by w
4. Optional left precision: #n
5. Optional right precision: .p
6. Required conversion character to indicate what conversion should be performed: i or n

Each directive is replaced by the appropriate characters, as described in the following list:

- %i The double argument is formatted according to the locale’s international currency format (for example, in USA: USD 1,234.56). An @euro codeset modifier can be used to request “EUR” instead of a national 4-character monetary string.
- %n The double argument is formatted according to the locale’s national
currency format (for example, in USA: $1,234.56). An @euro codeset modifier can be used to get <euro-sign> instead of <currency>.

%% is replaced by %. No argument is converted.

The following optional conversion specifications may immediately follow the initial % of a directive:

=f A flag, used in conjunction with the maximum digits specification #n (see below), specifies that the character f should be used as the numeric fill character. The default numeric fill character is the space character. This option does not affect the other fill operations that always use space as the fill character.

^ A flag. Do not format the currency amount with thousands grouping characters. The default is to insert the grouping characters if defined for the current locale.

Note: The code point for the ^ character will be determined according to the current LC_SYNTAX category.

+ | C | ( A flag, specifies the style of representing positive and negative currency amounts. Only one of +, C, or ( may be specified. If + is specified, the locale's equivalent of + and − are used (for example, in USA: the empty (NULL) string if positive and - if negative). If C is specified, the locale's equivalent of DB for negative and CR for positive are used. If ( is specified, the locale's equivalent of enclosing negative amounts within parentheses is used. If this option is not included, a default specified by the current locale is used.

[−]w The field width. The decimal digit string w specifies a minimum field width in which the result of the conversion is right-justified (or left-justified if the optional flag "−" is specified).

#n The left precision. The decimal digit string n specifies the maximum number of digits expected to be formatted to the left of the radix character. This option can be used to keep the formatted output from multiple calls to the strfmon() aligned in the same columns. It can also be used to fill unused positions with a special character as in $***123.45. This option causes an amount to be formatted as if it has the number of digits specified by n. If more digit positions are required than the number specified, conversion specification is ignored. Digit positions in excess of those actually required are filled with the numeric fill character. (See the =f specification above.)

If the thousands grouping is enabled, the behavior is:
1. Format the number as if it is an n digit number.
2. Insert fill characters to the left of the leftmost digit (for example, $0001234.56 or $***1234.56)
3. Insert the separator character (for example, $0,001,234.56 or $*,**1,234.56)
4. If the fill character is not the digit zero, the separators are replaced by the fill character (for example, $****1,234.56).

To ensure alignment, any characters appearing before or after the number in the formatted output such as currency or sign symbols are padded as necessary with space characters to make their positive and negative formats an equal length.
strfmon

**Note:** The code point for the # character (in #n) will be determined according to the current LC_SYNTAX category.

.p  The right precision. The decimal digit string p specifies the number of digits after the radix character. If the value of the precision p is zero, no radix character appears. If this option is not included, a default specified by the current locale is used. The amount being formatted is rounded to the specified number of digits before formatting.

!  A flag used to suppress the currency symbol from the output conversion.

**Note:** The code point for the ! character is determined according to the current LC_SYNTAX category.

The LC_MONETARY category of the program’s locale affects the behavior of this function including the monetary radix character (which is different from the numeric radix character affected by the LC_NUMERIC category), the thousands (or alternative grouping) separator, the currency symbols and formats. The international currency symbol must be in accordance with those specified in ISO4217 Codes for the representation of currencies and funds.

Formatting choices are indicated in the LC_MONETARY category for the output of both national and international monetary quantities. The national format is determined by the settings of p_cs_precedes, n_cs_precedes, p_sign_posn, n_sign_posn, p_sep_by_space, and n_sep_by_space. An equivalent set of members for international formats are added to conform with the ISO/IEC standard. See "locale.h" on page 40 for more information on international formats.

The following tables show expected results for the various combinations of sep_by_space and sign_posn. All examples are based on a positive monetary quantity of 123.00, positive sign of ‘+’, and currency symbol of ‘$’. Note that formatting rules are equivalent for negative and non-negative values as well as for national and international formats.

**Table 51. Monetary formats when cs_precedes = 1**

<td></td>
</tr>
</tbody>
</table>

**cs_precedes**

0  The currency symbol follows the value.

1  The currency symbol precedes the value.

**sep_by_space**
strfmon

0 No space separates the currency symbol and value.
1 If the currency symbol and sign string are adjacent, a space
separates them from the value; otherwise, a space separates the
currency symbol from the value.
2 If the currency symbol and sign string are adjacent, a space
separates them; otherwise, a space separates the sign string from
the value.

sign_posn

0 Parentheses surround the quantity and currency_symbol or
int_curr_symbol.
1 The sign string precedes the quantity and currency_symbol or
int_curr_symbol.
2 The sign string succeeds the quantity and currency_symbol or
int_curr_symbol.
3 The sign string immediately precedes the currency_symbol or
int_curr_symbol.
4 The sign string immediately succeeds the currency_symbol or
int_curr_symbol.

Returned value

If the total number of resulting bytes including the terminating NULL character is not
more than maxsize, strfmon() returns the number of bytes placed into the array
pointed to by s, not including the terminating NULL character.

If unsuccessful, the contents of the array are indeterminate, strfmon() returns -1,
and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2BIG</td>
<td>Conversion stopped due to lack of space in the buffer</td>
</tr>
</tbody>
</table>

Example

CELEBS41

```c
/* CELEBS41 */
#include <locale.h>
#include <monetary.h>
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    char string[100]; /* hold the string returned from strfmon() */
    double money = 1234.56;

    if (setlocale(LC_ALL, "En_US") == NULL) {
        printf("Unable to setlocale().\n");
        exit(1);
    }

    strfmon(string, 100, "%i", money);
    printf("%s\n", string);
    strfmon(string, 100, "%n", money);
    printf("%s\n", string);
}
```
Example

The following example shows euro currency support:

```c
/* EUROSAMP
   This example sets the locale to Fr_BE.IBM-1148
   and Fr_BE.IBM-1148@euro and prints a value with
   the locales national and international currency
   format.
*/
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>
int main(void)
{
    char string[100];
    double money = 1234.56;
    if (setlocale(LC_ALL,"Fr_BE.IBM-1148") == NULL) {
        printf("Unable to setlocale().\n");
        exit(1);
    }
    strfmon(string,100,"%i",money);
    printf("%s\n",string);
    strfmon(string,100,"%n",money);
    printf("%s\n",string);
    if (setlocale(LC_ALL,"Fr_BE.IBM-1148@euro") == NULL) {
        printf("Unable to setlocale().\n");
        exit(1);
    }
    strfmon(string,100,"%i",money);
    printf("%s\n",string);
    strfmon(string,100,"%n",money);
    printf("%s\n",string);
    return 0;
}
```

Output

1.234,56 BEF
1.234,56 BF
1.234,56 EUR
1.234,56 <euro-sign>

</tr>
</tbody>
</table>

Format

```c
#include <time.h>

size_t strftime(char *__restrict__ dest, size_t maxsize, const char *__restrict__ format, const struct tm *__restrict__ timeptr);
```

General description

Places characters into the array pointed to by `dest` according to the string pointed to by `format`. The format string is a multibyte character string which contains:

- Conversion specification characters
- Ordinary multibyte characters, which are copied into an array unchanged.

The characters that are converted are determined by the LC_CTYPE category of the current locale and by the values in the time structure pointed to by `timeptr`. The time structure pointed to by `timeptr` is usually obtained by calling the `gmtime()` or `localtime()` function.

Table 53. Conversion Specifiers Used by strftime()

</tbody>
</table>

If data has the form of a directive, but is not one of the above, the characters following the % are copied to the output.

The behavior is undefined when objects being copied overlap. maxsize specifies the maximum number of characters that can be copied into the array.
If strftime() is called by a non-POSIX application, it obtains appropriate time zone name information from LC_TOD locale category. Time zone name defaults to STD for Standard time name, DST for Daylight Savings time name, or UTC for Coordinated Universal Time (UTC), name, as appropriate, if time zone name information is unspecified in the current LC_TOD locale category.

**Note:** The strftime() function requires time zone name information to convert the %Z conversion specifier. It is obtained as follows:

- The strftime() functions calls the tzset() function to obtain time zone information by parsing the TZ (POSIX) or _TZ (non_POSIX) environment variable or from the current LC_TOD locale category. If the tm structure input to strftime() was produced by calling localtime(), strftime() converts %Z to the Standard or Daylight Savings name characters specified by the TZ environment variable or LC_TOD category (if TZ cannot be found or parsed).

- When neither TZ nor _TZ is defined, the current locale is interrogated for time zone information. If neither TZ nor _TZ is defined and LC_TOD time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock. For more information about customizing a time zone to work with local time, see `Customizing a time zone` in [z/OS XL C/C++ Programming Guide](#).

The tm_isdst flag in the time structure input to strftime() determines whether %Z is replaced by the Standard or Daylight Savings name characters. If Standard or Daylight Savings name characters are not available in the current LC_TOD locale category or from parsing TZ, strftime() uses the characters STD for Standard or DST for Daylight Savings time name.

If the tm structure input to strftime() was produced by the gmtime() function, strftime() replaces %Z by UCTNAME characters specified in the current LC_TOD locale category or by UTC if UCTNAME is not specified.

### Returned value

If successful, strftime() returns the number of characters (bytes) placed into the array, not including the terminating NULL character.

If unsuccessful, strftime() returns 0 and the content of the string is indeterminate.

### Example

**CELEBS42**

```c
/* CELEBS42

This example places characters into the array dest and prints the resulting string.
*/

#include <stdio.h>
#include <time.h>

int main(void)
{
    char dest[70];
    int ch;
    time_t temp;
    struct tm *timeptr;
```
temp = time(NULL);
timeptr = localtime(&temp);
ch = strftime(dest,sizeof(dest)−1,"Today is %A,
" %b %d. \n Time: %I:%M %p", timeptr);
printf("%d characters placed in string to make: \n %s", ch, dest);
}

Output
44 characters placed in string to make:

Today is Friday, Jun 16.
Time: 03:07 PM

</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>
size_t strlen(const char *string);
```

General description

The strlen() built-in function determines the length of string pointed to by `string`, excluding the terminating NULL character.

Returned value

`strlen()` returns the length of `string`.

Example

```c
CELEBS43
/* CELEBS43
   This example determines the length of the string that is
   passed to main.
*/
#include <stdio.h>
#include <string.h>
int main(int argc, char **argv)
{
    if ( argc != 2 )
        printf( "Usage: %s string\n", argv[0] );
    else
        printf( "Input string has a length of %i\n", strlen( argv[1] ));
}
```

Output

If the input is the string: "How long is this string?", then the expected output is:

Input string has a length of 24

strncasecmp

strncasecmp() — Case-insensitive string comparison

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

int strncasecmp(const char *string1, const char *string2, size_t n);
```

General description

The `strncasecmp()` function compares, while ignoring differences in case, the string pointed to by `string1` to the string pointed to by `string2`. At most `n` characters will be compared.

The string arguments to the function should contain a NULL character (\0) marking the end of the string.

The `strncasecmp()` function is locale-sensitive.

Returned value

`strncasecmp()` returns a value indicating the relationship between the strings, while ignoring case, as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td>String pointed to by <code>string1</code> is less than string pointed to by <code>string2</code>.</td>
</tr>
<tr>
<td>= 0</td>
<td>String pointed to by <code>string1</code> is equal to string pointed to by <code>string2</code>.</td>
</tr>
<tr>
<td>&gt; 0</td>
<td>String pointed to by <code>string1</code> is greater than string pointed to by <code>string2</code>.</td>
</tr>
</tbody>
</table>

There are no errno values defined.

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>
char *strncat(char * __restrict__ string1, const char * __restrict__ string2, size_t count);
```

General description

The `strncat()` built-in function appends the first `count` characters of `string2` to `string1` and ends the resulting string with a NULL character (\0). If `count` is greater than the length of `string2`, `strncat()` appends only the maximum length of `string2` to `string1`. The first character of the appended string overwrites the terminating NULL character of the string pointed to by `string1`.

If copying takes place between overlapping objects, the behavior is undefined.

Returned value

`strncat()` returns the value `string1`, the concatenated string.

Example

```c
CELEBS44
/* CELEBS44
   This example demonstrates the difference between &strcat. and  
   &strncat..  
   &strcat. appends the entire second string to the first, whereas &strncat. appends only the specified number of 
   characters in the second string to the first.
*/
#include <stdio.h>
#include <string.h>

#define SIZE 40

int main(void)
{
    char buffer1[SIZE] = "computer";
    char * ptr;
    /* Call strcat with buffer1 and " program" */
    ptr = strcat( buffer1, " program" );
    printf( "strcat : buffer1 = \"ss\"\n", buffer1 );
    /* Reset buffer1 to contain just the string "computer" again */
```
**strncat**

```c
memset( buffer1, '\0', sizeof( buffer1 ));
ptr = strcpy( buffer1, "computer" );

/* Call strncat with buffer1 and " program" */
ptr = strncat( buffer1, " program", 3 );
printf("strncat: buffer1 = \"ss\"\n", buffer1 );
}
```

**Output**
- `strcat`: buffer1 = "computer program"
- `strncat`: buffer1 = "computer pr"

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Format

```c
#include <string.h>

int strncmp(const char *string1, const char *string2, size_t count);
```

### General description

The `strncmp()` built-in function compares at most the first `count` characters of the string pointed to by `string1` to the string pointed to by `string2`.

The string arguments to the function should contain a NULL character (\0) marking the end of the string.

The relation between the strings is determined by the sign of the difference between the values of the leftmost first pair of characters that differ. The values depend on character encoding. This function is *not* locale sensitive.

### Returned value

`strncmp()` returns a value indicating the relationship between the substrings, as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td>String pointed to by <code>substring1</code> less than string pointed to by <code>substring2</code></td>
</tr>
<tr>
<td>= 0</td>
<td>String pointed to by <code>substring1</code> equivalent to string pointed to by <code>substring2</code></td>
</tr>
<tr>
<td>&gt; 0</td>
<td>String pointed to by <code>substring1</code> greater than string pointed to by <code>substring2</code></td>
</tr>
</tbody>
</table>

### Example

**CELEBS45**

```c
/* CELEBS45

   This example demonstrates the difference between &strcmp.
   and &strncmp.

*/
#include <stdio.h>
#include <string.h>

#define SIZE 10

int index = 3;

int main(void)
{
int result;
char buffer1[SIZE] = "abcdefg";
char buffer2[SIZE] = "abcfg";
void print_result( int, char *, char * );

result = strcmp( buffer1, buffer2 );
printf( " strcmp: compares each character\n" );
print_result( result, buffer1, buffer2 );

result = strncmp( buffer1, buffer2, index);
printf( "\n\nstrncmp: compares only the first %i characters\n", index );
print_result( result, buffer1, buffer2 );
}

void print_result( int res, char * p_buffer1, char * p_buffer2 )
{
    if ( res == 0 )
        printf( "first %i characters of \"%s\" is identical to \"%s\"\n",
            index, p_buffer1, p_buffer2);
    else if ( res < 0 )
        printf( \"\"%s\" is less than \"%s\", p_buffer1, p_buffer2 );
    else
        printf( \"\"%s\" is greater than \"%s\", p_buffer1, p_buffer2 );
}

Output

strcmp: compares each character
"abcdefg" is less than "abcfg"

strncmp: compares only the first 3 characters
first 3 characters of "abcdefg" is identical to "abcfg"

<td>XPG4.2</td>
<td>both</td>
</tr>
<tr>
<td>C99</td>
<td>both</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
</tr>
</tbody>
</table>

### Format

```c
#include <string.h>
char *strncpy(char * __restrict__ string1, const char * __restrict__ string2, size_t count);
```

### General description

The `strncpy()` built-in function copies at most `count` characters of `string2` to `string1`. If `count` is less than or equal to the length of `string2`, a NULL character (`\0`) is not appended to the copied string. If `count` is greater than the length of `string2`, the `string1` result is padded with NULL characters (`\0`) up to length `count`. If copying takes place between objects that overlap, the behavior is undefined.

### Returned value

`strncpy()` returns `string1`.

### Example

```c
CELEBS46
/* CELEBS46

This example demonstrates the difference between &strcpy.
and &strncpy.

*/
#include <stdio.h>
#include <string.h>
#define SIZE 40

int main(void)
{
    char source[ SIZE ] = "123456789";
    char source1[ SIZE ] = "123456789";
    char destination[ SIZE ] = "abcdefg";
    char destination1[ SIZE ] = "abcdefg";
    char * return_string;
    int index = 5;

    /* This is how strcpy works */
    printf( "destination is originally = '%s'\n", destination );
    return_string = strcpy( destination, source );
    printf( "After strcpy, destination becomes '%s'\n\n", destination );

    /* This is how strncpy works */
    printf( "destination is originally = '%s'\n", destination );
    return_string = strncpy( destination1, source, index );
    printf( "After strncpy, destination becomes '%s'\n\n", destination );

    return 0;
}
```

---

Chapter 3. Library functions 2081
strncpy

```c
printf( "destination1 is originally = '%s'\n", destination1 );
return_string = strncpy( destination1, source1, index );
printf( "After strncpy, destination1 becomes '%s'\n", destination1 );
```

Output

destination is originally = 'abcdefg'
After strcpy, destination becomes '123456789'

destination1 is originally = 'abcdefg'
After strncpy, destination1 becomes '12345fg'

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>
char *strpbrk(const char *string1, const char *string2);
```

General description

Locates the first occurrence in the string pointed to by `string1` of any character from the string pointed to by `string2`.

Returned value

If successful, `strpbrk()` returns a pointer to the character.

If `string1` and `string2` have no characters in common, `strpbrk()` returns a NULL pointer.

Example

**CELEBS47**

```c
/* CELEBS47

   This example returns a pointer to the first occurrence in the array string of either a or b.

   */

#include <stdio.h>
#include <string.h>

int main(void)
{
   char *result, *string = "A Blue Danube";
   char *chars = "ab";

   result = strpbrk(string, chars);
   printf("The first occurrence of any of the characters "\%s\" in "\n       "\%s\" is "\%s\n", chars, string, result);
}
```

Output

The first occurrence of any of the characters "ab" in "A Blue Danube" is "anube"
strpbrk

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <time.h>

char *strptime(const char * __restrict__ buf, const char * __restrict__ fmt, struct tm * __restrict__ tm);
```

General description

The strptime() function converts the character string pointed to by `buf` to values that are stored in the `tm` structure pointed to by `tm`, using the format specified by `fmt`. Only the fields in the `tm` structure for which there is a corresponding format item in `fmt` are updated by the strptime() function. Therefore, for a valid and conforming `tm` structure, provide strptime() with a format and data that completely specify the date and time being converted.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The format is composed of zero or more directives. Each directive is composed of one of the following: one or more white space characters (as specified by the isalnum() to isxdigit() function), an ordinary character other than a percent sign (%) or white space character, or a conversion specification. Each conversion specification is composed of a percent sign followed by a conversion character that specifies the replacement required. There must be a white space character or other nonalphanumeric character between any two conversion specifications.

Table 54. Conversion Specifiers Used by strptime()

<table>
<thead>

</tr>
</tbody>
</table>

A directive composed of white space characters is executed by scanning input up to the first character that is not white space (which remains unscanned) or until no more characters can be scanned.

A directive that is an ordinary character is executed by scanning the next character from the buffer. If the character scanned from the buffer differs from the one comprising the directive, the directive fails, and the differing and subsequent characters remain unscanned.

A series of directives composed or %n, %l, white space characters or any combination is executed by scanning up to the first character that is not white space (which remains unscanned), or until no more characters can be scanned.

Any other conversion specification is executed by scanning characters until a character matching the next directive is scanned, or until no more characters can be scanned. These characters, excepting the one matching the next directive, are then compared to the locale values associated with the conversion specifier. If a match is found, values for the appropriate tm structure members are set to values...
strptime

corresponding to the locale information. Case is ignored when matching items in
buf, such as month or weekday names. If no match is found, strptime() fails and no
more characters are scanned.

Returned value

If successful, strptime() returns a pointer to the character following the last
character parsed.

If unsuccessful, strptime() returns a NULL pointer.

Example

CELEBS48

/* CELEBS48 */
#include <stdio.h>
#include <stdlib.h>
#include <time.h>
#include <localdef.h>

int main(void)
{
    struct tm xmas;

    if (strptime("12/25/93 13:30:00", "%D %T", &xmas) == NULL) {
        printf("strptime() failed.\n");
        exit(1);
    }

    printf("tm_sec =%3d\n", xmas.tm_sec);
    printf("tm_min =%3d\n", xmas.tm_min);
    printf("tm_hour =%3d\n", xmas.tm_hour);
    printf("tm_mday =%3d\n", xmas.tm_mday);
    printf("tm_mon =%3d\n", xmas.tm_mon);
    printf("tm_year =%3d\n", xmas.tm_year);
    printf("tm_wday =%3d\n", xmas.tm_wday);
    printf("tm_yday =%3d\n", xmas.tm_yday);
}

Output

tm_sec = 0
tm_min = 30
tm_hour = 13
tm_mday = 25
tm_mon = 11
tm_year = 93
tm_wday = 0
print("tm_yday =%3d\n", xmas.tm_yday);

<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>
char *strrchr(const char *string, int c);
```

General description

The strrchr() function finds the last occurrence of `c` (converted to a char) in `string`. The ending NULL character is considered part of the `string`.

Returned value

If successful, strrchr() returns a pointer to the last occurrence of `c` in `string`.

If the given character is not found, strrchr() returns a NULL pointer.

Example

```c
CELEBS49
/* CELEBS49

   This example compares the use of &strchr. and &strrchr.
   It searches the string for the first and last occurrence of
   p in the string.

   */
#include <stdio.h>
#include <string.h>
#define SIZE 40

int main(void)
{
    char buf[SIZE] = "computer program";
    char * ptr;
    int ch = 'p';

    /* This illustrates strchr */
    ptr = strchr( buf, ch );
    printf( "The first occurrence of %c in '%s' is '%s'\n", ch, buf, ptr );

    /* This illustrates strrchr */
    ptr = strrchr( buf, ch );
    printf( "The last occurrence of %c in '%s' is '%s'\n", ch, buf, ptr );
}
```

Output
strrchr

The first occurrence of p in 'computer program' is 'puter program'
The last occurrence of p in 'computer program' is 'program'

</tbody>
</table>

Format

```c
#include <string.h>
size_t strspn(const char *string1, const char *string2);
```

General description

Calculates the length of the maximum initial portion of the string pointed to by `string1` that consists entirely of the characters contained in the string pointed to by `string2`.

Returned value

`strspn()` returns the length of the substring found.

Example

```c
CELEBS50
/* CELEBS50

This example finds the first occurrence in the array string of a character that is neither an a, b, nor c. Because the string in this example is cabbage, &strspn. returns 5, the length of the segment of cabbage before a character that is not an a, b or c.

*/
#include <stdio.h>
#include <string.h>

int main(void)
{
    char * string = "cabbage";
    char * source = "abc";
    int index;

    index = strspn( string, "abc" );
    printf( "The first %d characters of %"s are found in %"s\n", index, string, source );
}
```

Output

The first 5 characters of "cabbage" are found in "abc"
strspn

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <string.h>
char *strstr(const char *string1, const char *string2);
```

**General description**

Finds the first occurrence of the string pointed to by `string2` (excluding the NULL character) in the string pointed to by `string1`.

**Returned value**

If successful, `strstr()` returns a pointer to the beginning of the first occurrence of `string2` in `string1`.

If `string2` does not appear in `string1`, `strstr()` returns NULL.

If `string2` points to a string with zero length, `strstr()` returns `string1`.

**Example**

```c
CELEBS51
/* CELEBS51
   This example locates the string "haystack" in the string "needle in a haystack".
*/
#include <stdio.h>
#include <string.h>

int main(void)
{
    char *string1 = "needle in a haystack";
    char *string2 = "haystack";
    char *result;
    result = strstr(string1, string2);
    /* Result = a pointer to "haystack" */
    printf("%s\n", result);
}
```

**Output**

haystack

strtocoll() — Return collating element for string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <collate.h>

collel_t strtocoll(char *s);
```

General description

Determines whether the string pointed to by `s` represents the valid element as defined in the LC_COLLATE category of the current locale.

If a string pointed to by `s` contains only one character, the collating element representing this character always exists. Otherwise, a valid collating element exists if the LC_COLLATE category contains the definition of a sequence of characters that collate as one for the purpose of culture-sensitive string comparison. This many-characters-to-one-collating element relation is also called `many-to-one` mapping.

Returned value

The type `collel_t` represents the collating elements.

If many-to-one mapping is not defined in the LC_COLLATE of the current locale, `strtocoll()` returns `(collel_t)-1`.

Also, if the string is not a valid collating element or is of zero length, `strtocoll()` returns `(collel_t)-1`.

Example

```c
CELEBS52
/* CELEBS52

This example uses the strtocoll() function to get the collel_t value for the start and end collating-elements for the collrange() function.

*/
#include <stdio.h>
#include <stdlib.h>
#include <locale.h>
#include <collate.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
collel_t s, e, *rp;
int i;

setlocale(LC_ALL, "");
if ((s = strtocoll(argv[1])) == (collel_t)-1) {
    printf("ss collating element not defined\n", argv[1]);
    exit(1);
```
if ((e = strtocoll(argv[2])) == (collel_t)-1) {
    printf("%s collating element not defined\n", argv[2]);
    exit(1);
}
if ((i = collrange(s, e, &rp)) == -1) {
    printf("Invalid range for %s to %s\n", argv[1], argv[2]);
    exit(1);
}
for (; i-- > 0; rp++) {
    if (ismccollel(*rp))
        printf("%s' ", colltostr(*rp));
    else if (iswprint(*rp))
        printf("%lc' ", *rp);
    else
        printf("%x' ", *rp);
}

<td>both</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <stdlib.h>

double strtod(const char * __restrict__ nptr, char ** __restrict__ endptr);
```

**General description**

Converts a part of a character string, pointed to by `nptr`, to a double. The parameter `nptr` points to a sequence of characters that can be interpreted as a numerical value of the type `double`.

See the “`fscanf` Family of Formatted Input Functions” on page 707 for a description of special infinity and NaN sequences recognized by z/OS formatted input functions, including `atof()` and `strtod()` in IEEE Binary Floating-Point mode.

The `strtod()` function breaks the string into three parts:

1. A sequence of white space characters (as specified for the current locale, see `isspace()`)
2. A subject sequence interpreted as a floating-point constant or representing infinity or a NaN.
3. A sequence of unrecognized characters (including a NULL character).

The subject string is the longest string that matches the expected form.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent part. Where radix character is the character that separates the integer part of a number from the fractional part.
- A 0x or 0X, then a non-empty sequence of hexadecimal digits optionally containing a radix character, then an optional binary exponent part. Where radix character is the character that separates the integer part of a number from the fractional part.
- One of INF or INFINITY, ignoring case.
- One of NANQ or NANQ(n-char-sequence), ignoring case.
- One of NANS or NANS(n-char-sequence), ignoring case.
- One of NAN or NAN(n-char-sequence), ignoring case.

The pointer to the last string successfully converted is stored in the object pointed to by `endptr`, provided that `endptr` is not a NULL pointer. If the subject string is
empty or it does not have the expected form, then no conversion is performed. The value of *nptr* is stored in the object pointed to by *endptr*.

**Returned value**

If successful, *strtod()* returns the value of the floating-point number.

The double value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking the *strtod()* function. This function uses __isBFP() to determine the floating-point mode of the invoking thread.

In an overflow, *strtod()* returns ±HUGE_VAL. In an underflow, it returns 0. If no conversion is performed, *strtod()* returns 0. In both cases, errno is set to ERANGE, depending on the base of the value.

**Example**

```c
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    char *string, *stopstring;
    double x;

    string = "3.1415926This stopped it";
    x = strtod(string, &stopstring);
    printf("strtod = %f\n", x);
    printf(" Stopped scan at %s\n", stopstring);

    string = "100ergs";
    x = strtod(string, &stopstring);
    printf("strtod = %f\n", x);
    printf(" Stopped scan at " in stopstring);
}
```

**Output**

string = 3.1415926This stopped it
strtod = 3.141593
Stopped scan at This stopped it

string = 100ergs
strtod = 100.000000
Stopped scan at ergs

**strtod32, strtod64, strtod128**

**strtod32(), strtod64(), strtod128() — Convert character string to decimal floating point**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.8</td>
</tr>
</tbody>
</table>

**Format**

```c
#define __STDC_WANT_DEC_FP__
#include <stdlib.h>

 Decimal32 strtod32(const char * __restrict__ nptr, char ** __restrict__ endptr);
 Decimal64 strtod64(const char * __restrict__ nptr, char ** __restrict__ endptr);
 Decimal128 strtod128(const char * __restrict__ nptr, char ** __restrict__ endptr);
```

**General description**

The `strtod32()`, `strtod64()`, and `strtod128()` functions convert the initial portion of the string pointed to by `nptr` to `_Decimal32`, `_Decimal64`, and `_Decimal128` representation, respectively.

First, they decompose the input string into three parts:

1. An initial, possibly empty, sequence of white-space characters (as specified by the `isspace()` function).
2. A subject sequence resembling a floating-point constant or representing an infinity or NaN.
3. A final string of one or more unrecognized characters, including the terminating null character of the input string.

Then, they attempt to convert the subject sequence to a floating-point number, and return the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- a nonempty sequence of decimal digits optionally containing a decimal-point character, then an optional exponent part
- INF or INFINITY, ignoring case
- NAN, NAN(n-char-sequence), NANQ, NANQ(n-char-sequence), NANS, or NANS(n-char-sequence), ignoring case in the NAN, NANQ, or NANS part, where n-char-sequence is one or more decimal numeric digits.

**Note:** If the input string is not one of these forms (for example “INFINITE”), the output results are undefined.

The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is not of the expected form.

A character sequence NAN, NANQ, NAN(n-char-sequence), or NANQ(n-char-sequence) is interpreted as a quiet NaN. A character sequence of NANS, or NANS(n-char-sequence), is interpreted as a signalling NaN. A character
sequence INF or INFINITY is interpreted as an infinity. A character sequence NAN, NAN(), or NAN(n-char-sequence) is interpreted as a quiet NaN. A character sequence of NANS, NANS(), or NANS(n-char-sequence), is interpreted as a signalling NaN.

A pointer to the final string is stored in the object pointed to by endptr, provided that endptr is not a null pointer.

The converted value keeps the same precision as the input if possible, and the value may be denormalized. Otherwise, rounding may occur. Rounding happens after any negation.

In other than the “C” locale, additional locale-specific subject sequence forms are accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of nptr is stored in the object pointed to by endptr, provided that endptr is not a null pointer.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nptr</td>
<td>NULL, or a pointer to a output pointer field that is filled in with the address of the first character in the input string that is not used in the conversion.</td>
</tr>
</tbody>
</table>

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

These functions return the converted value, if any. If no conversion could be performed, the value +0.E0DF, +0.E0DD, or +0.E0DL is returned. If the correct value is outside the range of representable values, plus or minus HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128 is returned (according to the return type and sign of the value), and errno is set to ERANGE. If the result underflows, these functions return a value whose magnitude is no greater than the smallest normalized positive number in the return type. No signal is raised at the point of returning a signaling NaN.

<table>
<thead>
<tr>
<th>errno</th>

<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <stdlib.h>

float strtof(const char *__restrict__ nptr, char *__restrict__ endptr);
```

General description

strtof() converts a part of a character string, pointed to by `nptr`, to float. The parameter `nptr` points to a sequence of characters that can be interpreted as a numerical value of the type float.

The `strtof()` function breaks the string into three parts:

1. An initial, possibly empty, sequence of white-space characters (as specified by `isspace()`).
2. A subject sequence interpreted as a floating-point constant or representing infinity or a NAN.
3. A final string of one or more unrecognized characters, including the terminating null byte of the input string.

The function then attempts to convert the subject string into the floating-point number, and returns the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent part. A radix character is the character that separates the integer part of a number from the fractional part.
- A 0x or 0X, a non-empty sequence of hexadecimal digits optionally containing a radix character, then a base 2 decimal exponent part with a p or P as prefix, a plus or minus sign, then a sequence of at least one decimal digit. (Example `[-]0xh.hhhhp+/d`). A radix character is the character that separates the integer part of a number from the fractional part.
- One of INF or INFINITY, ignoring case.
- One of NANQ or NANQ(n-char-sequence), ignoring case.
- One of NANS or NANS(n-char-sequence), ignoring case.
- One of NAN or NAN(n-char-sequence), ignoring case.

See the "scanf Family of Formatted Input Functions" for a description of special infinity and NaN sequences recognized by z/OS formatted input functions in IEEE Binary Floating-Point mode.
strtof

The pointer to the last string successfully converted is stored in the object pointed to by endptr, provided that endptr is not a NULL pointer. If the subject string is empty or it does not have the expected form, then no conversion is performed. The value of nptr is stored in the object pointed to by endptr.

Returned value

If successful, strtof() returns the value of the floating-point number.

The float value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking the strtof() function. This function uses __isBFP() to determine the floating-point mode of the invoking thread.

In an overflow, strtof() returns +/-HUGE_VALF. In an underflow, it returns 0. If no conversion is performed, strtof() returns 0. In both cases, errno is set to ERANGE, depending on the base of the value.

strtoimax() — Convert character string to intmax_t integer type

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <inttypes.h>

intmax_t strtoimax(const char * __restrict__ nptr, char ** __restrict__ endptr, int base);
```

Compile requirement: Function strtoimax() requires LONGLONG to be available.

General description

The strtoimax() function converts the string nptr to an intmax_t integer type. Valid input values for base are 0 and in the range 2-36. The strtoimax() function is equivalent to strtol() and strtoll() with the only difference being that the return value is of type intmax_t. See strtol() for more information.

Returned value

If successful, strtoimax() returns the converted intmax_t value represented in the string.

If unsuccessful, strtoimax() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, strtoimax() returns INTMAX_MAX or INTMAX_MIN, according to the sign of the value. If the value of base is not supported, strtoimax() returns 0.

If unsuccessful strtoimax() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of base is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

Example

```c
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    intmax_t j;
    int base = 10;
    char *nptr, *endptr;
    nptr = "10345134932abc";
    printf("\n\n%"Intmax_t nptr = "\n\", nptr);
    j = strtoimax(nptr, &endptr, base);
    printf("\n\n%jd (%d)\n\", j, base);
    printf("\n\nStopped scan at \%s\n\", endptr);
    return 0;
}
```
strtoimax

Output
nptr = 10345134932abc
strtoimax = 10345134932(base 10)
Stopped scan at abc

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <string.h>

char *strtok(char * __restrict__ string1, const char * __restrict__ string2);
```

General description

Breaks a character string, pointed to by `string1`, into a sequence of tokens. The tokens are separated from one another by the characters in the string pointed to by `string2`.

The token starts with the first character not in the string pointed to by `string2`. If such a character is not found, there are no tokens in the string. `strtok()` returns a NULL pointer. The token ends with the first character contained in the string pointed to by `string2`. If such a character is not found, the token ends at the terminating NULL character. Subsequent calls to `strtok()` will return the NULL pointer. If such a character is found, then it is overwritten by a NULL character, which terminates the token.

If the next call to `strtok()` specifies a NULL pointer for `string1`, the tokenization resumes at the first character following the found and overwritten character from the previous call. For example:

```c
/* Here are two calls */
strtok(string," ")
strtok(NULL," ")

/* Here is the string they are processing */
    abc defg hij
   ↑ first call finds ↑
   ↑ second call starts
```

Returned value

The first time `strtok()` is called, it returns a pointer to the first token in `string1`. In later calls with the same token string, `strtok()` returns a pointer to the next token in the string. A NULL pointer is returned when there are no more tokens. All tokens are NULL-terminated.

Example

```
CELEBS54
/* CELEBS54 */
/* strtok() example: */
```
strtok

* This example parses tokens separated by commas, blanks and semicolons,
* from a string until no tokens are left. As the string is parsed,
* pointers to the the following tokens are returned by strtok(),
* and these tokens are written to stdout:
*  
*  a
*  string
*  of
*  tokens
*  
* The final call to strtok() returns NULL indicating that
* there are no more tokens.
*  
* Note that as the string is tokenized, it will be overwritten.
*  
* */

#include <stdio.h>
#include <string.h>

int main(void)
{
    char *token, string[] = "a string, of, ;; ;, tokens\0, after null terminator"
    
token = strtok(string, ", ;");
do
{    printf("token: \"%s\"\n", token);
    
while (token = strtok(NULL, ", ;"));
}

Output

token: "a string"
token: " of"
token: " 
token: "tokens"

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE 500
#include <string.h>

char *strtok_r(char *s, const char *sep, char **lasts);
```

General description

The function strtok_r() considers the NULL-terminated string `s` as a sequence of zero or more text tokens separated by spans of one or more characters from the separator string `sep`. The argument `lasts` points to a user-provided pointer which points to stored information necessary for strtok_r() to continue scanning the same string.

In the first call to strtok_r(), `s` points to a NULL-terminated string, `sep` to a NULL-terminated string of separator characters and the value pointed to by `lasts` is ignored. The function strtok_r() returns a pointer to the first character of the first token, writes a NULL character into `s` immediately following the returned token, and updates the pointer to which `lasts` points.

In subsequent calls, `s` is a NULL pointer and `lasts` will be unchanged from the previous call so that subsequent calls will move through the string `s`, returning successive tokens until no tokens remain. The separator string `sep` may be different from call to call. When no token remains in `s`, a NULL pointer is returned.

Returned value

If successful, strtok_r() returns a pointer to the token found.

When no token is found, strtok_r() returns a NULL pointer.

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <stdlib.h>

long int strtol(const char * __restrict__ nptr, char ** __restrict__ endptr, int base);
```

General description

Converts `nptr`, a character string, to a long int value.

The function decomposes the entire string into three parts:
1. A sequence of characters, which in the current locale are defined as white space characters. This part may be empty.
2. A sequence of characters interpreted as integer in some base notation. This is the subject sequence.
3. A sequence of unrecognized characters.

The base notation is determined by `base`, if base is greater than zero. If base is zero, the base notation is determined by the format of the sequence of characters that follow an optional plus—or optional minus—sign.

- 10 Sequence starts with nonzero decimal digit.
- 8 Sequence starts with 0, followed by a sequence of digits with values from 0 to 7.
- 16 Sequence starts with either 0x or 0X, followed by digits, and letters A through F or a through f.

If the base is greater than zero, the subject sequence contains decimal digits and letters, possibly preceded by either a plus or a minus sign. The letters a (or A) through z (or Z) represent values from 10 through 36, but only those letters whose value is less than the value of the base are allowed.

When you use the strtol() function, `nptr` should point to a string with the following form:

```
white space  [ + | - ]  [0-9]  [0-9a-fA-F]  [digits]
```

The pointer to the converted characters, even if conversion was unsuccessful, is stored in the object pointed to by endptr, as long as endptr is not a NULL pointer.

Returned value

If successful, strtol() returns the converted long int value.

If unsuccessful, strtol() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, strtol() returns LONG_MAX or LONG_MIN, according to the sign of the value. If the value of base is not supported, strtol() returns 0.

If unsuccessful strtol() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of base is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

Example

CELEBS55

```c
/* CELEBS55

This example converts the strings to a long.
It prints out the converted value and the substring that stopped the conversion.

*/
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    char *string, *stopstring;
    long l;
    int bs;

    string = "10110134932";
    printf("string = %s\n", string);
    for (bs = 2; bs <= 8; bs *= 2)
    {
        l = strtol(string, &stopstring, bs);
        printf("strtol = %ld (base %d)\n", l, bs);
        printf("Stopped scan at %s\n", stopstring);
    }
}
```

Output

string = 10110134932
strtol = 45 (base 2)
Stopped scan at 34932

strtol = 4423 (base 4)
Stopped scan at 4932

strtol = 2134108 (base 8)
Stopped scan at 932

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _ISOC99_SOURCE
#include <stdlib.h>

long double strtol(const char *__restrict__ nptr, char **__restrict__ endptr);
```

**General description**

`strtol()` converts a part of a character string, pointed to by `nptr`, to long double. The parameter `nptr` points to a sequence of characters that can be interpreted as a numerical value of the type long double.

The `strtol()` function breaks the string into three parts:

1. An initial, possibly empty, sequence of white-space characters (as specified by `isspace()`).
2. A subject sequence interpreted as a floating-point constant or representing infinity or NaN.
3. A final string of one or more unrecognized characters, including the terminating null byte of the input string.

The function then attempts to convert the subject string into the floating-point number, and returns the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent part. A radix character is the character that separates the integer part of a number from the fractional part.
- A 0x or 0X, a non-empty sequence of hexadecimal digits optionally containing a radix character, then a base 2 decimal exponent part with a p or P as prefix, a plus or minus sign, then a sequence of at least one decimal digit. (Example [-]0x.hhhhhp+/^-d). A radix character is the character that separates the integer part of a number from the fractional part.
- One of INF or INFINITY, ignoring case.
- One of NANQ or NANQ(n-char-sequence), ignoring case.
- One of NANS or NANS(n-char-sequence), ignoring case.
- One of NAN or NAN(n-char-sequence), ignoring case.

See the "scanf Family of Formatted Input Functions" for a description of special infinity and NaN sequences recognized by z/OS formatted input functions in IEEE Binary Floating-Point mode.
sstrtold

The pointer to the last string successfully converted is stored in the object pointed to by `endptr`, provided that `endptr` is not a NULL pointer. If the subject string is empty or it does not have the expected form, then no conversion is performed. The value of `nptr` is stored in the object pointed to by `endptr`.

Returned value

If successful, `strtold()` returns the value of the floating-point number.

The long double value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking the `strtold()` function. This function uses `__isBFP()` to determine the floating-point mode of the invoking thread.

In an overflow, `strtold()` returns +/-HUGE_VALL. In an underflow, it returns 0. If no conversion is performed, `strtold()` returns 0. In both cases, `errno` is set to ERANGE, depending on the base of the value.

</tbody>
</table>

Format

```c
#include <stdlib.h>

long long strtol(const char * __restrict__ nptr, char ** __restrict__ endptr, int base);
```

**Compile requirement:** Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

Converts `nptr`, a character string, to a signed long long value.

The function decomposes the entire string into three parts:

1. A sequence of characters, which in the current locale are defined as white space characters. This part may be empty.
2. A sequence of characters interpreted as an unsigned integer in some base notation. This is the subject sequence.
3. A sequence of unrecognized characters.

The base notation is determined by `base`, if `base` is greater than zero. If `base` is zero, the base notation is determined by the format of the sequence of characters that follow an optional plus or optional minus sign.

- 10   Sequence starts with nonzero decimal digit.
- 8    Sequence starts with 0, followed by a sequence of digits with values from 0 to 7.
- 16   Sequence starts with either 0x or 0X, followed by digits, and letters A through F or a through f.

If the base is greater than zero, the subject sequence contains decimal digits and letters, possibly preceded by either a plus or a minus sign. The letters a (or A) through z (or Z) represent values from 10 through 36, but only those letters whose value is less than the value of the base are allowed.

When you are using strtol(), `nptr` should point to a string with the following form:
**strtoll**

The pointer to the converted characters, even if conversion was unsuccessful, is stored in the object pointed to by `endptr`, as long as `endptr` is not a NULL pointer.

**Returned value**

If successful, `strtoll()` returns the converted signed long long value, represented in the string.

If unsuccessful, `strtoll()` returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, `strtoll()` returns `LLONG_MAX` (LONGLONG_MAX) or `LLONG_MIN` (LONGLONG_MIN), according to the sign of the value. If the value of base is not supported, `strtoll()` returns 0.

If unsuccessful `strtoll()` sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of base is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#include <stdlib.h>

unsigned long int strtol(const char * __restrict__ string1, char ** __restrict__ string2, int base);
```

#### General description

Converts `string1`, a character string, to an unsigned long int value.

The function decomposes the entire string into three parts:
1. A sequence of characters, which in the current locale are defined as white space characters. This part may be empty.
2. A sequence of characters interpreted as an unsigned integer in some base notation. This is the **subject sequence**.
3. A sequence of unrecognized characters.

The base notation is determined by `base`, if `base` is greater than zero. If `base` is zero, the base notation is determined by the format of the sequence of characters that follow an optional plus or optional minus sign.

- **10** Sequence starts with nonzero decimal digit.
- **8** Sequence starts with 0, followed by a sequence of digits with values from 0 to 7.
- **16** Sequence starts with either 0x or 0X, followed by digits, and letters A through F or a through f.

If the base is greater than zero, the subject sequence contains decimal digits and letters, possibly preceded by either a plus or a minus sign. The letters a (or A) through z (or Z) represent values from 10 through 36, but only those letters whose value is less than the value of the base are allowed. The function stops reading the string at the first character that it cannot recognize as part of a number. This character can be the first numeric character greater than or equal to the base. The `strtol()` function sets `string2` to point to the end of the resulting output string if a conversion is performed and provided that `string2` is not a NULL pointer.

When you are using the `strtol()` function, `string1` should point to a string with the following form:
If `base` is in the range of 2-36, it becomes the base of the number. If `base` is 0, the prefix determines the base (8, 16, or 10): the prefix 0 means base 8; the prefix 0x or 0X means base 16; using any other digit without a prefix means decimal.

The pointer to the converted characters, even if conversion was unsuccessful, is stored in the object pointed to by `string2`, as long as `string2` is not a NULL pointer.

**Returned value**

If successful, `strtoul()` returns the converted unsigned long int value, represented in the string.

If unsuccessful, `strtoul()` returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, `strtoul()` returns `ULONG_MAX`. If the value of `base` is not supported, `strtoul()` returns 0.

If unsuccessful `strtoul()` sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of <code>base</code> is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

**Example**

### CELEBS56

```c
#include <stdio.h>
#include <stdlib.h>
#define BASE 2

int main(void)
{
    char *string, *stopstring;
    unsigned long ul;
    string = "1000e13 e";
    printf("string = %s\n", string);
    ul = strtoul(string, &stopstring, BASE);
    printf(" strtoul = %ld (base %d)\n", ul, BASE);
    printf(" Stopped scan at %s\n", stopstring);
}
```

**Output**

```
string = 1000e13 e
strtoul = 8 (base 2)
Stopped scan at e13 e
```

Format

#include <stdlib.h>

unsigned long long strtol(const char * __restrict__ nptr, char ** __restrict__ endptr, int base);

Compile requirement: Use of this function requires the long long data type. See z/OS XL C/C++ Language Reference for information on how to make long long available.

General description

Converts nptr, a character string, to an unsigned long long value.

The function decomposes the entire string into three parts:

1. A sequence of characters, which in the current locale are defined as white space characters. This part may be empty.
2. A sequence of characters interpreted as an unsigned integer in some base notation. This is the subject sequence.
3. A sequence of unrecognized characters.

The base notation is determined by base, if base is greater than zero. If base is zero, the base notation is determined by the format of the sequence of characters that follow an optional plus or optional minus sign.

10 Sequence starts with nonzero decimal digit.
8 Sequence starts with 0, followed by a sequence of digits with values from 0 to 7.
16 Sequence starts with either 0x or 0X, followed by digits, and letters A through F or a through f.

If the base is greater than zero, the subject sequence contains decimal digits and letters, possibly preceded by either a plus or a minus sign. The letters a (or A) through z (or Z) represent values from 10 through 36, but only those letters whose value is less than the value of the base are allowed. The function stops reading the string at the first character that it cannot recognize as part of a number. This character can be the first numeric character greater than or equal to the base. The strtol() function sets endptr to point to the end of the resulting output string if a conversion is performed and provided that endptr is not a NULL pointer.

When you are using the strtol() function, nptr should point to a string with the following form:
If \( \text{base} \) is in the range of 2-36, it becomes the base of the number. If \( \text{base} \) is 0, the prefix determines the base (8, 16 or 10): the prefix 0 means base 8; the prefix 0x or 0X means base 16; using any other digit without a prefix means decimal.

The pointer to the converted characters, even if conversion was unsuccessful, is stored in the object pointed to by \( \text{endptr} \), as long as \( \text{endptr} \) is not a NULL pointer.

**Returned value**

If successful, `strtoull()` returns the converted unsigned long value, represented in the string.

If unsuccessful, `strtoull()` returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, `strtoull()` returns `ULLONG_MAX` (ULONGLONG_MAX). If the value of base is not supported, `strtoull()` returns 0.

If unsuccessful `strtoull()` sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of ( \text{base} ) is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

stroumax

stroumax() — Convert character string to uintmax_t integer type

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <inttypes.h>

uintmax_t stroumax(const char * __restrict__ nptr, char ** __restrict__ endptr, int base);
```

Compile requirement: Function stroumax() requires long long to be available.

General description

The stroumax() function converts the string nptr to an uintmax_t integer type. Valid input values for base are 0 and in the range 2-36. The stroumax() function is equivalent to strtoul() and strtoull(). The only difference being that the return value is of type uintmax_t. See strtoull for more information.

Returned value

If successful, stroumax() returns the converted uintmax_t value, represented in the string.

If unsuccessful, stroumax() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, stroumax() returns UINTMAX_MAX. If the value of base is not supported, stroumax() returns 0.

If unsuccessful stroumax() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of base is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

Example

```c
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    uintmax_t j;
    int base = 10;
    char *nptr, *endptr;
    nptr = "20690239864abc";
    printf("string = %s\n", nptr);
    j = stroumax(nptr, &endptr, base);
    printf("strtoumax = %ju (base %d)\n", j, base);
    printf("Stopped scan at %s\n", endptr);
}
```
Output

string = 20690239864abc
stroumax = 20690239864 (base 10)
Stopped scan at abc

strxfrm

strxfrm() — Transform string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <string.h>

size_t strxfrm(char * __restrict__ s1, const char * __restrict__ s2, size_t n);
```

General description

Transforms the string pointed to by `s2` and places the resulting string into the array pointed to by `s1`. The transformation is determined by the program's locale. The transformed string is not necessarily readable, but can be used with the `strcmp()` or `strncmp()` functions.

The transformation is such that, if `strcmp()` or `strncmp()` were applied to the two transformed strings, the results would be the same as applying the `strcoll()` function to the two corresponding untransformed strings.

No more than `n` bytes are placed into the area pointed to by `s1`, including the terminating NULL byte. If `n` is zero, `s1` is allowed to be a NULL pointer.

Returned value

If successful, `strxfrm()` returns the length of the transformed string (excluding the NULL byte). When `n` is zero and `s1` is a NULL pointer, the length returned is the number of bytes minus one required to contain the transformed string.

If unsuccessful, `strxfrm()` returns `(size_t)-1` and sets `errno` to indicate the error.

Notes:

1. The string returned by `strxfrm()` contains the weights for each order of the characters within the string. As a result, the string returned may be longer than the input string, and does not contain printable characters.
2. `strxfrm()` issues a `malloc()` when the `LC_COLLATE` category specifies `backward` on the `order_start` keyword, the `substitute` keyword is specified, or the locale has one-to-many mapping. The `strxfrm()` function will fail if the `malloc()` fails.
3. If the locale supports double-byte characters (`MB_CUR_MAX` specified as 4), the `strxfrm()` function validates the multibyte characters, whereas previously the `strxfrm()` function did not validate the string. The `strxfrm()` function will fail if the string contains invalid multibyte characters.
4. If `MB_CUR_MAX` is defined as 4, and no collation is defined for DBCS chars in the current locale, the DBCS characters will collate after the single-byte characters.
Example

CELEBS57
/* CELEBS57
This example prompts the user to input a string of characters, then uses strxfrm() to transform the string and return its length.
*/
#include <collate.h>
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
int main(void)
{
    char *string1="string1", *string2="string2";
    char *newstring1, *newstring2;
    int length1, length2;

    length1=strxfrm(NULL, string1, 0);
    length2=strxfrm(NULL, string2, 0);
    if (((newstring1=(char *)calloc(length1+1, 1))==NULL) ||
        ((newstring2=(char *)calloc(length2+1, 1))==NULL))
    {
        printf("insufficient memory\n");
        exit(99);
    }
    if ((strxfrm(newstring1, string1, length1+1) != length1) ||
        (strxfrm(newstring2, string2, length2+1) != length2))
    {
        printf("error in string processing\n");
        exit(99);
    }
    if (strcoll(string1, string2) != strcmp(newstring1, newstring2))
    {
        printf("wrong results\n");
        exit(99);
    }
    printf("correct results\n");
    exit(0);
}

_superkill

__superkill() — Sends "super" SIGKILL to terminate target process

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R6 POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <signal.h>

int __superkill(pid_t pid);
```

General description

The __superkill() function generates a more robust version of the SIGKILL signal to the process with `pid` as the process ID. The SIGKILL will be able to break through almost all of the current signal deterrents that can be an obstacle to the normal delivery of a SIGKILL and the resulting termination of the target process.

Function restrictions include:

- Cannot do a __superkill() to a group or specifying PID -1. An attempt to do so will result in a EINVAL/JrNoGroups.
- The superkill will be ignored if the target process has blocked all signals, in which case the __superkill() will not fail but simply be ignored (refer to BPX1SDD syscall in Chapter 2. Callable services descriptions, SA22-7803). Under a multithread environment, as long as BPX1SDD is called on the initial thread, __superkill() will be ignored. The sigprocmask() function cannot be used to block __superkill().
- A regular SIGKILL must be sent, at least 3 seconds, to a process before a superkill. Otherwise the attempt will result in EINVAL/JRSigkillNotSent.
- Runtime option POSIX(ON) is required to be set for this function to work properly.

If the environment is valid, then the target process will be abended with a '422'x abend reason code x'0109' reason code. The abend code will be sent to the first dubbed thread in the process. Under Language Environment, this is almost always the initial processing thread (IPT).

Returned value

When successful, the target process is terminated. Upon failure, __superkill() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>PID is -1 or a group process ID or the superkill was not sent 3 seconds after the regular SIGKILL.</td>
</tr>
<tr>
<td>EPERM</td>
<td>The caller does not have the permission to send the signal to any process that was specified by the process ID parameter.</td>
</tr>
<tr>
<td>ESRCH</td>
<td>No process or process groups that correspond to the process ID are found.</td>
</tr>
</tbody>
</table>
svc99() — Access supervisor call

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

int svc99(__S99parms *string);
```

General description

Provides access to SVC99 on z/OS, which provides ability to:
- Dynamically allocate or deallocate a resource
- Dynamically concatenate or deconcatenate data sets
- Dynamically retrieve information on data sets

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (for example, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The __S99parms structure must be in 31-bit addressable storage. A call to svc99() with 64-bit addressable storage will result in -1 return code.

The __S99TXTPP element needs to be a 32-bits wide pointer to 31-bit addressable storage containing an array of text unit pointers. Each of the text unit pointers must be a 32-bits wide pointer, each pointing to 31-bit addressable storage containing a text unit, or can be a NULL pointer. The last text unit pointer must have its high bit (traditional 31-bit amode high bit) turned on to denote the end of text units has been reached.

The __S99S99X element needs to be a 32-bits wide pointer to 31-bit addressable storage containing the __S99rbx structure, when needed. This is consistent with the __dyn_t structure element __rbx requirement outlined above.

The __S99parms structure is defined in stdio.h. It has been changed to include the address of the Request Block Extension. The Request Block Extension and the Error Message Parameter list can be used to process the messages returned by SVC99 when an error occurs. To use this feature, you must allocate and initialize these structures.

</tr>
</tbody>
</table>

Returned value

If the input pointer is NULL, svc99() returns 0 if running under CICS and nonzero otherwise. The nonzero value indicates that svc99() is supported under the current operating system (that is, z/OS non-CICS). If the input is not NULL, svc99() returns −1 if running under CICS (to indicate an error), otherwise it returns a code that results from svc99().

If the input is not NULL, and svc99() is not supported on the system, it returns −1.

Example

CELEBS58
/* CELEBS58
   This example uses the svc99() function to dynamically allocate a data set called USERID.EXAMPLE.
*/
#define MASK 0x80000000
#define _EXT
#include <stdio.h>
#include <string.h>
int main(void)
{
    int rc;
    struct __S99struc parmlist;
    char *s[10] = { /* array of text pointers */
        /* text units follow */
        "\0\x02\0\x01\0\x0e"USERID.EXAMPLE", /* DSN=EXAMPLE */
        "\0\x05\0\x01\0\x01\x02", /* DISP=(,CATLG) */
        "\0\x07\0\x0", /* SPACE=(TRK,... */
        "\0\x0a\0\x01\0\x03\0\x14", /* primary=20 */
        "\0\x0b\0\x01\0\x03\0\x01", /* secondary=1 */
        "\0\x15\0\x01\0\x03SYSDA", /* UNIT=SYSDA */
        "\0\x30\0\x01\0\x02\0\x50", /* BLKSIZE=80 */
        "\0\x3c\0\x01\0\x02\0\x40\0", /* DSORG=PS */
        "\0\x42\0\x01\0\x02\0\x50", /* LRECL=80 */
        "\0\x49\0\x01\0\x01\x80"}; /* RECFM=F */
    memset(&parmlist, 0, sizeof(parmlist));
    parmlist.__S99RBLN = 20;
    parmlist.__S99VERB = 1; /* verb for dsname allocation */
    parmlist.__S99FLAG1 = 0x4000; /* do not use existing allocation */
parmlist.__S99TXTPP = s; /* pointer to pointer to text units */
s[9] = (char *)((long unsigned) (s[9]) | MASK);

rc = svc99(&parmlist);
if (rc != 0)
    printf(" Error code = %d Information code = %d\n",
          parmlist.__S99ERROR, parmlist.__S99INFO);
}

If your user ID starts with one of the letters A-F, you must add two double quotation marks (") before the user ID so that the first letter of the user ID is interpreted as a character rather than as a hexadecimal digit.

The preceding example can be made more readable by using symbolic names and data structures as demonstrated in the example below. The members IEFZB4DB, IEFZB4D0 and IEFZB4D2 of SYS1.MACLIB contain symbolic names that will be familiar to most assembler language programmers.

This next example uses symbolic names taken from these members to define, in z/OS XL C/C++ the text unit representing primary=20 or s[3]. Similar definitions can be made for the remaining text units but will not be given here.

```
#include <stdio.h>
#include <string.h>
#define MASK 0x80000000
#define CHAR_BIT 4
/*@ Defines one text unit with an integer of size 'bytes' */

#define __S99TUNIT_INT(bytes) struct {
    short unsigned __S99TUKEY; /* KEY */
    short unsigned __S99TUNUM; /* NO. OF LENGTH+PARM ENTRIES */
    struct { /* TEXT ENTRY OF LENGTH+PARM */
        short unsigned __S99TULNG; /* LENGTH OF 1ST (ONLY) PARM */
        unsigned int __S99TUPAR : (bytes) * CHAR_BIT; /* PARAMETER */
    } __S99TUENT;
} /* initialize by: __S99TUNUM = 1; */
/*@ __S99TUENT.__S99TULNG = <bytes>; */
/*@ __S99TUENT.__S99TUPAR = <value>; */

#define __DALPRIME 0x000A /* PRIMARY SPACE QUANTITY */
static const __S99TUNIT_INT(3) primary = {__DALPRIME, 1, 3, 20};

int main(void)
{
    int rc;
    struct __S99struc parmlist;
    memset(&parmlist, 0, sizeof(parmlist));
    void *s[10] = {
        /* DSN=EXAMPLE */
        /* DISP=(,CATLG) */
        /* SPACE=(TRK,.. */
        &primary, /* primary=20 */
        /* secondary=1 */
        /* UNIT=SYSDA */
        /* BLKSIZE=80 */
        /* DSORG=PS */
        /* LRECL=80 */
        /* RECFM=F */
    };
    parmlist.__S99RBLN = 20;
```
svc99

parmlist.__S99VERB = 01; /* verb for dsname allocation */
parmlist.__S99FLAG1 = 0x4000; /* do not use existing allocation */
parmlist.__S99TXTPP = s; /* pointer to pointer to text units */
    s[9] = (char *)((long unsigned) (s[9]) | MASK);

rc = svc99(&parmlist);
if (rc != 0)
    printf(" Error code = %d Information code = %d\n",
            parmlist.__S99ERROR, parmlist.__S99INFO);
}

swab() — Copy and swap bytes

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <unistd.h>

void swab(const void *__restrict__src, void *__restrict__dest, ssize_t nbytes);
```

General description

The swab() function copies nbytes bytes, which are pointed to by src to the object pointed to by dest, exchanging adjacent bytes. The nbytes argument should be even. If nbytes is odd, swab() copies and exchanges nbytes-1 bytes and the disposition of the last byte is left unchanged in the target area. If nbytes is zero or negative, no copying is performed.

Returned value

swab() returns no values.

- "unistd.h" on page 81
swapcontext() — Save and restore user context

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <ucontext.h>

int swapcontext(ucontext_t *__restrict__ oucp, const ucontext_t *__restrict__ ucp);
```

General description

The swapcontext() function saves the current user context in the context structure pointed to by `oucp` and restores the user context structure pointed to by `ucp`. swapcontext() is equivalent to getcontext() with the `oucp` argument followed by setcontext() with the `ucp` argument.

Control does not return from the initial invocation of swapcontext(). However, if the saved context is not modified using makecontext(), and a subsequent setcontext() or swapcontext() is issued using the saved context, swapcontext() returns with a 0 return value.

Notes:

1. If the `ucontext` pointed to by `ucp` that is input to swapcontext(), has not been modified by makecontext(), you must ensure that the function that saved that context by calling either getcontext() or swapcontext() does not return before you call swapcontext() to restore that context. Calling swapcontext() after the function that saved the context returns causes unpredictable program behavior.

2. If swapcontext() is used to jump back into an XPLINK routine, any alloca() requests issued by the XPLINK routine after the earlier getcontext() was called and before swapcontext() is called are backed out. All storage obtained by these alloca() requests is freed before the XPLINK routine is resumed.

3. If swapcontext() is used to jump back into a non-XPLINK routine, alloca() requests made after getcontext() and before swapcontext() are not backed out.

4. Do not issue swapcontext() from any type of condition handling routine (for example, a signal catcher, a Language Environment user condition handler or an exception handler).

This function is supported only in a POSIX program.

The `<ucontext.h>` header file defines the `ucontext_t` type as a structure that includes the following members:

- `mcontext_t uc_mcontext`: A machine-specific representation of the saved context.
- `ucontext_t *uc_link`: Pointer to the context that will be resumed when this context returns.
- `sigset_t uc_sigmask`: The set of signals that are blocked when this context is active.
- `stack_t uc_stack`: The stack used by this context.
**swapcontext**

**Special behavior for C++**: If getcontext() and swapcontext() are used to transfer control in a z/OS XL C++ program, the behavior in terms of the destruction of automatic objects is undefined. This applies to both z/OS XL C++ and z/OS XL C++ ILC modules. The use of getcontext() and swapcontext() in conjunction with try(), catch(), and throw() is also undefined.

Do not issue getcontext() in a C++ constructor or destructor, since the saved context would not be usable in a subsequent setcontext() or swapcontext() after the constructor or destructor returns.

**Special behavior for XPLINK-compiled C/C++**: Restrictions concerning setjmp.h and ucontext.h:

**Notes:**
1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the jmp_buf, sigjmp_buf or ucontext_t types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define jmp_buf, sigjmp_buf or ucontext_t data items and pass them to XPLINK functions that call getcontext(), longjmp(), _longjmp(), setjmp(), _setjmp(), setcontext(), sigsetjmp(), or swapcontext() with these passed-in data items.
3. When __XPLINK__ is defined, the Language Environment V2R10 and later headers define a larger jmp_buf, sigjmp_buf or ucontext_t area that is required by setjmp(), getcontext(), and related functions when they are called from an XPLINK routine. If __XPLINK__ is not defined, the Language Environment V2R10 and later headers define a shorter jmp_buf, sigjmp_buf or ucontext_t area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls setjmp(), getcontext() or similar functions with a short jmp_buf, sigjmp_buf or ucontext_t area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

**Returned value**

If successful, swapcontext() does not return from the initial invocation. If the unmodified saved context is later restored, swapcontext() returns 0.

If unsuccessful, swapcontext() returns −1.

There are no errno values defined.

**Example**

This example uses two contexts. It creates the first, fcontext, in main with the getcontext() statement, and invokes the function func. It invokes the function with the swapcontext() statement, saving the context at that point in the second context, mcontext. The function returns to the point of the swapcontext() using the setcontext() statement and specifying mcontext as the context.

/* This example shows the usage of swapcontext(). */

#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>
#include <stdio.h>
#include <ucontext.h>
#include <errno.h>
#include <errno.h>
swapcontext

```c
#ifdef _LP64
#define STACK_SIZE 2097152+16384 /* large enough value for AMODE 64 */
#else
#define STACK_SIZE 16384 /* AMODE 31 addressing*/
#endif

void func(int);

ucontext_t fcontext,mcontext;
int x = 0;

int main(void) {
    int value = 1;
    getcontext(&fcontext);
    if ((fcontext.uc_stack.ss_sp = (char *) malloc(STACK_SIZE)) != NULL) {
        fcontext.uc_stack.ss_size = STACK_SIZE;
        fcontext.uc_stack.ss_flags = 0;
        errno = 0;
        makecontext(&fcontext,func,1,value);
        if (errno != 0){
            perror("Error reported by makecontext()");
            return -1 /* Error occurred exit */
        }
    } else {
        perror("not enough storage for stack");
        abort();
    }
    printf("context has been built\\n");
    swapcontext(&mcontext,&fcontext);
    if (!x) {
        perror("incorrect return from swapcontext");
        abort();
    } else {
        printf("returned from function\\n");
    }
}

void func(int arg) {
    printf("function called with value \%d\\n",arg);
    x++
    printf("function returning to main\\n");
    setcontext(&mcontext);
}
```

**Output**
context has been built
function called with value 1
function returning to main
returned from function

int symlink(const char *pathname, const char *slink);
```

General description

Creates the symbolic link named by `slink` with the file specified by `pathname`. File access checking is not performed on the file `pathname`, and the file need not exist. In addition, a symbolic link can cross file system boundaries.

A symbolic link path name is resolved in this fashion:

- When a component of a path name refers to a symbolic link rather than to a directory, the path name contained in the symbolic link is resolved.
- If the path name in the symbolic link begins with `/` (slash), the symbolic link path name is resolved relative to the process root directory.
- If the path name in the symbolic link does not start with `/` (slash), the symbolic link path name is resolved relative to the directory that contains the symbolic link.
- If the symbolic link is the last component of a path name, it may or may not be resolved. Resolution depends on the function using the path name. For example, `rename()` does not resolve a symbolic link when it appears as the final component of either the new or old path name. However, `open` does resolve a symbolic link when it appears as the last component.
- If the symbolic link is not the last component of the original path name, remaining components of the original path name are resolved relative to the symbolic link.
- When a `/` (slash) is the last component of a path name and it is preceded by a symbolic link, the symbolic link is always resolved.

Because the mode of a symbolic link cannot be changed, its mode is ignored during the lookup process. Any files and directories to which a symbolic link refers are checked for access permission.

Returned value

If successful, `symlink()` returns 0.

If unsuccessful, `symlink()` returns −1, does not affect any file it names, and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>A component of the <code>slink</code> path prefix denies search permission, or write permission is denied in the parent directory of the symbolic link to be created.</td>
</tr>
<tr>
<td>EEXIST</td>
<td>The file named by <code>slink</code> already exists.</td>
</tr>
</tbody>
</table>
EINVAL This may be returned for either of these reasons:

- There is a NULL character in *pathname*.
- *slink* has a slash as its last component, which indicates that the preceding component will be a directory. A symbolic link cannot be a directory.

EIO Added for XPG4.2: An I/O error occurred while reading from the file system.

ELOOP A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP symbolic links are encountered during resolution of the *slink* argument.

ENAMEETOOLONG

- *pathname* is longer than PATH_MAX characters, or some component of *pathname* is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined with pathconf().

ENOENT Added for XPG4.2: A component of *slink* does not name an existing file or *slink* is an empty string.

ENOSPC The new symbolic link cannot be created because there is no space left on the file system that will contain the symbolic link.

ENOTDIR A component of the path prefix of *slink* is not a directory.

EROFS The file *slink* cannot reside on a read-only system.

Example

```c
/* This example works only under z/OS XL C, not z/OS XL C++ */
#define _POSIX1_SOURCE 2
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#include <stdlib.h>
#include <stdio.h>

main() {
    char fn[]="test.file";
    char sln[]="test.symlink";
    int fd;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        puts("before symlink()");
        system("ls -Il test.*");
        if (symlink(fn, sln) != 0) {
            perror("symlink() error");
            unlink(fn);
        }
        else {
            puts("after symlink()");
            system("ls -Il test.*");
            unlink(fn);
            puts("after first unlink()"ailer"");
            system("ls -Il test.*");
```
symlink

    unlink(sln);
    }
    }

Output
before symlink()
4030 --w------- 1 MVSUSR1 SYS1 0 Apr 20 13:57 test.file
after symlink()
4030 --w------- 1 MVSUSR1 SYS1 0 Apr 20 13:57 test.file
4031 l--------- 1 MVSUSR1 SYS1 9 Apr 20 13:57 test.symlink -> test.file
after first unlink()
4031 l--------- 1 MVSUSR1 SYS1 9 Apr 20 13:57 test.symlink -> test.file

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

void sync(void);
```

General description

The `sync()` function causes all information in memory that updates file systems to be scheduled for writing out to all file systems.

The writing, although scheduled, is not necessarily complete upon return from `sync()`.

Returned value

`sync()` returns no values.

No errors are defined.

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

long sysconf(int name);
```

General description

Determines the value of a configurable system option.

int name

Specifies the system configuration option to be obtained. The value of name can be any one of the following set of symbols defined in the unistd.h header file, each corresponding to a system configuration option:

The following are available when _POSIX_SOURCE is defined.

_SC_ARG_MAX

Represents ARG_MAX, as defined by the values returned by sysconf(), the maximum number of bytes of arguments and environment data that can be passed in an exec function.

_SC_CHILD_MAX

Represents CHILD_MAX, as defined by the values returned by sysconf(), the maximum number of processes that a real user ID (UID) may have running simultaneously.

_SC_CLK_TCK

Represents the CLK_TCK macro defined in the time.h header file: the number of clock ticks in a second.

_SC_JOB_CONTROL

Represents the _POSIX_JOB_CONTROL macro that can be defined in the unistd.h header file. This indicates that certain job control operations are implemented by this version of the operating system. If _POSIX_JOB_CONTROL is defined, various functions (for example, setpgid()) have more functionality than when the macro is not defined.

_SC_NGROUPS_MAX

Represents NGROUPS_MAX, as defined by the values returned by sysconf(), the maximum number of supplementary group IDs (GIDs) that can be associated with a process.
**sysconf**

_SC_OPEN_MAX
Represents **OPEN_MAX**, as defined by the values returned by `sysconf()`, the maximum number of files that a single process can have open at one time.

_SC_SAVED_IDS
Represents the `_POSIX_SAVED_IDS` macro, which may be defined in `unistd.h` header file, indicating that this POSIX implementation has a saved set UID and a saved set GID. This symbol affects the behavior of such functions as `setuid()` and `setgid()`.

_SC_STREAM_MAX
Represents the _STREAM_MAX macro, which may be defined in the `unistd.h` header file, indicating the maximum number of streams that a process can have open at one time.

_SC_THREADS_MAX_NP
Represents the THREAD_MAX macro, as defined by the values returned by `sysconf()`, the maximum number of concurrent threads processed by `pthread_create()`, including running, queued, and exited undetached threads in the caller's process.

_SC_THREAD_TASKS_MAX_NP
Represents the THREAD_TASKS_MAX macro, as defined by the values returned by `sysconf()`, the maximum number of MVS tasks simultaneously in use for threads processed by `pthread_create()` in the caller's process.

_SC_TTY_GROUP
Retrieves the group number associated with the TTYGROUP() initialization parameter.

_SC_TZNAME_MAX
Represents the _TZNAME_MAX macro, which may be defined in the `unistd.h` header file, indicating the maximum length of the name of a time zone.

_SC_VERSION
Represents the _POSIX_VERSION macro, which will be defined in the `unistd.h` header file, indicating the version of the POSIX.1 standard that the system conforms to.

In addition to the symbols exposed by _POSIX_SOURCE, the following are visible when _XOPEN_SOURCE is defined:

_SC_XOPEN_CRYPT
Represents _XOPEN_CRYPT, the implementation supports the X/Open Encryption Option Group.

_SC_XOPEN_VERSION
Represents _XOPEN_VERSION, integer value indicating version of the X/Open Portability Guide to which the implementation conforms.

_SC_PASS_MAX
Represents PASS_MAX, as defined by the values returned by `sysconf()`, the maximum number of bytes allowed in a password, PassTicket, or password phrase.
Note:

It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro
_UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

In addition to the symbols exposed by _XOPEN_SOURCE, the following are visible when _XOPEN_SOURCE_EXTENDED is defined to be 1:

_SC_PAGE_SIZE
Returns the current page size in bytes.

_SC_PAGESIZE
Returns the current page size in bytes.

In addition to the symbols exposed by _POSIX_SOURCE, the following are visible when _POSIX_C_SOURCE is defined to be 2:

_SC_2_C_BIND
Represents _POSIX2_C_BIND, the implementation supports the C-Language Binding option.

_SC_2_C_DEV
Represents _POSIX2_C_DEV, the implementation supports the C-Language Development Utilities option.

_SC_2_LOCALEDEF
Represents _POSIX2_LOCALEDEF, the implementation supports the creation of locales by the localedef utility.

_SC_2_UPE
Represents _POSIX2_UPE, the implementation supports the User Portability Utilities option.

_SC_2_VERSION
Represents _POSIX2_VERSION, integer value indicating version of the Shell and Utilities to which the implementation conforms.

In addition to the symbols exposed by _POSIX_C_SOURCE defined to be 2, the following are visible when _POSIX_C_SOURCE is defined to be 200112L:

_SC_HOST_NAME_MAX
Represents HOST_NAME_MAX, Maximum length of a host name (not including the terminating null) as returned from the gethostname() function.

_SC_IPV6
Represents _POSIX_IPV6, the implementation supports the IPv6 option.

_SC_LOGIN_NAME_MAX
Represents LOGIN_NAME_MAX, Maximum length of a login name.
REPRESENTS _POSIX_READER_WRITER_LOCKS, the implementation supports the Read-Write Locks option. This is always set to a value greater than zero if the Threads option is supported.

SC_READER_WRITER_LOCKS

REPRESENTS _POSIX_REGEXP, the implementation supports the Regular Expression Handling option.

SC_REGEXP

REPRESENTS _POSIX_SHELL, the implementation supports the POSIX shell.

SC_SHELL

REPRESENTS SYMLOOP_MAX, maximum number of symbolic links that can be reliably traversed in the resolution of a path name in the absence of a loop.

SC_SYMLOOP_MAX

REPRESENTS _POSIX_THREAD_ATTR_STACKSIZE, the implementation supports the Thread Stack Size Attribute option.

SC_THREAD_ATTR_STACKSIZE

REPRESENTS PTHREAD_KEYS_MAX, maximum number of data keys that can be created by a process.

SC_THREAD_KEYS_MAX

REPRESENTS _POSIX_THREAD_PROCESS_SHARED, the implementation supports the Thread Process-Shared Synchronization option.

SC_THREAD_PROCESS_SHARED

REPRESENTS _POSIX_THREAD_SAFE_FUNCTIONS, the implementation supports the Thread-Safe Functions option.

SC_THREAD_SAFE_FUNCTIONS

REPRESENTS PTHREAD_STACK_MIN, minimum size in bytes of thread stack storage.

SC_THREAD_STACK_MIN

REPRESENTS PTHREAD_THREADS_MAX, maximum number of threads that can be created per process.

SC_THREAD_THREADS_MAX

REPRESENTS _POSIX_THREADS, the implementation supports the Threads option.

SC_THREADS

REPRESENTS TTY_NAME_MAX, maximum length of terminal device name.

SC_TTY_NAME_MAX

REPRESENTS _POSIX_V6_ILP32_OFF32, the implementation provides a C-language compilation environment with 32-bit int, long, pointer, and off_t types.

SC_V6_ILP32_OFF32

REPRESENTS _POSIX_V6_ILP32_OFFBIG, the implementation provides a C-language compilation environment with 32-bit int, long, and pointer types and an off_t type using at least 64 bits.

SC_V6_ILP32_OFFBIG
sysconf

_SC_V6_LP64_OFF64
Represents _POSIX_V6_LP64_OFF64, the implementation provides a C-language compilation environment with 32-bit int and 64-bit long, pointer, and off_t types.

_SC_V6_LPBIG_OFFBIG
Represents _POSIX_V6_LPBIG_OFFBIG, the implementation provides a C-language compilation environment with an int type using at least 32 bits and long, pointer, and off_t types using at least 64 bits.

_SC_XOPEN_LEGACY
Represents _XOPEN_LEGACY, the implementation supports the Legacy Option Group.

The following symbols are available under _XOPEN_SOURCE 500:

_SC_GETPW_R_SIZE_MAX
Maximum size of getpwuid_r() and getpwnam_r() data buffers

_SC_GETGR_R_SIZE_MAX
Maximum size of getgrgid_r() and getgrnam_r() data buffers

Returned value
If successful, sysconf() returns the value associated with the specified option.

If the variable corresponding to name exists but is not supported by the system, sysconf() returns -1 but does not change the value of errno. If sysconf() fails in some other way, it returns -1.

If unsuccessful, sysconf() sets errno to one of the following values:

Error Code Description
EINVAL The value specified for the name argument is incorrect.

Example
CELEBS61
/* CELEBS61
 This example determines the value of ARG_MAX.
*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <unistd.h>
#include <errno.h>
main() {
    long result;
    errno = 0;
    puts("examining ARG_MAX limit");
    if ((result = sysconf(_SC_ARG_MAX)) == -1)
        if (errno == 0)
            puts("ARG_MAX is not supported.");
        else perror("sysconf() error");
    else
        printf("ARG_MAX is %ld
", result);
}
Output
examining ARG_MAX limit
ARG_MAX is 1048576

</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <syslog.h>

void syslog(int priority, const char *message, ... /* argument */);
```

**General description**

The syslog() function sends a message to an implementation-specific logging facility, which loads it in an appropriate system log, writes it to the system console, forwards it to a list of users, or forwards it to the logging facility on another host over the network. The logged message includes a message header and a message body. The message header consists of a facility indicator, a severity indicator, a timestamp, a tag string, and optionally the process ID. The process ID is surrounded by square brackets. The code point values for the square brackets are taken from code page IBM-1047. The value for the left square bracket is 0xAD. The value for the right square bracket is 0xBD.

The message body is generated from the `message` and following arguments in the same manner as if these were arguments to the printf() function, except that occurrences of `%m` in the format string pointed to by the `message` argument are replaced by the error message string associated with the current value of errno. A trailing newline character is added if needed.

**Note:** If the total length of the format string and the parameters is greater than 4096 bytes, then the results are undefined.

Values of the `priority` argument are formed by ORing together a severity level values and an option facility value. If no facility value is specified, the current default facility value is used. Possible values of severity level include:

- **LOG_ALERT** A condition that should be corrected immediately, such as a corrupted system database.
- **LOG_CRIT** Critical conditions, such as hard device errors.
- **LOG_DEBUG** Messages that contain information normally of use only when debugging a program.
- **LOG_EMERG** A Panic condition. This is normally broadcast to all processes.
- **LOG_ERR** Errors.
- **LOG_INFO** Informational messages.
- **LOG_NOTICE** Conditions that are not error conditions, but that may require special handling.
- **LOG_WARNING** Warning messages.
The facility indicates the application or system component generating the message. Possible facility values include:

- LOG_USER Message generated by random processes. This is the default facility identifier if none is specified.
- LOG_LOCAL0 Reserved for local use.
- LOG_LOCAL1 Reserved for local use.
- LOG_LOCAL2 Reserved for local use.
- LOG_LOCAL3 Reserved for local use.
- LOG_LOCAL4 Reserved for local use.
- LOG_LOCAL5 Reserved for local use.
- LOG_LOCAL6 Reserved for local use.
- LOG_LOCAL7 Reserved for local use.

**Returned value**

syslog() returns no values.

Format

```c
#include <stdlib.h>

int system(const char *string);
```

General description

The system() function has two different behaviors. These behaviors are designated as ANSI system() and POSIX system(). The ANSI system() behavior is based on the ISO C standard definition of the function, whereas the POSIX system() behavior is based on the POSIX standard definition. The ANSI system() behavior is used when a) running POSIX(OFF) or b) when running POSIX(ON) and environment variable __POSIX_SYSTEM is set to NO. Otherwise the POSIX system() behavior is used.

Restrictions:
1. The ANSI system() behavior is not supported for AMODE 64 applications. If the ANSI system() behavior is requested using either mechanism described above, system() returns -1 and errno is set to ENOSYS.
2. The system() function is not supported under CICS. If the string argument is NULL, system() returns 0 since there is no command processor under CICS, otherwise it returns -1.

ANSI system() function:

Note: In this topic, MVS specifically refers to MVS batch (excluding batch TSO/E), whereas TSO/E includes both batch TSO/E (IKJEFT01 as the program specified on the JCL EXEC statement) and interactive TSO/E (which is TSO/E at a terminal).

Using the ANSI system() function, you can call commands, EXECs, CLISTs, or executable modules under MVS and TSO/E. You cannot use the ANSI system() function to invoke z/OS UNIX services shell programs.

The string argument can take one of the two formats:

command-line

A string with TSO/E command line syntax:

```c
command_name parm1 parm2 ...
```

Example:

```c
system("user_pgm1 1234 abcd xyz");
```
If the string argument is in the command-line format, the system() function passes the given string to the command processor, if available, for execution.

**named-program**

A string, of the following form, with no embedded blanks except in the PARM area.

"PGM=program_name[,PARM='....']"

Example:

system("PGM=user_pgm1, PARM='1234 abcd xyz'");

If the string argument is a named-program format, the system() function calls program_name with the parameters following “PARM=", if any.

The two formats are supported under both MVS and TSO/E, but not all targets can be called from all environments. For example, TSO/E commands cannot be called in an MVS environment. As a result, the two formats are equivalent under MVS, but are different under TSO/E. The details of each are provided below. For maximum portability when invoking executable modules under the different environments, use the named-program format.

If the specified executable module is a z/OS XL C or z/OS XL C++ module, full initialization and termination will be performed: including, but not limited to, automatic closing of files and releasing of fetched modules. In addition, if the ANSI system() call uses the named-program format under either MVS or TSO/E, or the command-line format under MVS, information can be passed across the program boundary using memory files. Memory files are not removed until either the highest level (root) program in the call chain terminates or the clrmemf() function is used. Standard streams are also shared in this environment.

**ANSI MVS considerations:** Under MVS, the ANSI system() function accepts either command-line or named-program format strings. However, the command-line string is restricted to specifying only executable modules (that is, TSO/E commands, EXECs, and CLISTs cannot be specified). Because of this restriction, both formats provide the same functionality.

In the case of either a command-line or named-program string, the ANSI system() function will search the usual MVS sources (STEPLIB/JOBLIB concatenation, Link Pack Area (LPA), Extended Link Pack Area (ELPA), and the link libraries) for the specified program name. The LINK SVC is used to give control to the program.

Under MVS, using ATTACH instead of ANSI system() will prevent you from sharing memory files or standard streams between the programs.

**ANSI TSO/E considerations:** Under TSO/E, the ANSI system() function accepts either command-line or named-program format strings.

Command-line format strings are presented to the TSO/E command processor and can be used to execute user modules, TSO/E commands, EXECs or CLISTs. If there is any ambiguity as to what is to be run when a command-line format string is supplied, the hierarchy is:

1. TSO/E command or user module
2. CLIST or EXEC
Therefore, if a command-line format string is used and a CLIST or EXEC exists with the same name as a TSO/E command or user module, the TSO/E EXEC command must be used to specifically invoke the CLIST or EXEC.

If the command-line format string is used to call a user module, it effectively uses ATTACH to execute the program. As with MVS, when using ATTACH, memory files and standard streams are not shared between the programs. This is the reason that named-program format strings should be used for maximum portability. The named-program format provides the same memory file and standard stream sharing in both the MVS and TSO/E environments.

Notes:
1. If an executable module is placed in the STEPLIB or ISPLLIB (under ISPF), TSO/E will allow the module to be activated as a command. Recall from the discussion above, that, if a CLIST or EXEC has the same name, the module would be activated first, due to the hierarchy rules. Activating a module as a command involves a different input interface. If required, you can use the CALL command to activate a module that is not prepared to take the TSO/E command input format. z/OS XL C and z/OS XL C++ modules can be called as TSO/E commands.

2. A module that exists in the Link Pack Area (LPA) or Extended Link Pack Area (ELPA) and not in the STEPLIB concatenation (ISPLLIB on ISPF) will not be activated as a TSO/E command, and is treated as an executable module.

Named-program format strings are not presented to the TSO/E command processor and can only be used to execute user modules.

**POSIX system() function:** Using the POSIX system() function, you can call z/OS UNIX services shell programs. You cannot use the POSIX system() function to call commands, EXEs, CLISTS, or executable modules under MVS and TSO/E.

The POSIX system() function passes `string` to the `sh` shell command for execution. The environment is established by the run-time library through a spawn() of the shell.

The POSIX system() function ignores the SIGINT and SIGQUIT signals, and blocks the SIGCHILD signal while it waits for the command specified by `string` argument to end.

**Special considerations for POSIX C:** The system() function has these additional considerations:

- A program running with POSIX(ON) can call another program that will also use POSIX(ON) only if the calling program uses the POSIX system() function to invoke the called program out of the shell. Using the ANSI system() function to call a program that will also use POSIX(ON) will result in message CEE3648S being issued, followed by ABENDU4093-AC.
- A program running with POSIX(ON) can receive signals other than SIGINT, SIGQUIT, or SIGCHLD while the POSIX system() function is waiting for the shell command to complete. If there is a signal catcher registered for the signal, it will be invoked immediately. If the signal catcher calls siglongjmp() or setcontext() to pass control back to the application, the SIGINT and SIGQUIT signals will remain ignored, and the SIGCHLD signal will remain blocked.
- If the calling program is the child of a forked process, it cannot use the ANSI system() function to run TSO/E commands since the TSO/E address space is not available.
system

- If the calling program was invoked using one of the exec or spawn functions, it cannot use the ANSI system() function to run TSO/E commands since the TSO/E address space is not available.
- The system() function is not thread-safe. It cannot be called simultaneously from more than one thread. A multithreaded application must ensure that no more than one system() call is ever outstanding from the various threads. Results are undefined if this restriction is violated.
- When using a signal handler and setting the default handler for SIGCHLD to be SIG_IGN, an errno value of ECHILD will be returned. This is due to the speed at which the process executes and finishes before system() can call waitpid() to wait for the child process to end. In this case, the ECHILD can be ignored because the process has already completed successfully and returned.

Note: If an application invokes a z/OS UNIX service shell command or utility that performs terminal I/O, the command may fail due to the z/OS UNIX services shell file descriptors not being initialized. z/OS UNIX files for terminal I/O must be defined. An example of how these can be defined in a C application are as follows:

```
stdin = fopen("/tmp/sys.stdin","r");
stdout = fopen("/tmp/sys.stdout","w");
stderr = fopen("/tmp/sys.stderr","w");
```

See z/OS XL C/C++ applications with z/OS UNIX System Services C functions in topic 1.9 for more information about using POSIX support.

Mixed environments across an ANSI system() call: The mixing of z/OS Language Environment, C/370 Library Version 1 or Version 2, and System Programming C (SPC) environments across a system() call is not supported. Whichever of these environments is active when the first system() call is made is the only one that is tolerated in the system() call chain. Results are undefined if this restriction is violated.

Returned value

If the string argument is a NULL pointer, the system() function returns nonzero if a command processor exists, or 0 if one does not exist.

ANSI MVS considerations: The returned value from ANSI system() will be that from the user module, if successfully called. If system() cannot call the specified module, the returned value is -1 and errno is set appropriately.

ANSI TSO/E considerations: The returned value from ANSI system() will be nonzero if the command processor cannot execute the command or user module. The macros __abendcode and __rsncode will contain the abend code and reason code from a failing TSO/E command, EXEC, or CLIST.

POSIX considerations: If the string argument is a NULL pointer, the POSIX system() function returns nonzero. If the string argument is not NULL, the POSIX system() function returns the termination status of the command language interpreter in the format specified by waitpid(). If a child process cannot be created, or if the termination status for the command language interpreter cannot be obtained, system() returns -1.

Note: When using a signal handler and setting the default handler for SIGCHLD to be SIG_IGN, an errno value of ECHILD will be returned. This is due to the speed at which the process executes and finishes before system() can call
waitpid() to wait for the child process to end. In this case, the ECHILD can be ignored because the process has already completed successfully and returned.

If system() returns -1, errno may be set to one of the following:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>There are insufficient resources to create another process, or the maximum number of processes you can run has been reached.</td>
</tr>
<tr>
<td>ECHILD</td>
<td>The new process finished before system() could call waitpid() to wait for the child process to end. This error can be ignored because the child process has already completed successfully and returned.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>The process requires more space than is available.</td>
</tr>
<tr>
<td>ENOSYS</td>
<td>The ANSI system() function was requested from an AMODE 64 application.</td>
</tr>
</tbody>
</table>

Example

```c
/* This example illustrates how to use system() to execute a command which returns the time. The example works only under TSO. */
#include <stdlib.h>

int main(void)
{
    int rc;
    rc = system("time");
    exit(0);
}

/* This example may only be used in a POSIX program. */
#include <stdlib.h>

int main(void)
{
    int result;
    result = system("date | tee result.log");
}
```

t_accept() — Accept a connect request

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_accept(int fd, int resfd, struct t_call *call);
```

General description

t_accept() is issued by a transport user to accept a connect request. The parameter `fd` identifies the local transport endpoint where the connect indication arrived. `resfd` specifies the local transport endpoint where the connection is to be established, and `call` contains information required by the transport provider to complete the connection. The parameter `call` points to a `t_call` structure which contains the following members:

```c
struct netbuf addr;
struct netbuf opt;
struct netbuf udata;
int sequence;
```

In `call`, `addr` is the protocol address of the calling transport user. `opt` indicates any options associated with the connection. `udata` points to any user data to be returned to the caller, and `sequence` is the value returned by `t_listen()` that uniquely associates the response with a previously received connect indication. The address of the caller, `addr` may be NULL (length zero). Where `addr` is not NULL, then it may optionally be checked by XTI.

A transport user may accept a connection on either the same, or on a different, local transport endpoint than the one on which the connect indication arrived. Before the connection can be accepted on the same endpoint (`resfd==fd`), the user must have responded to any previous connect indications received on that transport endpoint (using `t_accept()` or `t_snddis()`). Otherwise, `t_accept()` fails and sets `t_errno` to `TLOOK`.

If a different transport endpoint is specified (`resfd!=fd`), then the user may or may not choose to bind the endpoint before the `tAccept()` is issued. If the endpoint is not bound before the `tAccept()`, then the transport provider will automatically bind it to the same protocol address `fd` is bound to. If the transport user chooses to bind the endpoint it must be bound to a protocol address with a `qlen` of zero and must be in the `T_IDLE` state before the `tAccept()` is issued.

The call to `tAccept()` will fail with `t_errno` set to `TLOOK` if there are indications (for example, connect or disconnect) waiting to be received on the endpoint `fd`.

Return of user data over a connection accept is not supported under TCP, so the `udata` field is always meaningless.
When the user does not indicate any option \((\text{call->opt.len} == 0)\) it is assumed that
the connection is to be accepted unconditionally. The transport provider may choose
options other than the defaults to ensure that the connection is accepted
successfully.

Due to implementation restrictions, behavior is undefined if a different process
accepts a connection pending on an endpoint than obtained it (with \(t\_listen\)).

**Valid states:**

\(fd\): T\_INCON
\(resfd\) \((fd != resfd)\): T\_IDLE

**Returned value**

If successful, \(t\_accept()\) returns 0.

If unsuccessful, \(t\_accept()\) returns \(-1\) and sets \(t\_errno\) to one of the following
values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TACCES</td>
<td>The user does not have permission to accept a connection on the responding transport endpoint or to use the specified options.</td>
</tr>

takesocket

takesocket() — Acquire a socket from another program

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT
#include <sys/types.h>
#include <socket.h>

int takesocket(struct clientid *clientid, int sdesc);
```

General description

The takesocket() function acquires a socket from another program. Typically, the other program passes its client ID and socket descriptor, and/or process ID (PID), to your program through your program's startup parameter list.

Parameter Description

- **clientid**: A pointer to the clientid of the application from which you are taking a socket.
- **sdesc**: The descriptor of the socket to be taken.

If your program is using the PID to ensure integrity between givesocket() and takesocket(), before issuing the takesocket() call, your program should set the `c_pid.pid` field of the clientid structure to the PID of the giving program (that is, program that issued the givesocket() call). This identifies the process from which the socket is to be taken. If the `c_reserved.type` field of the clientid structure was set to SO_CLOSE on the givesocket() call, `c_close.SockToken` of clientid structure should be used as input to takesocket() instead of the normal socket descriptor. See "givesocket() — Make the specified socket available" on page 916 for a description of the clientid structure.

Returned value

If successful, takesocket() returns the new socket descriptor.

If unsuccessful, takesocket() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The other application did not give the socket to your application.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The sdesc parameter does not specify a valid socket descriptor owned by the other application, or the socket has already been taken.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using the clientid parameter as specified would result in an attempt to access storage outside the caller's address space.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The clientid parameter does not specify a valid client identifier. Either the client process cannot be found, or the client exists, but has no outstanding givesockets.</td>
</tr>
<tr>
<td>EMFILE</td>
<td>The socket descriptor table is already full.</td>
</tr>
</tbody>
</table>

t_alloc

t_alloc() — Allocate a library structure

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

char *t_alloc(int fd, int struct_type, int fields);

General description

Dynamically allocates memory for the various transport function argument structures as specified below. t_alloc() allocates memory for the specified structure, and memory for buffers referenced by the structure.

The structure to allocate is specified by struct_type and must be one of the following:

- T_BIND struct t_bind
- T_CALL struct t_call
- T_OPTMGMT struct t_optmgmt
- T_DIS struct t_discon
- T_UNITDATA struct t_unitdata
- T_UDERROR struct t_uderr
- T_INFO struct t_info

where each of these structures may subsequently be used as an argument to one or more transport functions.

Each of the above structures, except T_INFO, contains at least one field of type struct netbuf. For each field of this type, the user may specify that the buffer for that field should be allocated as well. The length of the buffer allocated will be equal to or greater than the appropriate size as returned in the info argument of t_open() or t_getinfo() . The relevant fields of the info argument are described in the following list. The fields argument specifies which buffers to allocate, where the argument is the bitwise OR of any of the following:

- T_ADDR The addr field of the t_bind, t_call, t_unitdata or t_uderr structures.
- T_OPT The opt field of the t_optmgmt, t_call, t_unitdata or t_uderr structures.
- T_UDATA The udata field of the t_call, t_discon or t_unitdata structures.
- T_ALL All relevant fields of the given structure. Fields which are not supported by the transport provider specified by fd will not be allocated.

For each relevant field specified in fields, t_alloc() allocates memory for the buffer associated with the field, and initializes the len field to zero and the buf pointer and maxlen field accordingly. Irrelevant or unknown values passed in fields are ignored.

Since the length of the buffer allocated will be based on the same size information that is returned to the user on a call to t_open() and t_getinfo(), fd must refer to the transport endpoint through which the newly allocated structure will be passed. In
t_alloc

this way the appropriate size information can be accessed. If the size value
associated with any specified field is -1 or -2 (see t_open() or t_getinfo() ), t_alloc()
will be unable to determine the size of the buffer to allocate and will fail, setting
t_errno to TSYSERR and errno to EINVAL. For any field not specified in fields, but will
be set to the NULL pointer and len and maxlen will be set to zero.

Use of t_alloc() to allocate structures helps ensure the compatibility of user
programs with future releases of the transport interface functions.

Valid states:

All - except for T_UNINIT

Returned value

If successful, t_alloc() returns a pointer to the newly allocated structure.

If unsuccessful, t_alloc() returns a NULL pointer and sets errno to one of the
following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint.</td>
</tr>

</tr>
</tbody>
</table>

Format

```c
#include <math.h>

double tan(double x);
float tanf(float x); /* C++ only */
long double tanl(long double x); /* C++ only */
float tanf(float x);
long double tanl(long double x);
```

General description

Calculates the tangent of \(x\), where \(x\) is expressed in radians. If \(x\) is large, a partial loss of significance in the result can occur.

**Note:** These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point " on page 94 for more information about IEEE Binary Floating-Point.

Returned value

Returns the calculated tangent of \(x\).

If the correct value would cause an underflow, 0 is returned. If the result overflows, \pm\text{HUGE}_\text{VAL} is returned. For both an underflow and an overflow, the value \text{ERANGE} is stored in \text{errno}.

Special behavior for XPG4.2:

The following error is added:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EDOM</td>
<td>The argument exceeded an internal limit for the function (approximately (2^{56})).</td>
</tr>
</tbody>
</table>

Example

**CELEBT01:**

```c
/* CELEBT01

This example computes \(x\) as the tangent of \(\pi/4\).

*/
```
#include <math.h>
#include <stdio.h>

int main(void)
{
    double pi, x;
    pi = 3.1415926;
    x = tan(pi/4.0);

    printf("tan( %lf ) is %lf\n", pi/4, x);
}

Output:
	tan( 0.785398 ) is 1.000000

</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.10</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 tand32(_Decimal32 x);
_Decimal64 tand64(_Decimal64 x);
_Decimal128 tand128(_Decimal128 x);
_Decimal32 tan(_Decimal32 x); /* C++ only */
_Decimal64 tan(_Decimal64 x); /* C++ only */
_Decimal128 tan(_Decimal128 x); /* C++ only */
```

General description

Calculates the tangent of \( x \), where \( x \) is expressed in radians. If \( x \) is large, a partial loss of significance in the result can occur.

These functions work in IEEE decimal floating-point format. See "IEEE decimal floating-point" on page 95 for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

Returns the calculated tangent of \( x \).

If the correct value would cause underflow, zero is returned. If the result overflows, ±HUGE_VAL_D32, ±HUGE_VAL_D64, or ±HUGE_VAL_D128 is returned. For both underflow and overflow, the value ERANGE is stored in errno.

Example

**CELEBT22:**

```c
/* CELEBT22 */

This example illustrates the tand64() function.

This example computes \( x \) as the tangent of PI/4.

*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 pi, x;
    pi = 3.1415926DD;
    x = tand64(pi);
    printf("Result: %.16DD\n", x);
    return 0;
}
```
\[ x = \text{tand64}(\pi/4.0\text{Df}); \]

\texttt{printf("tand64( }%Df\text{ ) is }%Df\text{\n", }\pi/4.0\text{Df}, x); \}

t_bind

**t_bind() — Bind an address to a transport endpoint**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_bind(int fd, struct t_bind *req, struct t_bind *ret);
```

**General description**

Associates a protocol address with the transport endpoint specified by `fd` and activates that transport endpoint. In connection mode, the transport provider may begin enqueuing incoming connect indications, or servicing a connection request on the transport endpoint. In connectionless mode, the transport user may send or receive data units through the transport endpoint.

The `req` and `ret` arguments point to a `t_bind` structure containing the following members:

```c
struct netbuf addr;
unsigned qlen;
```

The `addr` field of the `t_bind` structure specifies a protocol address, and the `qlen` field is used to indicate the maximum number of outstanding connect indications.

The parameter `req` is used to request that an address, represented by the `netbuf` structure, be bound to the given transport endpoint. The parameter `len` specifies the number of bytes in the address, and `buf` points to the address buffer. The parameter `maxlen` has no meaning for the `req` argument. On return, `ret` contains the address that the transport provider actually bound to the transport endpoint. This is the same as the address specified by the user in `req`. In `ret`, the user specifies `maxlen`, which is the maximum size of the address buffer, and `buf` which points to the buffer where the address is to be placed. On return, `len` specifies the number of bytes in the bound address, and `buf` points to the bound address. If `maxlen` is not large enough to hold the returned address, an error results.

If the requested address is not available, `t_bind()` returns -1 with `t_errno` set as appropriate. If no address is specified in `req` (the `len` field of `addr` in `req` is zero or `req` is NULL), the transport provider will assign an appropriate address to be bound, and will return that address in the `addr` field of `ret`. If the transport provider could not allocate an address, `t_bind()` fails with `t_errno` set to TNOADDR.

The parameter `req` may be a NULL pointer if the user does not wish to specify an address to be bound. Here, the value of `qlen` is assumed to be zero, and the transport provider assigns an address to the transport endpoint. Similarly, `ret` may be a NULL pointer if the user does not care what address was bound by the provider and is not interested in the negotiated value of `qlen`. It is valid to set `req` and `ret` to the NULL pointer for the same call, in which case the provider chooses the address to bind to the transport endpoint and does not return that information to the user.
The `qlen` field specifies the number of outstanding connect indications that the transport provider should support for the given transport endpoint. An outstanding connect indication is one that has been passed to the transport user by the transport provider, but which has not been accepted or rejected. A value of `qlen` greater than 0 is only meaningful when issued by a passive transport user that expects other users to call it. The value of `qlen` will be negotiated by the transport provider and will always be negotiated to 1 (one) from any nonzero value. On return, the `qlen` field in `ret` will contain the negotiated value.

If `fd` refers to a connection-oriented service, then multiple endpoints may be bound to the same protocol address by way of connections accepted on an endpoint using `t_accept`. The TCP transport provider will not permit the user to explicitly bind multiple endpoints to the same address. It is also not possible to bind an endpoint to more than one protocol address. If a user attempts to explicitly bind multiple endpoints to a protocol address, the second and subsequent binds will fail with `t_errno` set to `TADDRBUSY`. When a user accepts a connection on the transport endpoint that is being used as the listening endpoint, the bound protocol address will be found to be busy for the duration of the connection, until a `t_unbind()` or `t_close()` call has been issued. No other transport endpoints may be bound for listening on that same protocol address while that initial listening endpoint is active (in the data transfer phase or in the T_IDLE state). This prevents more than one transport endpoint bound to the same protocol address from accepting connect indications.

**Valid states:**

- T_UNBND

**Returned value**

If successful, `t_bind()` returns 0.

If unsuccessful, `t_bind()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TACCES</td>
<td>The user does not have permission to use the specified address.</td>
</tr>
<tr>
<td>TADDRBUSY</td>
<td>The requested address is in use.</td>
</tr>
<tr>
<td>TBADADDR</td>
<td>The specified protocol address was in an incorrect format or contained illegal information.</td>
</tr>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint.</td>
</tr>
<tr>
<td>TBUFOVFLW</td>
<td>The number of bytes allowed for an incoming argument (<code>maxlen</code>) is greater than 0 but not sufficient to store the value of that argument. The provider's state will change to T_IDLE and the information to be returned in <code>ret</code> will be discarded.</td>
</tr>
<tr>
<td>TNOADDR</td>
<td>The transport provider could not allocate an address.</td>
</tr>
<tr>
<td>TOUTSTATE</td>
<td>The function was issued in the wrong sequence.</td>
</tr>
<tr>
<td>TPROTO</td>
<td>This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).</td>
</tr>
<tr>
<td>TSYSERR</td>
<td>A system error has occurred during execution of this function.</td>
</tr>
</tbody>
</table>

tcdrain() — Wait until output has been transmitted

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <termios.h>

int tcdrain(int fildes);
```

General description

The tcdrain() function waits until all output sent to `fildes` has actually been sent to the terminal device.

If tcdrain() is called from a background process group against the caller's controlling terminal, a SIGTTOU signal may be generated depending how the process is handling SIGTTOUs:

<table>
<thead>
<tr>
<th>Processing for SIGTTOU</th>
<th>System Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default or signal handler</td>
<td>The SIGTTOU signal is generated, and the function is not performed. tcdrain() returns −1 and sets errno to EINTR.</td>
</tr>
<tr>
<td>Ignored or blocked</td>
<td>The SIGTTOU signal is not sent, and the function continues normally.</td>
</tr>
</tbody>
</table>

Returned value

If successful, tcdrain() returns 0.

If unsuccessful, tcdrain() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal interrupted tcdrain().</td>
</tr>
<tr>
<td>EIO</td>
<td>The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.</td>
</tr>
<tr>
<td>ENOTTY</td>
<td><code>fildes</code> is not associated with a terminal.</td>
</tr>
</tbody>
</table>

Example

```c
CELEBT03:
/* CELEBT03 */
#define _POSIX_SOURCE
#include <termios.h>
```
```c
#include <stdio.h>
#include <time.h>
#include <fcntl.h>
#include <unistd.h>
#include <sys/stat.h>

main() {
    char Master[]="master.tty";
    char Slave[]="slave.tty";
    char text[]="text to be written to tty";
    char data[80];
    int master, slave;
    time_t T;

    if (mknod(Master, S_IFCHR|S_IRUSR|S_IWUSR, 0x00010000 + 10) !=0)
        perror("mknod() error for master tty");
    else {
        if (mknod(Slave, S_IFCHR|S_IRUSR|S_IWUSR, 0x00020000 + 10) !=0)
            perror("mknod() error for slave tty");
        else {
            if ((master = open(Master, O_RDWR|O_NONBLOCK)) < 0)
                perror("open() error for master tty");
            else {
                if ((slave = open(Slave, O_RDWR|O_NONBLOCK)) < 0)
                    perror("open() error for slave tty");
                else {
                    if (fork() == 0) {
                        if (write(slave, text, strlen(text)+1) == −1)
                            perror("write() error");
                        time(&T);
                        printf("child has written to tty, tcdrain() started at %s",
                                ctime(&T));
                        if (tcdrain(slave) != 0)
                            perror("tcdrain() error");
                        time(&T);
                        printf("tcdrain() returned at %s", ctime(&T));
                        exit(0);
                    }
                    time(&T);
                    printf("parent is starting nap at %s", ctime(&T));
                    sleep(5);
                    time(&T);
                    printf("parent is done with nap at %s", ctime(&T));
                    if (read(master, data, sizeof(data)) == −1)
                        perror("read() error");
                    else printf("read 'text to be written to tty' from the tty
                                %s", data);
                    sleep(5);
                    close(slave);
                }
                close(master);
            }
        }
    }
}

Output:

parent is starting nap at Fri Jun 16 12:46:28 2001
child has written to tty, tcdrain() started at Fri Jun 16 12:46:28 2001
parent is done with nap at Fri Jun 16 12:46:34 2001
read 'text to be written to tty' from the tty
    tcdrain() returned at Fri Jun 16 12:46:34 2001
```

<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <termios.h>

int tcflow(int fildes, int action);
```

General description

Suspends or resumes transmission or reception of data on a terminal device.

**int fildes**

A file descriptor associated with a terminal device.

**int action**

Indicates the action you want to perform, represented by one of the following symbols defined in the termios.h include file:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCOFF</td>
<td>Suspends output.</td>
</tr>
<tr>
<td>TCOON</td>
<td>Resumes suspended output.</td>
</tr>
<tr>
<td>TCIFF</td>
<td>Sends a STOP character to the terminal, to stop the terminal from sending any further input.</td>
</tr>
<tr>
<td>TCION</td>
<td>Sends a START character to the terminal, to tell the terminal that it can resume sending input.</td>
</tr>
</tbody>
</table>

If tcflow() is called from a background process group against the caller's controlling terminal, a SIGTTOU signal may be generated depending how the process is handling SIGTTOUs:

<table>
<thead>
<tr>
<th>Processing for SIGTTOU</th>
<th>System Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default or signal handler</td>
<td>The SIGTTOU signal is generated, and the function is not performed. tcflow() returns -1 and sets errno to EINTR.</td>
</tr>
<tr>
<td>Ignored or blocked</td>
<td>The SIGTTOU signal is not sent, and the function continues normally.</td>
</tr>
</tbody>
</table>

Returned value

If successful, tcflow() returns 0.

If unsuccessful, tcflow() returns -1 and sets errno to one of the following values:

**Error Code**  **Description**

EBADF  fildes is not a valid open file descriptor.
EINTR A signal interrupted tcflow().
EINVAL action had an incorrect value.
EIO For either of the following reasons:
  • TCIOFF or TCION was requested, but the other side of the pseudoterminal connection is closed.
  • The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.
ENOTTY fildes is not associated with a terminal.

Example

CELEBT04:
/* CELEBT04 
   This example suspends and then resumes transmission.
*/
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>
#include <sys/stat.h>
main() {
  char Master[]="/dev/ptyp0010";
  char Slave[]="/dev/ttyp0010";
  char text[]="text to be written to tty";
  char data[80];
  int master, slave;

  if ((master = open(Master, O_RDWR|O_NONBLOCK)) < 0) {
    perror("open() error for master tty");
    exit(1);
  }
  if ((slave = open(Slave, O_RDWR|O_NONBLOCK)) < 0) {
    perror("open() error for slave tty");
    exit(1);
  }

  if (write(slave, text, strlen(text)+1) == -1) {
    perror("write() error");
    exit(1);
  }

  puts("output is suspended to tty");
  if (read(master, data, sizeof(data)) == -1)
    perror("read() error");
  else printf("read '%s' from the tty\n", data);
  if (tcflow(slave, TCOON) != 0)
    perror("tcflow() error");
  exit(1);

  puts("output is resumed to tty");
  if (read(master, data, sizeof(data)) == -1)
    perror("read() error");
  else printf("read '%s' from the tty\n", data);
  close(slave);
  close(master);
}
Output:
output is suspended to tty
read() error: Resource temporarily unavailable
output is resumed to tty
read 'text to be written to tty' from the tty

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <termios.h>

int tcflush(int fildes, int where);
```

General description

Flushes input or output on a terminal.

- `int fildes;` Indicates a file descriptor associated with a terminal device.
- `int where;` Indicates whether the system is to flush input or output, represented by one of the following symbols defined in the termios.h header file.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCIFLUSH</td>
<td>Flushes input data that has been received by the system but not read by an application.</td>
</tr>
<tr>
<td>TCOFLUSH</td>
<td>Flushes output data that has been written by an application but not sent to the terminal.</td>
</tr>
<tr>
<td>TCIOFLUSH</td>
<td>Flushes both input and output data.</td>
</tr>
</tbody>
</table>

If tcflush() is called from a background process group against the caller's controlling terminal, a SIGTTOU signal may be generated depending how the process is handling SIGTTOUs:

<table>
<thead>
<tr>
<th>Processing for SIGTTOU</th>
<th>System Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default or signal handler</td>
<td>The SIGTTOU signal is generated, and the function is not performed. tcflush() returns −1 and sets errno to EINTR.</td>
</tr>
<tr>
<td>Ignored or blocked</td>
<td>The SIGTTOU signal is not sent, and the function continues normally.</td>
</tr>
</tbody>
</table>

Returned value

If successful, tcflush() returns 0.

If unsuccessful, tcflush() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal interrupted tcflush().</td>
</tr>
<tr>
<td>EINVAL</td>
<td><code>where</code> has an incorrect value.</td>
</tr>
</tbody>
</table>
EIO  The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.

ENOTTY  *fdes* is not associated with a terminal.

**Example**

**CELEBT05:**

/* CELEBT05

This example flushes a string.

*/

#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>

<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <termios.h>

int tcgetattr(int fildes, struct termios *termptr);
```

General description

Gets a `termios` structure, which contains control information for a terminal associated with `fildes`. It stores that information in a memory location that `termptr` points to. The contents of a `termios` structure are described in `tcsetattr() — Set the attributes for a terminal` on page 2198.

tcgetattr() can run in either a foreground or background process; however, if the process is in the background, a foreground process may subsequently change the attributes.

tcgetattr() only works in an environment where either a controlling terminal exists, or `stdin` and `stderr` refer to tty devices. Specifically, it does not work in a TSO environment.

Note: The tcgetattr() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support " on page 2543 for details.

Returned value

If successful, tcgetattr() returns 0.

If unsuccessful, tcgetattr() returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>ENOTTY</td>
<td>The file associated with <code>fildes</code> is not a terminal.</td>
</tr>
</tbody>
</table>

Example

```c
CELEBT06:
/* CELEBT06

 This example provides information about the attributes.

 */
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>
#include <unistd.h>
```
main() {  
    struct termios term;  
    if (tcgetattr(STDIN_FILENO, &term) != 0)  
        perror("tcgetattr() error");  
    else {  
        if (term.c_iflag & BRKINT)  
            puts("BRKINT is set");  
        else  
            puts("BRKINT is not set");  
        if (term.c_cflag & PARODD)  
            puts("Odd parity is used");  
        else  
            puts("Even parity is used");  
        if (term.c_lflag & ECHO)  
            puts("ECHO is set");  
        else  
            puts("ECHO is not set");  
        printf("The end−of−file character is x'\%02x'\n", term.c_cc[VEOF]);  
    }  
}  

Output:  
ECHO is set  
The End Of File character is x'37'

__tcgetcp

__tcgetcp() — Get terminal code page names

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYSPTY_EXTENSIONS
#include <termios.h>

int __tcgetcp(int fildes, size_t termcplen, struct __termcp *termcpptr);
```

General description

The __tcgetcp() function gets the terminal session code page information contained in the termcp structure and the Code Page Change Notification (CPCN) capability for the terminal file.

The following arguments are used:

- `fildes` The file descriptor of the terminal for which you want to get the code page names and CPCN capability.
- `termcplen` The length of the passed termcp structure.
- `termcpptr` A pointer to a __termcp structure.

__tcgetcp() stores the termcp information in a memory location pointed to by `termcpptr`. The return value contains the CPCN capability. The following CPCN capabilities are defined:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>_CPCN_NAMES</td>
<td>Forward code page names only</td>
</tr>
<tr>
<td></td>
<td>Use the __tcsetcp() function to change the terminal session data conversion. The z/OS UNIX pseudotty device driver supports this CPCN capability.</td>
</tr>
<tr>
<td>_CPCN_TABLES</td>
<td>Forward code page names and tables</td>
</tr>
<tr>
<td></td>
<td>Use __tcsettables() to change the terminal session data conversion. The OCS remote-tty device driver supports this CPCN capability.</td>
</tr>
</tbody>
</table>

In the returned termcp structure, if the _TCCP_FASTP bit is set then the data conversion that is specified by the source and target code page names can be performed locally by the data conversion application. This is valid any time that a table-driven conversion can be performed. For example, the data conversion point (application) could use the z/OS UNIX iconv() service to build local data conversion tables and perform all data conversion using the local tables instead of using iconv() all in subsequent conversions. This provides for better-performing data conversion.
__tcgetcp

In the returned termcp structure, if the _TCCP_BINARY bit is set then no data conversion is being performed and the code page names contained in the termcp structure should be ignored.

__tcgetcp() can run in either a foreground or background process; however, if the process is in the background, a foreground process may subsequently change the terminal code pages.

Note: The __tcgetcp() function has a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support " on page 2543 for details.

Returned value

If successful, __tcgetcp() returns the termcp structure in a memory location pointed to by termcpptr. The return value contains the CPCN capability.

If unsuccessful, __tcgetcp() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>_fildes is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of termcplen was invalid.</td>
</tr>
</tbody>
</table>
| ENODEV     | One of the following error conditions exist:
|            | ● The terminal device driver does not support CPCN functions. |
|            | ● CPCN functions have not been enabled. |
|            | For a z/OS UNIX pseudotty terminal device file, issue the __tcsetcp() function against the master pty first to enable CPCN support. |
| ENOTTY     | The file associated with _fildes is not a terminal device. |

Example

The following example retrieves the current code pages used in the data conversion and CPCN capability. Here, the __tcgetcp() function is issued against a session using a pty terminal device; ISO8859-1 and IBM-1047 code pages are being used.

```c
#define _OPEN_SYS_PTY_EXTENSIONS
#include <unistd.h>
#include <stdio.h>
#include <fcntl.h>
#include <termios.h>

void main(void)
{
    struct __termcp mytermcp;
    int rv;
    int cterm_fd;

    if ((cterm_fd = open("/dev/tty",O_RDWR)) == -1)
        printf("No controlling terminal established.\n");
    else {
        if ((rv = __tcgetcp(cterm_fd,sizeof(mytermcp),&mytermcp)) == -1)
            perror("__tcgetcp() error");
        else {
            if (_CPCN_NAMES == rv)
                printf("Forward Code Page Names Only.\n");
            else
                printf("Forward Code Page Names and Tables.\n");
            if (_TCCP_BINARY == (mytermcp.__tccp_flags & _TCCP_BINARY))
                printf("Binary mode is in effect.\n");
        }
    }
}
__tcgetcp

else {
    printf("ASCII code page name is %s.\n", mytermcp.__tccp_fromname);
    printf("EBCDIC code page name is %s.\n", mytermcp.__tccp_toname);
}
} /* main */

Output:
Forward code page names only.
ASCII code page name is ISO8859-1.
EBCDIC code page name is IBM-1047.

<td>all</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

pid_t tcgetpgrp(int fildes);
```

General description

Gets the process group ID (PGID) of the foreground process group associated with the terminal referred to by `fildes`. `tcgetpgrp()` can run from a background process, but the information may subsequently be changed by a process in the foreground process group.

Returned value

If successful, `tcgetpgrp()` returns of the foreground process group's PGID.

If unsuccessful, `tcgetpgrp()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>ENOTTY</td>
<td>The calling process does not have a controlling terminal, or the file is not the controlling terminal.</td>
</tr>
</tbody>
</table>

Example

```c
CELEBT07:
/* CELEBT07

   This example gets the foreground PGID.

*/
#define _POSIX_SOURCE
#include <termios.h>
#include <unistd.h>
#include <sys/wait.h>       /*FIX: was #include <sys/wait.h> */
#include <stdio.h>

main() {
    pid_t pid;
    if ((pid = tcgetpgrp(STDOUT_FILENO)) < 0)
        perror("tcgetpgrp() error");
    else
        printf("the foreground process group id of stdout is %d\n", (int) pid);
}
```
Output:
the foreground process group id of stdout is 4063240

tcgetsid() — Get process group ID for session leader for controlling terminal

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <termios.h>

pid_t tcgetsid(int fildes);
```

General description

The tcgetsid() obtains the process group ID of the session for which the terminal specified by `fildes` is the controlling terminal.

Returned value

If successful, tcgetsid() returns the process group ID associated with the terminal.

If unsuccessful, tcgetsid() returns (pid_t)-1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The <code>fildes</code> argument is not associated with a controlling terminal. If the environment variable <code>_EDC_SUSV3</code> is set to 1, ENOTTY will be returned instead of EACCES.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The <code>fildes</code> argument is not a valid file descriptor.</td>
</tr>
<tr>
<td>ENOTTY</td>
<td>The calling process does not have a controlling terminal, or the file is not the controlling terminal.</td>
</tr>
</tbody>
</table>

**Note:** Starting with z/OS V1.9, environment variable `_EDC_SUSV3` can be used to control the behavior of tcgetsid() with respect to setting errno to ENOTTY instead of EACCES. By default, tcgetsid() will set EACCESS when fildes is not associated with a controlling terminal. When `_EDC_SUSV3` is set to 1, setenv() will set errno to ENOTTY in place of EACCES.

t_close

**t_close() — Close a transport endpoint**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_close(int fd);
```

**General description**

Informs the transport provider that the user is finished with the transport endpoint specified by `fd`, and frees any local library resources associated with the endpoint. `t_close()` also closes the file associated with the transport endpoint.

`t_close()` should be called from the T_UNBND state. However, `t_close()` does not check state information, so it may be called from any state to close a transport endpoint. If this occurs, the local library resources associated with the endpoint are freed automatically. In addition, `close()` is issued for that file descriptor. The `close()` will be abortive if there are no other descriptors in this, or in another process which references the transport endpoint, and in this case will break any transport connection that may be associated with that endpoint.

A `t_close()` issued on a connection endpoint may cause data previously sent, or data not yet received, to be lost. It is the responsibility of the transport user to ensure that data is received by the remote peer.

**Valid states:**

All - except for T_UNINIT

**Returned value**

If successful, `t_close()` returns 0.

If unsuccessful, `t_close()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint.</td>
</tr>
<tr>
<td>TPROTO</td>
<td>This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).</td>
</tr>
</tbody>
</table>

t_connect() — Establish a connection with another transport user

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_connect(int fd, struct t_call *call, struct t_call *rcvcall);
```

General description

Enables a transport user to request a connection to the specified destination transport user. This function can only be issued in the T_IDLE state. The parameter `fd` identifies the local transport endpoint where communication will be established, while `sndcall` and `rcvcall` point to a `t_call` structure which contains the following members:

```c
struct netbuf addr;
struct netbuf opt;
struct netbuf udata;
int sequence;
```

The parameter `sndcall` specifies information needed by the transport provider to establish a connection, and `rcvcall` specifies information that is associated with the newly established connection.

In `sndcall`, `addr` specifies the protocol address of the destination transport user. `opt` presents any protocol-specific information that might be needed by the transport provider. `udata` points to optional user data that may be passed to the destination transport user during connection establishment. `sequence` has no meaning for this function.

On return, in `rcvcall`, `addr` contains the protocol address associated with the responding transport endpoint. `opt` represents any protocol-specific information associated with the connection. `udata` points to optional user data that may be returned by the destination transport user during connection establishment. `sequence` has no meaning for this function.

The `opt` argument permits users to define the options that may be passed to the transport provider. See the discussion of supported options in `t_optmgmt()`. The user may choose not to negotiate protocol options by setting the `len` field of `opt` to zero. In this case, the provider may use default options.

If used, `sndcall->opt.buf` must point to a buffer with the corresponding options. The `maxlen` and `buf` fields of the `netbuf` structure pointed by `rcvcall->addr` and `rcvcall->opt` must be set before the call.

Since passing of user data over a connection request is not supported under TCP, the `udata` argument is always meaningless.

On return, the `addr`, `opt` and `udata` fields of `rcvcall` will be updated to reflect values associated with the connection. Thus, the `maxlen` field of each argument must be
set before issuing this function to indicate the maximum size of the buffer for each.
However, rcvcall may be a NULL pointer, in which case no information is given to
the user on return from t_connect().

By default, t_connect() executes in synchronous mode, and will wait for the
destination user's response before returning control to the local user. A successful
return (that is, return value of zero) indicates that the requested connection has
been established. However, if O_NONBLOCK is set (using t_open() or fcntl() ),
t_connect() executes in asynchronous mode. In this case, the call will not wait for
the remote user's response, but will return control immediately to the local user and
return -1 with t_errno set to TNODATA to indicate that the connection has not yet
been established. In this way, the function simply initiates the connection
establishment procedure by sending a connect request to the destination transport
user. The t_rcvconnect() function is used in conjunction with t_connect() to
determine the status of the requested connection.

When a synchronous t_connect() call is interrupted by the arrival of a signal, the
state of the corresponding transport endpoint is T_OUTCON, allowing a further call
to either t_rcvconnect(), t_rcvdis() or t_snddis().

Valid states:

T_IDLE

Returned value

If successful, t_connect() returns 0.
If unsuccessful, t_connect() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TACCES</td>
<td>The user does not have permission to use the specified address or options.</td>
</tr>
<tr>
<td>TADDRBUSY</td>
<td>This transport provider does not support multiple connections with the same local and remote addresses. This error indicates that a connection already exists.</td>
</tr>
<tr>
<td>TBADADDR</td>
<td>The specified protocol address was in an incorrect format or contained illegal information.</td>
</tr>
<tr>
<td>TBADDATA</td>
<td>The amount of user data specified was not within the bounds allowed by the transport provider.</td>
</tr>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint.</td>
</tr>
<tr>
<td>TBADOPT</td>
<td>The specified protocol options were in an incorrect format or contained illegal information.</td>
</tr>
<tr>
<td>TBUFOVFLW</td>
<td>The number of bytes allocated for an incoming argument (maxlen) is greater than 0 but not sufficient to store the value of that argument. If executed in synchronous mode, the provider's state, as seen by the user, changes to T_DATAXFER, and the information to be returned in rcvcall is discarded.</td>
</tr>
<tr>
<td>TLOOK</td>
<td>An asynchronous event has occurred on this transport endpoint and requires immediate attention.</td>
</tr>
</tbody>
</table>
TNODATA O NONINFRINGEMENT It was set, so the function successfully initiated the connection establishment procedure, but did not wait for a response from the remote user.

TNOTSUPPORT This function is not supported by the underlying transport provider.

TOUTSTATE The function was issued in the wrong sequence.

TPROTO This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).

TSYSERR A system error has occurred during execution of this function.

tcperror

tcperror() — Print the error messages of a socket function

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>
#include <stdio.h>
#include <errno.h>

void tcperror(const char *s);
```

General description

When a socket call produces an error, the call returns a negative value and the variable errno is set to an error value found in ERRNO.H. The tcperror() call prints a short error message describing the last error that occurred. If s is non-NULL, tcperror() prints the string s followed by a colon, followed by a space, followed by the error message, and terminated with a newline character. If s is NULL or points to a NULL string, only the error message and the newline character are output.

The tcperror() function is equivalent to the perror() function in UNIX.

Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>A NULL or NULL-terminated character string.</td>
</tr>
</tbody>
</table>

Returned value

tcperror() returns no values.

Example

The following are examples of the tcperror() call.

Example 1:

```c
if ((s=socket(AF_INET, SOCK_DGRAM, 0)) < 0) {
    tcperror("socket()");
    exit(2);
}
```

If the socket() call produces the error ENOMEM, socket() returns a negative value and sets errno to ENOMEM. When tcperror() is called, it prints the string:

```
socket(): not enough storage (ENOMEM)
```

Example 2:

```c
if ((s=socket(AF_INET, SOCK_DGRAM, 0)) < 0)
    tcperror(NULL);
```

If the socket() call produces the error ENOMEM, socket() returns a negative value and sets errno to ENOMEM. When tcperror() is called, it prints the string:

```
Not enough storage (ENOMEM)
```

tcsendbreak

**tcsendbreak() — Send a break condition to a terminal**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _POSIX_SOURCE
#include <termios.h>

int tcsendbreak(int fildes, int duration);
```

**General description**

Sends a break condition to a terminal (indicated by `fildes`) that is using asynchronous serial data transmission. `tcsendbreak()` sends a continuous stream of zero bits for the specified `duration`. `tcsendbreak()` is the usual method of sending a BREAK on a line.

If `tcsendbreak()` is issued against a pseudoterminal, this function has no effect.

If `tcsendbreak()` is called from a background process group against the caller's controlling terminal, a SIGTTOU signal may be generated depending how the process is handling SIGTTOUs:

<table>
<thead>
<tr>
<th>Processing for SIGTTOU</th>
<th>System Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default or signal handler</td>
<td>The SIGTTOU signal is generated, and the function is not performed. <code>tcsendbreak()</code> returns −1 and sets errno to EINTR.</td>
</tr>
<tr>
<td>Ignored or blocked</td>
<td>The SIGTTOU signal is not sent, and the function continues normally.</td>
</tr>
</tbody>
</table>

**Returned value**

If successful, `tcsendbreak()` returns 0.

If unsuccessful, `tcsendbreak()` returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal interrupted <code>tcsendbreak()</code>.</td>
</tr>
<tr>
<td>EIO</td>
<td>The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.</td>
</tr>
<tr>
<td>ENOTTY</td>
<td><code>fildes</code> is not associated with a terminal.</td>
</tr>
</tbody>
</table>
Example

CELEBT08:
/* CELEBT08
   This example breaks terminal transmission.
*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <termios.h>
#include <unistd.h>

main() {
    if (tcsendbreak(STDIN_FILENO, 100) != 0)
        perror("tcsendbreak() error");
    else
        puts("break sent");
}

<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <termios.h>

int tcsetattr(int fd, int when, const struct termios *termptr);
```

General description

tcsetattr() only works in an environment where either a controlling terminal exists, or stdin and stderr refer to tty devices. Specifically, it does not work in a TSO environment.

Changes the attributes associated with a terminal. New attributes are specified with a termios control structure. Programs should always issue a tcgetattr() first, modify the desired fields, and then issue a tcsetattr(). tcsetattr() should never be issued using a termios structure that was not obtained using tcgetattr(). tcsetattr() should use only a termios structure that was obtained by tcgetattr().

- **fd**: Indicates an open file descriptor associated with a terminal.
- **when**: Indicates a symbol, defined in the termios.h header file, specifying when to change the terminal attributes:
  - **Symbol**: Meaning
  - TCSANOW: The change should take place immediately.
  - TCSADRAIN: The change should take place after all output written to `fd` has been read by the master pseudoterminal. Use this value when changing terminal attributes that affect output.
  - TCSAFLUSH: The change should take place after all output written to `fd` has been sent; in addition, all input that has been received but not read should be discarded (flushed) before the change is made.

- ***termptr**: A pointer to a termios control structure containing the desired terminal attributes.

A termios structure contains the following members:

- **tcflag_t c_iflag**: Input modes. tcflag_t is defined in the termios.h header file. Each bit in c_iflag indicates an input attribute and is associated with a symbol defined in the termios.h include file. All symbols are bitwise distinct. Thus c_iflag is the bitwise inclusive-OR of several of these symbols. Possible symbols are:
## Symbol Meaning

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>BRKINT</td>
<td>Indicates that an interrupt should be generated if the user types a BREAK.</td>
</tr>
<tr>
<td>ICRNL</td>
<td>Automatically converts input carriage returns to newline (line-feed) characters before they are passed to the application that reads the input.</td>
</tr>
<tr>
<td>IGNBRK</td>
<td>Ignores BREAK conditions. If this bit is set to 1, applications are not informed of any BREAK condition on the terminal; the setting of BRKINT has no effect. If IGNBRK is 0 but BRKINT is 1, BREAK flushes all input and output queues. In addition, if the terminal is the controlling terminal of a foreground process group, the BREAK condition generates a single SIGINT signal for that foreground process group. If both IGNBRK and BRKINT are 0, a BREAK condition is taken as the single input character NULL, if PARMRK is 0, and as the three input characters <code>\377-NULL-NULL</code>, if PARMRK is 1.</td>
</tr>
<tr>
<td>IGNCR</td>
<td>Ignores input carriage returns. If this bit is set to 1, the setting of ICRNL has no effect. If IGNCR is 0 and ICRNL is 1, input carriage returns are converted to newline characters. For z/OS UNIX &quot;NL&quot; or &quot;\n&quot; is the EBCDIC character NL.</td>
</tr>
<tr>
<td>IGNPAR</td>
<td>Ignores input characters (other than BREAK) that have parity errors.</td>
</tr>
<tr>
<td>INLCR</td>
<td>Automatically converts input newline (line-feed) characters to carriage returns before they are passed to the application that reads the input.</td>
</tr>
<tr>
<td>INPCK</td>
<td>Enables input parity checking. If this bit is set to 0, it allows output parity generation without input parity errors. The enabling of input parity checking is independent of the enabling of parity checking in the control modes field. (See the description of &quot;tcflag_t c_cflag,&quot; which follows.) While the control modes may dictate that the hardware recognizes the parity bit, but the terminal special file does not check whether this bit is set correctly.</td>
</tr>
<tr>
<td>ISTRIP</td>
<td>Strips valid input bytes to 7 bits. If this bit is set to 0, the complete byte is processed. <strong>Note:</strong> Do not set this bit for pseudoterminals, since it will make the terminal unusable. If you strip the first bit off of EBCDIC characters, you destroy all printable EBCDIC characters.</td>
</tr>
</tbody>
</table>
| IUCLC | Map uppercase to lowercase on the received character. In locales other than the POSIX locale, the mapping is unspecified. Thus, this function only applies to the characters in the POSIX-portable locale.
character set that have lowercase equivalents, namely the characters A-Z.

Note:

This symbol is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro

Note: Do not use IXOFF while in DBCS mode. If you intersperse STOP and START characters inside DBCS data while using IXOFF, you could corrupt output data.

IXANY Enable any character to restart output. If IXOFF and IXANY are set and a previous STOP character has been received, then receipt of any input character will cause the STOP condition to be removed. For pseudoterminals, data in the output queue is passed to the application during master read() processing, and slave pseudoterminal writes are allowed to proceed. The character which caused the output to restart is also processed normally as well (unless it is a STOP character).

IXOFF Enables start/stop input control. If this bit is set to 1, the system attempts to prevent the number of bytes in the input queue from exceeding the MAX_INPUT value. It sends one or more STOP characters to the terminal device when the input queue is in danger of filling up. The character used as the STOP character is dictated by the

Note: Enables start/stop output control. If the system receives a STOP character as input, it will suspend output on the associated terminal until a START character is received. An application reading input from the terminal does not see STOP or START
Characters; they are intercepted by the system, which does all the necessary processing.

If IXON is 0, any STOP or START characters read are passed on as input to an application reading from the terminal.

**PARMRK**

Marks characters with parity errors. If this bit is set to 1 and IGNPAR is 0, a byte with a framing or parity error is sent to the application as the characters `\377` and NULL, followed by the data part of the byte that had the parity error. If ISTRIP is 0, a valid input character of `\377` is sent as a pair of characters `\377`, `\377` to avoid ambiguity.

If both PARMRK and IGNPAR are 0, a character with a framing or parity error is sent to the application as NULL.

**tcflag_t c_oflag**

Output modes. Each bit in c_oflag indicates an output attribute, and is associated with a symbol defined in the termios.h header file. Thus c_oflag is the bitwise inclusive-OR of a number of these symbols. Possible symbols are:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPOST</td>
<td>Modifies lines of text in an implementation-defined way to appear appropriately on the terminal device. If this bit is set to 0, characters that an application puts out are sent without change.</td>
</tr>
<tr>
<td>OLCUC</td>
<td>If OPOST and OLCUC are set, then map lowercase to uppercase on the output. In locales other that the POSIX locale, the mapping is unspecified. Thus, this function only applies to the characters in the POSIX-portable character set that have uppercase equivalents, namely the characters a-z.</td>
</tr>
</tbody>
</table>

**Note:**

This symbol is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ONLCR</td>
<td>If OPOST and ONLCR are set, the NL character is transmitted as the CR-NL character pair.</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>OCRNL</td>
<td>If OPOST and OCRNL are set, the CR character is transmitted as the NL character.</td>
</tr>
<tr>
<td>ONOCR</td>
<td>If OPOST and ONOCR are set, no CR character is transmitted if the current column is zero.</td>

</table>
### cflag_t c_cflag

Control modes. Each bit in c_cflag indicates a control attribute and is associated with a symbol defined in the termios.h header file. Thus c_cflag is the bitwise inclusive-OR of several of these symbols. Possible symbols are:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLOCAL</td>
<td>Ignores modem status lines. A call to open() returns immediately without waiting for a modem connection to complete. If this bit is set to 0, modem status lines are monitored and open() waits for the modem connection.</td>
</tr>
<tr>
<td>CREAD</td>
<td>Enables reception. If this bit is set to 0, no input characters are received from the terminal. Using z/OS UNIX pseudoterminal support, this bit is always enabled and set to 1.</td>
</tr>
<tr>
<td>CSIZE</td>
<td>Is a collection of bits indicating the number of bits per byte (not counting the parity bit, if any). These bits specify byte size for both transmission and reception. Possible settings of CSIZE are given with the following symbols:</td>
</tr>
<tr>
<td></td>
<td>CS5 - 5 bits per byte</td>
</tr>
<tr>
<td></td>
<td>CS6 - 6 bits per byte</td>
</tr>
<tr>
<td></td>
<td>CS7 - 7 bits per byte</td>
</tr>
<tr>
<td></td>
<td>CS8 - 8 bits per byte</td>
</tr>
<tr>
<td>CSTOPB</td>
<td>Sends two stop bits when necessary. If CSTOPB is 0, only one stop bit is used. Using z/OS UNIX pseudoterminal support, this bit is always 0. Using z/OS UNIX OCS support, the specified value is used.</td>
</tr>
<tr>
<td>HUPCL</td>
<td>Lowers the modem control lines for a port when the last process that has the port open closes the port (or the process ends). In other words, this tells the system to hang up when all relevant processes have finished using the port. For pseudoterminals HUPCL controls what happens when the slave pseudoterminals is closed. If HUPCL is set when the last file descriptor for the slave pseudoterminal is closed, then the slave pseudoterminal cannot be re-opened. The master terminal has to be closed and re-opened before the pair can be used again.</td>
</tr>
<tr>
<td>PARENB</td>
<td>Enables parity generation and detection. A parity bit</td>
</tr>
</tbody>
</table>

---

**tcsetattr**

- FF0  No delay.
- FF1  2 seconds delay.
is added to each character on output, and expected from each character on input.

Under z/OS UNIX, if this bit is set to 1 in a request, it is ignored. It is always set to 0. Using z/OS UNIX OCS support, the specified value is used.

PARODD Indicates odd parity (when parity is enabled). If PARODD is 0, even parity is used (when parity is enabled).

Under z/OS UNIX, if this bit is set to 1 in a request, it is ignored. It is always set to 0. Using z/OS UNIX OCS support, the specified value is used.

If the object for which the control modes are set is not an asynchronous serial connection, some bits may be ignored. For example, on a network connection, it may not be possible to set the baud rate.

tcflag_t c_lflag

Local modes. Each bit in c_lflag indicates a local attribute, and is associated with a symbol defined in the termios.h include file. Thus c_lflag is the bitwise inclusive-OR of a number of these symbols. Possible symbols are:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECHO</td>
<td>Echoes input characters back to the terminal. If this is bit is 0, input characters are not echoed.</td>
</tr>
<tr>
<td>ECHOE</td>
<td>Echoes the ERASE character as an error-correcting backspace. When the user inputs an ERASE character, the terminal erases the last character in the current line from the display (if possible). The character used as the ERASE character is dictated by the c_cc member of the termios structure. ECHOE has an effect only if the ICANON bit is 1.</td>
</tr>
<tr>
<td>ECHOK</td>
<td>Either causes the terminal to erase the line from the display, or echoes the KILL character followed by an \n character. ECHOK has an effect only if the ICANON bit is set to 1.</td>
</tr>
<tr>
<td>ECHONL</td>
<td>Echoes the newline (line-feed) character \n' even if the ECHO bit is off. ECHONL has an effect only if the ICANON bit is set to 1.</td>
</tr>
<tr>
<td>ICANON</td>
<td>Enables canonical input processing, also called line mode. Input is not delivered to the application until an entire line has been input. The end of a line is indicated by a newline, End Of File (EOF), or EOL character (where the character used as the EOL character is directed by the c_cc member of the termios structure [described shortly]). Canonical input processing uses the ERASE character to erase a single input character, and the KILL character to erase an entire line. The MAX_CANON value specifies the maximum number of bytes in an input line in canonical mode.</td>
</tr>
</tbody>
</table>
If ICANON is 0, read requests take input directly from the input queue; the system does not wait for the user to enter a complete line. This is called noncanonical mode. ERASE and KILL characters are not handled by the system but passed directly to the application. See also the descriptions of MIN and TIME in the \_c\_cc member.

**IEXTEN** Enables extended implementation-defined functions. These are not defined, and IEXTEN is always set to 0.

If the ERASE, KILL or EOF character is preceded by a backslash character, the special character is placed in the input queue without doing the "special character" processing and the backslash is discarded.

**ISIG** If ISIG is set to 1, signals are generated if special control characters are entered. SIGINT is generated if INTR is entered; SIGQUIT is generated if QUIT is entered; and SIGTSTP is generated if SUSP is entered and job control is supported. The special control characters are controlled by the \_c\_cc member.

If ISIG is 0, the system does not generate signals when these special control characters are entered.

**NOFLSH** If this bit is set to 1, the system does not flush the input and output queues if a signal is generated by one of the special characters described in ISIG above. If NOFLSH is set to 0, the queues are flushed if one of the special characters is found.

**TOSTOP** If this bit is set to 1, a SIGTTOU signal is sent to the process group of a process that tries to write to a terminal when it is not in the terminal's foreground process group. However, if the process that tries to write to the terminal is blocking or ignoring SIGTTOU signals, the system does not raise the SIGTTOU signal.

If TOSTOP is 0, output from background processes is output to the current output stream, and no signal is raised.

**XCASE** Do canonical lower and canonical upper presentation. In locales other than the POSIX locale, the effect is unspecified. XCASE set by itself makes all uppercase letters on input and output be preceded by a "\" character.

Some terminals can generate lowercase characters, but can display only uppercase characters. For these terminals, XCASE would be used by itself. Other terminals cannot generate lowercase characters either. For these terminals, XCASE would be used with IUCLC to generate lowercase characters when characters are typed without the
backslash, and uppercase characters when the typed character is preceded by a backslash.

If a terminal can generate only uppercase characters, but can display either upper or lowercase, then XCASE would be used with OLCUC.

**Note:**

This symbol is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

### CONTROL CHARACTERS

Control characters. This is an array of characters that may have special meaning for terminal handling. You can access characters in this array using subscripts that are symbols defined in the termios.h header file. For example, the STOP character is given by `c_cc[VSTOP]`. Possible subscript symbols are:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>VEOF</td>
<td>Gives the End Of File character EOF. It is recognized only in canonical (line) mode. When this is found in input, all bytes waiting to be read are immediately passed to the application without waiting for the end of the line. The EOF character itself is discarded. If EOF occurs at the beginning of a line, the <code>read</code> function that tries to read that line receives an End Of File (EOF) indication. Note that EOF results in End Of File only if it is at the beginning of a line; if it is preceded by one or more characters, it indicates only End Of Line (EOL).</td>
</tr>
<tr>
<td>VEOL</td>
<td>Gives the End Of Line character EOL. It is recognized only in canonical (line) mode. This is an alternate character for marking the end of a line (in addition to the newline <code>\n</code>).</td>
</tr>
<tr>
<td>VERASE</td>
<td>Gives the ERASE character. It is recognized only in canonical (line) mode. It deletes the last character in the current line. It cannot delete beyond the beginning of the line.</td>
</tr>
<tr>
<td>VINTR</td>
<td>Gives the interrupt character INTR. It is recognized only if ISIG is set to 1 in <code>c_iflag</code>. If the character is received, the system sends a SIGINT signal to all...</td>
</tr>
</tbody>
</table>
the processes in the foreground process group that has this device as its controlling terminal.

VKILL
Gives the KILL character. It is recognized only in canonical (line) mode. It deletes the entire contents of the current line.

VMIN
Gives the MIN value for noncanonical mode processing.
This is the minimum number of bytes that a call to read should return in noncanonical mode; it is not used in canonical mode.

If both MIN and TIME are greater than 0, read returns when MIN characters are available or when the timer associated with TIME runs out (whichever comes first). The timer starts running as soon as a single character has been entered; if there is already a character in the queue when read is called, the timer starts running immediately.

If MIN is greater than zero and TIME is zero, read waits for MIN characters to be entered, no matter how long that takes.

If MIN is zero and TIME is greater than zero, read returns when the timer runs out or when a single character is received (whichever comes first). read returns either one character (if one is received) or zero (if the timer runs out). The timer starts running as soon as read is called. (Contrast this with the case where MIN and TIME are both greater than zero, and the timer starts only when a character is received.)

If both MIN and TIME are zero, read returns immediately from every call. It returns the number of bytes that are immediately available, up to the maximum specified in the call to read.

VQUIT
Gives the quit character QUIT. It is recognized only if ISIG is set to 1 in c_lflag. If the character is received, the system sends a SIGQUIT signal to all the processes in the foreground process group that has this device as its controlling terminal.

VSUSP
Gives the suspend character SUSP. It is recognized only if ISIG is set to 1 in c_lflag. If the character is received, the system sends a SIGTSTP signal to all the processes in the foreground process group that has this device as its controlling terminal.

VTIME
Gives the TIME value, used in noncanonical mode in connection with MIN. It expresses a time in terms of tenths of a second.

VSTOP
Gives the STOP character. You can use this to suspend output temporarily when IXON is set to 1
tcsetattr

in c_iflag. Users can enter the STOP character to prevent output from running off the top of a display screen.

VSTART Gives the START character. You can use this to resume suspended output when IXON is set to 1 in c_iflag.

When tcsetattr() is called from a background session against a controlling terminal, SIGTTOU processing is as follows:

<table>
<thead>
<tr>
<th>Processing for SIGTTOU</th>
<th>Expected Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default or signal handler</td>
<td>The SIGTTOU signal is generated, and the function is not performed. tcsetattr() returns -1 and sets errno to EINTR.</td>
</tr>
<tr>
<td>Ignored or blocked</td>
<td>The SIGTTOU signal is not sent, and the function continues normally.</td>
</tr>
</tbody>
</table>

**Note:** The tcsetattr() function has a dependency on the level of the Enhanced ASCII Extensions. See Enhanced ASCII support on page 2543 for details.

**Returned value**

If successful, tcsetattr() returns 0.

If unsuccessful, tcsetattr() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><em>fildes</em> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal interrupted tcsetattr().</td>
</tr>
<tr>
<td>EINVAL</td>
<td><em>when</em> is not a recognized value, or some entry in the supplied termios structure had an incorrect value.</td>
</tr>
<tr>
<td>EIO</td>
<td>The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.</td>
</tr>
<tr>
<td>ENOTTY</td>
<td><em>fildes</em> is not associated with a terminal.</td>
</tr>
</tbody>
</table>

**Example**

**CELEBT09:**

```c
/* CELEBT09

The following attributes changes the terminal attributes.

*/
#define _POSIX_SOURCE
#include <termios.h>
#include <unistd.h>
#include <stdio.h>

int main() {
    struct termios term1, term2;

    if (tcgetattr(STDIN_FILENO, &term1) != 0)
        perror("tcgetattr() error");
    else {
```
printf("the original end-of-file character is x'\%02x'\n",
   term1.c_cc[VEOF]);
term1.c_cc[VEOF] = 'z';
if (tcsetattr(STDIN_FILENO, TCSANOW, &term1) != 0)
   perror("tcsetattr() error");
if (tcgetattr(STDIN_FILENO, &term1) != 0)
   perror("tcgetattr() error");
else
   printf("the new end-of-file character is x'\%02x'\n",
      term1.c_cc[VEOF]);
}

Output:
the original End Of File character is x'37'
the new End Of File character is x'a9'

<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_PTY_EXTENSIONS
#include <termios.h>

int __tcsetcp(int fildes, size_t termcplen, const struct __termcp *termcpptr);
```

General description

The __tcsetcp() function sets (or changes) the terminal session code page information contained in the termcp structure.

The following arguments are used:

- `fildes`: The file descriptor of the terminal for which you want to get the code page names and CPCN capability.
- `termcplen`: The length of the passed termcp structure.
- `termcpptr`: A pointer to a __termcp structure.

Use the __tcsetcp() function to send new code page information to the data conversion point in order to change the data conversion environment for the terminal session. This function is used with terminal devices that support the “forward code page names only” Code Page Change Notification (CPCN) capability. The z/OS UNIX pseudotty (pty) device driver supports this capability.

For terminal sessions that use the z/OS UNIX pty device driver, the data conversion point is the application that uses the master pty device. An example data conversion point is the z/OS UNIX `rlogin` server. Here, `rlogin` uses CPCN functions to determine the ASCII source and/or EBCDIC target code pages to use for the conversion of the terminal data. During its processing of the __tcsetcp() function, the pty device driver applies the __termcp structure once the pty outbound data queue is drained. When this occurs, the pty input data queue is also flushed and a TIOCPKT_CHCP packet exception event is generated if extended packet mode is enabled (PKTXTND is set in the termios structure) to notify the application using the master pty that the code page information has been changed. The master pty application can then use the __tcgetcp() function to retrieve the new code page information and establish a new data conversion environment.

The __tcsetcp() function is supported by both the master and slave pty device drivers, however, CPCN functions first must be enabled by the application that uses the master pty; enabling CPCN functions is performed by the system during the initial __tcsetcp() invocation against the master pty device. Once the __tcsetcp() function is performed against the master pty then it may be subsequently issued against the slave pty.

**Note:** The data conversion for a z/OS UNIX terminal session is performed on a session (terminal file) basis. If you change the data conversion
characteristics for one file descriptor, the new data conversion will apply to all open file descriptors associated with this terminal file.

**Attention:** Use this service carefully. By changing the code pages for the data conversion you may cause unpredictable behavior in the terminal session if the actual data used for the session is not encoded to the specified source (ASCII) and target (EBCDIC) code pages.

A __termcp structure contains the following members:

__tccp_flags  Flags. The following symbols are defined as bitwise distinct values. Thus, __tccp_flags is the bitwise inclusive-OR of these symbols:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>_TCCP_BINARY</td>
<td>Use _TCCP_BINARY to notify the data conversion point to stop data conversion. If this flag is set, the source and target code page names (__tccp_fromname and __tccp_toname respectively) are not changed from their current values.</td>
</tr>
</tbody>
</table>

**Attention:** Use this option carefully. Once the data conversion is disabled the z/OS UNIX Shell cannot be used until the data conversion is re-enabled, using valid code pages for the terminal session.

__TCCP_FASTP  Use _TCCP_FASTP to indicate to the data conversion point (for example, rlogin) that the data conversion specified by the source and target code page names can be performed locally to the application. This is valid any time that a table-driven conversion can be performed. For example, the data conversion point (application) could use the z/OS UNIX iconv() service to build the local data conversion tables and perform all data conversion using the local tables instead of using iconv() in subsequent conversions. This provides for better-performing data conversion.

__tccp_fromname  The source code page name; typically this is the ASCII code page name. __tccp_fromname is a NULL-terminated string with a maximum length of _TCCP_CPNAMEMAX, including the NULL (\00) character. __tccp_fromname is case-sensitive.

__tccp_toname  The target code page name; typically this is the EBCDIC code page name. __tccp_toname is a NULL-terminated string with a maximum length of _TCCP_CPNAMEMAX, including the NULL (\00) character. __tccp_toname is case-sensitive.
When \_tcsetcp() is issued against the slave pty from a process in a background process group, SIGTTOU processing is as follows:

<table>
<thead>
<tr>
<th>Processing for SIGTTOU</th>
<th>Expected Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default or signal handler</td>
<td>The SIGTTOU signal is generated. The function is not performed. _tcsetcp() returns -1 and sets errno to EINTR.</td>
</tr>
<tr>
<td>Ignored or blocked</td>
<td>The SIGTTOU signal is not sent. The function continues normally.</td>
</tr>
</tbody>
</table>

**Note:** The \_tcsetcp() function has a dependency on the level of the Enhanced ASCII Extensions. See Enhanced ASCII support on page 2543 for details.

### Returned value

If successful, \_tcsetcp() returns 0.

If unsuccessful, \_tcsetcp() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>

### Example

The following example retrieves the CPCN capability and code pages and then changes the ASCII code page to IBM-850.

```c
#define _OPEN_SYS_PTY_EXTENSIONS
#include <unistd.h>
#include <stdio.h>
#include <fcntl.h>
#include <termios.h>

void main(void)
{
    struct __termcp mytermcp;
    int rv;
    int cterm_fd;

    if ((cterm_fd = open("/dev/tty",O_RDWR)) == -1)
        printf("No controlling terminal established.\n");
    else {
        if ((rv = __tcgetcp(STDIN_FILENO,sizeof(mytermcp),&mytermcp))== -1)
            perror("__tcgetcp() error");
```
else {
    if (rv == CPCN_NAMES) {
        if (_TCCP_BINARY == (mytermcp.__tccp_flags & _TCCP_BINARY))
            printf("Binary mode is in effect. No change made.\n");
        else {
            strcpy(mytermcp.__tccp_fromname,"IBM-850");
            if (__tcsetcp(STDOUT_FILENO,sizeof(mytermcp),&mytermcp)!=0)
                perror("__tcsetcp() error");
            else
                printf("ASCII code page changed to IBM-850.\n");
        } /*not binary mode */
    } /*_CPCN_NAMES */
} /*__tcgetcp success */
} /* controlling terminal established */
} /* main */

Output:
ASCII code page changed to IBM-850.

tcsetpgrp

**tcsetpgrp() — Set the foreground process group ID**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```
#define _POSIX_SOURCE
#include <unistd.h>

int tcsetpgrp(int fildes, pid_t newid);
```

**General description**

Sets the process group ID (PGID) of the foreground process group associated with the terminal referred to by `fildes`. This terminal must be the controlling terminal of the process calling `tcsetpgrp()` and must be currently associated with the session of the calling process. `newid` must match a PGID of a process in the same session as the calling process.

After the PGID associated with the terminal is set, reads by the process group formerly associated with the terminal fail or cause the process group to stop from a SIGTTIN signal. Writes may also cause the process to stop (from a SIGTTOU signal), or they may succeed, depending on how `tcsetattr()` sets TOSTOP and the signal options for SIGTTOU.

`fildes` can be any of the descriptors representing the controlling terminal (such as standard input, standard output, and standard error), and the function affects future access from any file descriptor in use for the terminal. Consider using redirection when specifying the file descriptor.

If `tcsetpgrp()` is called from a background process group against the caller’s controlling terminal, a SIGTTOU signal may be generated depending how the process is handling SIGTTOUs:

<table>
<thead>
<tr>
<th>Processing for SIGTTOU</th>
<th>System Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default or signal handler</td>
<td>The SIGTTOU signal is generated, and the function is not performed. <code>tcsetpgrp()</code> returns −1 and sets errno to EINTR.</td>
</tr>
<tr>
<td>Ignored or blocked</td>
<td>The SIGTTOU signal is not sent, and the function continues normally.</td>
</tr>
</tbody>
</table>

**Returned value**

If successful, `tcsetpgrp()` returns 0.

If unsuccessful, `tcsetpgrp()` returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
</tbody>
</table>
tcsetpgrp

EINTR A signal interrupted the tcsetpgrp() function.
EINVAL The newid value is not supported by this implementation.
ENOTTY The process calling tcsetpgrp() does not have a controlling terminal, or fildes is not associated with the controlling terminal, or the controlling terminal is no longer associated with the session of the calling process.
EPERM The newid value is supported by the implementation but does not match the process group ID of any process in the same session as the process calling tcsetpgrp().

Example

CELEBT10:

/* CELEBT10
   This example changes the PGID.
*/
#define _POSIX_SOURCE
#include <termios.h>
#include <unistd.h>
#include <sys/wait.h>
#include <stdio.h>
#include <signal.h>
main() {
    pid_t pid;
    int status;
    if (fork() == 0) {
        if ((pid = tcgetpgrp(STDOUT_FILENO)) < 0)
            perror("tcgetpgrp() error");
        else {
            printf("original foreground process group id of stdout was \%d\n", (int) pid);
            if (setpgid(getpid(), 0) != 0)
                perror("setpgid() error");
            else {
                printf("now setting to \%d\n", (int) getpid());
                if (tcsetpgrp(STDOUT_FILENO, getpid()) != 0)
                    perror("tcsetpgrp() error");
                else if ((pid = tcgetpgrp(STDOUT_FILENO)) < 0)
                    perror("tcgetpgrp() error");
                else
                    printf("new foreground process group id of stdout was \%d\n", (int) pid);
            }
        }
    }
    else wait(&status);
}

Output:
original foreground process group id of stdout was 2228230
now setting to 2949128
new foreground process group id of stdout was 2949128

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td></td>
<td>both</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_PTY_EXTENSIONS
#include <termios.h>

int __tcsettables(int fildes, size_t termcplen,
                   const struct __termcp *termcpptr,
                   const char atoe[256],
                   const char etoa[256]);
```

General description

The __tcsettables() function changes the data conversion environment for terminal sessions that support the “forward code page names and tables” Code Page Change Notification (CPCN) capability. The OCS remote-tty (rty) device driver supports this capability.

The following arguments are used:

- `fildes` The file descriptor of the terminal for which you want to set the code page names and data conversion tables.
- `termcplen` The length of the passed termcp structure.
- `termcpptr` A pointer to a __termcp structure. A __termcp structure contains the following members:

  - `__tccp_flags` Flags. The following symbols are defined as bitwise distinct values. Thus, __tccp_flags is the bitwise inclusive-OR of these symbols:

    | Symbol       | Meaning                                                                 |
    |--------------|-------------------------------------------------------------------------|
    | _TCCP_BINARY| Use _TCCP_BINARY to notify the data conversion point to stop data conversion. If this flag is set the source and target code page names (__tccp_fromname and __tccp_toname respectively) are not changed, and the data conversion tables atoe and etoa are not used. |

  **Attention:** Use this option carefully. Once the data conversion is disabled the z/OS shell cannot be used until the data conversion is re-enabled, using valid code pages for the terminal session.
_tcsettables

_TCCP_FASTP

Use _TCCP_FASTP to indicate to the data conversion point that the data conversion specified by the source and target code page names can be performed locally by the application that performs the data conversion. This is valid any time that a table-driven conversion can be performed.

This value is not used by the OCS rty device driver and thus has no effect.

__tccp_fromname

The source code page name; typically this is the ASCII code page name. __tccp_fromname is a NULL-terminated string with a maximum length of _TCCP_CPNAMEMAX, including the NULL (\00) character.

__tccp_fromname is case-sensitive.

__tccp_toname

The target code page name; typically this is the EBCDIC code page name. __tccp_toname is a NULL-terminated string with a maximum length of _TCCP_CPNAMEMAX, including the NULL (\00) character.

__tccp_toname is case-sensitive.

const char atoe[256]

A 256-byte data conversion table for the source-to-target (ASCII-to-EBCDIC) data conversion. The byte offset into this table corresponds to the character code from the source (ASCII) code page. The data value at each offset is the "converted" target (EBCDIC) character code.

const char etoa[256]

A 256-byte data conversion table for the target-to-source (EBCDIC-to-ASCII) data conversion. The byte offset into this table corresponds to the character code from the target (EBCDIC) code page. The data value at each offset is the "converted" source (ASCII) character code.

Note: The data conversion for a z/OS UNIX terminal session is performed on a session (terminal file) basis. If you change the data conversion characteristics for one file descriptor, the new data conversion will apply to all open file descriptors associated with this terminal file.

For terminal sessions that use the OCS rty device driver, the ASCII/EBCDIC data conversion is performed outboard by OCS on the AIX server system. Use the __tcsettables() function to specify new code pages and conversion tables to be used in the data conversion.
During its processing of the `__tcsettables()` function, the OCS rty device driver applies the new code page names once the outbound data queue is drained. When this occurs, the rty input data queue is also flushed and the new conversion environment takes effect.

OCS processing of the `atoe` and `etoa` arguments is as follows:

- If the code page names specified in the `__termcp` structure are for supported double-byte data conversion then the `atoe` and `etoa` arguments are not used. The following double-byte translation is supported for OCS sessions:
- If `__fromname` specifies **ISO8859-1** and `__toname` specifies **IBM-1047** then OCS uses its own data conversion tables and `atoe` and `etoa` arguments are not used.
- Otherwise the conversion tables in `atoe` and `etoa` are used.

**Attention:** Use this service carefully. By changing the code pages for the data conversion you may cause unpredictable behavior in the terminal session if the actual data used for the session is not encoded to the specified source (ASCII) and target (EBCDIC) code pages.

When `__tcsettables()` is issued from a process in a background process group, SIGTTOU is processing in this way:

<table>
<thead>
<tr>
<th>Processing for SIGTTOU</th>
<th>Expected Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default or signal handler</td>
<td>The SIGTTOU signal is generated. The function is not performed. <code>__tcsettables()</code> returns -1 and sets errno to EINTR.</td>
</tr>
<tr>
<td>Ignored or blocked</td>
<td>The SIGTTOU signal is not sent. The function continues normally.</td>
</tr>
</tbody>
</table>

**Returned value**

If successful, `__tcsettables()` returns 0.

If unsuccessful, `__tcsettables()` returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td><code>fildes</code> is not a valid open file descriptor.</td>
</tr>
<tr>
<td>EINTR</td>
<td>A signal interrupted the call.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>One of the following error conditions exists:</td>
</tr>
<tr>
<td></td>
<td>• The value of <code>termcplen</code> was invalid.</td>
</tr>
<tr>
<td></td>
<td>• An invalid combination of multibyte code page names was specified in the <code>__termcp</code> structure.</td>
</tr>
<tr>
<td></td>
<td>One of the following applies:</td>
</tr>
<tr>
<td></td>
<td>• The source code page specified in <code>__tccp_fromname</code> specified a supported ASCII multibyte code page and the <code>__tccp_toname</code> did not specify a supported EBCDIC multibyte code page.</td>
</tr>
<tr>
<td></td>
<td>• The target code page specified in <code>__tccp_toname</code> specified a supported EBCDIC multibyte code page and the <code>__tccp_fromname</code> did not specify a supported ASCII multibyte code page.</td>
</tr>
<tr>
<td>EIO</td>
<td>The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.</td>
</tr>
</tbody>
</table>
**Example**

The following example retrieves the current code pages used in the data conversion and CPCN capability. The conversion tables using ASCII code page IBM-850 and the current EBCDIC code page are generated and exported to the data conversion point using `__tcsettables()`.

```c
#define _OPEN_SYS_PTY_EXTENSIONS
#include <fcntl.h>
#include <unistd.h>
#include <stdio.h>
#include <termios.h>
#include <iconv.h>

int main() {
  struct __termcp mytermcp; /* local __termcp */
  unsigned char *intabptr; /* pointer to input table */
  unsigned char *outtabptr; /* pointer to output table */
  unsigned char intab[256],
    atoe[256],
    etoa[256]; /* conversion tables */
  iconv_t cd; /* conversion descriptor */
  size_t inleft; /* number of bytes left in input */
  size_t outleft; /* number of bytes left in output */
  int i; /* loop variable */
  int rv; /* return value */
  int cterm_fd; /* file descriptor for controlling terminal */

  if ((cterm_fd = open("/dev/tty",O_RDWR)) == -1)
    { printf("No controlling terminal established. ");
      printf("Code pages were not changed.\n");
      exit(0); }

  if ((__tcgetcp(cterm_fd,sizeof(mytermcp),&mytermcp))== -1)
    { perror("__tcgetcp() error");
      exit(1); }

  if (_TCCP_BINARY == (mytermcp.__tccp_flags & _TCCP_BINARY))
    { printf("Binary mode is in effect. No change made.\n");
      exit(0); }

  if (rv == _CPCN_TABLES) {
    /* build ASCII -> EBCDIC conversion table */
    strcpy(mytermcp.__tccp_fromname,"IBM-850");
    if ((cd = iconv_open(mytermcp.__tccp_toname,
                     mytermcp.__tccp_fromname)) ==
        (iconv_t) (-1)) {
      fprintf(stderr,"Cannot open converter from %s to %s\n",
                  mytermcp.__tccp_fromname,mytermcp.__tccp_toname);
      exit(1); }

    __tcsettables(EXIT_SUCCESS);
  }
}
```
/* build input table with character values of 00 - FF */
for (i=0; i<256; i++ ) {
    intab[i] = (unsigned char) i;
} /* endfor */

inleft = 256;
outleft = 256;
intabptr = intab;
outtabptr = atoe;

/* build ASCII -> EBCDIC conversion table. */
rv = iconv(cd,&intabptr, &inleft, &outtabptr, &outleft);
if (rv == -1) {
    fprintf(stderr,"Error in building ASCII to EBCDIC table\n");
    exit(1);
}
iconv_close(cd);

/* build EBCDIC -> ASCII conversion table */
if ((cd = iconv_open(mytermcp.__tccp_fromname,
                     mytermcp.__tccp_toename)) ==
    (iconv_t) (-1)) {
    fprintf(stderr,"Cannot open converter from %s to %s\n",
            mytermcp.__tccp_toename,mytermcp.__tccp_fromname);
    exit(1);
}
inleft = 256;
outleft = 256;
intabptr = intab;
outtabptr = etoa;
rv = iconv(cd,&intabptr, &inleft, &outtabptr, &outleft);
if (rv == -1) {
    fprintf(stderr,"Error in building EBCDIC to ASCII table\n");
    exit(1);
}
iconv_close(cd);

/* Change the data conversion to use IBM-850 as the ASCII source */
if (__tcsettables(cterm_fd, mytermcp, &mytermcp,
                  atoe, etoa) == -1) {
    perror("__tcsettables() error");
    exit(1);
} else {
    printf("Data conversion now using ASCII IBM-850\n");
} /* endif */

Output:
Data conversion now using ASCII IBM-850.

tdelete

---

**tdelete() — Binary tree delete**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE
#include <search.h>

void *tdelete(const void *__restrict__ key, void **__restrict__ rootp,
               int (*compar)(const void *, const void *));
```

**General description**

The tdelete() function deletes a node from a binary search tree. The arguments are the same as for the tsearch() function. The variable pointed to by `rootp` will be changed if the deleted node was the root of the tree. tdelete() returns a pointer to the parent of the deleted node, or a NULL pointer if the node is not found. If the deleted node was the root of the tree, the function returns a pointer to the deleted node, since it had no parent. It frees the storage for this node before returning, so the contents of storage at the returned address are unreliable in this case.

Comparisons are made with a user-supplied routine, the address of which is passed as the `compar` argument. This routine is called with two arguments, the pointers to the elements being compared. The user-supplied routine must return an integer less than, equal to or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison functions need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

**Threading Behavior:** see "tsearch() — Binary tree search" on page 2295.

**Special behavior for C++:**

Because C and C++ linkage conventions are incompatible, tdelete() cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to tdelete(), the compiler will flag it as an error. You can pass a C or C++ function to tdelete() by declaring it as extern “C”.

**Returned value**

If successful, tdelete() returns a pointer to the parent of the deleted node.

If the node is not found, tdelete() returns a NULL pointer.

If `rootp` is a NULL pointer on entry, tdelete() returns a NULL pointer.

No errors are defined.

<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <dirent.h>

long telldir(DIR *dirp);
```

General description

The telldir() function obtains the current location associated with the directory stream specified by `dirp`.

If the most recent operation on the directory stream was a seekdir(), then the directory position returned from telldir() is the same as that supplied as a `loc` argument to seekdir().

Returned value

If successful, telldir() returns the current location of the specified directory stream.

If the `dirp` argument supplied is NULL or invalid, telldir() returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The <code>dirp</code> argument was invalid.</td>
</tr>
</tbody>
</table>

<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include _XOPEN_SOURCE
#include <stdio.h>
char *tempnam(const char *dir, const char *pfx);
```

General description

The tempnam() function generates a path name that may be used for a temporary file. If the environment variable TMPDIR is set, then the directory it specifies will be used as the directory part of the generated path name if it is accessible. Otherwise, if the `dir` argument is non-NULL and accessible, it will be used in the generated path name. Otherwise, the value of `{P_tmpdir}` defined in the `<stdio.h>` header is used as the directory component of the name. If that is inaccessible, then `/tmp` is used.

The `pfx` argument can be used to specify an initial component of the file name part of the path name. It may be a NULL pointer or point to a string of up to five bytes to be used as the beginning of a file name.

The names generated are unique across processes and threads, and over time, so multiple threads should be able to each repeatedly call tempnam() and consistently obtain unique names.

This function is supported only in a POSIX program.

Returned value

If successful, tempnam() allocates space for the generated name, copies the name into it, and returns a pointer to the name.

If unsuccessful, tempnam() returns a NULL pointer and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENAMETOOLONG</td>
<td>The generated name exceeded the maximum allowable path name length.</td>
</tr>

<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANSI/ISO C++</td>
<td>C++ only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <exception>

void terminate(void);
```

General description

The terminate() function is called when the C++ error handling mechanism fails. If terminate() is called directly by the program, the terminate_handler is the one most recently set by a call to set_terminate(). If terminate() is called for any of several other reasons during evaluation of a throw expression, the terminate_handler is the one in effect immediately after evaluating the throw expression. If set_terminate() has not yet been called, then terminate() calls abort().

In a multithreaded environment, if a thread issues a throw, the stack is unwound until a matching catcher is found, up to and including the thread start routine. (The thread start routine is the function passed to pthread_create().) If the exception is not caught, then the terminate() function is called, which in turn defaults to calling abort(), which in turn causes a SIGABRT signal to be generated to the thread issuing the throw. If the SIGABRT signal is not caught, the process is terminated. You can replace the default terminate() behavior for all threads in the process by using the set_terminate() function. One possible use of set_terminate() is to call a function which issues a pthread_exit(). If this is done, a throw of a condition by a thread that is uncaught results in thread termination but not process termination.

Returned value

terminate() returns no values.

Related information

- "exception" on page 26

t_error

**t_error() — Produce error message**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_error(char *errmsg);
```

**General description**

Produces a language-dependent message on the standard error output which describes the last error encountered during a call to a transport function. The argument string `errmsg` is a user-supplied error message that gives context to the error.

The error message is written as follows: first (if `errmsg` is not a NULL pointer and the character pointed to by `errmsg` is not the NULL character) the string pointed to by `errmsg` followed by a colon and a space; then a standard error message string for the current error defined in `t_errno`. If `t_errno` has a value different from T SYS ERR, the standard error message string is followed by a newline character. If, however, `t_errno` is equal to T SYS ERR, the `t_errno` string is followed by the standard error message string for the current error defined in `errno` followed by a newline.

If the calling program is running in any one of the SAA, S370, C or POSIX locales, the error message string describing the value in `t_errno` is identical to the comments following the `t_errno` codes defined in `xti.h`. It is noteworthy that message numbers are not produced in this situation. The contents of the error message strings describing the value in `errno` are the same as those returned by the `strerror(3C)` function with an argument of `errno`.

The error number, `t_errno`, is only set when an error occurs and it is not cleared on successful calls.

**Valid states:**

All - except for T_UNINIT

**Returned value**

No errors are defined for `t_error()`.

**Example**

If a `t_connect()` function fails on transport endpoint `fd2` because a bad address was given, the following call might follow the failure:

```c
int t_error("t_connect failed on fd2");
```

The diagnostic message to be printed would look like:

```c
  t_connect failed on fd2: incorrect addr format
```
where *incorrect addr format* identifies the specific error that occurred, and *t_connect failed on fd2* tells the user which function failed on which transport endpoint.

# tfind — Binary tree find node

## Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

## Format

```
#define _XOPEN_SOURCE
#include <search.h>

void *tfind(const void *key, void *const *rootp,
            int (*compar)(const void *, const void *));
```

## General description

The tfind() function, like tsearch(), will search for a node in the tree, returning a pointer to it if found. However, if it is not found, the tfind() function will return a NULL pointer. The arguments for the tfind() function are the same as for the tsearch() function.

Comparisons are made with a user-supplied routine, the address of which is passed as the compar argument. This routine is called with two arguments, the pointers to the elements being compared. The user-supplied routine must return an integer less than, equal to or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison functions need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

Threading Behavior: see "tsearch() — Binary tree search" on page 2295.

## Special behavior for C++:

Because C and C++ linkage conventions are incompatible, tfind() cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to tfind(), the compiler will flag it as an error. You can pass a C or C++ function to tfind() by declaring it as extern "C".

## Returned value

- If the node is found, tfind() returns a pointer to it.
- If unsuccessful, tfind() returns a NULL pointer.
- If rootp is a NULL pointer on entry, tfind() returns a NULL pointer.

No errors are defined.

t_free

**t_free() — Free a library structure**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_free(char *ptr, int struct_type);
```

**General description**

Frees memory previously allocated by `t_alloc()`. This function frees memory for the specified structure, and also frees memory for buffers referenced by the structure.

The argument `ptr` points to one of the seven structure types described for `t_alloc()` and `struct_type` identifies the type of that structure which must be one of the following:

- `T_BIND struct t_bind`
- `T_CALL struct t_call`
- `T_OPTMGMT struct t_optmgmt`
- `T_DIS struct t_discon`
- `T_UNITDATA struct t_unitdata`
- `T_UDERROR struct t_uderr`
- `T_INFO struct t_info`

where each of these structures is used as an argument to one or more transport functions.

`t_free()` checks the `addr`, `opt` and `udata` fields of the given structure (as appropriate) and frees the buffers pointed to by the `buf` field of the netbuf structure. If `buf` is a NULL pointer, `t_free()` does not attempt to free memory. After all buffers are freed, `t_free()` frees the memory associated with the structure pointed to by `ptr`.

Undefined results occur if `ptr` or any of the `buf` pointers points to a block of memory that was not previously allocated by `t_alloc()`.

**Valid states:**

All - except for `T_UNINIT`

**Returned value**

If successful, `t_free()` returns 0.

If unsuccessful, `t_free()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TNOSTRUCTYPE</td>
<td>Unsupported <code>struct_type</code> requested.</td>
</tr>
</tbody>
</table>
**TPROTO**  This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).

**TSYSERR**  A system error has occurred during execution of this function.

Format

```c
#define _ISOC99_SOURCE
#include <math.h>

double tgamma(double x);
float tgammaf(float x);
long double tgammal(long double x);

C++ TR1 C99:
#define _TR1_C99
#include <math.h>

float tgamma(float x);
long double tgamma(long double x);
```

General description

The tgamma functions compute the gamma function of \( x \). A domain error occurs if \( x \) is a negative integer or when \( x \) is zero and the result cannot be represented. A range error occurs if the magnitude of \( x \) is too large or too small.

**Note:** The following table shows the viable formats for these functions. See [IEEE binary floating-point](https://en.wikipedia.org/wiki/Binary_floating-point) on page 94 for more information about IEEE Binary Floating-Point.

<table>
<thead>
<tr>
<th>Function</th>
<th>Hex</th>
<th>IEEE</th>
</tr>
</thead>
<tbody>
<tr>
<td>tgamma</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>tgammaf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>tgammal</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned value

The tgamma functions return \( G(x) \).

Related information
tgammad32(), tgammad64(), tgammad128() - Calculate gamma function

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.10</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 tgammad32(_Decimal32 x);
_Decimal64 tgammad64(_Decimal64 x);
_Decimal128 tgammad128(_Decimal128 x);
_Decimal32 tgamma(_Decimal32 x); /* C++ only */
_Decimal64 tgamma(_Decimal64 x); /* C++ only */
_Decimal128 tgamma(_Decimal128 x); /* C++ only */
```

General description

The tgamma() functions compute the gamma function of x.

These functions work in IEEE decimal floating-point format. See IEEE decimal floating-point on page 95 for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

The tgamma functions return G(x).

A domain error occurs if x is a negative integer or when x is zero and the result cannot be represented. A range error occurs if the magnitude of x is too large or too small.

Example

```c
CELEBT24:
/* CELEBT24
    This example illustrates the tgammad128() function.
*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x, y;
    x = 5.6DL;
    y = tgammad128(x);
    printf("tgammad128(%DDf) = %DDf\n", x, y);
}
```

t_getinfo() — Get protocol-specific service information

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_getinfo(int fd, struct t_info *info);
```

General description

Returns the current characteristics of the underlying transport protocol and/or transport connection associated with file descriptor `fd`. The `info` pointer is used to return the same information returned by `t_open()`, although not necessarily precisely the same values. This function enables a transport user to access this information during any phase of communication. This argument points to a `t_info` structure which contains the following members:

- `long addr; /* max size of the transport protocol address */`
- `long options; /* max number of bytes of protocol-specific options */`
- `long tsdu; /* max size of a transport service data unit (TSDU) */`
- `long etsdu; /* max size of an expedited transport service data unit (ETSDU) */`
- `long connect; /* max amount of data allowed on connection establishment functions */`
- `long discon; /* max amount of data allowed on t_snddis() and t_rcvdis() functions */`
- `long servtype; /* service type supported by the transport provider */`
- `long flags; /* other info about the transport provider */`

The fields take on the following values:

- `addr` The size of a struct sockaddr_in is returned.
- `options` The value 304, which is the maximum number of bytes of options which can possibly be specified or requested, is returned.
- `tsdu` Zero is returned, indicating that the TCP transport provider does not support the concept of TSDUs.
- `etsdu` A value of -1 is returned, indicating that there is no limit on the size of an ETSDU.
- `connect` A value of -2 is returned, indicating that the TCP transport provider does not allow data to be sent with connection establishment functions.
- `discon` A value of -2 is returned, indicating that the transport provider does not allow data to be sent with the abortive release functions.
- `servtype` T_COTS is always returned, since this is the only service type supported.
- `flags` The T_SENDZERO bit is always set in this field, indicating that the TCP transport provider supports the sending of zero-length TSDUs.
t_getinfo

If a transport user is concerned with protocol independence, the above sizes may be accessed to determine how large the buffers must be to hold each piece of information. Alternatively, the t_alloc() function may be used to allocate these buffers. An error results if a transport user exceeds the allowed data size on any function. The value of each field may change as a result of protocol option negotiation during connection establishment (the t_optmgmt() call has no affect on the values returned by t_getinfo()). These values will only change from the values presented to t_open() after the endpoint enters the T_DATAFER state.

Valid states:

All - except for T_UNINIT

Returned value

If successful, t_getinfo() returns 0.

If unsuccessful, t_getinfo() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint.</td>
</tr>
<tr>

**t_getprotaddr**

*t_getprotaddr() — Get the protocol addresses*

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_getprotaddr(int fd, struct t_bind *boundaddr,
                   struct t_bind *peeraddr);
```

**General description**

Returns local and remote protocol addresses currently associated with the transport endpoint specified by `fd`. In `boundaddr` and `peeraddr` the user specifies `maxlen`, which is the maximum size of the address buffer, and `buf` which points to the buffer where the address is to be placed. On return, the `buf` field of `boundaddr` points to the address, if any, currently bound to `fd`, and the `len` field specifies the length of the address. If the transport endpoint is in the T_UNBND state, zero is returned in the `len` field of `boundaddr`. The `buf` field of `peeraddr` points to the address, if any, currently connected to `fd`, and the `len` field specifies the length of the address. If the transport endpoint is not in the T_DATAXFER state, zero is returned in the `len` field of `peeraddr`.

**Valid states:**

All - except for T_UNINIT

**Returned value**

If successful, `t_getprotaddr()` returns 0.

If unsuccessful, `t_getprotaddr()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint.</td>
</tr>
<tr>
<td>TBUFOVFLW</td>
<td>The number of bytes allocated for an incoming argument (maxlen) is greater</td>

</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_getstate(int fd);
```

**General description**

Returns the current state of the provider associated with the transport endpoint specified by `fd`.

**Valid states:**

All - except for T_UNINIT

**Returned value**

If successful, `t_getstate()` returns the state. The current state is one of the following:

- T_DATAFER Data transfer.
- T_IDLE Idle.
- T_INCON Incoming connection pending.
- T_OUTCON Outgoing connection pending.
- T_UNBND Unbound.

If the provider is undergoing a state transition when `t_getstate()` is called, the function will fail.

If unsuccessful, `t_getstate()` returns -1 and sets `errno` to one of the following values:

**Error Code**  | **Description**
--- | ---
TBADF | The specified file descriptor does not refer to a transport endpoint.
TPROTO | This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (`t_errno`).
TSTATECHNG | The transport provider is undergoing a transient state change.
TSYSERR | A system error has occurred during execution of this function.

</tbody>
</table>

Format

```c
#include <time.h>

time_t time(time64_t *timeptr);
#define _LARGE_TIME_API
#include <time.h>

time_t time64(time64_t *timer);
```

General description

Determines the current UTC time.

Returned value

The time() function returns the value of time in seconds since the Epoch.

Returns the current UTC time. The returned value is also stored in the location given by timeptr. If timeptr is NULL, the returned value is not stored. If the calendar time is not available, the value (time_t)-1 is returned.

The time() function returns the current value of the time-of-day (TOD) clock value obtained with the STCK instruction, rounded off to the nearest second, and normalized to the POSIX Epoch, January 1, 1970. The TOD clock value does not account for leap seconds. If you need more accuracy, use the STCK instruction or the TIME macro which does account for leap seconds using whatever value the system operator has entered for number of leap seconds in the CVT field. For more information about the STCK instruction, refer to z/Architecture Principles of Operation.

A returned value of 0 indicates the epoch, which was at the Coordinated Universal Time (UTC) of 00:00:00 on January 1, 1970.

The function time64() will behave exactly like time() except it will support calendar times beyond 03:14:07 UTC on January 19, 2038.

Example

**CELEBT11:**

```c
/* CELEBT11

This example gets the time and assigns it to ltime, then uses the &ctime. function to convert the number of seconds to the current date and time.
```
Finally, it prints a message giving the current time.

```c
#include <time.h>
#include <stdio.h>

int main(void)
{
    time_t ltime;
    time(&ltime);
    printf("The time is %s\n", ctime(&ltime));
}
```

Output:
The time is Fri Jun 16 11:01:41 2001

<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <sys/times.h>

clock_t times(struct tms *buffer);
```

General description

Gets processor times of interest to a process.

```c
struct tms *buffer
```
Points to a memory location where times() can store a structure of information describing processor time used by the current process and other related processes.

times() returns information in a `tms` structure, which has the following elements:

```c
clock_t tms_utime
```
Amount of processor time used by instructions in the calling process.

Under z/OS UNIX, this does not include processor time spent running in the kernel. It does include any processor time accumulated for the address space before it became a z/OS UNIX process.

```c
clock_t tms_stime
```
Amount of processor time used by the system.

Under z/OS UNIX, this value represents kernel busy time running on behalf of the calling process. It does not include processor time performing other MVS system functions on behalf of the process.

```c
clock_t tms_cutime
```
The sum of `tms_utime` and `tms_cutime` values for all waited-for child processes which have terminated.

```c
clock_t tms_cstime
```
The sum of `tms_stime` and `tms_cstime` values for all terminated child processes of the calling process.

clock_t is an integral type determined in the `time.h` header file. It measures times in terms of *clock ticks*. The number of clock ticks in a second (for your installation) can be found in `sysconf(_SC_CLK_TCK)`.

Times for a terminated child can be determined once `wait()` or `waitpid()` have reported the child’s termination.
Pthreads can not be separately clocked by the `times()` function because they do not run in a separate process like forked children do.

**Returned value**

If successful, `times()` returns a value giving the elapsed time since the process was last invoked (for example, at system startup). If this time value cannot be determined, `times()` returns `(clock_t)−1`.

If unsuccessful, `times()` sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERANGE</td>
<td>An overflow having occurred computing time values.</td>
</tr>
</tbody>
</table>

**Example**

**CELEBT12:**

```c
/* CELEBT12
 *
 * This example provides the amount of processor time used by instructions and the system for the parent and child processes.
 *
 */
#define _POSIX_SOURCE
#include <sys/times.h>
#include <time.h>
#include <sys/types.h>
#include <sys/wait.h>
#include <stdio.h>
#include <unistd.h>

main() {
    int status;
    long i, j;
    struct tms t;
    clock_t dub;

    int tics_per_second;
    tics_per_second = sysconf(_SC_CLK_TCK);

    if (fork() == 0) {
        for (i=0, j=0; i<1000000; i++)
        j += i;
        exit(0);
    }

    if (wait(&status) == −1)
        perror("wait() error");
    else if (!WIFEXITED(status))
        puts("Child did not exit successfully");
    else if ((dub = times(&t)) == −1)
        perror("times() error");
    else {
        printf("process was dubbed %.10f seconds ago.\n\n", ((double) dub)/tics_per_second);
        printf(" utime stime\n");
        printf("parent: \%f   \%f\n", ((double) t.tms_utime)/tics_per_second,
               ((double) t.tms_stime)/tics_per_second);
        printf("child: \%f   \%f\n", ((double) t.tms_utime)/tics_per_second,
                     ((double) t.tms_stime)/tics_per_second);
    }
}
```
Output:
process was dubbed 1.600000 seconds ago.

tinit

---

**tinit() — Attach and initialize MTF subtasks**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```
#include <mtf.h>

int tinit(const char *parallel_loadmod_name, int num_subtasks);
```

**General description**

**Restriction:** This function is not supported in AMODE 64.

Initializes the multitasking facility (MTF) environment under MVS.

To avoid infringing on the user’s name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

`tinit()` is invoked from a main task to dynamically attach and initialize the number of subtasks specified by `num_subtasks`, where `num_subtasks` ranges from 1 to `MAXTASK` (which is defined in the header file `mtf.h`). After the subtasks have been attached and initialized by `tinit()`, each of the subtasks will be given a `task_id` and can then compute independent pieces of the program, in parallel with the main task, under the control of the `tsched()` and `tsyncro()` library functions.

The parallel load module (`parallel_loadmod_name`) must contain all parallel functions and reside in a partitioned data set named in the STEPLIB DD statement of the JCL that runs the program.

The `tinit()` function may be called by a main task only once before invoking `tterm()`. Invocations of `tinit()` after the first are one are terminated with a returned value indicating that MTF is already active.

After `tterm()` has been called to terminate and remove the MTF environment, or after an abend, `tinit()` can be called again to create a new MTF environment. The new initialization is independent of the old one and may provide a different number of tasks and/or a different parallel load module.

If `tinit()` is called from a parallel function, `tinit()` will be terminated with a returned value indicating that MTF calls cannot be issued from a parallel function.
If tinit() is called by a program running under IMS, CICS, or DB2, the request will not be processed and the returned value will indicate that MTF calls are not supported under these systems.

**Returned value**

If the subtasks have been attached successfully and the MTF environment created, tinit() returns MTF_OK.

If unsuccessful, tinit() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACTIVE</td>
<td>MTF has already been initialized and is active.</td>
</tr>
<tr>
<td>EAUTOALC</td>

**t_listen() — Listen for a connect indication**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_listen(int fd, struct t_call *call);
```

**General description**

Lists for a connect request from a calling transport user. The argument `fd` identifies the local transport endpoint where connect indications arrive, and on return, `call` contains information describing the connect indication. The parameter `call` points to a `t_call` structure which contains the following members:

```c
struct netbuf addr;
struct netbuf opt;
struct netbuf udata;
int sequence;
```

In `call`, `addr` returns the protocol address of the calling transport user. This address is in a format usable in future calls to `t_connect()`. However, `t_connect()` may fail for other reasons; for example, `TADDRBUSY`. `opt` returns options associated with the connect request. `udata` is meaningless because transmission of user data is not supported across a connect request. `sequence` is a number that uniquely identifies the returned connect indication. The value of `sequence` enables the user to listen for multiple connect indications before responding to any of them.

Since this function returns values for the `addr`, `opt` and `udata` fields of `call`, the `maxlen` field of each must be set before issuing the `t_listen()` to indicate the maximum size of the buffer for each.

By default, `t_listen()` executes in synchronous mode and waits for a connect indication to arrive before returning to the user. However, if `O_NONBLOCK` is set using `t_open()` or `fcntl()`, `t_listen()` executes asynchronously, reducing to a poll for existing connect indications. If none are available, it returns -1 and sets `t_errno` to `TNODATA`.

**Valid states:**

T_IDLE, T_INCON

**Returned value**

If successful, `t_listen()` returns 0. The TCP transport provider does not differentiate between a connect indication and the connection itself. A successful return of `t_listen()` indicates an existing connection.

If unsuccessful, `t_listen()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
TBADF The specified file descriptor does not refer to a transport endpoint.
TBADQLEN The argument qlen of the endpoint referenced by fd is zero.
TBUFOVFLW The number of bytes allocated for an incoming argument (maxlen) is greater than 0 but not sufficient to store the value of that argument. The provider's state, as seen by the user, changes to T_INCON, and the connect indication information to be returned in call is discarded. The value of sequence returned can be used to do a t_snddis().
TLOOK An asynchronous event has occurred on this transport endpoint and requires immediate attention.
TNODATA O_NONBLOCK was set, but no connect indications had been queued.
TNOTSUPPORT This function is not supported by the underlying transport provider.
TOUTSTATE The function was issued in the wrong sequence on the transport endpoint referenced by fd.
TPROTO This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).
TQFULL The maximum number of outstanding indications has been reached for the endpoint referenced by fd.
TSYSERR A system error has occurred during execution of this function.

t_look

t_look() — Look at the current event on a transport endpoint

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_look(int fd);
```

General description

Returns the current event on the transport endpoint specified by `fd`. This function enables a transport provider to notify a transport user of an asynchronous event when the user is calling functions in synchronous mode. Certain events require immediate notification of the user and are indicated by a specific error, TLOOK, on the current or next function to be executed. This function also enables a transport user to poll a transport endpoint periodically for asynchronous events.

Additional functionality for handling events is provided through select and poll.

Valid states:

All - except for T_UNINIT

The following list describes the asynchronous events which cause an XTI call to return with a TLOOK error:

- `t_accept()` T_DISCONNECT, T_LISTEN
- `t_connect()` T_DISCONNECT, T_LISTEN
  - This occurs only when a `t_connect` is done on an endpoint which has been bound with a `qlen > 0` and for which a connect indication is pending.
- `t_listen()` T_DISCONNECT
  - This event indicates a disconnect on an outstanding connect indication.
- `t_rcv()` T_DISCONNECT
  - This occurs only when all pending data has been read.
- `t_rcvconnect()` T_DISCONNECT
- `t_rcvudata()` T_UDERR
- `t_snd()` T_DISCONNECT
- `t_sndudata()` T_UDERR
- `t_unbind()` T_LISTEN, T_DATA
  - T_DATA may only occur for the connectionless mode.
- `t_snddis()` T_DISCONNECT
t_look

Once a TLOOK error has been received on a transport endpoint using an XTI function, subsequent calls to that and other XTI functions, to which the same TLOOK error applies, will continue to return TLOOK until the event is consumed. An event causing the TLOOK error can be determined by calling t_look() and then can be consumed by calling the corresponding consuming XTI function as defined in Table 57.

Table 57. Events and t_look()

<table>
<thead>
<tr>
<th>Event</th>
<th>Cleared on t_look()?</th>
<th>Consuming XTI functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>T_LISTEN</td>
<td>No</td>
<td>t_listen()</td>
</tr>
<tr>
<td>T_CONNECT</td>
<td>No</td>
<td>t_(rcv)connect()</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>T_DATA</td>
<td>No</td>
<td>t_rcv()</td>
</tr>
<tr>
<td>T_EXDATA</td>
<td>No</td>
<td>t_rcvdis()</td>
</tr>
<tr>
<td>T_DISCONNECT</td>
<td>No</td>
<td>t_rcvdis()</td>
</tr>
<tr>
<td>T_GODATA</td>
<td>Yes</td>
<td>t_snd()</td>
</tr>
<tr>
<td>T_GOEXDATA</td>
<td>Yes</td>
<td>t_snd()</td>
</tr>
</tbody>
</table>

In the case of the t_connect() function the T_CONNECT event is both generated and consumed by the execution of the function and is therefore not visible to the application.

Returned value

If successful, t_look() returns a value that indicates which of the allowable events has occurred, or returns 0 if no event exists. One of the following events is returned:

- **T_CONNECT**: Connect confirmation received.
- **T_DATA**: Normal data received.
- **T_DISCONNECT**: Disconnect received.
- **T_EXDATA**: Expedited data received.
- **T_GODATA**: Flow control restrictions on normal data flow that led to a TFLOW error have been lifted. Normal data may be sent again.
- **T_GOEXDATA**: Flow control restrictions on expedited data flow that led to a TFLOW error have been lifted. Expedited data may be sent again.
- **T_LISTEN**: Connection indication received.

If unsuccessful, t_look() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint.</td>
</tr>
<tr>
<td>TPROTO</td>
<td>This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).</td>
</tr>
<tr>
<td>TSYSErr</td>
<td>A system error has occurred during execution of this function.</td>
</tr>
</tbody>
</table>

tmpfile() — Create temporary file

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>

FILE *tmpfile(void);
```

General description

Creates a temporary binary file. It opens the temporary file in `wb+` mode. The file is automatically removed when it is closed or when the program is terminated.

**Note:** When the tmpfile() function is issued from multiple tasks within one address space, the temporary file names may not be unique. The execution of the tmpfile() function concurrently within one address space will result in errors. For example, an open will fail because the file is already open.

Returned value

If successful, tmpfile() returns a pointer to the stream associated with the file created.

If tmpfile() cannot open the file, it returns a NULL pointer. On normal termination (exit()), these temporary files are removed. On abnormal termination, an effort is made to remove these files.

Returned value for POSIX C

When the calling application is a z/OS UNIX program, the temporary file is created in the hierarchical file system. The file is created in the directory referred to by the TMPDIR environment variable, or `/tmp` if TMPDIR is not defined.

Special behavior for XPG4:

The following are the possible values of errno:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINTR</td>
<td>A signal was caught during tmpfile().</td>
</tr>
<tr>
<td>EMFILE</td>
<td>OPEN_MAX file descriptors are currently open in the calling process.</td>
</tr>
<tr>
<td></td>
<td>{FOPEN_MAX} streams are currently open in the calling process.</td>
</tr>
<tr>
<td>ENFILE</td>
<td>The maximum allowable number of files is currently open in the system.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Insufficient storage space is available.</td>
</tr>
</tbody>
</table>
The directory or file system which would contain the new file cannot be expanded.

Example

CELEBT13:
/* CELEBT13
   This example creates a temporary file and if successful, writes tmpstring to it.
   At program termination, the file is removed.
   */
#include <stdio.h>
int main(void) {
    FILE *stream;
    char tmpstring[ ] = "This string will be written";

    if((stream = tmpfile( )) == NULL)
        printf("Cannot make a temporary file\n");
    else
        fprintf(stream, "%s", tmpstring);
}

tmpnam() — Produce temporary file name

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>POSIX.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdio.h>
char *tmpnam(char *string);
```

General description

Produces a valid file name that is not the same as the name of any existing file. It stores this name in `string`. If `string` is a NULL pointer, `tmpnam()` leaves the result in an internal static buffer. Any subsequent calls may modify this object. If `string` is not a NULL pointer, it must point to an array of at least `L_tmpnam` bytes. The value of `L_tmpnam` is defined in the `stdio.h` header file.

Returned value

If `string` is a NULL pointer, `tmpnam()` returns the pointer to the internal static object in which the generated unique name is placed. Otherwise, if `string` is not a NULL pointer, it returns the value of `string`. The `tmpnam()` function produces a different name each time it is called within a module up to at least `TMP_MAX` names. Files created using names returned by `tmpnam()` are not automatically discarded at the end of the program.

Returned value for POSIX C

The `tmpnam()` function behaves differently when a program is running with POSIX(ON).

When the `_POSIX_TMPNAM` environment variable is unset or is not set to `NO`, the file name returned is a unique file name in the UNIX file system. The directory component of the file name will be the value of the `TMPDIR` environment variable, or `/tmp` if `TMPDIR` is not defined.

When the `_POSIX_TMPNAM` environment variable is set to `NO`, the file name returned is as if the calling application were running POSIX(OFF).

Example

```c
CELEBT14:
/* CELEBT14
   This example calls tmpnam() to produce a valid file name.
*/
#include <stdio.h>
```
int main(void)
{
    char *name;
    if ((name = tmpnam(NULL)) != NULL)
        printf("%s can be used as a file name.\n", name);
    else printf("Cannot create a unique file name\n");
}

<td>both</td>
<td>POSIX(ON)</td>
</tr>
</tbody>
</table>

Format

_XOPEN_SOURCE:
#define _XOPEN_SOURCE
#include <ctype.h>

int toascii(int c);

_ALL_SOURCE:
#define _ALL_SOURCE
#include <ctype.h>

int toascii(int c);

General description

Special behavior for _XOPEN_SOURCE:

The toascii() function converts its argument to a 7-bit US-ASCII character code.

The toascii() function is not intended to be used to convert EBCDIC characters to ASCII, attempts to use it in this manner will not function as expected.

Special behavior for _ALL_SOURCE:

The toascii() function assumes $c$ modulo 256 is a single-byte EBCDIC encoding for a Latin 1 character, <input-character>, in the current locale. Then, toascii() determines to what character, <output-character>, toascii() would map <input-character> in an ASCII locale (for example, on an *IX system) and returns the EBCDIC encoding for <output-character> in the current locale.

For example, if the program invoking toascii() was compiled with _ALL_SOURCE defined and if the value $c$ input to toascii() modulo 256 is the EBCDIC encoding for <international-currency-symbol> in the current locale, toascii() returns the EBCDIC encoding for <dollar> in the current locale because toascii() maps <international-currency-symbol> to <dollar> on ASCII platforms.

Returned value

EBCDIC and ASCII encodings and <input-character> to <output-character> mapping performed by toascii() in an IBM-1047 locale are as follows:

/***************************************************************************/
/* */
/* IBM-1047 toascii table (sorted by ebc dic) */
/* */
/* For IS0-8859 character encoding toascii(ch) returns ch for */
### toascii

toascii

Chapter 3. Library functions 2261
toascii

/* <EO>   <IUS/IS1>   FF   1F    9F   1F   */
/* */
/*****************************************************************************/

Special behavior for _XOPEN_SOURCE:

The toascii() function returns the value (c & 0x7f).

Special behavior for _ALL_SOURCE:

If the current locale is not a single-byte locale (that is, mb_cur_max > 1), toascii() sets errno to ENOSYS and returns -1. Otherwise, toascii() assumes c modulo 256 is the encoding of a Latin 1 character, <input_character>, in the current locale and returns the EBCDIC encoding of the same or another Latin 1 character, <output_character>, in the current locale; where <output_character> corresponds to the character to which toascii() would map <input_character> on an ASCII platform.

__toCcsid

__toCcsid() — Convert codeset name to coded character set ID

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

```c
#include <_Ccsid.h>

__ccsid_t __toCcsid(char *codesetName);
```

General description

The __toCcsid() function returns the coded character set ID corresponding to the provided `codesetName` argument.

Returned value

If successful, __toCcsid() returns the corresponding CCSID for `codesetName`, if one exists. The returned __ccsid_t type is defined in <_Ccsid.h> as an unsigned short.

If unsuccessful, __toCcsid() returns 0 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The length of the <code>codesetName</code> argument is greater than _CSNAME_LEN_MAX as defined in header &lt;_Ccsid.h&gt;.</td>
</tr>
</tbody>
</table>

<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

```c
#include <_Ccsid.h>

int __toCSName(__ccsid_t Ccsid, char *codesetName);
```

General description

The __toCSName() function returns the codeset name, corresponding to coded character codeset ID, `Ccsid`, in `codesetName`.

Returned value

If successful, __toCSName() returns 0 and stores the codeset name in `codesetName`, when a corresponding codeset name exists for `Ccsid`.

If unsuccessful, __toCSName() returns -1.

If __toCSName() returns -1 for a reason other than no corresponding codeset name exists, it sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>
| EINVAL     | The corresponding `codesetName` length is greater than `_CSNAME_LEN_MAX` as defined in header `<_Ccsid.h>`.

<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <ctype.h>

int tolower(int c); /* Convert c to lowercase if appropriate */
int toupper(int c); /* Convert c to uppercase if appropriate */
```

General description

Converts `c` to a lowercase letter, if possible. Conversely, the `toupper()` function converts `c` to an uppercase letter, if possible.

The DBCS is not supported. The use of characters from the DBCS results in unspecified behavior.

Returned value

If successful, `tolower()` and `toupper()` return the corresponding character, as defined in the LC_CTYPE category of the current locale, if such a character exists.

If unsuccessful, `tolower()` and `toupper()` return the unchanged value `c`.

Example

```c
CELEBT15:
/* CELEBT15
   This example demonstrates the result of using 
   &toupper. and &tolower. on a lower-case a.
*/
#include <stdio.h>
#include <ctype.h>

int main(void)
{
    int ch;
    ch = 0x81;
    printf("toupper=%#04x\n", toupper(ch));
    printf("tolower=%#04x\n", tolower(ch));
}
```

<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <ctype.h>

int _tolower(int c);
```

General description

The _tolower() macro is equivalent to tolower(c) except that the argument c must be an uppercase letter.

Returned value

_typeof() returns the lowercase letter corresponding to the argument passed.

t_open

**t_open() — Establish a transport endpoint**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_open(char *name, int oflag, struct t_info *info);
```

**General description**

t_open() must be called as the first step in the initialization of a transport endpoint. This function establishes a transport endpoint by supplying a transport provider identifier that indicates a particular transport provider (that is, transport protocol) and returning a file descriptor that identifies that endpoint.

**Note:** There must be at least one available file descriptor less than 65536.

The argument `name` points to a transport provider identifier. The only supported transport provider is `/dev/tcp`, indicating a TCP transport provider. No device by that name actually exists in the file system. It is purely used to follow historical convention. The argument `oflag` identifies any open flags (as in open()). It is constructed from `O_RDWR` optionally bitwise inclusive-OR’ed with `O_NONBLOCK`. These flags are defined by the header `<fcntl.h>`. The file descriptor returned by t_open() will be used by all subsequent functions to identify the particular local transport endpoint.

This function also returns various default characteristics of the underlying transport protocol by setting fields in the `info` structure. This argument points to a `t_info` structure which contains the following members:

- `long addr; /* max size of the transport protocol address */`
- `long options; /* max number of bytes of protocol-specific options */`
- `long tsdu; /* max size of a transport service data unit (TSDU) */`
- `long etsdu; /* max size of an expedited transport service data unit (ETSDU) */`
- `long connect; /* max amount of data allowed on connection establishment functions */`
- `long discon; /* max amount of data allowed on t_snddis() and t_rcvdis() functions */`
- `long servtype; /* service type supported by the transport provider */`
- `long flags; /* other info about the transport provider */`

The fields take on the following values:

- `addr` The size of a struct sockaddr_in is returned.
- `options` The value 304, which is the maximum number of bytes of options which can possibly be specified or requested, is returned.
- `tsdu` Zero is returned, indicating that the TCP transport provider does not support the concept of TSDUs.
etsdu A value of -1 is returned, indicating that there is no limit on the size of an ETSDU.

connect A value of -2 is returned, indicating that the TCP transport provider does not allow data to be sent with connection establishment functions.

discon A value of -2 is returned, indicating that the transport provider does not allow data to be sent with the abortive release functions.

servtype T_COTS is always returned, since this is the only service type supported.

flags The T_SENDZERO bit is always set in this field, indicating that the TCP transport provider supports the sending of zero-length TSDUs.

If info is set to a NULL pointer by the transport user, no protocol information is returned by t_open().

Valid states:
T_UNINIT

Returned value
If successful, t_open() returns a valid file descriptor.

If unsuccessful, t_open() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBADFLAG</td>
<td>An invalid flag is specified.</td>
</tr>
<tr>
<td>TBADNAME</td>
<td>Invalid transport provider name.</td>
</tr>
<tr>
<td>TPROTO</td>
<td>This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).</td>
</tr>
<tr>
<td>TSYSERR</td>
<td>A system error has occurred during execution of this function.</td>
</tr>
</tbody>
</table>

Related information

t_optmgmt

**t_optmgmt() — Manage options for a transport endpoint**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_optmgmt(int fd, struct t_optmgmt *req, struct t_optmgmt *ret);
```

**General description**

Enables a transport user to retrieve, verify or negotiate protocol options with the transport provider. The argument `fd` identifies a transport endpoint. The `req` and `ret` arguments point to a `t_optmgmt` structure containing the following members:

```c
struct netbuf opt;
long flags;
```

The `opt` field identifies protocol options and the `flags` field is used to specify the action to take with those options.

The options are represented by a `netbuf` structure in a manner similar to the address in `t_bind()`. The `netbuf` structure contains the following members:

```c
unsigned int maxlen maximum buffer value length
unsigned int len actual buffer value length
char * buf pointer to buffer
```

The argument `req` is used to request a specific action of the provider and to send options to the provider. The argument `len` specifies the number of bytes in the options, `buf` points to the options buffer, and `maxlen` has no meaning for the `req` argument. The transport provider may return options and flag values to the user through `ret`. For `ret`, `maxlen` specifies the maximum size of the options buffer, and `buf` points to the buffer where the options are to be placed. On return, `len` specifies the number of bytes of options returned. The value in `maxlen` has no meaning for the `req` argument, but must be set in the `ret` argument to specify the maximum number of bytes the options buffer can hold.

Each option in the options buffer is of the form `struct t_opthdr` possibly followed by an option value. The `t_opthdr` structure contains the following members:

```c
unsigned long len sizeof(t_opthdr)+optval len
unsigned long level protocol affected
unsigned long name option value
unsigned long status status value
```

The `level` field of `struct t_opthdr` identifies the XTI level or a protocol of the transport provider. The `name` field identifies the option within the level, and `len` contains its total length. The total length is the length of the option header `t_opthdr` plus the length of the option value. If `t_optmgmt()` is called with the action `T_NEGOTIATE` set, the `status` field of the returned options contains information about the success or failure of a negotiation.
Each option in the input or output option buffer must start at a long-word boundary. The macro OPT_NEXTHDR(pbuf, buflen, poption) can be used for that purpose. The parameter pbuf denotes a pointer to an option buffer opt.buf, and buflen is its length. The parameter poption points to the current option in the option buffer. OPT_NEXTHDR returns a pointer to the position of the next option, or returns a NULL pointer if the option buffer is exhausted. The macro is helpful for writing and reading. See “xti.h” on page 86 for the exact definition.

If the transport user specifies several options on input, all options must address the same level.

If any option in the options buffer does not indicate the same level as the first option, or the level specified is unsupported, then the t_optmgmt() request will fail with TBADOPT. If the error is detected, some options have possibly been successfully negotiated. The transport user can check the current status by calling t_optmgmt() with the T_CURRENT flag set.

Before using this function, you should read Chapter 6, “Use of Options in XTI”, in X/Open CAE Specification, Networking Services, Issue 4.

The flags field of req must specify one of the following actions:

T_NEGOTIATE
This action enables the transport user to negotiate option values.

The user specifies the options of interest and their values in the buffer specified by req->opt.buf and req->opt.len. The negotiated option values are returned in the buffer pointed to by ret->opt.buf. The status field of each returned option is set to indicate the result of the negotiation. The value is T_SUCCESS if the proposed value was negotiated, T_PARTSUCCESS if a degraded value was negotiated, T_FAILURE if the negotiation failed (according to the negotiation rules), T_NOTSUPPORT if the transport provider does not support this option or illegally requests negotiation of a privileged option, and T_READONLY if modification of a read-only option was requested. If the status is T_SUCCESS, T_FAILURE, T_NOTSUPPORT or T_READONLY, the returned option value is the same as the one requested on input.

The overall result of the negotiation is returned in ret->flags.

This field contains the worst single result, whereby the rating is done according to the order T_NOTSUPPORT, T_READONLY, T_FAILURE, T_PARTSUCCESS, T_SUCCESS. The value T_NOTSUPPORT is the worst result and T_SUCCESS is the best.

For each level, the option T_ALLOPT (see below) can be requested on input. No value is given with this option; only the t_opthdr part is specified. This input requests to negotiate all supported options of this level to their default values. The result is returned option by option in ret->opt.buf. (Note that depending on the state of the transport endpoint, not all requests to negotiate the default value may be successful.)

T_CHECK
This action enables the user to verify whether the options specified in req are supported by the transport provider.

If an option is specified with no option value (it consists only of a t_opthdr structure), the option is returned with its status field set to
T_SUCCESS if it is supported, T_NOTSUPPORT if it is not or needs additional user privileges, and T_READONLY if it is read-only (in the current XTI state). No option value is returned.

If an option is specified with an option value, the status field of the returned option has the same value, as if the user had tried to negotiate this value with T_NEGOTIATE. If the status is T_SUCCESS, T_FAILURE, T_NOTSUPPORT or T_READONLY, the returned option value is the same as the one requested on input.

The overall result of the option checks is returned in ret->flags. This field contains the worst single result of the option checks, whereby the rating is the same as for T_NEGOTIATE.

Note that no negotiation takes place. All currently effective option values remain unchanged.

T_DEFAULT This action enables the transport user to retrieve the default option values. The user specifies the options of interest in req->opt.buf. The option values are irrelevant and will be ignored. It is sufficient to specify the t_opthdr part of an option only. The default values are then returned in ret->opt.buf.

The status field returned is T_NOTSUPPORT if the protocol level does not support this option or the transport user illegally requested a privileged option, T_READONLY if the option is read-only, and set to T_SUCCESS in all other cases. The overall result of the request is returned in ret->flags. This field contains the worst single result, whereby the rating is the same as for T_NEGOTIATE.

For each level, the option T_ALLOPT (see below) can be requested on input. All supported options of this level with their default values are then returned. In this case, ret->opt.maxlen must be given at least the value info->options (see t_getinfo(), t_open()) before the call.

T_CURRENT This action enables the transport user to retrieve the currently effective option values. The user specifies the options of interest in req->opt.buf. The option values are irrelevant and will be ignored. It is sufficient to specify the t_opthdr part of an option only. The currently effective values are then returned in ret->opt.buf.

The status field returned is T_NOTSUPPORT if the protocol level does not support this option, or the transport user illegally requested a privileged option, T_READONLY if the option is read-only, and set to T_SUCCESS in all other cases. The overall result of the request is returned in ret->flags. This field contains the worst single result, whereby the rating is the same as for T_NEGOTIATE.

For each level, the option T_ALLOPT (see below) can be requested on input. All supported options of this level with their currently effective values are then returned.

The option T_ALLOPT can only be used with t_optmgmt() and the actions T_NEGOTIATE, T_DEFAULT and T_CURRENT. It can be used with any supported level and addresses all supported options of this level. The option has no value; it consists of a t_opthdr only. Since in a t_optmgmt() call only options of one level may be addressed, this option should not be requested together with other options. The function returns as soon as this option has been processed.
Options are independently processed in the order they appear in the input option buffer. If an option is multiply input, it depends on the implementation whether it is multiply output or whether it is returned only once.

The function t_optmgmt() may block under various circumstances and depending on the implementation. The function will block, for instance, if the protocol addressed by the call resides on a separate controller. It may also block due to flow control constraints. For example, if data sent previously across this transport endpoint has not yet been fully processed. If the function is interrupted by a signal, the option negotiations that have been done so far may remain valid. The behavior of the function is not changed if O_NONBLOCK is set.

Valid states:

All - except for T_UNINIT

XTI-level options:

XTI-level options are not specific for a particular transport provider. An XTI implementation supports none, all or any subset of the options defined below. An implementation may restrict the use of any of these options by offering them only in the privileged or read-only mode, or if \texttt{fd} relates to specific transport providers.

The subsequent options are not association-related They may be negotiated in all XTI states except T_UNINIT. See Chapter 6, “Use of Options in XTI”, in \textit{X/Open CAE Specification, Networking Services, Issue 4} for more information.

The protocol level is XTI_GENERIC. For this level, the following options are defined:

\textbf{XTI_DEBUG} This option enables debugging. The valid values of this option are:

- None (option header only) - indicating that debug is to be turned off.
- -1 - indicating that debug output is to go to stderr.
- A file descriptor - indicating the destination file for debug output.

The debug output contains varying information depending on the XTI services invoked. It is meant to be used by customer support personnel.

\textbf{XTI_LINGER} This option is used to linger the execution of a t_close() or close() if send data is still queued in the send buffer. The option value specifies the linger period. If a close() or t_close() is issued and the send buffer is not empty, the system attempts to send the pending data within the linger period before closing the endpoint. Data still pending after the linger period has elapsed is discarded.

Depending on the implementation, t_close() or close() either block for at maximum the linger period, or immediately return, whereupon the system holds the connection in existence for at most the linger period.

The option value consists of a structure t_linger declared as:

\begin{verbatim}
struct t_linger {
    long l_onoff; /* switch option on/off */
    long l_linger; /* linger period in seconds */
}
\end{verbatim}
Legal values for the field `l_onoff` are:
- T_NO switch option off
- T_YES activate option

The value `l_onoff` is an absolute requirement.

The field `l_linger` determines the linger period in seconds. The transport user can request the default value by setting the field to T_UNSPEC. The default timeout value depends on the underlying transport provider (it is often T_INFINITE). Legal values for this field are T_UNSPEC, T_INFINITE and all nonnegative numbers.

The `l_linger` value is not an absolute requirement. The implementation may place upper and lower limits to this value. Requests that fall short of the lower limit are negotiated to the lower limit.

Note that this option does not linger the execution of `t_snddis()`.

**XTI_RCVBUF**
This option is used to adjust the internal buffer size allocated for the receive buffer. The buffer size may be increased for high-volume connections, or decreased to limit the possible backlog of incoming data.

This request is not an absolute requirement. The implementation may place upper and lower limits on the option value. Requests that fall short of the lower limit are negotiated to the lower limit.

Legal values are all positive numbers.

**XTI_SNDBUF**
This option is used to adjust the internal buffer size allocated for the send buffer.

This request is not an absolute requirement. The implementation may place upper and lower limits on the option value. Requests that fall short of the lower limit are negotiated to the lower limit.

Legal values are all positive numbers.

**TCP-level options:**

The protocol level is INET_TCP. The following TCP-level options are supported. They are not association-related.

**TCP_KEEPALIVE**
If this option is set, a keep-alive timer is activated to monitor idle connections that might no longer exist. If a connection has been idle since the last keep-alive timeout, a keep-alive packet is sent to check if the connection is still alive or broken.

The option value consists of a structure `t_kpalive` declared as:

```c
struct t_kpalive {
    long kp_onoff; /* switch option on/off */
    long kp_timeout; /* keep-alive timeout in minutes */
}
```

Legal values for the field `kp_onoff` are:
- T_NO switch keep-alive timer off
- T_YES activate keep-alive timer
The field **kp_timeout** determines the frequency of keep-alive packets being sent, in minutes. The transport user can request the default value by setting the field to T_UNSPEC. The default is 120 minutes. Legal values for this field are T_UNSPEC and all positive numbers.

The timeout value is not an absolute requirement. However, no limits are currently specified by the TCP transport provider.

**IP-level options:**

The protocol level is INET_IP. The following IP-level options are supported. They are not association-related.

**IP_REUSEADDR**

Generally, users are not allowed to bind more than one transport endpoint to addresses with identical port numbers. If IP_REUSEADDR is set to T_YES this restriction is relaxed in the sense that it is now permissible to bind a transport endpoint to an address with a port number and an under-specified internet address and further endpoints to addresses with the same port number and (mutually exclusive) fully specified internet addresses.

**Returned value**

If successful, t_optmgmt() returns 0.

If unsuccessful, t_optmgmt() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>

<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <ctype.h>

int _toupper(int c);
```

General description

The _toupper() macro is equivalent to toupper(c) except that the argument c must be a lowercase letter.

Returned value

_toupper() returns the uppercase letter corresponding to the argument passed.

<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wctype.h>

wint_t tolower(wint_t wc);
wint_t towupper(wint_t wc);
```

General description

Converts `wc` to the corresponding lowercase letter. The `towupper()` function converts `wc` to the corresponding uppercase letter.

Returned value

If `wc` is a wide character for which `iswupper()` (or `iswlower()`) is true and there is a corresponding wide character for which `iswlower()` (or `iswupper()`) is true, `tolower()` (or `towupper()`) returns the corresponding wide character; otherwise, `wc` is returned unchanged.

t_rcv

---

**t_rcv() — Receive data or expedited data sent over a connection**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_rcv(int fd, char *buf, unsigned int nbytes, int *flags);
```

**General description**

Receives either normal or expedited data. The argument `fd` identifies the local transport endpoint through which data will arrive. `buf` points to a receive buffer where user data is placed. `nbytes` specifies the size of the receive buffer. The argument `flags` may be set on return from `t_rcv()` and specifies optional flags as described below.

By default, `t_rcv()` operates in synchronous mode and will wait for data to arrive if none is currently available. However, if O_NONBLOCK is set (using `t_open()` or `fcntl()`), `t_rcv()` will execute in asynchronous mode and will fail if no data is available. (See `TNODATA` below.)

On return from the call, if T_MORE is set in `flags`, this indicates that there is more data, and the current expedited transport service data unit (ETSDU) must be received in multiple `t_rcv()` calls. In the asynchronous mode, the T_MORE flag may be set on return from the `t_rcv()` call even when the number of bytes received is less than the size of the receive buffer specified. Each `t_rcv()` with the T_MORE flag set indicates that another `t_rcv()` must follow to get more data for the current ETSDU. The end of the ETSDU is identified by the return of a `t_rcv()` call with the T_MORE flag not set. The T_MORE flag is not meaningful for normal data when using the TCP transport provider and should be ignored. If `nbytes` is greater than zero on the call to `t_rcv()`, `t_rcv()` will return 0 only if the end of a TSDU is being returned to the user.

On return, the data returned is expedited data if T_EXPEDITED is set in `flags`. If the number of bytes of expedited data exceeds `nbytes`, `t_rcv()` will set T_EXPEDITED and T_MORE on return from the initial call. Subsequent calls to retrieve the remaining ETSDU will have T_EXPEDITED set on return. The end of the ETSDU is identified by the return of a `t_rcv()` call with the T_MORE flag not set.

In synchronous mode, the only way for the user to be notified of the arrival of normal or expedited data is to issue this function or check for the T_DATA or T_EXDATA events using the `t_look()` function. Additionally, the process can arrange to be notified by the select/poll interface.

**Valid states:**

T_DATAXFER
t_rcv

Returned value

If successful, t_rcv() returns the number of bytes received.

If unsuccessful, t_rcv() returns -1 and sets errno to one of the following values:

<table>
<thead>

t_rcvconnect

### t_rcvconnect() — Receive the confirmation from a connect request

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_rcvconnect(int fd, struct t_call *call);
```

#### General description

Enables a calling transport user to determine the status of a previously sent connect request. t_rcvconnect() is used in conjunction with t_connect() to establish a connection in asynchronous mode. The connection will be established on successful completion of this function.

The argument `fd` identifies the local transport endpoint where communication will be established, and `call` contains information associated with the newly established connection. The argument `call` points to a `t_call` structure which contains the following members:

```c
struct netbuf addr;
struct netbuf opt;
struct netbuf udata;
int sequence;
```

In `call`, `addr` returns the protocol address associated with the responding transport endpoint. `opt` presents any options associated with the connection. `udata` is meaningless since the TCP transport provider does not support transmission of user data during connection establishment. `sequence` has no meaning for this function.

The `maxlen` field of each argument must be set before issuing this function to indicate the maximum size of the buffer for each. However, `call` may be a NULL pointer, in which case no information is given to the user on return from t_rcvconnect(). By default, t_rcvconnect() executes in synchronous mode and waits for the connection to be established before returning. On return, the `addr` field contains the address of the remote endpoint, and `opt` reflects the result of negotiation of the options the user specified on input.

If `O_NONBLOCK` is set (using `t_open()` or `fcntl()`), t_rcvconnect() executes in asynchronous mode, and reduces to a poll for existing connect confirmations. If none are available, t_rcvconnect() fails and returns immediately without waiting for the connection to be established. (See `TNODATA` below.) In this case, t_rcvconnect() must be called again to complete the connection establishment phase and retrieve the information returned in `call`.

#### Valid states:

- T_OUTCON
t_rcvconnect

Returned value

If successful, t_rcvconnect() returns 0.

If unsuccessful, t_rcvconnect() returns -1 and sets errno to one of the following values:

<table>

t_rcvdis

**t_rcvdis() — Retrieve information from disconnect**

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

### Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_rcvdis(int fd, struct t_discon *discon);
```

### General description

Used to identify the cause of a disconnect. The argument `fd` identifies the local transport endpoint where the connection existed, and `discon` points to a `t_discon` structure containing the following members:

```c
struct netbuf udata;
int reason;
int sequence;
```

The field `reason` specifies the reason for the disconnect through a protocol-dependent reason code; `udata` is always empty since the TCP transport provider does not support sending of user data with a disconnect, and `sequence` may identify an outstanding connect indication with which the disconnect is associated. The field `sequence` is only meaningful when `t_rcvdis()` is issued by a passive transport user who has executed one or more `t_listen()` functions and is processing the resulting connect indications. If a disconnect indication occurs, `sequence` can be used to identify which of the outstanding connect indications is associated with the disconnect.

If a user does not care if there is incoming data and does not need to know the value of `reason` or `sequence`, `discon` may be a NULL pointer. However, if a user has retrieved more than one outstanding connect indication (using `t_listen()` ) and `discon` is a NULL pointer, the user will be unable to identify with which connect indication the disconnect is associated.

### Valid states:

- `T_DATAXFER`, `T_OUTCON`, `T_INCON(ocnt > 0)`

### Returned value

If successful, `t_rcvdis()` returns 0.

If unsuccessful, `t_rcvdis()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint.</td>
</tr>
<tr>
<td>TBUFOVFLW</td>
<td>The number of bytes allocated for incoming data (maxlen) is greater than 0 but not sufficient to store the data. If <code>fd</code> is a passive endpoint with <code>ocnt &gt; 1</code>, it remains in state <code>T_INCON</code>; otherwise, the endpoint state is set to <code>T_IDLE</code>.</td>
</tr>
</tbody>
</table>
### t_rcvdis

<td>X</td>
<td>X</td>
</tr>
<tr>
<td>truncf</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>truncl</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

Returned value

The trunc functions return the truncated integer value of \( x \).

Related information

- "math.h" on page 43
truncd32, truncd64, truncd128

truncd32(), truncd64(), truncd128() — Truncate an integer value

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ DFP</td>
<td>both</td>
<td>z/OS V1.8</td>
</tr>
</tbody>
</table>

Format

```c
#define __STDC_WANT_DEC_FP__
#include <math.h>

_DECIMAL32 truncd32(_Decimal32 x);
_DECIMAL64 truncd64(_Decimal64 x);
_DECIMAL128 truncd128(_Decimal128 x);

_DECIMAL32 trunc(_Decimal32 x); /* C++ only */
_DECIMAL64 trunc(_Decimal64 x); /* C++ only */
_DECIMAL128 trunc(_Decimal128 x); /* C++ only */
```

General description

The trunc functions round \( x \) to the integer value, in decimal floating-point format, nearest to but no larger in magnitude than \( x \).

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The trunc functions return the truncated integer value of \( x \).

Example

```c
/* CELEBT21
   This example illustrates the truncd128() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
  _Decimal128 x = 123456789.40DL, y;
  y = truncd128(x);
  printf("The result of truncd128(%De) is %De\n", x, y);
}
```

Truncate a file to a specified length

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int truncate(const char *path, off_t length);
```

General description

Truncates the file indicated by the `path` to the indicated `length`. The calling process must have write permission for the file. If the file size exceeds `length`, any extra data is discarded. If the file size is smaller than length, bytes between the old and new lengths are read as zeros. A change to the size of the file has no impact on the file offset.

If `truncate()` would cause the file size to exceed the soft file size limit for the process, `truncate()` will fail and a SIGXFSZ signal will be generated for the process.

If successful, `truncate()` marks the `st_ctime` and `st_mtime` fields of the file.

If unsuccessful, the file is unchanged.

Large file support for z/OS UNIX files:

Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option `LANGLVL(LONGLONG)` and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `truncate()` returns 0.

If unsuccessful, `truncate()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFBIG</td>
<td>The length argument was greater than the maximum file size.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>A signal was caught during execution.</td>

tsched() — Schedule MTF subtask

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <mtf.h>

int tsched(int task_id, const char *func_name, ...);
```

General description

**Restriction:** This function is not supported in AMODE 64.

The tsched() built-in library function is used to schedule parallel functions under MVS.

The tsched() library function schedules a parallel function (*func_name*) to be executed in a subtask that has been attached and initialized by tinit(). The first argument *task_id* can be used to specify the task where the parallel function is to be executed. The *task_id* can be set to MTF_ANY to indicate that the parallel function can be run in any task or, *task_id* can be set to a specific task number between 1 and the number of subtasks specified on tinit().

The tsched() function allocates approximately 2K of space as a work area. This work area is not freed. However, a call to the tsyncro() function will make work areas previously allocated by tsched() available for reuse by tsched(). Because tsched() does not free the work area storage, it is possible the tsched() will cause an application Short on Storage condition to occur if enough calls are made to the tsched() function.

You can call tsched() from your main C task as often as necessary to schedule parallel functions for execution. If all of the subtasks are busy running previously scheduled functions, each call in excess of the number of subtasks will cause *func_name* to be run after previously scheduled functions in the first qualifying subtask that becomes available.

All scheduled functions must be computationally independent. A function cannot use variables that are modified by another scheduled function or the scheduling function. To determine if all other scheduled functions have completed, use the tsyncro() library function (see "tsyncro() — Wait for MTF subtask termination" on page 2306).

The name of the parallel function, *func_name*, must not be longer than 8 characters. If it is, the name will be truncated to the first 8 characters with no warning.

Usually tsched() returns to the calling main task program before the scheduled parallel function has completed execution. Therefore, you must call tsyncro() to ensure that your parallel functions have completed execution.
tsched

If tinit() has not been successfully called before tsched(), tsched() indicates that MTF is inactive.

If tinit() is called by a program running under IMS, CICS, or DB2, the request will not be processed and the returned value will indicate that MTF calls are not supported under these systems.

**Note:** This function is not supported under the z/OS UNIX with the POSIX(ON) runtime option.

**Returned value**

If successful, scheduling the parallel function for execution in a subtask, tsched() returns MTF_OK.

If unsuccessful, tsched() returns one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADLNKG</td>
<td>tsched() has been invoked using an invalid linkage. The header file mtf.h may have been missing from the source at compile.</td>
</tr>
<tr>
<td>EENTRY</td>
<td>The parallel function was not found in the parallel module.</td>
</tr>
<tr>
<td>EINACTIVE</td>
<td>MTF is inactive.</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>There was insufficient storage for MTF-internal areas.</td>
</tr>
<tr>
<td>ETASKABND</td>
<td>One or more subtasks have terminated abnormally.</td>
</tr>
<tr>
<td>ETASKID</td>
<td>The task id specified is not valid.</td>
</tr>
</tbody>
</table>

**Note:** These values are macros. They can be found in the mtf.h header file.

tsearch() — Binary tree search

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <search.h>

void *tsearch(const void *key, void **rootp, int (*compar)(const void *, const void *));
```

General description

The tsearch() function is used to build and access a binary search tree. The key argument is a pointer to an element to be accessed or stored. If there is a node in the tree whose element is equal to the value pointed to by key, a pointer to this found node is returned. Otherwise, the value pointed to by key is inserted (that is, a new node is created and the value of key is copied to this node), and a pointer to this node returned. Only pointers are copied, so the calling routine must store the data. The rootp argument points to a variable that points to the root node of the tree. A NULL pointer value for the variable pointed to by rootp denotes an empty tree; in this case, the variable will be set to point to the node which will be at the root of the new tree.

Comparisons are made with a user-supplied routine, the address of which is passed as the compar argument. This routine is called with two arguments, the pointers to the elements being compared. The user-supplied routine must return an integer less than, equal to or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison functions need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

Threading Behavior: Since the tree is anchored by the user's rootp pointer, the tree storage is visible to the user and could be shared among threads. The user would be responsible for serializing access to a shared tree. There are no variables related to these functions which are internal to the library and/or give rise to multithreading considerations.

Special behavior for C++:

Because C and C++ linkage conventions are incompatible, tsearch() cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to tsearch(), the compiler will flag it as an error. You can pass a C or C++ function to tsearch() by declaring it as extern “C”.

Returned value

If the node is found, tsearch() returns a pointer to it, otherwise it returns a pointer to the inserted item.
tsearch

If there is not enough space available to create a new node, or if rootp is a NULL pointer on entry, tsearch() returns a NULL pointer.

No errors are defined.

t_snd() — Send data or expedited data over a connection

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define __XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_snd(int fd, char *buf, unsigned int nbytes, int flags);
```

General description

Sends either normal or expedited data. The argument `fd` identifies the local transport endpoint over which data should be sent, `buf` points to the user data, `nbytes` specifies the number of bytes of user data to be sent, and `flags` specifies any optional flags described below:

- **T_EXPEDITED**
  - If set in `flags`, the data will be sent as expedited data and will be subject to the interpretations of the transport provider.

- **T_MORE**
  - Since the TCP transport provider does not support the concept of a TSDU, the T_MORE flag is not meaningful and will be ignored if set.

By default, `t_snd()` operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if `O_NONBLOCK` is set (using `t_open()` or `fcntl()`), `t_snd()` will execute in asynchronous mode, and will fail immediately if there are flow control restrictions. The process can arrange to be informed when the flow control restrictions are cleared using either `t_look()` or `select/poll`.

If successful, `t_snd()` returns the number of bytes accepted by the transport provider. Normally this will equal the number of bytes specified in `nbytes`. However, if `O_NONBLOCK` is set, it is possible that only part of the data will actually be accepted by the transport provider. In this case, `t_snd()` will return a value that is less than the value of `nbytes`.

The size of each TSDU or ETSDU must not exceed the limits of the transport provider as specified by the current values in the TSDU or ETSDU fields in the `info` argument returned by `t_getinfo()` . The error `TL00K` may be returned to inform the process that an event (for example, a disconnect) has occurred.

**Valid states:**

- `T_DATAXFER`

**Returned value**

If successful, `t_snd()` returns the number of bytes accepted by the transport provider.
t_snd

Note that in asynchronous mode, if the number of bytes accepted by the transport provider is less than the number of bytes requested, this may indicate that the transport provider is blocked due to flow control.

If unsuccessful, t_snd() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBADDATA</td>
<td>Illegal amount of data:</td>
</tr>
<tr>
<td></td>
<td>• A single send was attempted specifying a TSDU (ETSDU) or fragment TSDU (ETSDU) greater than that specified by the current values of the TSDU or ETSDU fields in the info argument.</td>
</tr>
<tr>
<td></td>
<td>• Multiple sends were attempted resulting in a TSDU (ETSDU) larger than that specified by the current value of the TSDU or ETSDU fields in the info argument.</td>
</tr>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint.</td>
</tr>
<tr>
<td>TBADFLAG</td>
<td>An invalid flag was specified.</td>
</tr>
<tr>
<td>TFLOW</td>
<td>O_NONBLOCK was set, but the flow control mechanism prevented the transport provider from accepting any data at this time.</td>
</tr>
<tr>
<td>TLOOK</td>
<td>An asynchronous event has occurred on this transport endpoint.</td>
</tr>
<tr>
<td>TNOTSUPPORT</td>
<td>This function is not supported by the underlying transport provider.</td>
</tr>
<tr>
<td>TOUTSTATE</td>
<td>The function was issued in the wrong sequence on the transport endpoint referenced by fd.</td>
</tr>
<tr>
<td>TPROTO</td>
<td>This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).</td>
</tr>
<tr>
<td>TSYERR</td>
<td>A system error has occurred during execution of this function.</td>
</tr>
</tbody>
</table>

It is important to remember that the transport provider treats all users of a transport endpoint as a single user. Therefore if several processes issue concurrent t_snd() calls then the different data may be intermixed. Multiple sends which exceed the maximum TSDU or ETSDU size may not be discovered by XTI. In this case an implementation-dependent error will result (generated by the transport provider) perhaps on a subsequent XTI call. This error may take the form of a connection abort, a TSYERR, a TBADDATA or a TPROTO error. If multiple sends which exceed the maximum TSDU or ETSDU size are detected by XTI, t_snd() fails with TBADDATA.

t_snddis() — Send user-initiated disconnect request

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_snddis(int fd, struct t_call *call);
```

General description

Initiates an abortive release on an already established connection, or rejects a connect request. The argument `fd` identifies the local transport endpoint of the connection, and `call` specifies information associated with the abortive release. The argument `call` points to a `t_call` structure which contains the following members:

```c
struct netbuf addr;
struct netbuf opt;
struct netbuf udata;
int sequence;
```

The values in `call` have different semantics, depending on the context of the call to `t_snddis()`. When rejecting a connect request, `call` must be non-NULL and contain a valid value of `sequence` to uniquely identify the rejected connect indication to the transport provider. The `sequence` field is only meaningful if the transport connection is in the `T_INCON` state. The `addr` and `opt` fields of `call` are ignored. In all other cases, `call` should be a NULL pointer, since its only use would be to specify user data to be passed on the disconnect request, which is not supported by the TCP transport provider.

`t_snddis()` is an abortive disconnect. Therefore a `t_snddis()` issued on a connection endpoint may cause data previously sent using `t_snd()`, or data not yet received, to be lost (even if an error is returned).

Because of implementation restrictions, a `t_snddis()` called on one descriptor referring to an endpoint will not affect descriptors in other processes referring to the same endpoint. If descriptors in multiple processes refer to the same endpoint, the endpoint will not actually be disconnected by a `t_snddis` in one process. Multiple processes cooperating on an endpoint are responsible for providing their own explicit synchronization to support coordinated disconnects.

Valid states:

- `T_DATAxFER`, `T_OUTCON`, `T_INCON`(ocnt > 0)

Returned value

If successful, `t_snddis()` returns 0.

If unsuccessful, `t_snddis()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
t_snddis

TBADDATA The amount of user data specified was not within the bounds allowed by the transport provider.
TBADF The specified file descriptor does not refer to a transport endpoint.
TBADSEQ An invalid sequence number was specified, or a NULL call pointer was specified, when rejecting a connect request.
TLOOK An asynchronous event, which requires attention, has occurred.
TNOTSUPPORT This function is not supported by the underlying transport provider.
TOUTSTATE The function was issued in the wrong sequence on the transport endpoint referenced by \textit{fd}.
TPROTO This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (\textit{errno}).
TSYSERR A system error has occurred during execution of this function.

**t_strerror() — Produce an error message string**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

char *t_strerror(int errnum);
```

**General description**

Maps the error number in `errnum` that corresponds to an XTI error to a language-dependent error message string and returns a pointer to the string. The string pointed to should not be modified by the program, but may be overwritten by a subsequent call to the `t_strerror` function. The string is not terminated by a newline character. If the calling program is operating in any one of the C, POSIX, SAA or S370 locales, then the error message string describing the value in `t_errno` is identical to the comments following the `t_errno` codes defined in `<xti.h>`. Note that no message number is prefixed to the message text in this situation. If an error code is unknown, and the language is English, `t_strerror()` returns the string:

```
"<error>: error unknown"
```

where `<error>` is the error number supplied as input. In other languages, an equivalent text is provided.

**Valid states:**

All - except for T_UNINIT

**Returned value**

t_strerror() returns a pointer to the generated message string.

**Related information**

- "xti.h" on page 86
- "t_error() — Produce error message" on page 2228
t_sync

### t_sync() — Synchronize transport library

#### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

#### Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_sync(int fd);
```

#### General description

Synchronizes the data structures managed by the transport library with information from the underlying transport provider, for the transport endpoint specified by `fd`. In doing so, it can convert an uninitialized file descriptor (obtained using `open()`, `dup()`, or as a result of a `fork()` and `exec()` ) to an initialized transport endpoint, assuming that the file descriptor referenced a transport endpoint, by updating and allocating the necessary library data structures. This function also allows two cooperating processes to synchronize their interaction with a transport provider.

For example, if a process forks a new process and issues an `exec()`, the new process must issue a `t_sync()` to build the private library data structure associated with a transport endpoint and to synchronize the data structure with the relevant provider information.

It is important to remember that the transport provider treats all users of a transport endpoint as a single user. If multiple processes are using the same endpoint, they should coordinate their activities so as not to violate the state of the transport endpoint. The function `t_sync()` returns the current state of the transport endpoint to the user, thereby enabling the user to verify the state before taking further action. This coordination is only valid among cooperating processes. It is possible that a process or an incoming event could change the endpoint's state after a `t_sync()` is issued.

If the transport endpoint is undergoing a state transition when `t_sync()` is called, the function will fail.

#### Valid states:

All - except for T_UNINIT

#### Returned value

If successful, `t_sync()` returns the state of the transport endpoint. The state returned is one of the following:

- **T_DATAFER** Data transfer.
- **T_IDLE** Idle.
- **T_INCON** Incoming connection pending.
- **T_OUTCON** Outgoing connection pending.
t_sync

T_UNBND            Unbound.

If unsuccessful, t_sync() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint. This error may be returned when the fd has been previously closed or an erroneous number may have been passed to the call.</td>
</tr>
<tr>
<td>TPROTO</td>
<td>This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).</td>
</tr>
<tr>
<td>TSTATECHNG</td>
<td>The transport endpoint is undergoing a state change.</td>
</tr>
<tr>
<td>TSYSERR</td>
<td>A system error has occurred during execution of this function.</td>
</tr>
</tbody>
</table>

Related information

tsyncro

**tsyncro() — Wait for MTF subtask termination**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <mtf.h>

int tsyncro(int MTF_ANY|MTF_ALL|nn);
```

**General description**

Waits for termination of parallel functions under MVS.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

The tsyncro() library function causes the main task to wait for the first subtask, a particular subtask, or all subtasks to finish executing all of the parallel functions that have been scheduled for them. You can monitor the completion of any, all, or a specific subtask by specifying:

- **MTF_ANY** To wait for the completion of any subtask.
- **MTF_ALL** To wait for the completion of all subtasks.
- **nn** To wait for the completion of the subtask having a task_id of nn.

See the `tinit() — Attach and initialize MTF subtasks` on page 2246 for a description of task_id.

You can invoke tsyncro() from your main task program as often as necessary.

If tinit() is called by a program running under IMS, CICS, or DB2, the request will not be processed and the returned value will indicate that MTF calls are not supported under these systems.

**Note:** This function is not supported under the z/OS UNIX with the POSIX(ON) runtime option.

**Returned value**

If successful, tsyncro() will always return a value suitable for use as a target task on a subsequent sched(). In particular, the return codes on success depend on the nature of the tsyncro() call, and the state of the subtasks at the time of the tsyncro() call as follows:
tsyncro

<table>
<thead>
<tr>
<th>Task_id passed to tsyncro()</th>
<th>Return code (if successful)</th>
</tr>
</thead>
<tbody>
<tr>
<td>MTF_ANY (and at least one subtask not previously returned from a tsyncro())</td>
<td>( nn = task_id ) of first subtask to become free</td>
</tr>
<tr>
<td>MTF_ANY (and all subtasks have previously been returned from a tsyncro())</td>
<td>MTF_ANY</td>
</tr>
<tr>
<td>MTF_ALL</td>
<td>MTF_ANY</td>
</tr>
<tr>
<td>( nn = task_id )</td>
<td>( nn )</td>
</tr>
</tbody>
</table>

If tinit() has not been successfully called before the tsyncro() call, tsyncro() indicates that MTF is inactive and returns one of the following values:

**Error Code** | **Description**
--- | ---
EINACTIVE | MTF is inactive.
ETASKABND | One or more subtasks have terminated abnormally.
ETASKID | The \( task_id \) argument specified is out of range.

**Note:** These values are macros. They can be found in the mtf.h header file.

**Related information**

- "mtf.h" on page 48
- "tinit() — Attach and initialize MTF subtasks" on page 2246
- "tsched() — Schedule MTF subtask" on page 2293
- "tterm() — Terminate MTF subtasks" on page 2308
tterm

**tterm() — Terminate MTF subtasks**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>C only</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <mtf.h>

int tterm(void);
```

**General description**

**Restriction:** This function is not supported in AMODE 64.

Terminates the MTF environment under MVS. The function is invoked by a main task to await the completion of all parallel functions that were scheduled by tsched() and to detach all subtasks and remove the MTF environment created by tinit(), see "tinit() — Attach and initialize MTF subtasks" on page 2245.

To avoid infringing on the user’s name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

If tinit() has not been successfully called before a tterm() call, tterm() indicates that MTF is already inactive.

If a tterm() call is not issued before main program termination, a system abend with completion code A03 will occur. The program’s termination will terminate the main task while subtasks are still active even if all scheduled parallel functions have completed execution.

If tinit() is called by a program running under IMS, CICS, or DB2, the request will not be processed and the returned value will indicate that MTF calls are not supported under these systems.

**Note:** This function is not supported under the z/OS UNIX with the POSIX(ON) runtime option.

**Returned value**

If successful, detaching the subtasks and removing the MTF environment, tterm() returns MTF_OK.

If unsuccessful, tsched() returns one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>

2308  z/OS V1R13.0 XL C/C++ Run-Time Library Reference
EINACTIVE MTF is inactive.
ETASKABND One or more subtasks have terminated abnormally.

Note: These values are macros. They can be found in the mtf.h header file.

ttyname

ttyname() — Get the name of a terminal

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

char *ttyname(int fildes);
```

General description

Returns a string containing the path name of the terminal associated with the given file descriptor, `fildes`. Subsequent calls to `ttyname()` may overwrite this string, because the pointer returned may point to static data.

Returned value

If successful, `ttyname()` returns a string containing a path name.

If unsuccessful because `fildes` is not a terminal, or the path name cannot be determined, `ttyname()` returns a NULL pointer.

Special behavior for XPG4:

The `ttyname()` function sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The <code>fildes</code> argument is not a valid open file descriptor.</td>
</tr>
<tr>
<td>ENOTTY</td>
<td>The <code>fildes</code> argument is not associated with a terminal.</td>
</tr>
</tbody>
</table>

Example

**CELEBT16:**

```c
CELEBT16:

/* CELEBT16
   This example provides the pathname of the terminal associated with stdin.
*/

#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>

main() {
  char *ret, tty[40];
  if ((ret = ttyname(STDIN_FILENO)) == NULL)
    perror("ttyname() error");
  else {
    strcpy(tty, ret);
```
printf("The ttyname associated with my stdin is %s\n", tty);
}

Output:
The ttyname associated with my stdin is /dev/ttyp0000

ttynamer_r

**ttynamer_r() — Find path name of a terminal**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, Version 2</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE 500
#include <unistd.h>

int ttynamer_r(int fildes, char *name, size_t namesize);
```

**General description**

The `ttynamer_r()` function stores the NULL-terminated path name of the terminal associated with the file descriptor, `fildes`, in the character array referenced by `name`. The array is `namesize` characters long and should have space for the name and the terminating NULL character. The maximum length of the terminal name is `TTY_NAME_MAX`.

**Returned value**

If successful, `ttynamer_r()` returns 0.

If unsuccessful, `ttynamer_r()` sets `errno` to one of the following values:

- **EBADF** The `fildes` argument is not a valid file descriptor.
- **ENOTTY** The `fildes` argument does not refer to a tty.
- **ERANGE** The value of `namesize` is smaller than the length of the string to be returned including the terminating NULL character.

**Related information**

- “unistd.h” on page 81
- “isatty() — Test if descriptor represents a terminal” on page 1037

ttyslot() — Find the slot in the utmpx file of the current user

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int ttyslot(void);
```

General description

The ttyslot() function returns the index of the current user's entry in the utmpx database. The current user's entry is an entry for which the ut_line member matches the name of a terminal device associated with any of the process's file descriptors 0, 1 or 2. The ttyname() function is used to obtain the terminal device. The "/dev/" part returned by ttyname() is not used when searching the utmpx database member ut_line.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro __UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, ttyslot() returns the index of the current user's entry in the utmpx database.

If unsuccessful, ttyslot() returns -1 if an error was encountered while searching the database or if none of the file descriptors 0, 1, or 2 is associated with a terminal device.

No errors are defined.

t_unbind

**t_unbind() — Disable a transport endpoint**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_unbind(int fd);
```

**General description**

Disables the transport endpoint specified by `fd` which was previously bound by `t_bind()`. On completion of this call, no further data or events destined for this transport endpoint will be accepted by the transport provider. An endpoint which is disabled by using `t_unbind()` can be enabled by a subsequent call to `t_bind()`.

Due to implementation-imposed restrictions, `t_unbind` does not affect descriptors in processes other than the caller which were derived from `fd` by normal descriptor inheritance. Processes cooperating on an endpoint in this way must explicitly provide their own synchronization for endpoint takedown.

**Valid states:**

T_IDLE

**Returned value**

If successful, `t_unbind()` returns 0.

If unsuccessful, `t_unbind()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBADF</td>
<td>The specified file descriptor does not refer to a transport endpoint.</td>
</tr>
<tr>
<td>TLOOK</td>
<td>An asynchronous event has occurred on this transport endpoint.</td>
</tr>
<tr>
<td>TOUTSTATE</td>
<td>The function was issued in the wrong sequence.</td>
</tr>
<tr>
<td>TPROTO</td>
<td>This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).</td>
</tr>
<tr>
<td>TSYSERR</td>
<td>A system error has occurred during execution of this function.</td>
</tr>
</tbody>
</table>

twalk() — Binary tree walk

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <search.h>

void *twalk(const void *root, void (*action)(const void *, VISIT, int));
```

General description

The twalk() function traverses a binary search tree. The root argument is a pointer to the root node of the tree to be traversed. (Any node in a tree may be used as the root for a walk below that node.) The argument action is the name of a routine to be invoked at each node. This routine is, in turn, called with three arguments. The first argument is the address of the node being visited. The structure pointed to by this argument is unspecified and must not be modified by the application, but is guaranteed that a pointer-to-node can be converted to pointer-to-pointer-to-element to access the element stored in the node. The second argument is a value from an enumeration data type:

```c
typedef enum {preorder, postorder, endorder, leaf} VISIT;
```

(defined in the <search.h> header), depending on whether this is the first, second or third time that the node is visited (during a depth-first, left-to-right traversal of the tree), or whether the node is a leaf. The third argument is the level of the node in the tree, with the root being level zero.

Threading Behavior: see "tsearch() — Binary tree search" on page 2295.

Special behavior for C++:

Because C and C++ linkage conventions are incompatible, twalk() cannot receive a C++ function pointer as the argument. If you attempt to pass a C++ function pointer to twalk(), the compiler will flag it as an error. You can pass a C or C++ function to twalk() by declaring it as extern "C".

Returned value

twalk() returns no values.

No errors are defined.

tzset() — Set the time zone

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>

<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>z/OS UNIX</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <time.h>

void tzset(void);
```

General description

The tzset() function uses the value of the environment variable TZ to set time conversion information used by ctime(), localtime(), mktime(), and strftime(). If TZ is absent from the environment, or it is incorrect, time-conversion information is obtained from the LC_TOD locale category.

tzset() also sets the external variable tzname:

```c
extern char *tzname[2] = {"std", "dst"};
```

Here, std and dst are Standard and Daylight Savings time zone names, specified by TZ or the LC_TOD local category, respectively.

tzset() is called by ctime(), localtime(), mktime(), setlocale(), and strftime(). It can also be called explicitly by an application program.

The format of TZ values recognized by tzset() is as follows:

```c
std[offset][dst[offset]][,rule]
```

**std** and **dst**

Indicate no fewer than three, but not more than TZNAME_MAX, bytes that are the designation for the standard (std) and daylight savings (dst) time zones. If more than TZNAME_MAX bytes are specified for std or dst, tzset() truncates to TZNAME_MAX bytes. Only std is required; if dst is missing, daylight savings time does not apply in this locale. Uppercase and lowercase letters are explicitly allowed. Any character except a leading colon (:) or digits, the comma (,), the minus (-), the plus (+), and the NULL character are permitted to appear in these fields. The meaning of these letters and characters is unspecified.

**offset**

Indicates the value that must be added to the local time to arrive at Coordinated Universal Time (UTC). offset has the form:

```c
hh[:mm[:ss]]
```

The minutes (mm) and seconds (ss) are optional. The hour (hh) is required and may be a single digit. offset following std is required. If no offset follows dst, daylight savings time is assumed to be 1 hour ahead of standard time. One or more digits may be used; the value is always interpreted as a decimal number. The hour must be between 0 and 24; minutes and seconds, if
present, between 0 and 59. The difference between standard time offset and daylight savings time offset must be greater than or equal to 0, but the difference may not be greater than 24 hours. Use of values outside of these ranges causes tzset() to use the LC_TOD category rather than the TZ environment variable for time conversion information. An offset preceded by a minus (−) indicates a time zone east of the Prime Meridian. A plus (+) preceding offset is optional and indicates the time zone west of the Prime Meridian.

**rule**

Indicates when to change to and back from daylight savings time.
The rule has the form: date[/time],date[/time]
The first date describes when the change from standard to daylight savings time occurs and the second date describes when the change back happens. Each time field describes when, in current local time, the change to the other time is made.
The format of date must be one of the following:

- **Jn**
The Julian day \( n \) (1\( \leq n \leq 365 \)). Leap days are not counted. That is, in all years—including leap years—February 28 is day 59 and March 1 is day 60. It is impossible to explicitly refer to the occasional February 29.

- **n**
The zero-based Julian day (0\( \leq n \leq 365 \)). Leap days are counted, and it is possible to refer to February 29.

- **Mm.n.d**
The \( d \)th day (0\( \leq d \leq 6 \)) of week \( n \) of month \( m \) of the year (1\( \leq n \leq 5 \), and 1\( \leq m \leq 12 \), where week 5 means “the last \( d \) day in month \( m \),” which may occur in either the fourth or the fifth week). Day zero is Sunday.

The time has the same format as offset except that no leading sign, minus (−) or plus (+), is allowed. The default, if time is not given, is 02:00:00.

If \( dst \) is specified and \( rule \) is not specified by TZ or in LC_TOD category, the default for the daylight savings time start date is M4.1.0 and for the daylight savings time end date is M10.5.0.

**Special behavior for XPG4:**

The tzset() function sets the external variable timezone to the difference, in seconds, between Coordinated Universal Time (UTC) and local standard time. tzset() sets the external variable daylight to 0 if summer time conversions should never be applied for the time zone in use; otherwise to nonzero.

Since the external variables timezone and daylight are global to the process, they cannot be reliably used in a multithreaded application or an application running from a DLL. The runtime library provides two special functions, __tzone() and __dlght(), which return the address of thread-specific versions of these external variables.

**Special behavior for POSIX C:**

The tzset() function only parses the TZ environment variable if it is called from the initial processing thread (IPT) by a threaded application.
Note: This function is sensitive to time zone information which is provided by:

- The TZ environmental variable when POSIX(ON) and TZ is correctly defined, or by the _TZ environmental variable when POSIX(OFF) and _TZ is correctly defined.
- The LC_TOD category of the current locale if POSIX(OFF) or TZ is not defined.
- When neither TZ nor _TZ is defined, the current locale is interrogated for time zone information. If neither TZ nor _TZ is defined and LC_TOD time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock. For more information about customizing a time zone to work with local time, see Customizing a time zone in z/OS XL C/C++ Programming Guide.

The time zone external variables tzname, timezone, and daylight declarations remain feature test protected in time.h.

Returned value
tzset() returns no values.

There are no documented errno values.

Example

CELEBT17:
/* CELEBT17
   This example set time conversion information for Eastern Standard and Eastern Daylight Savings Time in the United States.
*/
#define _POSIX_SOURCE
#include <env.h>
#include <time.h>

int main(void)
{
    setenv("TZ", "EST5EDT", 1);
    tzset();
}

<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single Unix Standard, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

useconds_t ualarm(useconds_t uscs, useconds_t intrval)
```

General description

The ualarm() function causes the SIGALRM signal to be generated for the calling process after the number of real-time microseconds specified by the uscs argument has elapsed. When the intrval argument is nonzero, repeated timeout notification occurs with a period in microseconds specified by the intrval argument. If the notification signal, SIGALRM, is not caught or ignored, the calling process is terminated.

The ualarm() function is a simplified interface to setitimer() and uses the ITIMER_REAL interval timer.

Note: The ualarm() and usleep() functions have been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The setitimer(), timer_create(), timer_delete(), timer_getoverrun(), timer_gettime(), or timer_settime() functions are preferred for portability.

Returned value

ualarm() returns the number of microseconds remaining from the previous ualarm(), alarm(), or setitimer(ITIMER_REAL) call.

If no timeouts are pending, ualarm() returns 0.

No errnos are defined for the ualarm() function.

__ucreate

__ucreate() — Create a heap using user-provided storage

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <uheap.h>

__uheapid_t __ucreate(void *block,
           size_t size,
           __uheap_cellpool_attrib_table_t *cellpool_attrib_table,
           void *rsvd1,
           void *rsvd2,
           void *rsvd3,
           void *rsvd4);

General description

The __ucreate() function creates a heap out of storage that is provided by the caller. The heap is divided up into cell pools based on the information provided in the cellpool_attrib_table. Up to 12 cell pools can be created within the heap. Note that this is a fixed-size heap; when storage within a given cell pool is exhausted, no additional storage will be allocated. __ucreate() returns a uheapid that is used to identify the heap on subsequent user-created heap function calls, such as __umalloc(), __ufree(), and __uheapreport() calls.

Parameter | Description
---|---
block | A pointer to the storage which is to be used for the heap.
size | The size of the block of storage. Note that Language Environment reserves approximately 328 bytes of this storage for use in allocating heap management control blocks. Additional storage is reserved if storage report usage statistics are being collected for the heap. The amount of this storage is related to the largest cell size and the granularity of the statistics, and is calculated as: storage amount = ((largestcellsize+granularity−1)/granularity)*4.

cellpool_attrib_table | A pointer to a structure describing the attributes of the cell pools to be created by __ucreate().

The first field of the structure, number_of_pools, indicates the number of cell pools to be created. Up to 12 cell pools can be created in the heap.

The second field of the structure, granularity, indicates the granularity to which storage usage statistics is to be collected. This value must be zero, or a power of 2 greater than or equal to 8. If the value is zero, then statistics are not collected.

Following these words are pairs of words describing the attributes of each cell pool in the heap:

The first field in the pair, size, is the size of the cell in the cell pool. The cell size must be a multiple of 8 and greater than or equal to 8, up to a maximum of 64K (65536). Note that Language Environment
__ucreate

adds an additional 8 bytes to the size of the cell for use in managing the cells. The second field in the pair, count, is the number of cells of this size to be allocated. Note the minimum is four.

rsvd1-rsvd4  Reserved for future use.

Returned value

If successful, __ucreate() returns a uheapid.

If unsuccessful, __ucreate() returns -1 and sets errno to EINVAL.

Related information

__uheapreport

__uheapreport() — Produce a storage report for a user-created heap

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <uheap.h>

void __uheapreport(__uheapid_t heapid);
```

General description

The __uheapreport() function generates a report of the storage used within the user-created heap identified by `heapid`. The report is directed to the ddname specified in the MSGFILE run-time option except for AMODE 64 applications, in which case the report is directed to the stderr stream. The report format is similar to the heap pools portion of the storage report generated for the RPTSTG run-time option.

Statistics for the user-created heap will only be collected if the granularity field of the cellpool_attrib_table passed to __ucreate() is nonzero and a valid value.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>heapid</td>
<td>The identifier of the user-created heap for which a report is to be produced.</td>
</tr>
</tbody>

ulimit

ulimit() — Get or set process file size limits

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE
#include <ulimit.h>

long int ulimit(int cmd, ...);
```

General description

The ulimit() function provides control over the process file size limits. The `cmd` argument controls whether the file size limits are obtained or set. The `cmd` argument can be one of the following, defined in `<ulimit.h>`:

- **UL_GETFSIZE**
  - Return the soft (current) file size limit of the process. The limit returned is in units of 512-byte blocks. The return value is the integer portion of the soft file size limit divided by 512. Refer to the `setrlimit()` function, RLIMIT_FSIZE resource description for more detail.

- **UL_SETFSIZE**
  - Set the hard (maximum) and soft (current) file size limits for output operations of the process. The value of the second argument is used, and is treated as a long int. Refer to the `setrlimit()` function, RLIMIT_FSIZE resource description for more detail and restrictions on lowering and raising file size limits. The hard and soft file size limits are set to the specified value multiplied by 512. The new file size limit (in 512 byte increments) is returned.

Returned value

If successful, `ulimit()` returns the value of the requested limit.

If unsuccessful, `ulimit()` returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The <code>cmd</code> argument is not valid.</td>
</tr>
<tr>
<td>EPERM</td>
<td>To increase the file size limit, superuser authority is required.</td>
</tr>
</tbody>
</table>

ulltoa() — Convert unsigned long long into a string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R5</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * ulltoa(uint64_t ll, char * buffer, int radix);
```

Compile Requirement

Use of this function requires the long long data type. See z/OS XL C/C++ Language Reference for information on how to make long long available.

General description

The ulltoa() function converts the uint64_t ll into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, ulltoa() produces the same result as the following statement:

```c
(void) sprintf(buffer, "%llu", ll);
```

with buffer the returned character string. When the radix is OCTAL, ulltoa() formats uint64_t ll into an octal constant. When the radix is HEX, ulltoa() formats uint64_t ll into a hexadecimal constant. The hexadecimal value will include lower case abcdef, as necessary.

Returned value

String pointer (same as buffer) will be returned. When passed an invalid radix argument, function will return NULL and set errno to EINVAL.

Portability considerations

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

ultoa

ultoa() — Convert unsigned long into a string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R5</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>
char * ultoa(unsigned long l, char * buffer, int radix);
```

General description

The ultoa() function converts the unsigned long l into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, ultoa() produces the same result as the following statement:

```c
(void) sprintf(buffer, "%lu", l);
```

with buffer the returned character string. When the radix is OCTAL, ultoa() formats unsigned long l into an octal constant. When the radix is HEX, ultoa() formats unsigned long l into a hexadecimal constant. The hexadecimal value will include lower case abcdef, as necessary.

Returned value

String pointer (same as buffer) will be returned. When passed an invalid radix argument, function will return NULL and set errno to EINVAL.

Portability considerations

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

__umalloc() — Allocate storage from a user-created heap

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Environment</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <uheap.h>

void *__umalloc(__uheapid_t heapid, size_t size);
```

General description

The __umalloc() function allocates storage from the heap identified by the heapid. __umalloc() will search for an available cell within the cell pool that contains cells at least as large and closest in size to the requested size.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>heapid</td>
<td>The identifier of the user-created heap from which the storage is to be allocated.</td>
</tr>
<tr>
<td>size</td>
<td>The amount of storage to be allocated.</td>
</tr>
</tbody>
</table>

Returned value

If successful, __umalloc() returns a pointer to the reserved cell.

If a cell of the required size is not available, if size was larger than the largest available cell size, or if size was specified as 0, __umalloc() returns NULL.

If there is not enough storage or if the requested size was too large, __umalloc() returns NULL and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2BIG</td>
<td>Requested amount of storage is larger than the largest available cell size</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>Insufficient memory is available</td>
</tr>
</tbody>
</table>

umask

**umask() — Set and retrieve file creation mask**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _POSIX_SOURCE
#include <sys/stat.h>

mode_t umask(mode_t newmask);
```

**General description**

Changes the file creation mask of the process. `newmask` specifies new file-permission bits for the file creation mask of the process.

This mask restricts the setting of (or turns off) file-permission bits specified in the ‘mode’ argument used with all open(), creat(), mkdir(), and mkfifo() functions issued by the current process. File-permission bits set to 1 in the file creation mask are set to 0 in the file-permission bits of files that are created by the process.

For example, if a call to open() specifies a `mode` argument with file-permission bits, the file creation mask of the process affects the `mode` argument; bits that are 1 in the mask are set to 0 in the `mode` argument, and therefore in the mode of the created file.

Only the file-permission bits of the new mask are used. The meaning of other bits is implementation-defined. For more information on these symbols, refer to "[chmod()] — Change the mode of a file or directory" on page 284.

The `_EDC_UMASK_DFLT` environment variable controls how the C run-time library sets the default umask. If z/OS UNIX are available, the run-time library establishes a default umask value of 022 octal, and queries the value of the `_EDC_UMASK_DFLT` environment variable. `_EDC_UMASK_DFLT` can have the following values:

- NO (case insensitive) The library should not change the umask.
- A valid octal value The library should use this as the default value for the umask.

Any other value for the environment variable causes the run-time library to use 022 octal as the umask value.

**Returned value**

`umask()` is always successful and returns the previous value of the file creation mask.

There are no documented errno values.
Example

CELEBU01
/*/ CELEBU01

This example will work only from C/MVS, not C++/MVS.
*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
  int fd;
  mode_t oldmask;

  printf("Your old umask is %i\n",oldmask=umask(S_IRWXG));
  if ((fd = creat("umask.file", S_IRWXU|S_IRWXG)) < 0)
    perror("creat() error");
  else {
    system("ls −l umask.file");
    close(fd);
    unlink("umask.file");
  }
  umask(oldmask);
}

Output
-rwx------ 1 WELLIE SYS1 0 Apr 19 14:50 umask.file

umount()

Remove a virtual file system

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/stat.h>

int umount(const char *filesystem, mtm_t mtm);
```

General description

Removes a file system from the file hierarchy, or changes the mount mode of a mounted file system between read-only and read/write. The `filesystem` argument is a NULL-terminated string containing the file-system name. This is the same name that was specified when the file system was mounted.

In order to umount a file system, the caller must be an authorized program, or must be running for a user with appropriate privileges.

The `mtm` argument can be one of the following:

- **MTM_UMOUNT**
  
  A normal umount request. If the files in the named file system are not in use, the umount is done. Otherwise, the request is rejected.

- **MTM_DRAIN**
  
  An unmount drain request. The requester is willing to wait for all uses of this file system to be ended normally before the file system is unmounted.

- **MTM_IMMED**
  
  An immediate unmount request. The file system is unmounted immediately, forcing any users of files in the specified file system to fail. All data changes that were made up to the time of the request are saved. If there is a problem saving the data, the unmount request fails.

- **MTM_FORCE**
  
  A forced unmount request. The file system is unmounted immediately, forcing any users of any files in the specified file system to fail. All data changes that were made up to the time of the request are saved. If there is a problem saving the data, the request continues, and the data may be lost. To prevent lost data, issue an immediate umount() request before issuing a forced umount() request.

- **MTM_RESET**
  
  A reset unmount request. This allows a previous unmount drain request to be stopped.

- **MTM_REMOUNT**
  
  A remount request. This changes the mount mode of a file system from read-only to read/write or from read/write to read-only. If neither MTM_RDONLY nor MTM_RDWR is specified, the mode is set to the opposite of its current state. If a mode is specified, it must be the opposite of the current state.

- **MTM_SAMEMODE**
  
  A remount request to unmount and mount back without changing
the mount mode. If either MTM_RDONLY or MTM_RDWR is also specified, it must be the current state. This can be used to attempt to regain use of a file system that has had I/O errors.

Returned value

If successful, umount() returns 0.

If unsuccessful, umount() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBUSY</td>
<td>The file system is busy, for one of these reasons:</td>
</tr>
<tr>
<td></td>
<td>• A umount() (MTM_UMOUNT) was requested, and the file system still has open files or other file systems mounted under it.</td>
</tr>
<tr>
<td></td>
<td>• A file system is currently mounted on the requested file system.</td>
</tr>
<tr>
<td></td>
<td>• A RESET was requested, and the previous umount() request was either immediate or forced, instead of a drain request.</td>
</tr>
<tr>
<td></td>
<td>• There is a umount() request already in progress for the specified file system.</td>
</tr>
<tr>
<td></td>
<td>• A umount() drain request is being reset.</td>
</tr>
<tr>
<td>EINTR</td>
<td>umount() was interrupted by a signal.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>A parameter was incorrectly specified. Verify the spelling of the file-system name and the setting of mtm.</td>
</tr>
<tr>
<td>EIO</td>
<td>An I/O error occurred.</td>
</tr>
<tr>
<td>EPERM</td>
<td>Superuser authority is required to issue an unmount.</td>
</tr>
</tbody>
</table>

Example

CELEBU02

/* CELEBU02 */

This example removes a file, using umount().

*/
#define _OPEN_SYS 1
#include <sys/stat.h>
#include <stdio.h>
#include <unistd.h>

main() {
    char HFS[]="POSIX.NEW.HFS";
    char filesystype[9]="HFS ";
    setvbuf(stdout, NULL, _IOLBF, 0);
    puts("before umount() ");
    system("df -Pk");
    if (umount(HFS, MTM_UMOUNT) != 0)
        perror("umount() error");
    else {
        puts("After umount() ");
        system("df -Pk");
    }
}

Output

before umount()

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <sys/utsname.h>

int uname(struct utsname *name);
```

General description

The uname() function retrieves information identifying the operating system you are running on. The argument *name* points to a memory area where a structure describing the operating system the process is running on can be stored.

The information about the operating system is returned in a utsname structure, which has the following elements:

- `char *sysname;`  
  The name of the implementation of the operating system.

- `char *nodename;`  
  The node name of this particular machine. The node name is set by the SYSNAME sysparm (specified at IPL), and usually differentiates machines running at a single location.

- `char *release;`  
  The current release level of the implementation.

- `char *version;`  
  The current version level of the release.

- `char *machine;`  
  The name of the hardware type the system is running on.

Each of the utsname structure elements is a normal C string, terminated with a NULL character.

As of OS/390 Release 2, the uname() function will return “OS/390” as the sysname value, even if the true name of the operating system is different. This is for compatibility purposes. The version value will increase at every new version of the operating system. The release value will increase at every new release of the operating system.

Table 58 on page 2336 lists the operating system names and corresponding values returned by the uname() function. To retrieve the true operating system name, version, and release, use the __osname() function.

</tbody>
</table>

Returned value

If successful, the uname() function returns a nonnegative value.

If unsuccessful, the uname() function returns −1. An errno might be set to indicate the reason for the failure, but no errno values are specified by the POSIX.1 standard.

Example

CELEBU03

/* CELEBU03
   This example gets information about the system you are running on.
*/

#define _POSIX_SOURCE
#include <sys/utsname.h>
#include <stdio.h>

main() {
    struct utsname uts;

    if (uname(&uts) < 0)
      perror("uname() error");
    else {
      printf("Sysname: %s\n", uts.sysname);
      printf("Nodename: %s\n", uts.nodename);
      printf("Release: %s\n", uts.release);
      printf("Version: %s\n", uts.version);
      printf("Extra: %s\n", uts.extra);
    }
uname

    printf("Version: \%s\n", uts.version);
    printf("Machine: \%s\n", uts.machine);
}

Output
Sysname: OS/390
Nodename: SY1
Release: 23.00
Version: 03
Machine: 2097

uncaught_exception

uncaught_exception() — Determine if an exception is being processed

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANSI/ISO C++</td>
<td>C++ only</td>
<td>z/OS V1R2</td>
</tr>
</tbody>
</table>

Format

```c
#include <exception>

bool uncaught_exception(void);
```

General description

The `uncaught_exception()` function returns true only if a thrown exception is currently being processed.

When `uncaught_exception()` is true, throwing an exception can result in a call of `terminate()`.

Returned value

`uncaught_exception()` returns true after completing evaluation of a throw expression and before completing initialization of the exception declaration in the matching handler or calling `unexpected()` as a result of the throw expression.

Otherwise, `uncaught_exception()` returns false.

Example

```c
#include <exception>
#include <iostream.h>
using namespace std;

class X
{
public:
   "X();
};

X::"X()
{
   if (uncaught_exception())
      printf (" X::\"X called during stack unwind\n");
   else
      printf (" X::\"X called normally\n");
}

int main()
{
   X x1;
   try
   {
      X x2;
      throw 1;
   }
   catch (...) { /*...*/ }
   return 0;
}
```
uncaught_exception

// under a Standard-conforming implementation, this program yields
// X::"X called during stack unwind"
// X::"X called normally"

</tbody>
</table>

Format

```c
#include <sys/__wlm.h>
int UnDoExportWorkUnit(wlmxtok_t *exporttoken, unsigned long *conntoken);
```

**AMODE 64:**

```c
#include <sys/__wlm.h>
int UnDoExportWorkUnit(wlmxtok_t *exporttoken, unsigned int *conntoken);
```

General description

Undoes an earlier request to export an enclave using the ExportWorkUnit() function. The caller is expected to invoke UnDoExportWorkUnit() after all importing systems have invoked the UnDoImportWorkUnit() function.

The UnDoExportWorkUnit() function uses the following parameters:

- `*exporttoken` Points to a work unit export token that was returned from a call to ExportWorkUnit().
- `*conntoken` Specifies the connect token that represents the connection to WLM.

Returned value

If successful, UnDoExportWorkUnit() returns 0.

If unsuccessful, UnDoExportWorkUnit() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFAULT</td>
<td>An argument of this function contained an address that was not accessible to the caller.</td>
</tr>

unexpected()

unexpected() — Handle exception not listed in exception specification

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANSI/ISO C++</td>
<td>C++ only</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <exception>

void unexpected(void);
```

General description

The unexpected() function is part of the z/OS XL C++ error handling mechanism. If unexpected() is called directly by the program, the unexpected_handler is the one most recently set by a call to set_unexpected(). If unexpected() is called when control leaves a function by a thrown exception of a type not permitted by an exception specification for the function, as in:

```c
void f() throw()    // function may throw no exceptions
    {throw "bad"; } // throw calls unexpected()
```

the unexpected_handler is the one in effect immediately after evaluating the throw expression.

An unexpected_handler may not return to its caller. It may terminate execution by:

- Throwing an object of a type listed in the exception specification (or an object of any type if the unexpected handler is called directly by the program).
- Throwing an object of type bad_exception.
- Calling terminate(), abort(), or exit(int).

If set_unexpected() has not yet been called, then unexpected() calls terminate().

In a multithreaded environment, if a thread throws an exception that is not listed in its exception specification, then unexpected() is called. The default for unexpected() is to call terminate(), which defaults to calling abort(), which then causes a SIGABRT signal to be generated to the thread issuing the throw. If the SIGABRT signal is not caught, the process is terminated. You can replace the default unexpected() behavior for all threads in the process by using the set_unexpected() function. One possible use of set_unexpected() is to call a function which issues a pthread_exit(). If this is done, a throw of a condition by a thread that is not in the exception specification results in thread termination, but not process termination.

Returned value

unexpected() returns no values.

Refer to [z/OS XL C/C++ Language Reference](https://www.ibm.com/support/knowledgecenter/en/SSLVMB_11.1.0/cxxhxxref/exception.html) for more information about z/OS XL C++ exception handling, including the unexpected() function.

Format

```c
#include <stdio.h>

int ungetc(int c, FILE *stream);
```

```c
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int ungetc_unlocked(int c, FILE *stream);
```

General description

Pushes the character specified by the value of `c` converted to the unsigned char back onto the given input stream. The pushed-back characters are returned by any subsequent read on the same stream in the reverse order of their pushing. That is, the last character pushed will be returned first.

Up to 4 characters can be pushed back to a given input stream. You can call `ungetc()` up to 4 times consecutively; this will result in 4 characters being pushed back in total.

The `stream` must be open for reading. A subsequent read operation on the `stream` starts with `c`. You cannot push EOF back on the stream using `ungetc()`. A successful call to the `ungetc()` function clears the EOF indicator for the stream.

Characters pushed back by `ungetc()`, and subsequently not read in, will be erased if a `fseek()`, `fsetpos()`, `rewind()`, or `fflush()` function is called before the character is read from the `stream`. After all the pushed-back characters are read in, the file position indicator is the same as it was before the characters were pushed back.

Each character of pushback backs up the file position by one byte. This affects the value returned by `ftell()` or `fgetpos()`, the result of an `fseek()` using SEEK_CUR, or the result of an `fflush()`. For example, consider a file that contains: `a b c d e f g h`

After you have just read 'a', the current file position is at the start of 'b'. The following operations will all result in the file position being at the start of 'a', ready to read 'a' again.

```c
/* 1 */
    ungetc('a', fp);
    fflush(fp); /* flushes ungetc char and keeps position */

/* 2 */
    ungetc('a', fp);
    pos = ftell(fp); /* points to first character */
```
### Ungetc

```c
fseek(fp, pos, SEEK_SET);
/* 3 */ ungetc('a', fp);
fseek(fp, 0, SEEK_CUR) /* starts at new file pos'n */
/* 4 */ ungetc('a', fp);
ungetpos(fp, &fpos); /* gets position of first char */
fsetpos(fp, &fpos);
```

You can use the environment variable _EDC_COMPAT to cause a z/OS XL C/C++ application to ignore ungetc() characters for fflush(), ungetpos(), and fseek() using SEEK_CUR. For more details, see [z/OS XL C/C++ Programming Guide](https://www.ibm.com/support/docview.wss?uid=swg21424656).

The ungetc() function is not supported for files opened with type=record.

ungetc() has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

ungetc_unlocked() is functionally equivalent to ungetc() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

### Returned Value

If successful, ungetc() returns the integer argument c converted to an unsigned char.

If c cannot be pushed back, ungetc() returns EOF.

ungetc() is treated as a read operation. A flush or reposition is required after a call to ungetc() and before the next write operation.

### Example

**CELEBU04**

/* CELEBU04

In this example, the while statement reads decimal digits from an input data stream by using arithmetic statements to compose the numeric values of the numbers as it reads them. When a nondigit character appears before the EOF, &ungetc replaces it in the input stream so that later input functions can process it.

*/

#include <stdio.h>
#include <ctype.h>

int main(void)
{
  FILE *stream;
  int ch;
  unsigned int result = 0;

  stream = fopen("myfile.dat","r+");
  while ((ch = getc(stream)) != EOF && isdigit(ch))
  {
    result = result * 10 + ch - '0';
  }
  
  return 0;
}`
```c
}
printf("result is %i\n",result);
if (ch != EOF)
{
    ungetc(ch,stream);    /* Put the nondigit character back */
    ch=getc(stream);
    printf("value put back was %c\n",ch);
}
```

</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wint_t ungetwc(wint_t wc, FILE *stream);
```

```c
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t ungetwc_unlocked(wint_t wc, FILE *stream);
```

General description

Pushes the wide character specified by `wc` back onto the input stream pointed to by `stream`. The pushed-back wide characters will be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call (with the stream pointed to by `stream`) to a file positioning function (`fseek()`, `fsetpos()`, or `rewind()`) discards any pushed-back wide characters for the stream. The external storage corresponding to the stream is unchanged. There is always at least one wide character of push-back.

If the value of `wc` equals that of the macro WEOF, the operation fails and the input stream is unchanged.

A successful call to the ungetwc() function clears the EOF indicator for the stream. The value of the file position indicator for the stream after reading or discarding all pushed-back wide characters is the same as it was before the wide characters were pushed back.

For a text stream, the file position indicator is backed up by one wide character. This affects `ftell()`, `fflush()`, `fseek()` using SEEK_CUR, and `fgetpos()`. The environment variable _EDC_COMPAT can be used to cause a pushed-back wide character to be ignored by `fflush()`, `fseek()` with SEEK_CUR, and `fgetpos()`. For details, see [z/OS XL C/C++ Programming Guide](https://www.ibm.com/mahonlineli). For a binary stream, the position indicator is unspecified until all characters are read or discarded, unless the last character is pushed back, in which case the file position indicator is backed up by one wide character. This affects `ftell()` and `fseek()` with SEEK_CUR, `fgetpos()`, and `fflush()`. The environment variable _EDC_COMPAT can be used to cause the pushed-back wide character to be ignored by `fflush()`, `fgetpos()`, and `fseek()`.

ungetwc() is not supported for files opened with type=record.

ungetwc() has the same restriction as any read operation for a read immediately following a write, or a write immediately following a read. Between a write and a
ungetwc

subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

ungetwc_unlocked() is functionally equivalent to ungetwc() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, ungetwc() returns the wide character pushed back after conversion.

If unsuccessful, ungetwc() returns WEOF.

Notes:

1. For z/OS XL C/C++ applications, only 1 wide character can be pushed back.
2. The position on the stream after a successful ungetwc() is one wide character before the current position. See z/OS XL C/C++ Programming Guide for details on backing up a wide char.

Example

```c
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    FILE *stream;
    wchar_t wc;
    unsigned int result = 0;

    while ((wc = fgetwc(stream)) != WEOF && iswdigit(wc))
        result = result * 10 + wc - L'0';

    if (wc != WEOF)
        ungetwc(wc, stream);
    /* Put the nondigit wide character back */
}
```

unlink

unlink() — Remove a directory entry

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

int unlink(const char *pathname);
```

General description

Removes a directory entry. This unlink() deletes the link named by `pathname` and decrements the link count for the file itself.

`pathname` can refer to a pathname, a link, or a symbolic link. If the `pathname` refers to a symbolic link, unlink() removes the symbolic link but not any file or directory named by the contents of the symbolic link.

If the link count becomes 0 and no process currently has the file open, the file itself is deleted. The space occupied by the file is freed for new use, and the current contents of the file are lost. If one or more processes have the file open when the last link is removed, unlink() removes the link, but the file itself is not removed until the last process closes the file.

unlink() cannot be used to remove a directory; use rmdir() instead.

If unlink() succeeds, the change and modification times for the parent directory are updated. If the file’s link count is not 0, the change time for the file is also updated. If unlink() fails, the link is not removed.

Returned value

If successful, unlink() returns 0.

If unsuccessful, unlink() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The process did not have search permission for some component of <code>pathname</code>, or did not have write permission for the directory containing the link to be removed.</td>
</tr>
<tr>
<td>EBUSY</td>
<td><code>pathname</code> cannot be unlinked because it is currently being used by the system or some other process.</td>
</tr>
<tr>
<td>ELOOP</td>
<td>A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP symbolic links are detected in the resolution of <code>pathname</code>.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td><code>pathname</code> is longer than PATH_MAX characters, or some</td>
</tr>
</tbody>
</table>
component of pathname is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined using pathconf().

ENOENT  pathname does not exist, or it is an empty string.
ENOTDIR Some component of the pathname prefix is not a directory.
EPERM  pathname is a directory, and unlink() cannot be used on directories.
EROFS The link to be removed is on a read-only file system.

Example

CELEBU06
/* CELEBU06

This example removes a directory entry, using unlink().

*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
main() {
  int fd;
  char fn[]="unlink.file";
  if ((fd = creat(fn, S_IWUSR)) < 0)
    perror("creat() error");
  else {
    close(fd);
    if (unlink(fn) != 0)
      perror("unlink() error");
  }
}

<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int unlockpt(int fildes);
```

**General description**

The unlockpt() function unlocks the slave pseudoterminal device associated with the master to which `fildes` refers.

Portable applications must call unlockpt() before opening the slave side of a pseudoterminal device.

**Returned value**

If successful, unlockpt() returns 0.

If unsuccessful, unlockpt() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCESS</td>
<td>Either a grantpt() has not yet been issued, or an unlockpt() has already been issued. An unlockpt() must be issued after a grantpt(), and can only be issued once.</td>
</tr>
<tr>
<td>EBADF</td>
<td>The <code>fildes</code> argument is not a file descriptor open for writing.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The <code>fildes</code> argument is not associated with a master pseudoterminal device.</td>
</tr>
</tbody>
</table>

unsetenv() — Delete an environment variable

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single UNIX Specification, version 3</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
</tbody>
</table>

Format

```c
#define _UNIX03_SOURCE
#include <stdlib.h>

int unsetenv(const char *name);
```

General description

unsetenv() deletes an environment variable from the environment of the calling process. The `name` argument points to a string, which is the name of the variable to be removed. If the string pointed to by `name` contains an `=' character, unsetenv() will fail. If the named variable does not exist in the current environment, the environment will not be changed and unsetenv() will succeed.

Returned value

If successful, unsetenv() returns 0. If unsuccessful, unsetenv() returns -1 and sets errno to indicate the error.

- EINVAL – The name argument is a null pointer, points to an empty string, or points to a string containing an `=' character.

usleep

usleep() — Suspend execution for an interval

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int usleep(useconds_t useconds);
```

General description

The usleep() function suspends thread execution for the number of microseconds specified by the useconds argument. Because of other activity, or because of the time spent processing the call, the actual suspension time may be longer than the amount of time specified.

The useconds argument must be less than 1,000,000. If the value of useconds is 0, then the call has no effect.

The usleep() function will not interfere with a previous setting of the real-time interval timer. If the thread has set this timer before calling usleep(), and if the time specified by useconds equals or exceeds the interval timer’s prior setting, then the thread will be awakened when the previously set timer interval expires.

Note: The ualarm() and usleep() functions have been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The setitimer(), timer_create(), timer_delete(), timer_gettime(), or timer_settime() functions are preferred for portability.

Returned value

If successful, usleep() returns 0.

If unsuccessful, usleep() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The useconds argument was greater than or equal to 1,000,000.</td>
</tr>
</tbody>
</table>

uname() — Set file access and modification times

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX.1</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <utime.h>
int utime(const char *pathname, const struct utimbuf *newtimes);
```

General description

Sets the access and modification times of `pathname` to the values in the `utimbuf` structure. If `newtimes` is a NULL pointer, the access and modification times are set to the current time.

Normally, the effective user ID (UID) of the calling process must match the owner UID of the file, or the calling process must have appropriate privileges. However, if `newtimes` is a NULL pointer, the effective UID of the calling process must match the owner UID of the file, or the calling process must have write permission to the file or appropriate privileges.

The contents of a `utimbuf` structure are:

- `time_t actime`: The new access time (The `time_t` type gives the number of seconds since the epoch.)
- `time_t modtime`: The new modification time

Returned value

If successful, `utime()` returns 0 and updates the access and modification times of the file to those specified.

If unsuccessful, `utime()` returns −1, does not update file times, and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
</table>
| EACCES     | The process does not have search permission on some component of the `pathname` prefix; or all of the following are true:  
- `newtimes` is NULL.  
- The effective user ID of the process does not match the file’s owner.  
- The process does not have write permission on the file.  
- The process does not have appropriate privileges. |
| ELOOP      | A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLOOP` symbolic links (defined in the limits.h header file) are detected in the resolution of `pathname`. |
The `utime` function sets the modification time and access time of a file or directory. If the times are specified, they are set; otherwise, they are updated if the function is called with non-zero times, or cleared if called with zero times. The return value is 0 if successful, or -1 if an error occurred.

**Example**

**CELEBU07**

```c
/* CELEBU07 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <stdio.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <time.h>
#include <unistd.h>
#include <utime.h>

main() {
    int fd;
    char fn[]="utime.file";
    struct utimbuf ubuf;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        puts("before utime()");
        system("ls -l utime.file");
        ubuf.modtime = 0;
        time(&ubuf.actime);
        if (utime(fn, &ubuf) != 0)
            perror("utime() error");
        else {
            puts("after utime()");
            system("ls -l utime.file");
        }
        unlink(fn);
    }
}
```

**Output**

```
before utime()
--w-------  1 WELLIE SYS1 0 Apr 19 15:23 utime.file
after utime()
--w-------  1 WELLIE SYS1 0 Dec 31 1969 utime.file
```

<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2, Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/time.h>

int utimes(const char *path, const struct timeval times[2]);
```

General description

The `utimes()` function sets the access and modification times of the file pointed to by the `path` argument to the value of the `times` argument.

The `times` argument is an array of two `timeval` structures. The first array member represents the date and time of the last access, and the second member represents the date and time of the last modification. The times in the `timeval` structure are measured in seconds and microseconds since the Epoch, but the actual time stored with the file are rounded to the nearest second. The `timeval` members are:

- `tv_sec` seconds since January 1, 1970 (UTC)
- `tv_usec` microseconds

If the `times` argument is a NULL pointer, the access and modification times of the file are set to the current time. The same process privilege requirements of the `utime()` function are required by `utimes()`. The last file status change, field `st_ctime` in a `stat()`, is updated with the current time.

**Note:** The `utimes()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `utime()` function is preferred for portability.

Returned value

If successful, `utimes()` returns 0.

If unsuccessful, `utimes()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EACCES</td>
<td>The process does not have search permission on some component of the <code>path</code> prefix; or all of the following are true:</td>
</tr>
<tr>
<td></td>
<td>- <code>times</code> is NULL</td>

General description

The __utmpxname() function changes the name of the utmpx database file for the current thread from default /etc/utmpx to the name specified by file. The __utmpxname() function does not open the file. It closes the old utmpx database file, if it is currently opened for the current thread, and saves the new utmpx database file name. If the file does not exist no indication is given.

Because the __utmpxname() function processes thread-specific data the __utmpxname() function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the endutxent() function is called by the calling thread.

Programs must not reference the data passed back by getutxline(), getutxid(), getutxent(), or pututxline() after __utmpxname() has been called (the storage has been freed.) The endutxent() function resets the name of the utmpx database back to the default value. If you must do additional utmpx operations on a nonstandard utmpx database after calling endutxent(), then call __utmpxname() again, to reestablish the nonstandard name.

Returned value

If successful, __utmpxname() returns 0.

If unsuccessful, __utmpxname() returns −1.

utoa() — Convert unsigned int into a string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>z/OS V1R5</td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * utoa(unsigned int n, char * buffer, int radix);
```

General description

The utoa() function converts the unsigned integer `n` into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, utoa() produces the same result as the following statement:

```c
(void) sprintf(buffer, "%u", n);
```

with buffer the returned character string. When the radix is OCTAL, utoa() formats unsigned integer `n` into an octal constant. When the radix is HEX, utoa() formats unsigned integer `n` into a hexadecimal constant. The hexadecimal value will include lower case abcdef, as necessary.

Returned value

String pointer (same as buffer) will be returned. When passed an invalid radix argument, function will return NULL and set errno to EINVAL.

Portability considerations

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

</tr>
</tbody>
</table>

Format

```
#include <stdarg.h>

var_type va_arg(va_list arg_ptr, var_type);
void va_end(va_list arg_ptr);
void va_start(va_list arg_ptr, variable_name);

C99:
#define _ISOC99_SOURCE
#include <stdarg.h>

var_type va_arg(va_list arg_ptr, var_type);
void va_end(va_list arg_ptr);
void va_start(va_list arg_ptr, variable_name);
void va_copy(va_list dest, va_list src);
```

General description

The va_arg(), va_end(), and va_start() macros access the arguments to a function when it takes a fixed number of required arguments and a variable number of optional arguments. You declare required arguments as ordinary parameters to the function and access the arguments through the parameter names.

The va_start() macro initializes the arg_ptr pointer for subsequent calls to va_arg() and va_end().

The argument variable_name is the identifier of the rightmost named parameter in the parameter list (preceding , ...). Use the va_start() macro before the va_arg() macro. Corresponding va_start() and va_end() macro calls must be in the same function. If variable_name is declared as a register, with a function or an array type, or with a type that is not compatible with the type that results after application of the default argument promotions, then the behavior is undefined.

The va_arg() macro retrieves a value of the given var_type from the location given by arg_ptr and increases arg_ptr to point to the next argument in the list. The va_arg() macro can retrieve arguments from the list any number of times within the function.

The macros also provide fixed-point decimal support under z/OS XL C. The sizeof(xx) operator is used to determine the size and type casting that is used to generate the values. Therefore, a call, such as, x = va_arg(ap, _Decimal(5,2)); is valid. The size of a fixed-point decimal number, however, cannot be made a variable. Therefore, a call, such as, z = va_arg(ap, _Decimal(x,y)) where x = 5 and y = 2 is invalid.

The va_end() macro is needed by some systems to indicate the end of parameter scanning.
va_start() and va_arg() do not work with parameter lists of functions whose linkages were changed with the #pragma linkage directive.

stdarg.h and varargs.h are mutually exclusive. Whichever #include comes first, determines the form of macro that is visible.

The type definition for the va_list type is normally "char *va_list[2]". Some applications (especially ported applications) require that the va_list type be defined as "char *va_list". This alternate va_list type is available if the user defines the feature test macro _VARARG_EXT_ before the inclusion of any system header file. If the _VARARG_EXT_ feature test macro is defined, va_list will be typed as char * va_list, and the functions vprintf(), vfprintf(), vsprintf(), and vswprintf() will use this alternate va_list type.

The va_copy() function creates a copy (dest) of a variable of type va_list (src). The copy appear as if it has gone through a va_start() and the exact set of sequences of va_arg() as that of src.

After va_copy() initializes dest, the va_copy() macro shall not be invoked to reinitialize dest without an intervening invocation of the va_end() macro for the same dest.

Returned value

The va_arg() macro returns the current argument.

The va_end(), va_copy(), and va_start() macros return no values.

Example

CELEBV01
/* CELEBV01
   This example passes a variable number of arguments to a function,
   stores each argument in an array, and prints each argument.
*/

#include <stdio.h>
#include <stdarg.h>

valloc

valloc() — Page-aligned memory allocator

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

void *valloc(size_t size);
```

General description

**Restriction:** This function is not supported in AMODE 64.

The `valloc()` function has the same effect as `malloc()`, except that the allocated memory will be aligned to a multiple of the value returned by `sysconf(_SC_PAGESIZE)`.

**Note:** When `free()` is used to release storage obtained by `valloc()`, the storage is not made available for reuse. The storage will not be freed until the enclave goes away.

**Special behavior for C++:** The C++ keywords `new` and `delete` are not interoperable with `valloc()`, `calloc()`, `free()`, `malloc()`, or `realloc()`.

**Note:**

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. The `malloc()` or `mmap()` functions are preferred for portability.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `valloc()` returns a pointer to the reserved storage. The storage space to which the returned value points is guaranteed to be aligned on a page boundary.

If unsuccessful, `valloc()` returns NULL if there is not enough storage available, or if `size` is 0. If `valloc()` returns NULL because there is not enough storage, it sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENOMEM</td>
<td>Insufficient memory is available</td>
</tr>
</tbody>
</table>

vfork()

Create a new process

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <unistd.h>

pid_t vfork(void);
```

Note: Although POSIX.1 does not require that the `<sys/types.h>` include file be included, XPG4 has it as an optional header. Therefore it is recommended that you include it for portability.

General description

The `vfork()` function creates a new process. The `vfork()` function has the same effect as `fork()`, except that the behavior is undefined, if the process created by `vfork()` attempts to call any other C/370 function before calling either `exec()` or `_exit()`. The new process (the child process) is an exact duplicate of the process that calls `vfork()` (the parent process), except for the following:

- The child process has a unique process ID (PID), which does not match any active process group ID.
- The child has a different parent process ID, that is, the process ID of the process that called `vfork()`.
- The child has its own copy of the parent's file descriptors. Each file descriptor in the child refers to the same open file description as the corresponding file descriptor in the parent.
- The child has its own copy of the parent's open directory streams. Each child's open directory stream may share directory stream positioning with the corresponding parent's directory stream.
- The following elements in the `tms` structure are set to 0 in the child:
  ```
  tms_utime
  tms_stime
  tms_cutime
  tms_cstime
  ```
  For more information about these elements, see "times() — Get process and child process times" on page 2243.
- The child does not inherit any file locks previously set by the parent.
- The child process has no alarms set (similar to the results of a call to `alarm()` with an argument value of 0).
- The child has no pending signals.
- The child process may have its own copy of the parent's message catalog descriptors.
- All semadj values are cleared.
- Interval timers are reset in the child process.
In all other respects, the child is identical to the parent. Because the child is a duplicate, it contains the same call to vfork() that was in the parent. Execution begins with this vfork() call, which returns a value of 0; the child then proceeds with normal execution.

The vfork() function is not supported from a multithread environment.

For more information on vfork() from a z/OS perspective, refer to z/OS UNIX System Services Programming: Assembler Callable Services Reference, SA22-7803.

You can use z/OS memory files from a z/OS UNIX program. However, use of the vfork() function from the program removes access from a hiperspace memory file for the child process. Use of an exec function from the program clears a memory file when the process address space is cleared.

Special behavior for C: For POSIX resources, vfork() behaves as just described. But in general, MVS resources that existed in the parent do not exist in the child. This is true for open streams in MVS data sets and assembler-accessed z/OS facilities, such as STIMERS. In addition, z/OS allocations (through JCL, SVC99, or ALLOCATE) are not passed to the child process.

Note: The vfork() function has been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The fork() function is preferred for portability.

Returned value

If successful, vfork() returns 0 to the child process and the process ID of the newly created child to the parent process.

If unsuccessful, vfork() fails to create a child process and returns −1 to the parent. vfork() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>There are insufficient resources to create another process, or else the process has already reached the maximum number of processes you can run.</td>
</tr>
<tr>
<td>ELEMSGERR</td>
<td>Language Environment message file not available.</td>
</tr>
<tr>
<td>ELEMULTITHREAD</td>
<td>vfork() was invoked from a multi-threaded environment.</td>
</tr>
<tr>
<td>ELENOFORK</td>
<td>Application contains a language that does not support fork().</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>The process requires more space than is available.</td>
</tr>
</tbody>
</table>

</tr>
</tbody>
</table>

Format

```c
#include <stdarg.h>
#include <stdio.h>

int vfprintf(FILE * __restrict__ stream, const char * __restrict__ format, va_list arg_ptr);
```

```c
#include <stdio.h>

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int vfprintf_unlocked(FILE * __restrict__ stream, const char * __restrict__ format, va_list arg_ptr);
```

General description

The vfprintf() function is similar to fprintf(), except that `arg_ptr` points to a list of arguments whose number can vary from call to call in the program. These arguments should be initialized by `va_start()` for each call. In contrast, fprintf() can have a list of arguments, but the number of arguments in that list is fixed when you compile the program. For a specification of the `format` string, see "printf(), fprintf(), sprintf() — Format and write data" on page 665.

vfprintf() is not supported for files opened with `type=record`.

vfprintf() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`vfprintf_unlocked()` is functionally equivalent to `vfprintf()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, vfprintf() returns the number of characters written to `stream`.

If unsuccessful, vfprintf() returns a negative value.

Note: In contrast to some UNIX-based implementations of the C language, the z/OS XL C/C++ implementation of the vprintf() family increments the pointer to the variable arguments list. To control whether the pointer to the argument is incremented, call the `va_end` macro after each call to `vsprintf()`.
vfprintf

Example

CELEBV03

/* CELEBV03
   This example prints out a variable number of strings to the
   file myfile.dat, using &vfprintf.. *

*/
#include <stdarg.h>
#include <stdio.h>

void vout(FILE *stream, char *fmt, ...);
char fmt1[] = "%s %s %s\n";

int main(void)
{
    FILE *stream;
    stream = fopen("myfile.dat", "w");
    vout(stream, fmt1, "Sat", "Sun", "Mon");
}

void vout(FILE *stream, char *fmt, ...)
{
    va_list arg_ptr;
    va_start(arg_ptr, fmt);
    vfprintf(stream, fmt, arg_ptr);
    va_end(arg_ptr);
}

Output:
Sat Sun Mon

int vscanf_unlocked(const char *__restrict__ format, va_list arg);

int vsscanf_unlocked(const char *__restrict__ format, va_list arg);
```

General description

The `vfscanf()`, `vscanf()`, and `vsscanf()` functions are equivalent to the `fscanf()`, `scanf()`, and `sscanf()` functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined in `stdarg.h`.

The argument list should be initialized using the `va_start` macro before each call. These functions do not invoke the `va_end` macro, but instead invoke the `va_arg` macro causing the value of `arg` after the return to be unspecified.

`vfscanf()` and `vscanf()` are not supported for files opened with a record type. They also have the same restrictions as a write immediately following a read or a read immediately following a write. This is because, between a write and a subsequent read, there must be an intervening flush or reposition and between a read and a subsequent write, there must also be an intervening flush or reposition unless EOF has been reached.

**Note:** In contrast to some UNIX-based implementations of the C language, the z/OS XL C/C++ implementation of the `vscanf()` family increments the pointer to the variable arguments list. To control whether the pointer is incremented, call the `va_end` macro after each function call.

`vfscanf_unlocked()` and `vscanf_unlocked()` are functionally equivalent to `vfscanf()` and `vscanf()` with the exception that they are not thread-safe. These functions may
vfscanf, vscanf, vsscanf

safely be used in a multithreaded application if and only they are called while the
invoking thread owns the (FILE*) object, as is the case after a successful call to
either the flockfile() or ftrylockfile() function.

Returned value

Refer to fscanf().

              const wchar_t * __restrict__ format, va_list arg);
int vwprintf(const wchar_t * __restrict__ format, va_list arg);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int vfwprintf_unlocked(FILE * __restrict__ stream,
                        const wchar_t * __restrict__ format, va_list arg);
int vswprintf_unlocked(const wchar_t * __restrict__ format, va_list arg);
```

General description

vfwprintf(), vswprintf(), and vwprintf() functions are equivalent to fprintf(), sprintf(),
and printf() functions, respectively, except for the following:

- Instead of being called with a variable number of arguments, they are called with
  an argument list as defined in stdarg.h.
- For vswprintf(), the argument `wcs` specifies an array of type `wchar_t`, rather than
  an array of type `char`, into which the generated output is to be written.
- The argument `format` specifies an array of type `wchar_t`, rather than an array of
  type `char`, which describes how subsequent arguments are converted for output.
vfwprintf, vswprintf, vwprintf

- `%c` without an `l` prefix means an integer argument is to be converted to `wchar_t`, as if by calling `mbtowc()`, and then written.
- `%c` with an `l` prefix means a `wint_t` is converted to `wchar_t` and then written.
- `%s` without an `l` prefix means a character array containing a multibyte character sequence is to be converted to an array of `wchar_t` and written. The conversion will take place as if `mbtowc()` were called repeatedly.
- `%s` with an `l` prefix means an array of `wchar_t` will be written. The array is written up to but not including the terminating NULL character, unless the precision specifies a shorter output.

For `vswprintf()`, a NULL wide character is written at the end of the wide characters written; the NULL wide character is not counted as part of the returned sum. If copying takes place between objects that overlap, the behavior is undefined.

**Note:** The `vfwprintf()` and `vwprintf()` functions have a dependency on the level of the Enhanced ASCII Extensions. See "Enhanced ASCII support" on page 2543 for details.

`vfwprintf_unlocked()` and `vwprintf_unlocked()` are functionally equivalent to `vfwprintf()` and `vwprintf()` with the exception that they are not thread-safe. These functions may safely be used in a multithreaded application if and only if they are called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

**Special behavior for XPG4:** If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `vfwprintf()`, `vswprintf()`, or `vwprintf()` function in the `wchar` header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

### Returned value

If successful, `vfwprintf()`, `vswprintf()`, and `vwprintf()` return the number of wide characters written, not counting the terminating NULL wide character.

If unsuccessful, a negative value is returned.

If `n` or more wide characters were requested to be written, `vswprintf()` returns a negative value and sets `errno` to indicate the error.

**Note:** In contrast to some UNIX-based implementations of the C language, the `z/OS XL C/C++` implementation of the `vprintf()` family increments the pointer to the variable arguments list. To control whether the pointer to the argument is incremented, call the `va_end` macro after each call to `vfwprintf()`, `vswprintf()`, or `vwprintf()`.

### Example

```c
/* CELEBV06 */
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <stdio.h>
#include <stdarg.h>
#include <wchar.h>
```

2378  z/OS V1R13.0 XL C/C++ Run-Time Library Reference
void vout(wchar_t *, size_t, wchar_t *, ...);

wchar_t *format3 = L "%S %d %S";
wchar_t *format5 = L "%S %d %S %d %S";

int main(void)
{
    wchar_t wcstr[100];

    vout(wcstr, 100, format3, L "ONE", 2L, L "THREE");
    printf("%S\n", wcstr);
    vout(wcstr, 100, format5, L "ONE", 2L, L "THREE", 4L, L "FIVE");
    printf("%S\n", wcstr);
}

void vout(wchar_t *wcs, size_t n, wchar_t *fmt, ...)
{
    va_list arg_ptr;

    va_start(arg_ptr, fmt);
    if(vswprintf(wcs, n, fmt, arg_ptr)<0)
        perror("vswprintf() error");
    va_end(arg_ptr);
}

int vwscanf_unlocked(const wchar_t *__restrict__ ws, const wchar_t *__restrict__ format, va_list arg);
```

General description

The vfwscanf(), vwscanf(), and vswscanf() functions are equivalent to the fwscanf(), swscanf(), and wscanf() functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined in stdarg.h.

The argument list should be initialized using the `va_start` macro before each call. These functions do not invoke the `va_end` macro, but instead invoke the `va_arg` macro causing the value of `arg` macro causing the value of `arg` after the return to be unspecified.

vfwscanf() and vwscanf() are not supported for files opened with a record type. They also have the same restrictions as a write immediately following a read or a read immediately following a write. This is because, between a write and a subsequent read, there must be an intervening flush or reposition and between a read and a subsequent write, there must also be an intervening flush or reposition unless EOF has been reached.

Note: In contrast to some UNIX-based implementations of the C language, the z/OS XL C/C++ implementation of the vwscanf() family increments the pointer to the variable arguments list. To control whether the pointer is incremented, call the `va_end` macro after each function call.
vfscanf_unlocked() and vwscanf_unlocked() are functionally equivalent to
vfscanf() and vwscanf() with the exception that they are not thread-safe. These
functions may safely be used in a multithreaded application if and only if they are
called while the invoking thread owns the (FILE*) object, as is the case after a
successful call to either the flockfile() or ftrylockfile() function.

Returned value
Refer to fwscanf().

</tr>
</tbody>
</table>

Format

```
#include <stdarg.h>
#include <stdio.h>

int vprintf(const char * __restrict__ format, va_list arg_ptr);
```

```
#include <stdio.h>

int vprintf_unlocked(const char * __restrict__ format, va_list arg_ptr);
```

General description

The vprintf() function is similar to printf(), except that arg_ptr points to a list of arguments whose number can vary from call to call in the program. These arguments should be initialized by va_start() for each call. In contrast, printf() can have a list of arguments, but the number of arguments in that list is fixed when you compile the program. For a specification of the format string, see "fprintf(), printf(), sprintf() — Format and write data" on page 665.

vprintf() is not supported for files opened with type=record.

vprintf() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

vprintf_unlocked() is functionally equivalent to vprintf() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

 Returned value

If successful, vprintf() returns the number of characters written to stdout.

If unsuccessful, vprintf() returns a negative value.

Note: In contrast to some UNIX-based implementations of the C language, the z/OS XL C/C++ implementation of the vprintf() family increments the pointer to the variable arguments list. To control whether the pointer to the argument is incremented, call the va_end macro after each call to vprintf().
Example

CELEBV04

/* CELEBV04 */

This example prints out a variable number of strings to stdout, using \&vprintf. .

*/
#include <stdarg.h>
#include <stdio.h>

void vout(char *fmt, ...);
char fmt1[] = "%s %s %s %s %s\n";

int main(void)
{
    FILE *stream;
    stream = fopen("myfile.dat", "w");
    vout(fmt1, "Mon", "Tues", "Wed", "Thurs", "Fri");
}

void vout(char *fmt, ...)
{
    va_list arg_ptr;
    va_start(arg_ptr, fmt);
    vprintf(fmt, arg_ptr);
    va_end(arg_ptr);
}

Output
Mon Tues Wed Thurs Fri

<td>C99 Single UNIX Specification, Version 3</td>
<td>both</td>
<td>z/OS V1R6</td>
</tr>
<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <stdio.h>
#include <stdarg.h>

int vsnprintf(char * restrict s, size_t n,
              const char * restrict format, va_list arg);
```

General description

Equivalent to snprintf(), except that instead of being called with a variable number of arguments, it is called with an argument list as defined by <stdarg.h>.

Returned value

Returns the number of characters that would have been written had \( n \) been sufficiently large, not counting the terminating null character, or a negative value if an encoding error occurred. Thus, the null-terminated output has been completely written if and only if the returned value is nonnegative and less than \( n \).
vsprintf() — Format and print data to buffer

Standards

<table>
<thead>

<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdarg.h>
#include <stdio.h>

int vsprintf(char * __restrict__ target-string,
             const char * __restrict__ format, va_list arg_ptr);
```

General description

The vsprintf() function is similar to sprintf(), except that `arg_ptr` points to a list of arguments whose number can vary from call to call in the program. In contrast, sprintf() can have a list of arguments, but the number of arguments in that list is fixed when you compile the program. For a specification of the `format` string, see `fprintf(), printf(), sprintf() — Format and write data` on page 665.

Returned value

If successful, vsprintf() returns the number of characters written `target-string`.

If unsuccessful, vsprintf() returns a negative value.

**Note:** In contrast to some UNIX-based implementations of the C language, the z/OS XL C/C++ implementation of the vprintf() family increments the pointer to the variable arguments list. To control whether the pointer to the argument is incremented, call the `va_end` macro after each call to vsprintf().

Example

**CELEBV05**

```c
/* CELEBV05

This example assigns a variable number of strings to string
and prints the resultant string, using &vsprintf.

*/
#include <stdarg.h>
#include <stdio.h>

void vout(char *string, char *fmt, ...);
char fmt1[] = "%s  %s  %s\n";

int main(void)
{
    char string[100];

    vout(string, fmt1, "Sat", "Sun", "Mon");
    printf("The string is: %s\n", string);
}
void vout(char *string, char *fmt, ...)
```
vsprintf

{
    va_list arg_ptr;
    va_start(arg_ptr, fmt);
    vsprintf(string, fmt, arg_ptr);
    va_end(arg_ptr);
}

Output
The string is: Sat Sun Mon

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <sys/wait.h>

pid_t wait(int *status_ptr);
```

General description

Suspended the calling process until any one of its child processes ends. More precisely, `wait()` suspends the calling process until the system obtains status information on the ended child. If the system already has status information on a completed child process when `wait()` is called, `wait()` returns immediately. `wait()` is also ended if the calling process receives a signal whose action is either to execute a signal handler or to end the process.

The argument `status_ptr` points to a location where `wait()` can store a status value. This status value is zero if the child process explicitly returns zero status. If it is not zero, it can be analyzed with the status analysis macros, described in “Status Analysis Macros,” below.

The `status_ptr` pointer may also be NULL, in which case `wait()` ignores the child's return status.

The following function calls are equivalent:

```c
wait(status_ptr);
waitpid(-1, status_ptr, 0);
wait3(status_ptr, 0, NULL);
```

For more information, see “waitpid() — Wait for a specific child process to end” on page 2394.

Special behavior for XPG4.2: If the calling process has SA_NOCLDWAIT set or has SIGCHLD set to SIG_IGN, and the process has no unwaited for children that were transformed into zombie processes, it will block until all of the children terminate, and wait() will fail and set errno to ECHILD.

Status analysis macros: If the `status_ptr` argument is not NULL, `wait()` places the child's return status in `*status_ptr`. You can analyze this return status with the following macros, defined in the sys/wait.h header file:

- `WIFEXITED(*status_ptr)`
  - This macro evaluates to a nonzero (true) value if the child process ended normally, that is, if it returned from `main()` or called one of the `exit()` or `_exit()` functions.

- `WEXITSTATUS(*status_ptr)`
  - When `WIFEXITED()` is nonzero, `WEXITSTATUS()`
wait evaluates to the low-order 8 bits of the child's return status passed on the exit() or _exit() function.

WIFSIGNALED(*status_ptr) This macro evaluates to a nonzero (true) value if the child process ended because of a signal that was not caught.

WIFSTOPPED(*status_ptr) This macro evaluates to a nonzero (true) value if the child process is currently stopped. This should only be used after a waitpid() with the WUNTRACED option.

WSTOPSIG(*status_ptr) When WIFSTOPPED() is nonzero, WSTOPSIG() evaluates to the number of the signal that stopped the child.

WTERMSIG(*status_ptr) When WIFSIGNALED() is nonzero, WTERMSIG() evaluates to the number of the signal that ended the child process.

Returned value

If successful, wait() returns a value that is the process ID (PID) of the child whose status information has been obtained.

If unsuccessful, wait() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECHILD</td>
<td>The caller has no appropriate child processes, that is, it has no child processes whose status has not been obtained by previous calls to wait(), waitid(), waitpid(), or wait3(). ECHILD is also returned when the SA_NOCLDWAIT flag is set.</td>
</tr>
<tr>
<td>EINTR</td>
<td>wait() was interrupted by a signal. The value of *status_ptr is undefined.</td>
</tr>
</tbody>
</table>

Example

CELEBW01

/* CELEBW01

This example suspends the calling process until any child processes ends.

*/

#define _POSIX_SOURCE
#include <sys/types.h>
#include <sys/wait.h>
#include <unistd.h>
#include <stdio.h>
#include <time.h>

main() {
    pid_t pid;
    time_t t;
    int status;

    if ((pid = fork()) < 0)
        perror("fork() error");
    else if (pid == 0) {
        time(&t);
        printf("child (pid %d) started at %s", (int) gettid(), ctime(&t));
        sleep(5);
        time(&t);

        /* Additional code */
    } else {
        status = wait(NULL);
        printf("wait() returned %d\n", status);
    }
}

2390 z/OS V1R13.0 XL C/C++ Run-Time Library Reference
```c
printf("child exiting at %s, ctime(&t));
exit(42);
}
else {
    printf("parent has forked child with pid of %d
", (int) pid);
    time(&t);
    printf("parent is starting wait at %s", ctime(&t));
    if ((pid = wait(&status)) == -1)
        perror("wait() error");
    else {
        time(&t);
        printf("parent is done waiting at %s", ctime(&t));
        printf("the pid of the process that ended was %d", (int) pid);
        if (WIFEXITED(status))
            printf("child exited with status of %d
", WEXITSTATUS(status));
        else if (WIFSIGNALED(status))
            printf("child was terminated by signal %d
", WTERMSIG(status));
        else if (WIFSTOPPED(status))
            printf("child was stopped by signal %d
", WSTOPSIG(status));
        else puts("reason unknown for child termination");
    }
}
}

Output:

parent has forked child with pid of 65546
parent is starting wait at Fri Jun 16 10:53:03 2001
child (pid 65546) started at Fri Jun 16 10:53:04 2001
child exiting at Fri Jun 16 10:53:09 2001
parent is done waiting at Fri Jun 16 10:53:10 2001
the pid of the process that ended was 65546
child exited with status of 42

waitid()

— Wait for child process to change state

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/wait.h>

int waitid(idtype_t idtype, id_t id, siginfo_t *infop, int options);
```

General description

The `waitid()` function suspends the calling process until one of its children changes state. It records the current state of a child in the structure pointed to by `infop`. If a child process changed state before the call, `waitid()` returns immediately.

The `idtype` and `id` arguments are used to specify which children `waitid()` will wait for.

If `idtype` is P_PID `waitid()` will wait for the child with a process ID equal to `(pid_t)id`.

If `idtype` is P_GID `waitid()` will wait for any child with a process group ID equal to `(pid_t)id`.

If `idtype` is P_ALL `waitid()` will wait for any children and `id` is ignored.

The `options` argument is used to specify which state changes to wait for. It is formed by OR-ing together one or more of the following flags:

- **WCONTINUED** Status will be returned for any child that has stopped and has been continued.
- **WEXITED** Wait for processes that have exited.
- **WNOHANG** Return immediately if there are no children to wait for.
- **WNOWAIT** Keep the process whose status is returned in `infop` in a waitable state. This will not affect the state of the process; the process may be waited for again after this call completes.
- **WSTOPPED** Status will be returned for any child that has stopped upon receipt of a signal.

The `infop` argument must point to a `siginfo_t` structure. If `waitid()` returns because a child process was found that specified the conditions indicated by the arguments `idtype` and `options` then the structure pointed to by `infop` will be filled in by the system with the status of the process. The `si_signo` member will always be equal to SIGCHLD.

Returned value

If `waitid()` returns due to the change of state of one of its children, it returns 0.

If unsuccessful, `waitid()` returns -1 and sets `errno` to one of the following values:
<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECHILD</td>
<td>The calling process has no existing unwaited-for child processes.</td>
</tr>

</tr>
</tbody>
</table>

Format

```c
#define _POSIX_SOURCE
#include <sys/wait.h>

pid_t waitpid(pid_t pid, int *status_ptr, int options);
```

General description

Suspends the calling process until a child process ends or is stopped. More precisely, waitpid() suspends the calling process until the system gets status information on the child. If the system already has status information on an appropriate child when waitpid() is called, waitpid() returns immediately. waitpid() is also ended if the calling process receives a signal whose action is either to execute a signal handler or to end the process.

**pid_t pid** Specifies the child processes the caller wants to wait for:
- If `pid` is greater than 0, waitpid() waits for termination of the specific child whose process ID is equal to `pid`.
- If `pid` is equal to zero, waitpid() waits for termination of any child whose process group ID is equal to that of the caller.
- If `pid` is −1, waitpid() waits for any child process to end.
- If `pid` is less than −1, waitpid() waits for the termination of any child whose process group ID is equal to the absolute value of `pid`.

**int *status_ptr** Points to a location where waitpid() can store a status value. This status value is zero if the child process explicitly returns zero status. Otherwise, it is a value that can be analyzed with the status analysis macros described in “Status Analysis Macros”, below.

The `status_ptr` pointer may also be NULL, in which case waitpid() ignores the child's return status.

**int options** Specifies additional information for waitpid(). The `options` value is constructed from the bitwise inclusive-OR of zero or more of the following flags defined in the `sys/wait.h` header file:

- **WCONTINUED**

  Special behavior for XPG4.2: Reports the status of any continued child processes as well as terminated ones. The WIFCONTINUED macro lets a process distinguish between a continued process and a terminated one.

- **WNOHANG**

  Demands status information immediately. If status information is immediately available on an appropriate child process, waitpid() returns this
waitpid

Otherwise, waitpid() returns immediately with an error code indicating that the information was not available. In other words, WNOHANG checks child processes without causing the caller to be suspended.

WUNTRACED Reports on stopped child processes as well as terminated ones. The WIFSTOPPED macro lets a process distinguish between a stopped process and a terminated one.

Special behavior for XPG4.2: If the calling process has SA_NOCLDWAIT set or has SIGCHLD set to SIG_IGN, and the process has no unwaited for children that were transformed into zombie processes, it will block until all of the children terminate, and waitpid() will fail and set errno to ECHILD.

Status analysis macros: If the status_ptr argument is not NULL, waitpid() places the child's return status in *status_ptr. You can analyze this return status with the following macros, defined in the sys/wait.h header file:

WEXITSTATUS(*status_ptr) When WIFEXITED() is nonzero, WEXITSTATUS() evaluates to the low-order 8 bits of the status argument that the child passed to the exit() or _exit() function, or the value the child process returned from main().

WIFCONTINUED(*status_ptr) Special behavior for XPG4.2: This macro evaluates to a nonzero (true) value if the child process has continued from a job control stop. This should only be used after a waitpid() with the WCONTINUED option.

WIFEXITED(*status_ptr) This macro evaluates to a nonzero (true) value if the child process ended normally (that is, if it returned from main(), or else called the exit() or _exit() function).

WIFSIGNALED(*status_ptr) This macro evaluates to a nonzero (true) value if the child process ended because of a signal that was not caught.

WIFSTOPPED(*status_ptr) This macro evaluates to a nonzero (true) value if the child process is currently stopped. This should only be used after a waitpid() with the WUNTRACED option.

WSTOPSIG(*status_ptr) When WIFSTOPPED() is nonzero, WSTOPSIG() evaluates to the number of the signal that stopped the child.

WTERMSIG(*status_ptr) When WIFSIGNALED() is nonzero, WTERMSIG() evaluates to the number of the signal that ended the child process.

Returned value

If successful, waitpid() returns a value of the process (usually a child) whose status information has been obtained.
waitpid

If WNOHANG was given, and if there is at least one process (usually a child) whose status information is not available, waitpid() returns 0.

If unsuccessful, waitpid() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECHILD</td>
<td>The process specified by pid does not exist or is not a child of the calling process, or the process group specified by pid does not exist or does not have any member process that is a child of the calling process.</td>
</tr>
<tr>
<td>EINTR</td>
<td>waitpid() was interrupted by a signal. The value of *status_ptr is undefined.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The value of options is incorrect.</td>
</tr>
</tbody>
</table>

Example

CELEBW02

/* CELEBW02 */

The following function suspends the calling process using &waitpid. until a child process ends.

<code>
#define _POSIX_SOURCE
#include <sys/types.h>
#include <sys/wait.h>
#include <unistd.h>
#include <stdio.h>
#include <time.h>

main()
{
    pid_t pid;
    time_t t;
    int status;
    if ((pid = fork()) < 0)
        perror("fork() error");
    else if (pid == 0)
    {
        sleep(5);
        exit(1);
    }
    else do {
        if ((pid = waitpid(pid, &status, WNOHANG)) == -1)
            perror("wait() error");
        else if (pid == 0)
        {
            time(&t);
            printf("child is still running at %s", ctime(&t));
            sleep(1);
        }
        else
        {
            if (WIFEXITED(status))
                printf("child exited with status of %d\n", WEXITSTATUS(status));
            else puts("child did not exit successfully");
        }
    } while (pid == 0);
}
</code>

Output:

child is still running at Fri Jun 16 11:05:43 2001
child is still running at Fri Jun 16 11:05:44 2001
child is still running at Fri Jun 16 11:05:45 2001
child is still running at Fri Jun 16 11:05:46 2001

wait3() — Wait for child process to change state

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/wait.h>

pid_t wait3(int *stat_loc, int options, struct rusage *resource_usage);
```

General description

The `wait3()` function allows the calling process to obtain status information for specified child processes.

The following call:
```
wait3(stat_loc, options, resource_usage)
```

is equivalent to the call:
```
waitpid((pid_t)-1, stat_loc, options);
```

except that on successful completion, if the `resource_usage` argument to `wait3()` is not a NULL pointer, the rusage structure that the third argument points to is filled in for the child process identified by the return value.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. The `waitpid()` function is preferred for portability.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

See "waitpid() — Wait for a specific child process to end" on page 2394.

In addition to the error conditions specified on `waitpid()`, under the following conditions, `wait3()` may fail and set `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECHILD</td>
<td>The calling process has no existing unwaited-for child processes, or if the set of processes specified by the argument <code>pid</code> can never be in the states specified by the argument <code>options</code>.</td>
</tr>
</tbody>
</table>

wcrtomb

wcrtomb() — Convert a wide character to a multibyte character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

Non-XPG4:

```c
#include <wchar.h>

size_t wcrtomb(char *__restrict__ s, wchar_t wchar, mbstate_t *__restrict__ pss);
```

XPG4:

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t wcrtomb(char *s, wchar_t wchar, mbstate_t *pss);
```

General description

If `s` is a NULL pointer, the wcrtomb() function determines the number of bytes necessary to enter the initial shift state (zero if encodings are not state-dependent or if the initial conversion state is described). The resulting state described is the initial conversion state.

If `s` is not a NULL pointer, the wcrtomb() function determines the number of bytes needed to represent the multibyte character that corresponds to the wide character given by `wchar` (including any shift sequences), and stores the resulting bytes in the array whose first element is pointed to by `s`. At most, MB_CUR_MAX bytes are stored. If `wchar` is a NULL wide character, the resulting state described is the initial conversion state.

wcrtomb() is a “restartable” version of wctomb(). That is, shift state information is passed as one of the arguments and is updated on return. With wcrtomb(), you can switch from one multibyte string to another, provided that you have kept the shift-state information for each multibYTE string.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

**Special behavior for XPG4:** If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the wcrtomb() function in the wchar header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

If `s` is a NULL pointer, wcrtomb() returns the number of bytes needed to enter the initial shift state. The value returned will not be greater than that of MB_CUR_MAX.
If s is not a NULL pointer, wcrtomb() returns the number of bytes stored in the array object (including any shift sequences) when wchar is a valid wide character. Otherwise, when wchar is not a valid wide character, an encoding error occurs, the value of the macro EILSEQ is stored in errno and −1 is returned, but the conversion state remains unchanged.

Example

```c
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    char *string;
    wchar_t wc;
    size_t length;
    length = wcrtomb(string, wc, NULL);
}
```

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wchar_t *wcscat(wchar_t * __restrict__ string1, const wchar_t * __restrict__ string2);
```

General description

Appends a copy of the string pointed to by `string2` to the end of the string pointed to by `string1`.

The `wcscat()` function operates on NULL-terminated wide-character strings. The string arguments to this function must contain a wide NULL character marking the end of the string. Bounds checking is not performed.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

`wcscat()` returns the value of `string1`.

Example

```c
CELEBW04

/* CELEBW04

 This example creates the wide character string "computer program" using &wcscat..

 */
#include <stdio.h>
#include <wchar.h>

#define SIZE 40

int main(void)
{
    wchar_t buffer1[SIZE] = L"computer"
    wchar_t * string = L" program"
    wchar_t * ptr;

    ptr = wcscat( buffer1, string );
    printf( "buffer1 = %ls\n", buffer1 );
}

Output:

buffer1 = computer program
```

<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wchar_t *wcschr(const wchar_t *string1, wchar_t character);
```

General description

Searches `string` for the occurrence of `character`. The `character` may be a wide NULL character (\0). The wide NULL character at the end of `string` is included in the search. The `wcschr()` function operates on NULL-terminated wide-character strings. The argument to this function must contain a wide NULL character marking the end of the string.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, `wcschr()` returns a pointer to the first occurrence of `character` in `string`.

If the character is not found, `wcschr()` returns a NULL pointer.

Example

```c
CELEBW05
/* CELEBW05

   This example finds the first occurrence of the character p in
   the wide character string "computer program" using &wcschr..

   */
#include <stdio.h>
#include <wchar.h>
#define SIZE 40
int main(void)
{
   wchar_t buffer1[SIZE] = L"computer program";
   wchar_t * ptr;
   wint_t ch = L'p';

   ptr = wcschr( buffer1, ch );
   printf( "The first occurrence of %lc in '%ls' is '%ls'\n",
           ch, buffer1, ptr );
}
```
Output:
The first occurrence of p in 'computer program' is 'puter program'

<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

int wcscompare(const wchar_t *string1, const wchar_t *string2);
```

General description

Compares two wide-character strings. The wcscompare() function operates on
NULL-terminated wide-character strings. The string arguments to this function must
contain a wide NULL character marking the end of the string.

The behavior of this wide-character function is affected by the LC_CTYPE category
of the current locale. If you change the category, undefined results can occur.

Returned value

wcscompare() returns a value indicating the relationship between the two strings, as
follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td>string pointed to by string1 less than string pointed to by string2</td>
</tr>
<tr>
<td>= 0</td>
<td>string pointed to by string1 identical to string pointed to by string2</td>
</tr>
<tr>
<td>&gt; 0</td>
<td>string pointed to by string1 greater than string pointed to by string2</td>
</tr>
</tbody>
</table>

Example

```c
CELEBW06

/* CELEBW06

   This example compares the wide character string string1 to
   string2 using &wcscompare..

*/
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    int result;
    wchar_t string1[] = L"abcdef";
    wchar_t string2[] = L"abcdefg";
    result = wcscompare(string1, string2);
    if ( result == 0 )
        printf("\"%ls\" is identical to \"%ls\"\n", string1, string2);
    else if ( result < 0 )
        printf("\"%ls\" is less than \"%ls\"\n", string1, string2);
    else
        printf("\"%ls\" is greater than \"%ls\"\n", string1, string2);
}
```
printf("\"%ls\" is less than \"%ls\"\n", string1, string2);
else
    printf("\"%ls\" is greater than \"%ls\"\n", string1, string2);
}

Output:
"abcdef" is less than "abcdefg"

wcscoll

wcscoll() — Language collation string comparison

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <wchar.h>

int wcscoll(const wchar_t *wcs1, const wchar_t *wcs2);

General description

Compares the wide-character string pointed to by wcs1 to the wide-character string pointed to by wcs2, both interpreted as appropriate to the LC_COLLATE category of the current locale.

Returned value

wcscoll() returns an integer greater than, equal to, or less than zero, according to whether the wide string pointed to by wcs1 is greater than, equal to, or less than the wide-character string pointed to by wcs2, when both wide-character strings are interpreted as appropriate to the LC_COLLATE category of the current locale.

wcscoll() differs from wcscmp(). wcscoll() function performs a comparison between two wide character strings based on language collation rules as controlled by the LC_COLLATE category. On the other hand, wcscmp() performs a wide-character code to wide-character code comparison.

wcscoll() indicates error conditions by setting errno; however, there is no returned value to indicate an error. To check for errors, errno should be set to zero, and then checked upon return from wcscoll(). If errno is nonzero, an error has occurred.

The EILSEQ error can be set to indicate that the wcs1 or wcs2 arguments contain characters outside the domain of the collating sequence.

Note: The ISO/C Multibyte Support Extensions do not indicate that the wcscoll() function may return with an error.

Example

CELEBW07

/* CELEBW07 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    int result;
    wchar_t *wcs1 = L"first_wide_string";
    wchar_t *wcs2 = L"second_wide_string";
wcscoll

result = wcscoll(wcs1, wcs2);
if ( result == 0)
  printf("%ls" is identical to %ls\n", wcs1, wcs2);
else if ( result < 0)
  printf("%ls" is less than %ls\n", wcs1, wcs2);
else
  printf("%ls" is greater than %ls\n", wcs1, wcs2);
}

Output:
"first_wide_string" is less than "second_wide_string"

<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wchar_t *wcscpy(wchar_t * __restrict__ string1, const wchar_t * __restrict__ string2);
```

General description

Copies the contents of `string2` (including the ending wide NULL character) into `string1`. The wcscpy() function operates on NULL-terminated wide-character strings. The string arguments to this function must contain a wide NULL character marking the end of the string. Bounds checking is not performed.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

`wcscpy()` returns the value of `string1`.

Example

**CELEBW08**

/* CELEBW08 */

This example copies the contents of `source` to `destination` using `wcscpy()`.

```c
#include <stdio.h>
#include <wchar.h>
#define SIZE 40

int main(void)
{
    wchar_t source[ SIZE ] = L"This is the source string";
    wchar_t destination[ SIZE ] = L"And this is the destination string";
    wchar_t * return_string;

    printf("destination is originally = "%ls",
    destination);
    return_string = wcscpy( destination, source );
    printf("After wcscpy, destination becomes \"%ls\"\n", destination);
}
```

Output:

destination is originally = "And this is the destination string"
After wcscpy, destination becomes "This is the source string"

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <wchar.h>

size_t wcscspn(const wchar_t *string1, const wchar_t *string2);
```

**General description**

Determines the number of wide characters in the initial segment of the string pointed to by `string1` that do not appear in the string pointed to by `string2`. The `wcscspn()` function operates on NULL-terminated wide-character strings. The string arguments to these functions must contain a NULL wide character marking the end of the string.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

**Returned value**

`wcscspn()` returns the number of wide characters in the segment.

**Example**

**CELEBW09**

/* CELEBW09

This example uses `wcscspn` to find the first occurrence of any of the characters a, x, l, or e in string.

*/

```c
#include <stdio.h>
#include <wchar.h>

#define SIZE 40

int main(void)
{
    wchar_t string[ SIZE ] = L"This is the source string";
    wchar_t * substring = L"axle";

    printf( "The first %i characters in the string "%ls" are not in the "string "%ls" \n", wcscspn( string, substring), string, substring );
}
```

**Output:**

The first 10 characters in the string "This is the source string" are not in the string "axle"

</tr>
</tbody>
</table>

Format

Non-XPG4:

```c
#include <wchar.h>

size_t wcsftime(wchar_t * __restrict__ wcs, size_t maxsize,
                const wchar_t * __restrict__ format,
                const struct tm * __restrict__ time_ptr)
```

XPG4:

```c
#define _XOPEN_SOURCE
#include <wchar.h>

size_t wcsftime(wchar_t * __restrict__ wcs, size_t maxsize,
                const wchar_t * __restrict__ format,
                const struct tm * __restrict__ time_ptr)
```

XPG4 and MSE:

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t wcsftime(wchar_t * __restrict__ wcs, size_t maxsize,
                const wchar_t * __restrict__ format,
                const struct tm * __restrict__ time_ptr)
```

General description

Format date and time into a wide character string. The wcsftime() function is equivalent to the strftime() function, except that:

- The argument `wcs` specifies an array of a wide string into which the generated output is to be placed.
- The argument `maxsize` indicates a number of wide characters.
- The argument `format` specifies an array of wide characters comprising the format string.
- The returned value indicates a number of wide characters.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then the compiler assumes that your program is using the XPG4 variety of the wcsftime() function unless you also define the _MSE_PROTOS feature test macro. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

The prototype for the XPG4 variety of the wcsftime() function is:
size_t wcsftime(wchar_t *wcs, size_t maxsize, const char *format, const struct tm *time_ptr)

The difference between this variety and the MSE variety of the wcsftime() function is that the third argument *format specifies an array of characters rather than an array of wide characters comprising the format string.

Returned value

If the total number of resulting wide characters including the terminating NULL wide character is not more than maxsize, wcsftime() returns the number of wide characters placed into the array pointed to by wcs not including the terminating NULL wide character.

If unsuccessful, wcsftime() returns 0 and the contents of the array are indeterminate.

Example

CELEBW10
/* CELEBW10 */
#include <stdio.h>
#include <time.h>
#include <wchar.h>

int main(void)
{
    struct tm *timeptr;
    wchar_t dest[100];
    time_t temp;
    size_t rc;

    temp = time(NULL);
    timeptr = localtime(&temp);
    rc = wcsftime(dest, sizeof(dest)-1, L" Today is %A," L" %b %d.\n Time: %I:%M %p", timeptr);
    printf("%d characters placed in string to make:\n\n%S", rc, dest);
}

Output:
42 characters placed in string to make:

Today is Friday, Jun 16.
Time: 01:48 pm

wcsid

wcsid() — Character set ID for wide character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>
int wcsid(const wchar_t c)
```

External entry point: @WSID, __wcsid

General description

 Determines the character set identifier for the specified wide character.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when you use LANGLVL(EXTENDED).

To use this function, you must either invoke the function using its external entry point name (that is, the name that begins with two underscore characters), or compile with LANGLVL(EXTENDED). When you use LANGLVL(EXTENDED) any relevant information in the header is also exposed.

Returned value

If successful, wcsid() returns the character set identifier for the wide character.

If the wide character is not valid, wcsid() returns -1.

Example

```c
CELEBW11
/* CELEBW11
This example checks character set id for wide character.
*/
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>
main() {
    wchar_t wc = L'A';
    int rc;
    rc = wcsid(wc);
    printf("wide character '%lc' is in character set id %i\n", wc, rc);
}
```

<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h> /* or #include <wcstr.h> */

size_t wcslen(const wchar_t *string);
```

General description

Computes the number of wide characters in the string pointed to by `string`.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

`wcslen()` returns the number of wide characters that precede the terminating wide NULL character.

Example

```c
CELEBW12
/* CELEBW12*/

This example computes the length of a wide-character string, using `wcslen`.

*/
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t * string = L"abcdef"
    printf( "Length of \"%ls\" is %i\n", string, wcslen( string ));
}
```

Output:

Length of "abcdef" is 6

Format

```c
#include <wchar.h>

wchar_t *wcsncat(wchar_t * __restrict__ string1,
                 const wchar_t * __restrict__ string2, size_t count);
```

General description

Appends up to `count` wide characters from `string2` to the end of `string1` and appends a NULL wide character to the result. The wcsncat() function operates on NULL-terminated wide-character strings. The string arguments to this function must contain a NULL wide character marking the end of the string.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

wcsncat() returns `string1`.

Example

CELEBW13

/* CELEBW13 */

/* This example demonstrates the difference between &wcscat. and &wcsncat. */

/* &wcscat. appends the entire second string to the first */

/* whereas &wcsncat. appends only the specified number of */

/* characters in the second string to the first. */

/* */

#include <stdio.h>
#include <wchar.h>
#include <string.h>

#define SIZE 40

int main(void)
{
  wchar_t buffer1[SIZE] = L"computer";
  wchar_t * ptr;

  /* Call wcscat with buffer1 and " program" */

  ptr = wcscat( buffer1, L" program" );

  printf( "wcscat : buffer1 = "%ls"\n", buffer1 );

  /* Reset buffer1 to contain just the string "computer" again */
wcsncat

```c
memset( buffer1, L'\0', sizeof( buffer1 ));
ptr = wcscpy( buffer1, L"computer" );

/* Call wcsncat with buffer1 and " program" */
ptr = wcsncat( buffer1, L" program", 3 );
printf( "wcsncat: buffer1 = \"%ls\\\n\", buffer1 );
}

Output:
wcsncat: buffer1 = "computer program"
wcsncat: buffer1 = "computer pr"
```

<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

int wcsncmp(const wchar_t *string1, const wchar_t *string2, size_t count);
```

General description

Compares up to `count` wide characters in `string1` to `string2`. The wcsncmp() function operates on NULL-terminated wide-character strings. The string arguments to this function must contain a NULL wide character marking the end of the string.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

`wcsncmp()` returns a value indicating the relationship between the two strings, as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td>string pointed to by <code>string1</code> less than the string pointed to by <code>string2</code></td>
</tr>
<tr>
<td>= 0</td>
<td>string pointed to by <code>string1</code> identical to string pointed to by <code>string2</code></td>
</tr>
<tr>
<td>&gt; 0</td>
<td>string pointed to by <code>string1</code> greater than string pointed to by <code>string2</code></td>
</tr>
</tbody>
</table>

Example

CELEBW14

```c
/* CELEBW14

This example demonstrates the difference between &wcscmp.
    and &wcsncmp.

*/
#include <stdio.h>
#include <wchar.h>

#define SIZE 10

int main(void)
{
    int result;
    int index = 3;
    wchar_t buffer1[SIZE] = L"abcdefg";
    wchar_t buffer2[SIZE] = L"abcfg";
    void print_result( int, wchar_t *, wchar_t * );

    result = wcscmp( buffer1, buffer2 );
```
printf( "Comparison of each character\n" );
printf( " wcscmp: ");
print_result( result, buffer1, buffer2 );

result = wcsncmp( buffer1, buffer2, index);
printf("\nComparison of only the first %i characters\n", index );
printf( " wcsncmp: ");
print_result( result, buffer1, buffer2 );
}

void print_result( int res, wchar_t * p_buffer1, wchar_t * p_buffer2 )
{
    if ( res == 0 )
        printf("\%ls\" is identical to \%ls\"\n", p_buffer1, p_buffer2);
    else if ( res < 0 )
        printf("\%ls\" is less than \%ls\"\n", p_buffer1, p_buffer2);
    else
        printf("\%ls\" is greater than \%ls\"\n", p_buffer1, p_buffer2);
}

Output:
Comparison of each character
wcscmp: "abcdefg" is less than "abcfg"

Comparison of only the first 3 characters
wcscmp: "abcdefg" is identical to "abcfg"

</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wchar_t *wcsncpy(wchar_t * __restrict__ string1,
                 const wchar_t * __restrict__ string2,
                 size_t count);
```

General description

Copies up to `count` wide characters from `string2` to `string1`. If `string2` is shorter than `count` characters, `string1` is padded out to `count` characters with NULL wide characters. The wcsncpy() function operates on NULL-terminated wide-character strings. The string arguments to this function must contain a NULL wide character marking the end of the string.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

wcsncpy() returns `string1`.

Example

```c
/* CELEBW15
   This example demonstrates the difference between wcscpy and wcsncpy.
*/
#include <stdio.h>
#include <wchar.h>
#define SIZE 40

int main(void)
{
    wchar_t source[SIZE] = L"123456789";
    wchar_t source1[SIZE] = L"123456789";
    wchar_t destination[SIZE] = L"abcdefg";
    wchar_t destination1[SIZE] = L"abcdefg";
    wchar_t *return_string;
    int index = 5;

    /* This is how wcsncpy works */
    printf("destination is originally = '%ls'\n", destination);
    return_string = wcsncpy(destination, source);
    printf("After wcsncpy, destination becomes '%ls'\n", destination);

    /* This is how wcscpy works */
```
wcsncpy

```c
printf("destination1 is originally = '\ls\n', destination1);
return_string = wcsncpy( destination1, source1, index );
printf("After wcsncpy, destination1 becomes '\ls\n', destination1 );
}
```

**Output:**

destination is originally = 'abcdefg'
After wcscpy, destination becomes '123456789'

destination1 is originally = 'abcdefg'
After wcsncpy, destination1 becomes '12345fg'

<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wchar_t *wcspbrk(const wchar_t *string1, const wchar_t *string2);
```

General description

Locates the first occurrence in the string pointed to by `string1` of any character from the string pointed to by `string2`.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, `wcspbrk()` returns a pointer to the character.

If no `wchar_t` from `string2` occurs in `string1`, `wcspbrk()` returns `NULL`.

Example

```c
CELEBW16
/* CELEBW16

This example returns a pointer to the first occurrence in the array string of either a or b, using &wcspbrk..

*/

#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *result;
    wchar_t *string = L"The Blue Danube";
    wchar_t *chars = L"ab";

    result = wcspbrk( string, chars);
    printf("The first occurrence of any of the characters \%ls\ in \%ls\n", chars, string, result);
}
```

Output:

The first occurrence of any of the characters "ab" in "The Blue Danube" is "anube"

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wchar_t *wcsrchr(const wchar_t *string, wchar_t character);
```

General description

Locates the last occurrence of `character` in the string pointed to by `string`. The terminating NULL wide character is considered to be part of the string.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, wcsrchr() returns a pointer to the character.

If `character` does not occur in the string, wcsrchr() returns NULL.

Example

```c
CELEBW17

/* CELEBW17

This example compares the use of wcschr() and wcsrchr().
It searches the string for the first and last occurrence of p in the
wide character string.

*/
#include <stdio.h>
#include <wchar.h>
#define SIZE 40

int main(void)
{
    wchar_t buf[SIZE] = L"computer program";
    wchar_t * ptr;
    int    ch = 'p';

    /* This illustrates wcschr */
    ptr = wcschr( buf, ch );
    printf( "The first occurrence of %c in '%ls' is '%ls'\n", ch, buf, ptr );

    /* This illustrates wcsrchr */
    ptr = wcsrchr( buf, ch );
    printf( "The last occurrence of %c in '%ls' is '%ls'\n", ch, buf, ptr );
}
```
wcsrchr

Output:
The first occurrence of p in 'computer program' is 'puter program'
The last occurrence of p in 'computer program' is 'program'

wcsrtombs() — Convert wide-character string to multibyte string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

Non-XPG4:

```c
#include <wchar.h>

size_t wcsrtombs(char * __restrict__ dst,
                  const wchar_t ** __restrict__ src, size_t len,
                  mbstate_t * __restrict__ ps);
```

XPG4:

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t wcsrtombs(char *dst,
                  const wchar_t **src, size_t len, mbstate_t *ps);
```

General description

Converts a sequence of wide characters from the array indirectly pointed to by `src` into a sequence of corresponding multibyte characters that begin in the shift state described by `ps`, which, if `dst` is not a NULL pointer, are then stored into the array pointed to by `dst`. Conversion continues up to and including the terminating NULL wide character; the terminating NULL wide character (byte) shall be stored.

Conversion shall stop earlier in two cases:

- When a code is reached that does not correspond to a valid multibyte character.
- If `dst` is not a NULL pointer, conversion stops when the next multibyte element would exceed the limit of `len` total bytes to be stored into the array pointed to by `dst`.

Each conversion takes places as if by a call to the wcrtomb() function.

If `dst` is not NULL a pointer, the object pointed to by `src` shall be assigned either a NULL pointer (if conversion stopped due to reaching a terminating NULL wide character) or the address of the code just past the last wide character converted. If conversion stopped due to reaching a terminating NULL wide character, the resulting state described shall be the initial conversion state.

wcsrtombs() is a “restartable” version of wcstombs(). That is, shift state information is passed as one of the arguments, and gets updated on exit. With wcsrtombs(), you may switch from one multibyte string to another, provided that you have kept the shift state information.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.
wcsrtombs

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the wcsrtombs() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

If successful, wcsrtombs() returns the number of bytes in the resulting multibyte character sequence, which is the same as the number of array elements modified when dst is not a NULL pointer.

If the string contains an invalid wide character, an encoding error occurs. wcsrtombs() returns (size_t)−1 and stores the value of the macro EILSEQ in errno, but the conversion state shall be unchanged.

Example

CELEBW18

/* CELEBW18 */
#include <stdio.h>
#include <string.h>
#include <wchar.h>
#define SIZE 20

int main(void)
{
    char  dest[SIZE];
    wchar_t *wcs = L"string";
    const wchar_t *ptr;
    size_t  count = SIZE;
    size_t  length;

    ptr = (wchar_t *) wcs;
    length = wcsrtombs(dest, &ptr, count, NULL);
    printf("%d characters were converted.\n", length);
    printf("The converted string is \"%s\"\n\n", dest);

    /* Reset the destination buffer */
    memset(dest, '\0', sizeof(dest));

    /* Now convert only 3 characters */
    ptr = (wchar_t *) wcs;
    length = wcsrtombs(dest, &ptr, 3, NULL);
    printf("%d characters were converted.\n", length);
    printf("The converted string is \"%s\"\n\n", dest);
}

Output:

6 characters were converted.
The converted string is "string"

3 characters were converted.
The converted string is "str"

</tr>
</tbody>
</table>

**Format**

```c
#include <wchar.h>

size_t wcspn(const wchar_t *string1, const wchar_t *string2);
```

**General description**

Computes the number of wide characters in the initial segment of the string pointed to by `string1`, which consists entirely of wide characters from the string pointed to by `string2`.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

**Returned value**

`wcspn()` returns the number of wide characters in the segment.

**Example**

**CELEBW19**

```c
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t * string = L"cabbage";
    wchar_t * source = L"abc";
    int index;

    index = wcspn( string, L"abc" );
    printf( "The first %d characters of "%ls" are found in "%ls"
            index, string, source );
}
```

**Output:**

The first 5 characters of "cabbage" are found in "abc"

<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

Non-XPG4:
#include <wchar.h>

wchar_t *wcsstr(const wchar_t *__restrict__ wcs1,
                 const wchar_t *__restrict__ wcs2);

XPG4:
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

wchar_t *wcsstr(const wchar_t *__restrict__ wcs1,
                 const wchar_t *__restrict__ wcs2);

General description

Locates the first occurrence in the wide-character string pointed to by wcs1 of the sequence of wide characters (excluding the terminating NULL character) in the wide-character string pointed to by wcs2.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the wcsstr() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

If successful, wcsstr() returns a pointer to the located wide string. If wcs2 points to a wide-character string with zero length, wcsstr() returns wcs1.

If the wide-character string is not found, wcsstr() returns NULL.

Example

CELEBW20
/* CELEBW20 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs1 = L"needle in a haystack";
}
```c
wchar_t *wcs2 = L"hay";
wchar_t *result;
result = wcsstr(wcs1, wcs2);
/* result = a pointer to "hatstack" */
printf("result: \%S\n", result);
```

**Related information**

- "wchar.h" on page 83
- "strstr() — Locate substring" on page 2093
The wcstod() function converts a wchar_t * type floating-point number input string to a double value.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent part. Where radix character is the character that separates the integer part of a number from the fractional part.
- A 0x or 0X, then a non-empty sequence of hexadecimal digits optionally containing a radix character, then an optional binary exponent part. Where radix character is the character that separates the integer part of a number from the fractional part.
- One of INF or INFINITY, ignoring case.
- One of NAN or NANQ(n-char-sequence), ignoring case.
- One of NANS or NANSQ(n-char-sequence), ignoring case.
- One of NANS or NANSQ(n-char-sequence), ignoring case.
The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide-character string is empty or consists entirely of white space wide characters, or if the first non-white space wide character is other than a sign, a digit, or a decimal-point wide character.

If the subject sequence has the expected form, the sequence of wide characters starting with the first digit or the decimal-point wide character (whichever occurs first) is interpreted as a floating constant according to the rules of ISO/IEC 9899: subclause 6.1.3.1, except the decimal-point wide character is used in place of a period, and if neither an exponent part nor a decimal-point wide character appears, a decimal-point is assumed to follow the last digit in the wide-character string. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final wide-character string is stored in the object pointed to by endptr, provided that endptr is not a NULL pointer.

In a locale other than the C locale, additional implementation-defined subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of nptr is stored in the object pointed to by endptr, provided that endptr is not a NULL pointer.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, wcstod() returns the converted value, if any.

If no conversion could be performed, wcstod() returns 0.

The double value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking wcstod(). The wcstod() function uses __isBFP() to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of the invoking thread.

If the correct value is outside the range of representable values, wcstod() returns ±HUGE_VAL—according to the sign of the value—and the value of the macro ERANGE is stored in errno.

Example

CELEBW21

/* CELEBW21 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs;
    wchar_t *stopwcs;
    double d;

    wcs = L"3.1415926This stopped it";
    d = wcstod(wcs, &stopwcs);
wcstod

```c
printf("wcs = \"%ls\"\n", wcs);
printf(" wcstod = %f\n", d);
printf(" Stopped scan at \"%ls\"\n", stopwcs);
}
```

Related information

- "wcstof() — Convert a wide-character string to float" on page 2442
- "wcstold() — Convert a wide-character string to long double" on page 2450
The wcstod32() wcstod64(), and wcstod128() functions convert the initial portion of the wide-character string pointed to by *nptr* to _Decimal32, _Decimal64, and _Decimal128 representation, respectively.

First, they decompose the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space wide characters (as specified by the iswspace() function).
2. A subject sequence resembling a floating-point constant or representing an infinity or NaN.
3. A final wide-character string of one or more unrecognized wide characters, including the terminating null wide character of the input wide-character string.

Then, they attempt to convert the subject sequence to a floating-point number, and return the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- a nonempty sequence of decimal digits optionally containing a decimal-point wide character, then an optional exponent part
- INF or INFINITY, ignoring case
- NaN, NaN(n-char-sequence), NaNQ, NaNQ(n-char-sequence), NANS, or NANS(n-char-sequence), ignoring case in the NaN, NaNQ, or NANS part, where n-char-sequence is one or more decimal numeric digits

**Note:** If the input string is not one of these forms (for example "INFINITE"), the output results are undefined.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white-space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide character string is not of the expected form.
If the subject sequence has the expected form for a floating-point number, the sequence of wide characters starting with the first digit or the decimal-point wide character (whichever occurs first) is interpreted as a floating constant. If neither an exponent nor a decimal-point character appears in a decimal floating point number, an exponent with value zero is assumed to follow the last digit in the string. If the subject sequence begins with a minus sign, the sequence is interpreted as negated. A wide character sequence INF or INFINITY is interpreted as an infinity. A wide character sequence NAN, NAN(), or NAN(n-char-sequence) is interpreted as a quiet NaN. A wide character sequence of NANS, NANS(), or NANS(n-char-sequence), is interpreted as a signalling NaN.

A pointer to the final wide-character string is stored in the object pointed to by endptr, provided that endptr is not a null pointer.

The converted value keeps the same precision as the input if possible, and the value may be denormalized. Otherwise, rounding may occur. Rounding happens after any negation.

In other than the "C" locale, additional locale-specific subject sequence forms are accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of nptr is stored in the object pointed to by endptr, provided that endptr is not a null pointer.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nptr</td>
<td>Input pointer to start of the wide-character string to be converted</td>
</tr>
<tr>
<td>endptr</td>
<td>NULL, or a pointer to a output pointer field that is filled in with the address of the first wide character in the input wide-character string that is not used in the conversion.</td>
</tr>
</tbody>
</table>

**Note:** To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

**Returned value**

The functions return the converted value, if any. If no conversion could be performed, the value +0.E0DF, +0.E0DD, or +0.E0DL is returned. If the correct value is outside the range of representable values, plus or minus HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128 is returned (according to the return type and sign of the value), and errno is set to ERANGE. If the result underflows, the functions return a value whose magnitude is no greater than the smallest normalized positive number in the return type. No signal is raised at the point of returning a signaling NaN.

<table>
<thead>
<tr>
<th>errno</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <wchar.h>

float wcstof(const wchar_t *__restrict__ nptr, wchar_t **__restrict__ endptr);
```

General description

wcstof() converts a wchar_t * floating-point number input string to a float value. The parameter `nptr` points to a sequence of wide-characters that can be interpreted as a numerical float value.

It decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space character codes (as specified by `iswspace()`).
2. A subject sequence resembling a floating-point constant, infinity, or NaN.
3. A final wide-character string of one or more unrecognized wide-characters codes, including the terminating NULL wide-character of the input wide-character string.

The function then attempts to convert the subject string into the floating-point number, and returns the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent. A radix character is the character that separates the integer part of a number from the fractional part.
- A 0x or 0X, a non-empty sequence of hexadecimal digits optionally containing a radix character, then a base 2 decimal exponent part with a p or P as prefix, a plus or minus sign, then a sequence of at least one decimal digit. (Example [-]0x.hhhhp+/d). A radix character is the character that separates the integer part of a number from the fractional part.
- One INF or INFINITY, ignoring case.
- One NANQ or NANQ(n-char-sequence), ignoring case.
- One NANS or NANS(n-char-sequence), ignoring case.
- One NAN or NAN(n-char-sequence), ignoring case.

See the "scanf() Family of Formatted Input Functions" for a description of special infinity and NaN sequences recognized by z/OS formatted input functions in IEEE Binary Floating-Point mode. A pointer to the final wide-character string is stored in the object pointed to by `endptr`, provided that `endptr` is not a NULL pointer.
Returned value

If successful, wcstof() returns the converted value, if any. If no conversion could be performed, it returns 0.

The float value is a hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking wcstof(). This function uses __isBFP() to determine the floating-point mode of the invoking thread.

If the correct value is outside the range of representable values, then +/-HUGE_VALF, according to the sign of the value, is returned and the value of the ERANGE macro is stored in errno. If the correct value would cause an underflow, 0 is returned and the value of the ERANGE macro is stored in errno.

<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <inttypes.h>

intmax_t wcstoiimax(const wchar_t * __restrict__ nptr, wchar_t ** __restrict__ endptr, int base);
```

Compile requirement: Function wcstoiimax() requires long long to be available.

General description

The wcstoiimax() function converts the wide-character string nptr to an intmax_t integer type. Valid input values for base are 0 and in the range 2-36. The wcstoiimax() function is equivalent to wcstol() and wcstoll(). The only difference being that the return value is of type intmax_t. See wcstoll() for more information.

Returned value

If successful, wcstoiimax() returns the converted value, if any.

If unsuccessful, wcstoiimax() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, wcstoiimax() returns INTMAX_MAX or INTMAX_MIN, according to the sign of the value. If the value of base is not supported, wcstoiimax() returns 0.

If unsuccessful wcstoiimax() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of base is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

Example

```c
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    wchar_t *nptr;
    wchar_t *endptr;
    intmax_t j;
    int base = 10;
    nptr = L"10110134932";
    printf("nptr = \"%ls\"\n", nptr);
    j = wcstoiimax(nptr, &endptr, base);
    printf("wcstoiimax = %jd\n", j);
    printf("Stopped scan at \"%ls\"\n\n", endptr);
    return 0;
}

wcstok

wcstok() — Break a wide-character string into tokens

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

Non-XPG4:

```
#include <wchar.h>

wchar_t *wcstok(wchar_t * __restrict__ wcs1,
                const wchar_t * __restrict__ wcs2, wchar_t ** __restrict__ ptr);
```

XPG4:

```
#define _XOPEN_SOURCE
#include <wchar.h>

wchar_t *wcstok(wchar_t *wcs1, const wchar_t *wcs2);
```

XPG4 and MSE:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

wchar_t *wcstok(wchar_t *wcs1,
                const wchar_t *wcs2, wchar_t **ptr);
```

General description

A sequence of calls to the wcstok() function breaks the wide string pointed to by `wcs1` into a sequence of tokens, each of which is delimited by a wide character from the wide string pointed to by `wcs2`. The third argument points to a caller-provided wide-character pointer into which the wcstok() function stores information necessary for it to continue scanning the same string.

The first call in the sequence, `wcs1` shall point to a wide-character string, while in subsequent calls for the same wide string, `wcs1` shall be a NULL pointer. If `wcs1` is a NULL pointer, the value pointed to by `ptr` shall match that set by the previous call for the same wide-character string; otherwise its value is ignored. The separator wide-character string pointed to by `wcs2` may be different from call to call.

The first call in the sequence, searches the wide-character string pointed to by `wcs1` for the first wide character that is not contained in the current separator wide-character string pointed to by `wcs2`. If no such wide character is found, then there are no tokens in the wide-character string pointed to by `wcs1` and wcstok() returns a NULL pointer. If such a wide character is found, it is the start of the first token.

wcstok() then searches from there for a wide character that is contained in the current separator wide string. If no such wide character is found, the current token extends to the end of the wide-character string pointed to by `wcs1`, and subsequent
wcstok

searches for a token will return a NULL pointer. If such a wide character is found, it is overwritten by a NULL character, which terminates the current token.

In all cases, the wcstok() function stores sufficient information in the pointer ptr so that subsequent calls, with a NULL pointer as the value of the first argument and the unmodified pointer value as the third, will start searching just past the end of the previously returned token (if any).

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then the compiler assumes that your program is using the XPG4 variety of the wcstok() function, unless you also define the _MSE_PROTOS feature test macro. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

The prototype for the XPG4 variety of the wcstok() function is:

```
wchar_t *wcstok(wchar_t *wcs1, const wchar_t *wcs2);
```

This variety of the wcstok() function is missing a third parameter to specify the address of restart information in your program storage. Instead, C/370 provides comparable restart information in run-time library storage. Please note that this library storage is provided on a per thread basis making the XPG4 wcstok() function thread-specific for a threaded application.

Returned value

If successful, wcstok() returns a pointer to the first wide character of a token.

If there is no token, wcstok() returns a NULL pointer.

Example

CELEBW22

```c
/* CELEBW22 */
#include <wchar.h>
int main(void)
{
    static wchar_t str1[] = L"?a??b,,,\#c";
    static wchar_t str2[] = L"\t \t";
    wchar_t *t, *ptr1, *ptr2;
    t = wcstok(str1, L"?", &ptr1); /* t points to the token L"a" */
    t = wcstok(NULL, L"\", &ptr1); /* t points to the token L"??b" */
    t = wcstok(str2, L"\t," , &ptr2); /* t is a null pointer */
    t = wcstok(NULL, L"\#," , &ptr1); /* t points to the token L"c" */
    t = wcstok(NULL, L"?", &ptr1); /* t is a null pointer */
}
```

| Single UNIX Specification, Version 3 |         |                  |

Format

```c
#include <wchar.h>

long int wcstol(const wchar_t * __restrict__ nptr, wchar_t ** __restrict__ endptr, int base);
```

General description

Converts the initial portion of the wide-character string pointed to by `nptr` to long int representation. First it decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white space wide characters (as specified by the `iswspace()` function).
2. A subject sequence resembling an integer determined by the value of base.
3. A final wide-character string of one or more unrecognized wide characters, including the terminating NULL character of the input wide-character string.

Then it attempts to convert the subject sequence to an integer, and returns the result.

If the value of base is zero, the expected form of the subject sequence is that of an integer constant as described in ISO/IEC 9899: subclause 6.1.3.2, optionally preceded by a plus or minus sign, but not including an integer suffix. If the value of base is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits from the portable character set representing an integer with the radix specified by base, optionally preceded by a plus or minus sign, but not including an integer suffix. The letters from a (or A) through z (or Z) are ascribed the values 10 to 35; only letters whose ascribed values are less than that of base are permitted. If the value of base is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide-character string is empty or consists entirely of white space, or if the first non-white space wide character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of base is zero, the sequence of wide characters starting with the first digit is interpreted as an integer constant according to the rules of ISO/IEC 9899: subclause 6.1.3.2. If the subject sequence has the expected form and the value of base is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final wide-character string is stored in the object pointed to by `endptr`, provided that `endptr` is not a NULL pointer.
In a locale other than the C or POSIX locale, additional implementation-defined subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of `nptr` is stored in the object pointed to by `endptr`, provided that `endptr` is not a NULL pointer.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Since 0, (LONG_MIN) and (LONG_MAX) are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, then call `wcstol()`, then check `errno`.

**Returned value**

If successful, `wcstol()` returns the converted value, if any.

If unsuccessful, `wcstol()` returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, `wcstol()` returns LONG_MAX or LONG_MIN, according to the sign of the value. If the value of `base` is not supported, `wcstol()` returns 0.

If unsuccessful `wcstol()` sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of <code>base</code> is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

**Example**

```c
CELEBW23
/* CELEBW23 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs;
    wchar_t *stopwcs;
    long l;
    int base;

    wcs = L"10110134932";
    printf("wcs = \%ls\n", wcs);
    for (base=2; base<=8; base*=2) {
        l = wcstol(wcs, &stopwcs, base);
        printf(" wcstol = %ld\n", l);
        printf(" Stopped scan at \%ls\n\n", stopwcs);
    }
}
```

<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#define _ISOC99_SOURCE
#include <wchar.h>

long double wcstold(const wchar_t *__restrict__ nptr, wchar_t **__restrict__ endptr);
```

General description

wcstold() converts a wchar_t * floating-point number input string to a long double value. The parameter nptr points to a sequence of wide-characters that can be interpreted as a numerical long double value.

It decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by iswspace()).
2. A subject sequence resembling a floating-point constant, infinity, or NaN.
3. A final wide-character string of one or more unrecognized wide-characters codes, including the terminating NULL wide-character of the input wide-character string.

The function then attempts to convert the subject string into the floating-point number, and returns the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent. A radix character is the character that separates the integer part of a number from the fractional.
- A 0x or 0X, a non-empty sequence of hexadecimal digits optionally containing a radix character, then a base 2 decimal exponent part with a p or P as prefix, a plus or minus sign, then a sequence of at least one decimal digit. (Example [-]0xh.hhhhp+/-d). A radix character is the character that separates the integer part of a number from the fractional part.
- One INF or INFINITY, ignoring case.
- One NANQ or NANQ(n-char-sequence), ignoring case.
- One NANS or NANS(n-char-sequence), ignoring case.
- One NAN or NAN(n-char-sequence), ignoring case.

See the "scanf() Family of Formatted Input Functions" for a description of special infinity and NaN sequences recognized by z/OS formatted input functions in IEEE Binary Floating-Point mode. The pointer to the final wide-character string is stored in the object pointed to by endptr, provided that endptr is not a NULL pointer.
Returned value

If successful, wcstold() returns the converted value, if any. If no conversion could be performed, it returns 0.

The long double value is a hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the invoking thread. This function uses __isBFP() to determine the floating-point mode of the invoking thread.

If the correct value is outside the range of representable values, then +/-HUGE_VALL, according to the sign of the value, is returned and the value of the ERANGE macro is stored in errno.

</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

long long wcstoll(const wchar_t * __restrict__ nptr, wchar_t ** __restrict__ endptr, int base);
```

Compile requirement: Use of this function requires the long long data type. See z/OS XL C/C++ Language Reference for information on how to make long long available.

General description

Converts the initial portion of the wide-character string pointed to by `nptr` to long long representation. First it decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white space wide characters (as specified by the `iswspace()` function).
2. A subject sequence resembling an integer determined by the value of `base`.
3. A final wide-character string of one or more unrecognized wide characters, including the terminating NULL character of the input wide-character string.

Then it attempts to convert the subject sequence to a long long integer, and returns the result.

If the value of `base` is zero, the expected form of the subject sequence is that of an integer constant as described in ISO/IEC 9899: subclause 6.1.3.2, optionally preceded by a plus or minus sign, but not including an integer suffix. If the value of `base` is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits from the portable character set representing an integer with the radix specified by `base`, optionally preceded by a plus or minus sign, but not including an integer suffix. The letters from a (or A) through z (or Z) are ascribed the values 10 to 35; only letters whose ascribed values are less than that of `base` are permitted. If the value of `base` is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide-character string is empty or consists entirely of white space, or if the first non-white space wide character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of `base` is zero, the sequence of wide characters starting with the first digit is interpreted as an integer constant according to the rules of ISO/IEC 9899: subclause 6.1.3.2. If the subject sequence has the expected form and the value of `base` is between 2 and 36, it is...
used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final wide-character string is stored in the object pointed to by endptr, provided that endptr is not a NULL pointer.

In a locale other than the C or POSIX locale, additional implementation-defined subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of nptr is stored in the object pointed to by endptr, provided that endptr is not a NULL pointer. The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Since 0, {LLONG_MIN} and {LLONG_MAX} are returned on error and are also valid returns on success, an application wishing to check for error situations should set errno to 0, then call wcstoll(), then check errno.

**Returned value**

If successful, wcstoll() returns the converted value, if any.

If unsuccessful, wcstoll() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, wcstoll() returns LLONG_MAX (LONGLONG_MAX) or LLONG_MIN (LONGLONG_MIN), according to the sign of the value. If the value of base is not supported, wcstoll() returns 0.

If unsuccessful wcstoll() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of base is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

**Example**

```c
/* Long Long example */
#define _LONG_LONG 1
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs;
    wchar_t *stopwcs;
    long long l;
    int base;

    wcs = L"10110134932";
    printf("wcs = \%ls\n", wcs);
    for (base=2; base<=8; base*=2) {
        l = wcstoll(wcs, &stopwcs, base);
        printf(" wcstoll = %lld\n", l);
        printf(" Stopped scan at \%ls\n\n", stopwcs);
    }
}
```

wcstombs() — Convert wide-character string to multibyte character string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>

size_t wcstombs(char * __restrict__ dest,
                 const wchar_t * __restrict__ string,
                 size_t count);
```

General description

Converts the wide-character string pointed to by `string` into the multibyte array pointed to by `dest`. The converted string begins in the initial shift state. The conversion stops after `count` bytes in `dest` are filled up or a NULL wide character is encountered.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

If unsuccessful, mbstowcs() returns (size_t)-1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The input argument is a NULL rather than a pointer to a wide character.</td>
</tr>
<tr>
<td>EILSEQ</td>
<td>wcstombs() encountered a sequence that is not a valid wide character code.</td>
</tr>
</tbody>
</table>

The mbstowcs() interface checks for an invalid input arg. If the third arg, which should be a pointer to a string of wchar_t elements, is NULL, the interface will set errno to EINVAL as well as returning -1. This clearly differentiates from the situation in which the third arg is a pointer to null, in which case should return 1 and the multibyte target string will contain a null byte.

Returned value

Returns the length in bytes of the multibyte character string, not including a terminating NULL wide character. The value (size_t)-1 is returned if an invalid multibyte character is encountered or if *string is a NULL pointer.

If `count` is the returned value, the array is not NULL-terminated.

If *`dest` is a NULL pointer, the number of characters required to convert the wide-character string is returned.
If the area pointed to by *dest is too small (as indicated by the value of count) to contain the wide character codes represented as multibyte characters, the number of bytes containing complete multibyte characters is returned.

**Note:** wcstombs() does not generate redundant shift characters between the DBCS characters. When the wctomb() function is called for each character, redundant shift characters are generated.

### Example

**CELEBW24**

/* CELEBW24

In this example, a wide-character string is converted to a char string twice. The first call converts the entire string, while the second call only converts three characters. The results are printed each time.

*/
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#define SIZE 20

int main(void)
{
    char dest[SIZE];
    wchar_t * dptr = L"string";
    size_t count = SIZE;
    size_t length;

    length = wcstombs( dest, dptr, count );
    printf( "%d characters were converted.\n", length );
    printf( "The converted string is "%s"\n", dest );

    /* Reset the destination buffer */
    memset( dest, '\0', sizeof(dest));

    /* Now convert only 3 characters */
    length = wcstombs( dest, dptr, 3 );
    printf( "%d characters were converted.\n", length );
    printf( "The converted string is "%s"\n", dest );
}

**Output:**

6 characters were converted.
The converted string is "string"

3 characters were converted.
The converted string is "str"

### General description

Converts the initial portion of the wide-character string pointed to by nptr to unsigned long long integer representation. First it decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white space wide characters (as specified by the iswspace() function).
2. A subject sequence resembling an unsigned integer represented in some radix determined by the value of `base`.
3. A final wide-character string of one or more unrecognized wide characters, including the terminating NULL character of the input wide-character string.

Then it attempts to convert the subject sequence to an unsigned long long integer, and returns the result.

If the value of `base` is zero, the expected form of the subject sequence is that of an integer constant as described in ISO/IEC 9899: subclause 6.1.3.2, optionally preceded by a plus or minus sign, but not including an integer suffix. If the value of `base` is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits from the portable character set representing an integer with the radix specified by `base`, optionally preceded by a plus or minus sign, but not including an integer suffix. The letters from a (or A) through z (or Z) are ascribed the values 10 to 35; only letters whose ascribed values are less than that of `base` are permitted. If the value of `base` is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial sub-sequence of the input wide-character string, starting with the first non-white space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide-character string is empty or consists entirely of white space, or if the first non-white space wide character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of `base` is zero, the sequence of wide characters starting with the first digit is interpreted as an integer.
wcestoull

constant according to the rules of ISO/IEC 9899: subclause 6.1.3.2. If the subject sequence has the expected form and the value of base is between 2 and 36, it is used as the base for conversion, assigning to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by endptr, provided that endptr is not a NULL pointer. In a locale other than the C or POSIX locale, additional implementation-defined subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of nptr is stored in the object pointed to by endptr, provided that endptr is not a NULL pointer.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Since 0 and {ULLONG_MAX} are returned on error and 0 is also a valid return on success, an application wishing to check for error situations should set errno to 0, then call wcestoull(), then check errno.

Returned value

If successful, wcstoull() returns the converted value, if any.

If unsuccessful, wcstoull() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, wcstoull() returns ULLONG_MAX (ULONGLONG_MAX). If the value of base is not supported, wcstoull() returns 0.

If unsuccessful wcstoull() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of base is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

Example

```c
/* LongLong conversion */
#define _LONG_LONG 1
#include <stdio.h>
#include <wchar.h>
#define BASE 2

int main(void)

{    wchar_t *wcs = L"1000e13 camels";
    wchar_t **endptr;
    unsigned long long answer;

    answer = wcstoull(wcs, endptr, BASE);
    printf("The input wide string used: %ls\n", wcs);
    printf("The unsigned long long produced: %llu\n", answer);
    printf("The substring of the input wide string that was not converted to unsigned long long: %ls\n", *endptr);
    }```

<td>C99</td>
<td>both</td>
<td>z/OS V1R7</td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C++ TR1 C99</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _ISOC99_SOURCE
#include <inttypes.h>

uintmax_t wcstoumax(const wchar_t * __restrict__ nptr, wchar_t ** __restrict__ endptr, int base);
```

Compile requirement: Function wcstoumax() requires long long to be available.

General description

The wcstoumax() function converts the wide-character string nptr to an uintmax_t integer type. Valid input values for base are 0 and in the range 2-36. The wcstoumax() function is equivalent to wcstoul() and wcstoull(). The only difference being that the return value is of type uintmax_t. See wcstoul() for more information.

Returned value

If successful, wcstoumax() returns the converted value, if any.

If unsuccessful, wcstoumax() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, wcstoumax() returns UINTMAX_MAX. If the value of base is not supported, wcstoumax() returns 0.

If unsuccessful wcstoumax() sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>The value of base is not supported.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The conversion caused an overflow.</td>
</tr>
</tbody>
</table>

Example

```c
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    wchar_t *nptr;
    wchar_t *endptr;
    uintmax_t j;
    int base = 10;
    nptr = L"10110134932";
    printf("nptr = \"%ls\"
    nptr);
    j = wcstoumax(nptr, &endptr, base);
    printf("wcstoumax = %ju\n", j);
    printf("Stopped scan at \"%ls\"
    nptr);
}
```

Output

<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```
#include <wchar.h>

wchar_t *wcswcs(const wchar_t *string1, const wchar_t *string2);
```

General description

Locates the first occurrence in the string pointed to by `string1` of the sequence of wide characters (excluding the terminating wide NULL character) in the string pointed to by `string2`.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

**Note:** The `wcswcs()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `wcsstr()` function is preferred for portability.

Returned value

If successful, `wcswcs()` returns a pointer to the located string.

If `string2` points to a string with zero length, `wcswcs()` returns `string1`.

If the string is not found, `wcswcs()` returns NULL.

Example

```
CELEBW26
/* CELEBW26

This example finds the first occurrence of the wide character string pr
in buffer1, using wcswcs().

*/
#include <stdio.h>
#include <wchar.h>

#define SIZE 40

int main(void)
{
  wchar_t buffer1[SIZE] = L"computer program";
  wchar_t *ptr;
  wchar_t *wch = L"pr";
```
ptr = wcswcs( buffer1, wch );
printf( "The first occurrence of %ls in '%ls' is '%ls'\n",
        wch, buffer1, ptr );
}

Output:
The first occurrence of pr in 'computer program' is 'program'

wcswidth

wcswidth() — Determine the display width of a wide-character string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

int wcswidth(const wchar_t *wcs, size_t n);
```

General description

Determines the number of printing positions that a graphic representation of \( n \) wide characters (or fewer than \( n \) wide characters, if a NULL wide character is encountered before \( n \) wide characters have been exhausted), in the wide-character string pointed to by `wcs`, occupies on a display device. The number of printing positions is independent of its location on the device.

Returned value

If successful, `wcswidth()` returns the number of printing positions occupied by the wide-character string pointed to by `wcs`.

If `wcs` points to a NULL wide character, `wcswidth()` returns 0.

If any wide character in the wide-character string pointed to by `wcs` is not a printing wide character, `wcswidth()` returns -1.

The behavior of `wcswidth()` is affected by the LC_CTYPE category.

**Note:** Under z/OS XL C/C++ applications, the width returned will be 1 for each single-byte character and 2 for each double-byte character.

Example

```c
CELEBW27
/* CELEBW27 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs = L"ABC";
    printf("wcs has a width of: %d\n", wcswidth(wcs,3));
}
```

Output:

```
wcs has a width of: 3
```

wcsxfrm() — Transform a wide-character string

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

size_t wcsxfrm(wchar_t * __restrict__ wcs1,
               const wchar_t * __restrict__ wcs2, size_t n);
```

General description

Transforms the wide-character string pointed to by `wcs2` to values which represent character collating weights and places the resulting wide-character string into the array pointed to by `wcs1`. The transformation is such that if the `wcsncmp()` function is applied to two transformed wide-character strings, it returns a value greater than, equal to, or less than zero, corresponding to the result of the `wcsoll()` function applied to the same two original wide-character strings. No more than `n` elements are placed into the resulting array pointed to by `wcs1`, including the terminating NULL wide-character code. If `n` is zero, `wcs1` is permitted to be a NULL pointer. If copying takes place between objects that overlap, the behavior is undefined.

Since no return value is reserved to indicate an error, an application wishing to check for error situations should set `errno` to 0, then call `wcsxfrm()`, then check `errno`.

Returned value

Returns the length of the transformed wide-character string (not including the terminating NULL wide character code). If the value returned is `n` or more, the contents of the array pointed to by `wcs1` are indeterminate.

If `wcs1` is a NULL pointer, `wcsxfrm()` returns the number of elements required to contain the transformed wide string.

The transformed value of invalid wide-character codes shall be either less than or greater than the transformed values of valid wide-character codes depending on the option chosen for the particular locale definition. In this case `wcsxfrm()` returns `(size_t)-1`.

`wcsxfrm()` is controlled by the LC_COLLATE category.

The EILSEQ error may be set, indicating that the wide character string pointed to by `wcs2` contains wide character codes outside the domain of the collating sequence.

**Note:** The ISO/C Multibyte Support Extensions do not indicate that the `wcsxfrm()` function may return with an error.
Example

CELEBW28

/* CELEBW28 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs;
    wchar_t buffer[80];
    int length;

    printf("Type in a string of characters.\n");
    wcs = fgetws(buffer, 80, stdin);
    length = wcsxfrm(NULL, wcs, 0);
    printf("You would need a %d element array to hold the wide string", length);
    printf(" transformed according", wcs);
    printf(" to this program's locale.\n");
}

wctob() — Convert wide character to byte

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

Non-XPG4:

```c
#include <wchar.h>

int wctob(wint_t c);
```

XPG4:

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int wctob(wint_t c);
```

General Description

Determines whether `c` corresponds to a member of the extended character set whose multibyte character corresponds to a single byte when in initial shift state.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the wctob() function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

If successful, wctob() returns the single-byte representation.

If `c` does not correspond to a multibyte character with length one, wctob() returns EOF.

Example

```c
CELEBW29
/* CELEBW29 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wint_t wc = L'A';
    if (wctob(wc) == wc)
    ```
wctob

    printf("wc is a valid single byte character\n");
    else
        printf("wc is not a valid single byte character\n");
    }

Output:
wc is a valid single-byte character

  • "wchar.h" on page 83
wctomb() — Convert wide character to multibyte character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>XPG4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <stdlib.h>
int wctomb(char *string, wchar_t character);
```

General description

Converts the wchar_t value of character into a multibyte array pointed to by string. If the value of character is 0, the function is left in the initial shift state. At most, wctomb() stores MB_CUR_MAX characters in string.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, wctomb() returns the length in bytes of the multibyte character.

If character is not a valid multibyte character, wctomb() returns -1.

If string is a NULL pointer, wctomb() returns nonzero if shift-dependent encoding is used, or 0 otherwise.

Example

```c
CELEBW30
/* CELEBW30
   This example converts the wide character c to a character using wctomb().
*/
#include <stdio.h>
#include <stdlib.h>
#define SIZE 40
int main(void)
{
    static char buffer[ SIZE ];
    wchar_t wch = L'c';
    int length;

    length = wctomb( buffer, wch );
    printf( "The number of bytes that comprise the multibyte "
            "character is %i
", length );
    printf( "And the converted string is "%s
", buffer );
}
```
wctomb

Output:
The number of bytes that comprise the multibyte character is 1
And the converted string is "c"

wctrans(), towctrans — Transliterate wide character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO C Amendment</td>
<td>both</td>
<td></td>
</tr>
<tr>
<td>C99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <wchar.h>

wctrans_t wctrans(const char * charclass);

wint_t towctrans(wint_t wc, wctrans_t desc);
```

General description

These two functions work together to provide transliteration of wide characters. For valid results, the setting of the LC_CTYPE category of the current locale must remain the same across the two calls. Character mapping rules are defined in the LC_CTYPE category.

The wctrans() function takes the character mapping name pointed to by charclass and returns a value of type wctrans_t for use as the second argument to the towctrans() function.

The towctrans() function applies the indicated mapping to wide-character code wc from the codeset identified in the current locale. The towctrans() function applies the mapping returned by wctrans() and passed as desc.

The following character mapping names are reserved by the standard and are defined in all locales: tolower and toupper.

Notes:
1. towctrans(wc, wctrans("tolower")) is equivalent to towlower(wc)
2. towctrans(wc, wctrans("toupper")) is equivalent to towupper(wc)

Returns value

If successful, wctrans() returns the non-zero value of type wctrans_t for use in calls to towctrans().

If unsuccessful, wctrans() returns 0 and sets errno to EINVAL if the mapping name pointed to by charclass is not valid for the current locale.

If successful, the towctrans() function returns the mapped value of wc using the mapping described by desc.

If unsuccessful, towctrans() returns wc unchanged. If the value of desc is invalid, towctrans() returns 0.

Related information

- "wctype.h" on page 85
- "tolower(), toupper ()— Convert character case" on page 2265
void wctype(const char *property);

#include <wchar.h>

wctype_t wctype(const char *property);

SUSV3:
#define _POSIX_C_SOURCE 200112L
#include <wctype.h>
wctype_t wctype(const char *property);

General description
The wctype() function is defined for valid property names as defined in the current locale. The property is a string identifying a generic character class for which code-page-specific type information is required. The function returns a value of type wctype_t, which can be used as the second argument to a call of iswctype(). The wctype() function determines values of wctype_t according to rules of the coded character set defined by character type information in the program’s locale (category LC_CTYPE). Values returned by wctype() are valid until a call to setlocale() that modifies the category LC_CTYPE.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value
If successful, wctype() returns a value of type wctype_t that can be used in calls to iswctype().

If the given property name is not valid for the current locale (category LC_CTYPE), wctype() returns 0.

Related information
- "wchar.h" on page 83
- "wctype.h" on page 85
wcwidth() — Determine the display width of a wide character

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td></td>
<td>both</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

Non-XPG4:

```c
#include <wchar.h>

int wcwidth(const wint_t wc);
```

XPG4:

```c
#define _XOPEN_SOURCE
#include <wchar.h>

int wcwidth(const wchar_t wc);
```

General description

Determines the number of printing positions that a graphic representation of `wc` occupies on a display device. Each of the printing wide characters occupies its own number of printing positions on a display device. The number is independent of its location on the device.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then the compiler assumes that your program is using the XPG4 variety of the wcwidth() function. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

The prototype for the XPG4 variety of the wcwidth() function is:

```c
int wcwidth(const wchar_t wc);
```

The difference between this variety and the C/370, non-XPG4 variety of the wcwidth() function is that its parameter, `wc`, is a wchar_t rather than a wint_t type.

Returned value

If successful, wcwidth() returns the number of printing positions occupied by `wc`.

If `wc` is a NULL or non-spacing wide character, wcwidth() returns 0.

If `wc` is not a printing wide character, wcwidth() returns -1.

The behavior of wcwidth() is affected by the LC_CTYPE category.

Notes:

1. Under z/OS XL C/C++ applications, the width returned will be zero for a NULL or non-spacing character, 1 for a single-byte character, and 2 for a double-byte character.
wcwidth

2. A non-spacing character is a character belonging to the charclass named _zlc (zero length character class) in the LC_CTYPE category.

Example

CELEBW31
/* CELEBW31 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
  wint_t wc = L'A';

  printf("wc has a width of: %d\n", wcwidth(wc));
}

Output:
wc has a width of: 1

Related information
• "wchar.h" on page 83
w_getmntent() — Get information on mounted file systems

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SYS
#include <sys/mntent.h>

int w_getmntent(char *buffer, int size);
```

General description

Gets information about all currently mounted file systems.

- **buffer**: A pointer to storage that is to be filled with the retrieved information. The storage consists of a header and an entry table that correspond to one of the available mapping formats. The mappings available are defined in the `<sys/mntent.h>` header file. Each entry in the entry table will contain information for a single mounted file system.

- **size**: The length of the buffer. If `size` is zero, the total number of mount entries is returned. You can use this information to obtain a buffer large enough to hold all the information about all the entries. Use the new buffer on the subsequent call.

Three mapping formats available. Their corresponding headers are:

<table>
<thead>
<tr>
<th>Header</th>
<th>Eye Catcher</th>
<th>Entry</th>
</tr>
</thead>
<tbody>
<tr>
<td>struct mnte3</td>
<td>MNTE3H (struct mnte3h)</td>
<td>MNTE3H_ID (&quot;MNT3&quot;)</td>
</tr>
<tr>
<td>struct mnte2</td>
<td>MNTE2H (struct mnte2h)</td>
<td>MNTE2H_ID (&quot;MNT2&quot;)</td>
</tr>
<tr>
<td>struct mnte</td>
<td>W_MNTH (struct w_mnth)</td>
<td>&quot;MNTE&quot;</td>
</tr>
</tbody>
</table>

The buffer should be set to zero prior to setting of fields or the `w_getmntent()` call. The default mapping format is struct mnte when the eyecatcher field is unset.

**Using structure w_mntent3**: Prior to calling `w_getmntent()` with the w_mntent3 structure mapping, set the following fields in MNTE3H:

1. mnt3H_cbid eyecatcher to MNTE3H_ID
2. mnt3H_cblen to the size of struct mnte3
3. mnt3H_bodylen to the size of struct w_mntent3

In the header, the field mnt3H_cblen returns the number of bytes of data put in the buffer. The field mh3_cursor contains positioning information that `w_getmntent()` uses to store the information. If multiple calls are made, use the same buffer
because the positioning information in mh3_cursor indicates where the function should continue with its list. The positioning information should not be changed between calls.

After a successful call to w_getmntent(), the following w_mntent3 structure fields will be available for reference:

- mnt3_fstype: The file system type.
- mnt3_mode: The mount mode of the file system. A flag field that specifies the mount mode and additional mount options: mntentfsaunmount.
  - mntentfsaunmount: If it is 1 after the file system is mounted, the file system will be unmounted when a system leaves the sysplex. If it is 0, then the setting of mntentfsnoautomove will be used. See mntentfsnoautomove below.
  - mntentfsclient: If it is 0, then the file system is a sysplex client. If it is 1, then the file system is not a sysplex client.
  - mntentfsnoautomove: If it is 0 after the file system is mounted, it can be moved automatically. If it is 1 after the file system is mounted, it will not be moved automatically.
  - mntentfsmodenosec: If it is 1, then the file system will not enforce security checks. If it is 0, then the file system will enforce security checks.
  - mntentfsmodeexport: If it is 0, then the file system has not been exported by DFS. If it is 1, then the file system has been exported by DFS.
  - mntentfsmoderdonly: If it is 0, then the file system is mounted as read/write. If it is 1, then the file system is mounted as read-only.
  - mntentfsmodenosuid: If it is 1, then the SETUID and SETGID mode flags will be ignored for programs that reside in this file system. If it is 0, then the SETUID and SETGID mode flags will be enforced for programs that reside in this file system.
- mnt3_dev: Device number which stat() will return for all files in this file system.
- mnt3_parentdev: st_dev of parent file system.
- mnt3_rootino: The ino of the mount point.
- mnt3_status: The status of the file system.
- mnt3_ddname: The ddname specified on mount.
- mnt3_fstname: The name of the file system type specified by the FILESYS statement. The name for the file system that performed the mount.
mnt3_fstype     The name of the file system that was mounted.
mnt3_pathlen    The length of mount point path.
mnt3_mountpoint
The name of the directory where the file system is mounted.
mnt3_jobname    If this file system is quiesced, this is the job that made the request.
mnt3_PID        If this file system is quiesced, this is the PID that made the request.
mnt3_parmoffset Offset of mount parameter parm_point, starting from the address of the mnt3_fstype member of the w_mnte3 struct.
mnt3_parmlen    The length of the mount parameter parm_point.
mnt3_parmname   The name of the target system.
mnt3_qsystem    The name of the quiesce system.
mnt3_fromsys    The name of the system from which the file system has moved.
mnt3_flags      The field containing the request flags.
mnt3_status2    The file system status extensions.
mnt3_readct     The number of reads done.
mnt3_writect    The number of writes done.
mnt3_diribc     The number of directory I/O blocks.
mnt3_readibc    The number of read I/O blocks.
mnt3_writeibc   The number of write I/O blocks.
mnt3_bytesreadhw Total number of bytes read from high word.
mnt3_bytesreadlw Total number of bytes read from low word.
mnt3_byteswrittenhw Total number of bytes written to high word.
mnt3_byteswrittenlw Total number of bytes written to low word.
mnt3_filetag    Mount tag.
mnt3_syslistoff  Offset of system list.
mnt3_syslistlength Length of system list.
mnt3_aggnamelength
Length of the aggregate name in mnt2_aggname. The length does not include the null terminating character, and is only valid if mnt3_aggnameoffset has a non-zero value.
mnt3_aggnameoffset The offset of mnt2_aggname from w_mnte3. If the value is zero, then no aggregate name is returned.
mnt3_mntsec     The mount time in seconds when the file system was mounted.
w_getmntent

mnt3_fstoken  This field is a virtual file system pointer for the file system.
mnt3_pfsnormalstatusoffset  
  This field provides the offset of the physical file system normal status string location.
mnt3_pfsnormalstatuslength  
  This field provides the length of the physical file system normal status string.
mnt3_pfsexcpstatuslength  
  This field provides the length of the exception status string of the physical file system.
mnt3_pfsexcpstatusoffset  
  This field provides the offset of the exception status string of the physical file system.
mnt3_fsusrmntUID  
  The effective UID (EUID) of the user that mounted the file system.
parm_point  
  This field contains the mount point parameters to be used when mounting a file system. It is a separate field in the mnte3 structure but contiguously allocated following the w_mnte3 body, its address is the sum of the address of w_mnte3 and mnt3_parmoffset.

If all entries do not fit in the buffer supplied, multiple calls are required. If an entry together with its mount parameter will not fit in the buffer, the entry is returned without the mount parameter. In this case, mnt3_parmlen contains the length of the mount parameter, and mnt3_parmoffset is zero.

To assure that at least one entry, including the mount parameter, is returned, it is advisable to allocate space for at least two entries.

When the final entry has been placed in the buffer, w_getmntent() returns no entries.

Using structure w_mntent2: Prior to calling w_getmntent() with the w_mntent2 structure mapping, set the following fields in MNTE2H:
1. mh2_hdr.mnth2_cbid eyecatcher to MNTE2H_ID
2. mh2_hdr.mnt2h_cblen to the size of struct mnte2
3. mh_bodylen to the size of struct w_mntent2

In the header, the field mnt2h_cblen returns the number of bytes of data put in the buffer. The field mh2_cursor contains positioning information that w_getmntent() uses to store the information. If multiple calls are made, use the same buffer because the positioning information in mh2_cursor indicates where the function should continue with its list. The positioning information should not be changed between calls.

After a successful call to w_getmntent(), the following w_mntent2 structure fields will be available for reference:
mnt2_fstype  The file system type.
mnt2_mode  
  The mount mode of the file system. A flag field that specifies the mount mode and additional mount options:
mntentfsaunmount
  If it is 1 after the file system is mounted, the file system will
  be unmounted when a system leaves the sysplex. If it is 0,
  then the setting of mntentfsnoautomove will be used. See
  mntentfsnoautomove below.

mntentfsclient
  If it is 0, then the file system is a sysplex client. If it is 1,
  then the file system is not a sysplex client.

mntentfsnoautomove
  If it is 0 after the file system is mounted, it can be moved
  automatically. If it is 1 after the file system is mounted, it will
  not be moved automatically.

mntentfsmodenosec
  If it is 1, then the file system will not enforce security
  checks. If it is 0, then the file system will enforce security
  checks.

mntentfsmodeexport
  If it is 0, then the file system has not been exported by
  DFS. If it is 1, then the file system has been exported by
  DFS.

mntentfsmoderdonly
  If it is 0, then the file system is mounted as read/write. If it
  is 1, then the file system is mounted as read-only.

mntentfsmodenosuid
  If it is 1, then the SETUID and SETGID mode flags will be
  ignored for programs that reside in this file system. If it is 0
  then the SETUID and SETGID mode flags will be enforced
  for programs that reside in this file system.

mnt2_dev
  Device # which stat() will return for all files in this file system.

mnt2_parentdev
  st_dev of parent file system.

mnt2_rootino
  The ino of the mount point.

mnt2_status
  status of the file system.

mnt2_ddname
  The ddname specified on mount.

mnt2_fstname
  The name of the file system type specified by the FILESYS
  statement. The name for the file system that performed the mount.

mnt2_fsname
  The name of the file system that was mounted.

mnt2_pathlen
  The length of mount point path.

mnt2_mountpoint
  The name of the directory where the file system is mounted.

mnt2_jobname
  If this file system is quiesced, this is the job that made the request.

mnt2_PID
  If this file system is quiesced, this is the PID that made the request.

mnt2_parmoffset
  Offset of mount parameter parm_point, starting from the address of
  the mnt2_fstype member of the w_mnte2 struct.
mnt2_parmlen
    The length of the mount parameter parm_point.

mnt2_sysname
    The name of the target system.

mnt2_qsystem
    The name of the quiesce system.

mnt2_fromsys
    The name of the system from which the file system has moved.

mnt2_flags
    The field containing the request flags.

mnt2_status2
    The file system status extensions.

mnt2_success
    This field is used to return the number of successfully moved file systems when moving a collection of file systems.

mnt2_readct
    The number of reads done.

mnt2_writect
    The number of writes done.

mnt2_diribc
    The number of directory I/O blocks.

mnt2_readibc
    The number of read I/O blocks.

mnt2_writeibc
    The number of write I/O blocks.

mnt2_bytesreadhw
    Total number of bytes read from high word.

mnt2_bytesreadlw
    Total number of bytes read from low word.

mnt2_byteswrittenhw
    Total number of bytes written to high word.

mnt2_byteswrittenlw
    Total number of bytes written to low word.

mnt2_filetag
    Mount tag.

mnt2_syslistoffset
    Offset of system list.

mnt2_syslistlength
    Length of system list.

mnt2_aggnamelen
    Length of the aggregate name in mnt2_agagname. The length does not include the null terminating character, and is only valid if mnt2_agagnameoffset has a non-zero value.

mnt2_agagnameoffset
    The offset of mnt2_agagname from w_mntent2. If the value is zero, then no aggregate name is returned.

parm_point
    This field contains the mountpoint parameters to be used when mounting a file system. It is a separate field in the mnte2 structure but contiguously allocated following the w_mnte2 body, its address is the sum of the address of w_mnte2 and mnt2_parmoffset.

If all entries do not fit in the buffer supplied, multiple calls are required. If an entry together with its mount parameter will not fit in the buffer, the entry is returned without the mount parameter. In this case, mnt2_parmlen contains the length of the mount parameter, and mnt2_parmoffset is zero.
w_getmntent

To assure that at least one entry, including the mount parameter, is returned, it is advisable to allocate space for at least two entries.

When the final entry has been placed in the buffer, w_getmntent() returns no entries.

**Using structure w_mntent:** Prior to calling w_getmntent() with the w_mntent structure mapping, set the following fields in W_MNTH:

1. mnth_hid eyecatcher to "MNTE"
2. mnth_size to the size of struct mnte
3. mh_bodylen to the size of struct w_mntent

In the header, the field mnth_size returns the number of bytes of data put in the buffer. The fields mnth_cur1 and mnth_cur2 contain positioning information that w_getmntent() uses to store the information. If multiple calls are made, use the same buffer because the positioning information in mnth_cur1 and mnth_cur2 indicates where the function should continue with its list. The positioning information should not be changed between calls.

After a successful call to w_getmntent(), the following w_mntent structure fields will be available for reference:

- **mnt_fstype** The file system type.
- **mnt_mode** File system mount mode.
- **mnt_dev** Device # which stat() will return for all files in this file system.
- **mnt_parentdev** st_dev of parent file system.
- **mnt_rootino** The ino of the mount point.
- **mnt_status** The status of the file system.
- **mnt_ddname** The ddname specified on mount.
- **mnt_fstname** The name of the file system type specified by the FILESYS statement.
- **mnt_fsname** The file system name, which is up to 45 characters long and ends with a NULL.
- **mnt_pathlen** The length of mount point path.
- **mnt_mountpoint** The pathname of the directory where the file system is mounted. This field ends with a NULL.

If the caller of w_getmntent() lacks search authorization to one or more of the directories in the mount point pathname, **mnt_mountpoint** is returned empty. That is, **mnt_pathlen** is zero and **mnt_mountpoint** contains a NULL as the first character.

- **mnt_jobname** If the file system is quiesced, this is the job that made the request.
- **mnt_PID** If the file system is quiesced, this is the PID that made the request.
- **mnt_parmoffset** Offset of mount parameter from w_mntent.
- **mnt_parmlen** Length of mount parameter.
w_getmntent

mnt_parm

The file-system-specific parameter specified on the mount() function when the file system was mounted. This field ends with a NULL.

If no parameter was specified, mnt_parmlen and mnt_parmoffset are each zero. If a parameter was specified, its address is the sum of the address of w_mntent and mnt_parmoffset.

If all entries do not fit in the buffer supplied, multiple calls are required. If an entry together with its mount parameter will not fit in the buffer, the entry is returned without the mount parameter. In this case, mnt_parmlen contains the length of the mount parameter, and mnt_parmoffset is zero.

To assure that at least one entry, including the mount parameter, is returned, it is advisable to allocate space for at least two entries.

When the final entry has been placed in the buffer, w_getmntent() returns no entries.

Returned value

If successful, w_getmntent() returns the number of entries in the buffer.

If unsuccessful, w_getmntent() returns −1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>A parameter was specified incorrectly.</td>
</tr>
<tr>
<td>ERANGE</td>
<td>The result is too large to fit in the available buffer space.</td>
</tr>
</tbody>
</table>

Example

CELEBW49

/* CELEBW49

This example uses w_getmntent() to retrieve information about currently mounted systems in the MNTE3 mapping format.

The MNTE3 mapping format is only available on z/OS V1.10 or higher, target value of 0x410A0000.

*/
#define _OPEN_SYS
#include <sys/mntent.h>
#include <stdio.h>
main() {
    int entries, entry;
    struct {
        MNTE3H header;
        W_MNTENT3 mount_table[10];
    } work_area;
    memset(&work_area, 0x00, sizeof(work_area));
    /* 'header' initialization to specify MNTE3 mapping format */
    memcpy(work_area.header.mnt3H_cbid, MNTE3H_ID, 4);
    work_area.header.mnt3H_cblen = sizeof(struct mnte3);
    work_area.header.mnt3H_bodylen = sizeof(struct w_mntent3);
    do {
        /* code */
    } while (w_getmntent(stdout, work_area) != -1);

<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <sys/ps.h>

int w_getpsent(int token, W_PSPROC *buffptr, size_t length);
```

General description

Provides information about the status of any process that the calling process has access to.

*token* A relative number that identifies the relative position of a process in the system. Zero represents the first process in the system. On the first call to w_getpsent(), pass the token 0; the function then returns the token that identifies the next process to which the caller has access. Use that token on the next call.

*buffptr* The address of the buffer where the data is to be stored.

*length* The length of the buffer.

The data returned is described in the ps.h header file. See Table 59 for the format of the structure stored in the buffer.

</tr>
<tr>
<td>int</td>
<td>ps_cmdlen</td>
<td>Length of command</td>
</tr>
<tr>
<td>char</td>
<td>*ps_cmdptr</td>
<td>Command and arguments</td>
</tr>
</tbody>
</table>

**Note:** The ps_cmdlen and ps_cmdptr elements of W_PSPROC identify the length and location where w_getpsent() is to return the command and arguments used to start the process. As of z/OS V1R11, the maximum length in bytes, including the null terminator, that can be returned is defined by PS_CMDBLEN_LONG. The actual maximum length of the command and arguments returned is PS_CMDBLEN_LONG minus the length of the path. Prior to z/OS V1R11, the maximum length in bytes, including the null terminator, that can be returned is defined by PS_CMDBLEN. The actual maximum length of the command and arguments returned can be less than PS_CMDBLEN and depends on the number of arguments. The system will truncate the command and arguments as needed to allow for the null terminator. Both PS_CMDBLEN_LONG and PS_CMDBLEN are defined in <sys/ps.h>.

**Usage notes**

1. ps_usertime reports the user's CPU time consumed for the address space the process is running within. When only one process is running in the address space, this CPU time represents the accumulated user CPU time for that process. When more than one process is running in an address space, the information returned is actually the accumulated CPU time consumed by the address space. It is the sum of the CPU time used by all of the work running in that address space not including the system time.

2. ps_systime reports the system's CPU time consumed for the address space the process is running within. When only one process is running in the address space, this time represents the accumulated system CPU time for that process. However, when more than one process is running in an address space, the information returned is actually the accumulated system CPU time consumed by all of the work running in the address space.

**Returned value**

If successful, w_getpsent() returns the process token for the next process for which the caller has access. For the last active process to which the user has access, w_getpsent() returns 0, indicating there are no more processes to be accessed.

If unsuccessful, w_getpsent() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>An incorrect process token or NULL buffer address was specified.</td>
</tr>
<tr>
<td>E2BIG</td>
<td>An insufficient buffer length was provided.</td>
</tr>
</tbody>
</table>

**Example**

CELEBW33
/* CELEBW33

This example provides status information, using wgetpsent().

*/
#define _OPEN_SYS
#include <stdlib.h>
#include <stdio.h>
#include <sys/ps.h>
#include <sys/types.h>
#include <pwd.h>
#include <time.h>
#include <string.h>

int main(void) {
    int token;
    W_PSPROC buf;
    struct passwd *pw;
    token = 0;
    memset(&buf, 0x00, sizeof(buf));
    buf.ps_conttptr = (char *) malloc(buf.ps_conttylen = PS_CONTTYBLEN);
    buf.ps_pathptr = (char *) malloc(buf.ps_pathlen = PS_PATHBLEN);
    buf.ps_cmdptr = (char *) malloc(buf.ps_cmdlen = PS_CMDBLEN_LONG);
    if ((buf.ps_conttptr == NULL) ||
        (buf.ps_pathptr == NULL) ||
        (buf.ps_cmdptr == NULL))
        perror("buffer allocation error");
    else do {
        if ((token = w_getpsent(token, &buf, sizeof(buf))) == -1)
            perror("w_getpsent() error");
        else if (token > 0)
            if ((pw = getpwuid(buf.ps_ruid)) == NULL)
                perror("getpwuid() error");
            else printf("token=%d: pid=%10d, user=%8s, started=%s", token,
            (int) buf.ps_pid, pw->pw_name, ctime(&buf.ps_starttime));
    } while (token > 0);
    return 0;
}

Output:
token 2: pid 131074, user MVSUSR1, started Fri Jun 16 08:09:17 2001
token 3: pid 65539, user MVSUSR1, started Fri Jun 16 08:09:41 2001
token 6: pid 589830, user MVSUSR1, started Fri Jun 16 10:29:17 2001
token 7: pid 851975, user MVSUSR1, started Fri Jun 16 10:30:04 2001

w_ioctl(), __w_pioctl() — Control of devices

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td>OS/390 V2R8</td>
</tr>
</tbody>
</table>

General Format

```c
#define _OPEN_SYS
#include <termios.h>

int w_ioctl(int fildes, int cmd, int arglen, void *arg);
int __w_pioctl(const char *pathname, int cmd, int arglen, void *arg);
```

ACL format:

```c
#define _OPEN_SYS
#include <termios.h>
#include <sys>

int w_ioctl(int fildes, int cmd, int arglen, void arg);
int __w_pioctl(const char pathname, int cmd, int arglen, void arg);
```

General description

The `w_ioctl()` and `__w_pioctl()` functions are general entry points for device-specific commands. The specific actions specified by `w_ioctl()` and `__w_pioctl()` vary with the device, and they are defined by the device driver.

- `fildes`: A descriptor for an open character special file (used by `w_ioctl`).
- `pathname`: The pathname of a file (used by `__w_pioctl`).
- `cmd`: The command to be passed to the device driver as an integer value.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIOCGPARTNERINFO</td>
<td>Provides an interface for an application to retrieve security information about its partner. For more information, see [z/OS Communications Server: IP Programmer’s Guide and Reference](<a href="https://www.ibm.com/support/docview.ws/docview/-/DocGuide.do?req=">https://www.ibm.com/support/docview.ws/docview/-/DocGuide.do?req=</a> wings)</td>
</tr>
</tbody>
</table>

- `arglen`: The length of the argument passed to the device driver.
- `arg`: The address of the buffer where the argument to be passed to the device driver is stored.

`w_ioctl()` and `__w_pioctl()` pass the `cmd`, `arglen`, and `arg` arguments to the device driver to be interpreted and processed. When `w_ioctl()` and `__w_pioctl()` complete successfully, the device driver returns `arglen` and `arg`, if appropriate.

**Note:** The `__w_pioctl()` function has a dependency on the level of the Enhanced ASCII Extensions. See [Enhanced ASCII support](https://www.ibm.com/support/docview.ws/docview/-/DocGuide.do?req=2543) for details.
### Returned value

If successful, `w_ioctl()` returns 0.

If unsuccessful, `w_ioctl()` returns −1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>An incorrect length was specified for <code>arglen</code>. The correct argument length range is 0 to 50,000.</td>
</tr>
<tr>
<td>ENAMETOOLONG</td>
<td>The length of the <code>pathname</code> argument exceeds <code>PATH_MAX</code>, or a <code>pathname</code> component is longer than <code>NAME_MAX</code> and <code>(_POSIX_NO_TRUNC)</code> is in effect for that file. For symbolic links, the length of the <code>pathname</code> string substituted for a symbolic link exceeds <code>PATH_MAX</code>. <code>PATH_MAX</code> and <code>NAME_MAX</code> values can be determined by using <code>pathconf()</code>.</td>
</tr>
<tr>
<td>ENODEV</td>
<td>The device does not exist. The function is not supported by the device driver.</td>
</tr>
<tr>
<td>ENOENT</td>
<td>Either there is no file named <code>pathname</code> or <code>pathname</code> is an empty string.</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>A component of the <code>pathname</code> prefix is not a directory.</td>
</tr>
<tr>
<td>ENOTSUP</td>
<td>Operation not supported. The following occurred: <code>Command _IOCC_REGFILEINT</code> was used and <code>fildes</code> (<code>w_ioctl</code>) or <code>pathname</code> (<code>__w_pioctl</code>) refers to a file residing in a R/W file system that is shared across a sysplex with zFS, or is accessed through an NFS Client. In these cases, the file is able to be changed on a remote system without the local system being aware. Because the program would not receive notification, this operation is rejected. Use <code>__errno2()</code> to obtain more diagnostic information.</td>
</tr>
<tr>
<td>ENOTTY</td>
<td>An incorrect file descriptor was specified. <code>fildes</code> was not a character special file.</td>
</tr>
</tbody>
</table>

### ACLs description

The `w_ioctl()` and `__w_pioctl()` functions are general entry points for SETFACL and GETFACL HFS commands. SETFACL is used to set information into an Access Control List. GETFACL is used to retrieve information from an Access Control List.

- `fildes` A descriptor for an open character special file (used by `w_ioctl`).
- `pathname` The pathname of a file (used by `__w_pioctl`).
- `cmd` The command to be passed to the device driver as an integer value, either SETFACL or GETFACL.
- `arglen` The length of the user buffer passed to the HFS device driver as a value from 1 to 50,000 bytes. `arglen` is the combined size of the `struct ACL_buf` and the array of `struct ACL_entries`.
- `arg` `arg` specifies the user buffer which is mapped by `struct ACL_buf` followed immediately by an array of `struct ACL_entries`. See [z/OS UNIX System Services Programming: Assembler Callable Services Reference](z/OS UNIX System Services Programming: Assembler Callable Services Reference) for more information about `ACL_buf` and the `ACL_entries`. 
w_ioctl

w_ioctl() and __w_pioctl() pass the cmd, arglen, and arg arguments to the device driver to be interpreted and processed. When w_ioctl() and __w_pioctl() complete successfully, the device driver returns arglen and arg, if appropriate.

**ACLs returned value**

If successful, w_ioctl() returns 0.

If unsuccessful, w_ioctl() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBADF</td>
<td>The fildes parameter is not a valid file descriptor.</td>
</tr>
<tr>
<td>EINVAL</td>
<td>The request is invalid or not supported.</td>
</tr>
<tr>
<td>EMVSPARM</td>
<td>Incorrect parameters were passed to the service.</td>
</tr>
<tr>
<td>ENODEV</td>
<td>The device is incorrect. The function is not supported by the device driver.</td>
</tr>
</tbody>
</table>

**Example**

CELEBW34

/* CELEBW34
   
   This example shows a general entry point for device-specific commands.
   */

#include <termios.h>
#include <stdio.h>

main() {
   char buf[256];
   int ret;

   memset(buf, 0x00, sizeof(buf));
   if ((ret = w_ioctl(0, 1, sizeof(buf), buf)) != 0)
      perror("w_ioctl() error");
   else
      printf("w_ioctl() returned '%s'\n", buf);
}

Output:

w_ioctl() error: Invalid argument

**Note:** w_ioctl() is dependent upon the file system device driver.

</tr>
</tbody>
</table>

Format

Non-XPG4:

```c
#include <wchar.h>

wchar_t *wmemchr(const wchar_t *s, wchar_t c, size_t n);
```

XPG4:

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

wchar_t *wmemchr(const wchar_t *s, wchar_t c, size_t n);
```

General description

Locates the first occurrence of the wide character `c` in the initial `n` wide chars of the object pointed to by `s`.

If `n` has the value 0, `wmemchr()` finds no occurrence of `c` and returns a NULL pointer.

**Note:** The function is now available as a built-in function under ARCH(7) when LP64 is not used.

**Special behavior for XPG4:** If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `wmemchr()` function in the wchar header available when you compile your program. See Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

If successful, `wmemchr()` returns a pointer to the first occurrence of the wide character `c` in object `s`.

If the wide character `c` does not occur within the first `n` wide characters of `s`, `wmemchr()` returns the NULL pointer.

Example

```c
#include <stdio>
#include <wchar>

main()
{
    wchar_t *in = L"1234ABCD";
    wchar_t *ptr;
```
wchar_t fnd = L'A';

printf("\nEXPECTED: ABCD\n");
ptr = wmemchr(in, L'A', 6);
if (ptr == NULL)
    printf("\n** ERROR ** ptr is NULL, char L'A' not found\n");
else
    printf("\nRECEIVED: %ls \n",ptr);

Format

**Non-XPG4:**

```c
#include <wchar.h>

int wmemcmp(const wchar_t * __restrict__ s1, const wchar_t * __restrict__ s2, size_t n);
```

**XPG4:**

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int wmemcmp(const wchar_t *s1, const wchar_t *s2, size_t n);
```

General description

Compares the first `n` wide chars of the object pointed to by `s1` to the first `n` wide chars of the object pointed to by `s2`. If `n` has the value 0, `wmemcmp()` returns 0.

**Note:** The function is now available as a built-in function under ARCH(7) when LP64 is not used.

**Special behavior for XPG4:** If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the wmemcmp function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

`wmemcmp()` returns an integer that is:

- `< 0` if `s1` is less than `s2`.
- `= 0` if `s1` is equal to `s2`.
- `> 0` if `s1` is greater than `s2`.

Example

```c
#include <wchar.h>
#include <stdio.h>

main()
{
    int ptr;
```
wchar_t *in = L"12345678";
wchar_t *out = L"12AAAAAB";

printf("\nGREATER is the expected result");
ptr = wmemcmp(in, out, 3);
if (ptr == 0)
    printf("\nArrays are EQUAL %ls %ls \n", in, out);
else
{
    if (ptr > 0)
        printf("\nArray %ls GREATER than %ls \n", in, out);
    else
        printf("\nArray %ls LESS than %ls \n", in, out);
}

Non-XPG4:

```c
#include <wchar.h>

wchar_t *wmemcpyp wchar_t * __restrict__ s1,
    const wchar_t * __restrict__ s2, size_t n);
```

XPG4:

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

wchar_t *wmemcpyp wchar_t *s1, const wchar_t *s2, size_t n);
```

General description

Copies \( n \) wide chars of the object pointed to by \( s2 \) to the object pointed to by \( s1 \).

Result of the copy is unpredictable if \( s1 \) and \( s2 \) overlap. If \( n \) has the value 0, wmemcpyp copies zero wide characters.

**Note:** The function is now available as a built-in function under ARCH(7) when LP64 is not used.

**Special behavior for XPG4:** If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the wmemcpyp function in the wchar header available when you compile your program. Please see Table 2 on page 4 for a list of XPG4 and other feature test macros.

Returned value

wmemcpyp() returns the value of \( s1 \).

Example

```c
#include <wchar.h>
#include <stdio.h>

main()
{
    wchar_t *in  = L"12345678";
    wchar_t *out = L"ABCDEFGH";
    wchar_t *ptr;

    printf("-nExpected result: First 4 chars of in change");
    printf(" and are the same as first 4 chars of out");
```
ptr = wmemcpy(in, out, 4);
if (ptr == in)
    printf("-nArray in %ls array out %ls -n", in, out);
else
    { printf("-n*** ERROR ***");
      printf(" returned pointer wrong");
    }

Format

Non-XPG4:

```c
#include <wchar.h>

wchar_t *wmemmove(wchar_t *s1, const wchar_t *s2, size_t n);
```

XPG4:

```c
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

wchar_t *wmemmove(wchar_t *s1, const wchar_t *s2, size_t n);
```

General description

Copies \( n \) wide chars of the object pointed to by \( s2 \) to the object pointed to by \( s1 \). Copying takes place as if the \( n \) wide characters from \( s2 \) are first copied into a temporary array of \( n \) wide characters that does not overlay the objects pointed to by \( s1 \) and \( s2 \), and then copied from the temporary array into the object pointed to by \( s1 \).

If \( n \) has the value 0, wmemmove() copies zero wide characters.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the wmemmove() function in the wchar header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

wmemmove() returns the value of \( s1 \).

Example

```c
#include <wchar.h>
#include <stdio.h>

main()
{
    wchar_t *in = L"12345678";
    wchar_t *out = L"ABCDEFGH";
    wchar_t *ptr;

    printf("\nExpected result: First 4 chars of in and out the same\n");
    ptr = wmemmove(in, out, 4);
```
if (ptr == in)
    printf("\nArray in %ls array out %ls \n", in, out);
else
{
    printf("\n*** ERROR ***\n");
    printf(" Returned pointer not correct.\n");
}

wordexp

**wordexp() — Perform shell word expansions**

### Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4</td>
<td>both</td>
<td>POSIX(ON)</td>
</tr>
<tr>
<td>XPG4.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Single UNIX Specification, Version 3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Format

```c
#define _XOPEN_SOURCE
#include <wordexp.h>

int wordexp(const char *__restrict__ words,
            wordexp_t *__restrict__ pwordexp, int flags);

void wordfree(wordexp_t *pwordexp);
```

### General description

The `wordexp()` function performs word expansions as described in *X/Open CAE Specification, Commands and Utilities, Issue 4, Version 2 (XCU) Section 2.6, Word Expansions*, subject to quoting as in the *XCU* specification, *Section 2.2, Quoting*, and places the list of expanded words into the structure pointed to by `pwordexp`.

The `words` argument is a pointer to a string containing one or more words to be expanded. The expansions will be the same as would be performed by the shell described by the *XCU* specification if `words` were the part of a command line representing the arguments to a utility. Therefore, `words` must not contain an unquoted `<newline>` or any of the unquoted special shell characters: `| & ; < >`

except in the context of command substitution as specified in the *XCU* specification, *Section 2.6.3, Command Substitution*. It also must not contain unquoted parentheses or braces, except in the context of command or variable substitution.

The structure type `wordexp_t` is defined in the header `<wordexp.h>` and includes the following members:

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>size_t</td>
<td>we_wordc</td>
<td>Count of words matched by <code>words</code>.</td>
</tr>
<tr>
<td>char **</td>
<td>we_wordv</td>
<td>Pointer to list of expanded words.</td>
</tr>
<tr>
<td>size_t</td>
<td>we_offs</td>
<td>Slots to reserve at the beginning of <code>pwordexp-&gt;we_wordv</code>.</td>
</tr>
</tbody>
</table>

The `wordexp()` function stores the number of generated words into `pwordexp->we_wordc` and a pointer to a list of pointers to words in `pwordexp->we_wordv`. Each individual field created during field splitting (see the *XCU* specification, *Section 2.6.5, Field Splitting*) or pathname expansion (see the *XCU* specification, *Section 2.6.6, Pathname Expansion*) is a separate word in the `pwordexp->we_wordv` list. The words are in order as described in the *XCU* specification, *Section 2.6, Word Expansions*. The first pointer after the last word pointer will be a NULL pointer. The expansion of special parameters described in the *XCU* specification, *Section 2.5.2, Special Parameters* is unspecified.
wordexp

It is the caller's responsibility to allocate the storage pointed to by `pwordexp`. The `wordexp()` function allocates the other space as needed, including memory pointed to by `pwordexp->we_wordv`. The `wordfree()` function frees any memory associated with `pwordexp` from a previous call to `wordexp()`.

The `flags` argument is used to control the behavior of `wordexp()`. The value of `flags` is the bitwise inclusive-OR or zero or more of the following constants, which are defined in `<wordexp.h>`:

- **WRDE_APPEND**
  Append words generated to the ones from a previous call to `wordexp()`.

- **WRDE_DOOFFS**
  Make use of `pwordexp->we_offs`. If this flag is set, `pwordexp->we_offs` is used to specify how many NULL pointers to add to the beginning of `pwordexp->we_wordv`. In other words, `pwordexp->we_wordv` will point to `pwordexp->we_offs` NULL pointers followed by `pwordexp->we_wordc` word pointers, followed by a NULL pointer.

- **WRDE_NOCMD**
  Fail if command substitution, as specified in the XCU specification, Section 2.6.3, Command Substitution, is requested.

- **WRDE_REUSE**
  The `pwordexp` argument was passed to a previous successful call to `wordexp()`, and has not been passed to `wordfree()`. The result will be the same as if the application had called `wordfree()` and then called `wordexp()` without WRDE_REUSE.

- **WRDE_SHOWERR**
  Do not redirect stderr to `/dev/null`.

- **WRDE_UNDEF**
  Report error on an attempt to expand an undefined shell variable.

The WRDE_APPEND flag can be used to append a new set of words to those generated by a previous call to `wordexp()`. The following rules apply when two or more calls to `wordexp()` are made with the same value of `pwordexp` and without intervening calls to `wordfree()`:

1. The first such call must not set WRDE_APPEND. All subsequent calls must set it.
2. All of the calls must set WRDE_DOOFFS, or all must not set it.
3. After the second and each subsequent call, `pwordexp->we_wordv` will point to a list containing the following:
   a. zero or more NULL pointers, as specified by WRDE_DOOFFS and `pwordexp->we_offs`
   b. pointers to the words that were in the `pwordexp->we_wordv` list before the call, in the same order as before
   c. pointers to the new words generated by the latest call, in the specified order
4. The count returned in `pwordexp->we_wordc` will be the total number of words from all of the calls.
5. The application can change any of the fields after a call to `wordexp()`, but if it does, it must reset them to the original value before a subsequent call, using the same `wordexp` value, to `wordfree()` or `wordexp()` with the WRDE_APPEND or WRDE_REUSE flag.
wordexp

If `words` contains an unquoted

```
<newline> | & ; < > ( ) {}
```

in an inappropriate context, `wordexp()` will fail, and the number of expanded words
will be 0.

Unless `WRDE_SHOWERR` is set in `flags`, `wordexp()` will redirect `stderr` to `/dev/null
for any utilities executed as a result of command substitution while expanding
`words`. If `WRDE_SHOWERR` is set, `wordexp()` may write messages to `stderr` if
syntax errors are detected while expanding `words`.

If `WRDE_DOFFS` is set, then `pwordexp->we_offs` must have the same value for
each `wordexp()` call and `wordfree()` call using a given `pwordexp`.

The following constants are defined in `<wordexp.h>` as error return values:

**WRDE_BADCHAR**

One of the unquoted characters:

```
<newline> | & ; < > ( ) {}
```

appears in `words` in an inappropriate context.

**WRDE_BADVAL**

Reference to undefined shell variable when `WRDE_UNDEF` is set in `flags`.

**WRDE_CMDSUB**

Command substitution requested when `WRDE_NOCMD` is set in `flags`.

**WRDE_NOSPACE**

Attempt to allocate memory failed.

**WRDE_SYNTAX**

Shell syntax error, such as unbalanced parentheses or
unterminated string.

**WRDE_NOSYS**

POSIX shell not available.

**WRDE_EPOPEN**

`wordexp()` was invoked in an environment that does not supported
a multi-threaded fork, or `wordexp()` was invoked from a
multithreaded process in TSO or MVS batch.

**WRDE_INTRUPT**

`wordexp()` was interrupted by a signal, such as an alarm. In this event, the
caller may re-issue `wordexp()`.

For further information about the cause of a failure, please refer to `__errno2()` and
`errno` in addition to the above error return values.

**Returned value**

If successful, `wordexp()` returns 0.

If unsuccessful, `wordexp()` returns a nonzero value, as defined in `<wordexp.h>` and
described above, to indicate an error. If `wordexp()` returns the value
WRDE_NOSPACE, then pwrdexp->we_wordc, and pwrdexp->we_wordv will be updated to reflect any words that were successfully expanded. In other cases, they will not be modified.

Format

```c
#define _POSIX_SOURCE
#include <unistd.h>

ssize_t write(int fs, const void *buf, size_t N);
```

X/Open:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

ssize_t write(int fs, const void *buf, ssize_t N);
```

Berkeley sockets:

```c
#define _OE_SOCKETS
#include <unistd.h>

ssize_t write(int fs, const void *buf, ssize_t N);
```

General description

Writes \( N \) bytes from \( buf \) to the file or socket associated with \( fs \). \( N \) should not be greater than INT_MAX (defined in the limits.h header file). If \( N \) is zero, write() simply returns 0 without attempting any other action.

If \( fs \) refers to a regular file or any other type of file on which a process can seek, write() begins writing at the file offset associated with \( fs \). A successful write() increments the file offset by the number of bytes written. If the incremented file offset is greater than the previous length of the file, the length of the file is set to the new file offset.

If \( fs \) refers to a file on which a process cannot seek, write() begins writing at the current position. There is no file offset associated with such a file.

If O_APPEND (defined in the fcntl.h header file) is set for the file, write() sets the file offset to the end of the file before writing the output.

If there is not enough room to write the requested number of bytes (for example, because there is not enough room on the disk), write() outputs as many bytes as the remaining space can hold.

If write() is interrupted by a signal, the effect is one of the following:
- If write() has not written any data yet, it returns −1 and sets errno to EINTR.
- If write() has successfully written some data, it returns the number of bytes it wrote before it was interrupted.
Write operations on pipes or FIFO special files are handled in the same way a write operation on a regular file, with the following exceptions:

- A pipe has no associated file offset, so every write appends to the end of the pipe.
- If \( N \) is less than or equal to PIPE_BUF, the output is not interleaved with data written by other processes that are writing to the same pipe. If \( N \) is greater than PIPE_BUF bytes, the output can be interleaved with other data (regardless of the setting of O_NONBLOCK, which is defined in the fcntl.h header file). A write to a pipe never returns with errno set to EINTR if it has transferred any data.
- If O_NONBLOCK (defined in the fcntl.h header file) is not set, write() may block process execution until normal completion.
- If O_NONBLOCK is set, write() does not block process execution. If \( N \) is less than or equal to PIPE_BUF, write() succeeds completely and returns the value of \( N \), or else it writes nothing, sets errno to EAGAIN, and returns -1. If \( N \) is greater than PIPE_BUF, write() writes as many bytes as it can and returns this number as its result, or else it writes nothing, sets errno to EAGAIN, and returns -1.

With other files that support nonblocking writes and cannot accept data immediately, the effect is one of the following:

- If O_NONBLOCK is not set, write() blocks until the data can be written.
- If O_NONBLOCK is set, write() does not block the process. If some data can be written without blocking the process, write() writes what it can and returns the number of bytes written. Otherwise, it sets errno to EAGAIN and returns -1.

write() causes the signal SIGTTOU to be sent if all of these conditions are true:

- The process is attempting to write to its controlling terminal and TOSTOP is set as a terminal attribute.
- The process is running in a background process group and the SIGTTOU signal is not blocked or ignored.
- The process is not an orphan.

A successful write() updates the change and modification times for the file.

If \( fs \) refers to a socket, write() is equivalent to send() with no flags set.

**Behavior for sockets**

The write() function writes data from a buffer on a socket with descriptor \( fs \). The socket must be a connected socket. This call writes up to \( N \) bytes of data.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( fs )</td>
<td>The file or socket descriptor.</td>
</tr>
<tr>
<td>( buf )</td>
<td>The pointer to the buffer holding the data to be written.</td>
</tr>
<tr>
<td>( N )</td>
<td>The length in bytes of the buffer pointed to by the ( buf ) parameter.</td>
</tr>
</tbody>
</table>

If there is not enough available buffer space to hold the socket data to be transmitted, and the socket is in blocking mode, write() blocks the caller until additional buffer space becomes available. If the socket is in nonblocking mode, write() returns -1 and sets the error code to EWOULDBLOCK. See "fcntl() — Control open file descriptors" on page 539 or "ioctl() — Control device" on page 1002 for a description of how to set the nonblocking mode.

When the socket is not ready to accept data and the process is trying to write data to the socket:
Unless FNDELAY or O_NONBLOCK is set, write() blocks until the socket is ready to accept data.

If FNDELAY is set, write() returns 0.

If O_NONBLOCK is set, write() does not block the process. If some data can be written without blocking the process, write() writes what it can and returns the number of bytes written. Otherwise, it sets the error code to EAGAIN and returns -1.

For datagram sockets, this call sends the entire datagram, provided that the datagram fits into the TCP/IP buffers. Stream sockets act like streams of information with no boundaries separating data. For example, if an application program wishes to send 1000 bytes, each call to this function can send 1 byte or 10 bytes or the entire 1000 bytes. Therefore, application programs using stream sockets should place this call in a loop, calling this function until all data has been sent.

**Special behavior for C++ and sockets:** To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

**Large file support for z/OS UNIX files:**

Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the option LANGVL(LONGLONG) and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

**Returned value**

If successful, write() returns the number of bytes actually written, less than or equal to \( N \).

A value of 0 or greater indicates the number of bytes sent. However, this does not assure that data delivery was complete. A connection can be dropped by a peer socket and a SIGPIPE signal generated at a later time if data delivery is not complete.

If unsuccessful, write() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAGAIN</td>
<td>Resources temporarily unavailable. Subsequent requests may complete normally.</td>
</tr>
<tr>
<td>EBADF</td>
<td>fs is not a valid file or socket descriptor.</td>
</tr>
<tr>
<td>ECONNRESET</td>
<td>A connection was forcibly closed by a peer.</td>
</tr>
<tr>
<td>EDESTADDRREQ</td>
<td>The socket is not connection-oriented and no peer address is set.</td>
</tr>
<tr>
<td>EFAULT</td>
<td>Using the ( buf ) and ( N ) parameters would result in an attempt to access storage outside the caller's address space.</td>
</tr>
<tr>
<td>EFBIG</td>
<td>Writing to the output file would exceed the maximum file size supported by the implementation.</td>
</tr>
</tbody>
</table>
write

An attempt was made to write a file that exceeds the system established maximum file size or the process's file size limit.

The file is a regular file, nbyte is greater than 0 and the starting position is greater than or equal to the offset maximum established in the open file description associated with fields.

EINTR write() was interrupted by a signal before it had written any output.

EINVAL The request is invalid or not supported. The STREAM or multiplexer referenced by fs is linked (directly or indirectly) downstream from a multiplexer.

EIO The process is in a background process group and is attempting to write to its controlling terminal, but TOSTOP (defined in the termios.h header file) is set, the process is neither ignoring nor blocking SIGTTOU signals, and the process group of the process is orphaned. An I/O error occurred.

EMSGSIZE The message was too big to be sent as a single datagram.

ENOBUFS Buffer space is not available to send the message.

ENOSPC There is no available space left on the output device.

ENOTCONN The socket is not connected.

ENXIO A hang-up occurred on the STREAM being written to.

EPIPE write() is trying to write to a pipe that is not open for reading by any other process. This error also generates a SIGPIPE signal. For a connected stream socket the connection to the peer socket has been lost.

ERANGE The transfer request size was outside the range supported by the STREAMS file associated with fs.

EW OULD BLOCK socket is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.

A write to a STREAMS file may fail if an error message has been received at the STREAM head. In this case, errno is set to the value included in the error message.

Note: z/OS UNIX System Services does not supply any STREAMS devices or pseudodevices. It is impossible for write() to write any data on a STREAM. None of the STREAMS errnos will be visible to the invoker. See Open a file on page 1343

Example

CELEBW35

/* CELEBW35

This example writes a certain amount of bytes to a file, using write().

*/
#define __POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef __POSIX_SOURCE
```c
#include <stdlib.h>
#include <stdio.h>

#define mega_string_len 1000000

main() {
    char *mega_string;
    int fd, ret;
    char fn[]="write.file";
    if ((mega_string = (char*) malloc(mega_string_len)) == NULL)
        perror("malloc() error");
    else if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        memset(mega_string, '0', mega_string_len);
        if ((ret = write(fd, mega_string, mega_string_len)) == -1)
            perror("write() error");
        else printf("write() wrote %d bytes
", ret);
        close(fd);
        unlink(fn);
    }
}
```

Output:
```
write() wrote 1000000 bytes
```

write

- “writev() — Write data on a file or socket from an array” on page 2519
The __writedown() function will enable callers to query or change the setting of the write-down privilege of an ACEE (access control environment element) at the address space level or task level. Users having write-down privilege can write data to a resource protected by a seclabel of lower authority than that of the seclabel represented in the address space level ACEE.

To activate the write-down privilege the userid in the target ACEE must be permitted to the the IRR.WRITEDOWN.BYUSER profile in the FACILITY class. The FACILITY class must be active and RACLISTed, and the SETROPTS MLS option must be active.

See z/OS V1R5 Planning for Multilevel Security for more details on the usage of this function.

**writedownop**

The operation to be performed

- **__WD_QUERY**
  
  Query the current setting of the write-down privilege

- **__WD_ACTIVATE**
  
  Activate the write-down privilege

- **__WD_INACTIVATE**
  
  Inactivate the write-down privilege

- **__WD_RESET**
  
  Reset the write-down privilege to the user's original default value.

**writedownslope**

Scope of the write-down operation.

- **__WD_SCOPE_AS**
  
  Perform write-down operation on the address space level ACEE.

- **__WD_SCOPE_THD**
  
  Perform write-down operation on the task level ACEE.

**Returned value**

For the __writedown() activate, inactivate, and reset operations:

If successful, __writedown() returns 0.
For the __writedown() query operation:

If successful, __writedown() returns one of the following values indicating the state of the current setting of the writedown privilege.

__WD_IS_ACTIVE
- The write-down privilege is active for the ACEE.

__WD_IS_INACTIVE
- The write-down privilege is inactive for the ACEE.

For all __writedown() operations:

If unsuccessful, all __writedown() operations return -1 and sets errno to EINVAL.

writev() — Write data on a file or socket from an array

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>XPG4.2 Single UNIX Specification, Version 3</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

X/Open:

```c
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/uio.h>

ssize_t writev(int fs, const struct iovec *iov, int iovcnt);
```

Berkeley sockets:

```c
#define _OE_SOCKETS
#include <sys/uio.h>

int writev(int fs, struct iovec *iov, int iovcnt);
```

General description

The `writev()` function writes data to a file or socket with descriptor `fs` from a set of buffers. The data is gathered from the buffers specified by `iov[0]...iov[iovcnt-1]`. When the descriptor refers to a socket, it must be a connected socket.

Parameter Description

- `fs` The file or socket descriptor.
- `iov` A pointer to an array of `iovec` buffers.
- `iovcnt` The number of buffers pointed to by the `iov` parameter.

The `iovec` structure is defined in `uio.h` and contains the following fields:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iov_base</code></td>
<td>Pointer to the buffer.</td>
</tr>
<tr>
<td><code>iov_len</code></td>
<td>Length of the buffer.</td>
</tr>
</tbody>
</table>

This call writes the sum of the `iov_len` bytes of data.

If there is not enough available buffer space to hold the socket data to be transmitted, and the socket is in blocking mode, `writev()` blocks the caller until additional buffer space becomes available. If the socket is in a nonblocking mode, `writev()` returns -1 and sets the error code to EWOULDBLOCK. See "fcntl() — Control open file descriptors" on page 539 or "ioctl() — Control device" on page 1002 for a description of how to set nonblocking mode.

When the socket is not ready to accept data and the process is trying to write data to the socket:

- Unless FNDELAY or O_NONBLOCK is set, `writev()` blocks until the socket is ready to accept data.
- If FNDELAY is set, `writev()` returns a 0.
writev

- If O_NONBLOCK is set, writev() does not block the process. If some data can be written without blocking the process, writev() writes what it can and returns the number of bytes written. Otherwise, it sets the error code to EAGAIN and returns -1.

For datagram sockets, this call sends the entire datagram, provided that the datagram fits into the TCP/IP buffers. Stream sockets act like streams of information with no boundaries separating data. For example, if an application program wishes to send 1000 bytes, each call to this function can send 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, application programs using stream sockets should place this call in a loop, calling this function until all data has been sent.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, writev() returns the number of bytes written from the buffer.

A value of 0 or greater indicates the number of bytes sent, however, this does not assure that data delivery was complete. A connection can be dropped by a peer socket and a SIGPIPE signal generated at a later time if data delivery is not complete.

If unsuccessful, writev() returns −1 and sets errno to one of the following values:

<table>

___wsinit

___wsinit() — Reinitialize writable static

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Library</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

#include <unistd.h>

int __wsinit(void (*func_ptr)());

General description

The __wsinit() function reinitializes the writable static area of a module that was loaded by the fetch() library call. func_ptr must be a valid fetch pointer returned by fetch() or fetchep(). If the module contains C++, __wsinit() first runs any C++ static destructors, then __wsinit() runs the static constructors that are present in the load module.

Program variables with the static or extern storage class and writable strings receive the initial value defined in the program, if any initial value was assigned. The C header files contain external variable declarations for those variables defined by the POSIX, XPG4 and XPG4.2 standards. If the fetched module contains these variables, __wsinit() reinitializes them as described in z/OS XL C/C++ Programming Guide.

Returned value

If successful, __wsinit() returns 0.

If unsuccessful, __wsinit() returns -1 and sets errno to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>func_ptr is not a valid fetch pointer.</td>
</tr>
</tbody>
</table>

**w_statfs() — Get the file system status**

**Standards**

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

**Format**

```c
#include <sys/statfs.h>

int w_statfs(const char *filesystem, struct w_statfs *statbuf, size_t length);
```

**General description**

Gets status about a specific file system.

- **filesystem**: The name of the file system for which status is being retrieved. This file system name can be one of the following:
  - The name specified in the FILESYSTEM parameter of the ROOT or MOUNT statements in the BPXPRMxx parmlib member.
  - The name specified in a TSO/E MOUNT command.
  - The name returned on a previous call to w_getmntent().

- **statbuf**: A buffer that the status information is put into. The status information is mapped by the sys/statfs.h header file.
  - `int statfs_len` Length of `statfs`
  - `int statfs_blksize` Block size
  - `unsigned int statfs_total_space` Total space in block size units
  - `unsigned int statfs_used_space` Allocated space in block size units
  - `unsigned int statfs_free_space` Space available to unprivileged users in block size units

- **length**: The length of the buffer. The length of the buffer and the length of the structure are compared, and the shorter of the two is used to determine how much information to return in the buffer.

If the buffer length is zero, only the return value is returned. A process can use a length of zero to detect if a file system exists or not.

**Special behavior for XPG4.2:** `w_statfs()` is replaced by `w_statvfs()`.

**Returned value**

- If successful, `w_statfs()` returns the length of the data in the buffer.
- If unsuccessful, `w_statfs()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>A parameter was incorrectly specified.</td>
</tr>
</tbody>
</table>
Example

CELEBW36

/* CELEBW36 */
#define _OPEN_SYS
#include <sys/statfs.h>
#include <stdio.h>

main() {
    char fs[]="POSIX.ROOT.FS";
    struct w_statfs buf;

    if (w_statfs(fs, &buf, sizeof(buf)) == -1)
        perror("w_statfs() error");
    else {
        printf("each block in %s is %d bytes big\n", fs,
                buf.statfs_blksize);
        printf("there are %d blocks in use out of a total of %d\n",
                buf.statfs_used_space, buf.statfs_total_space);
        printf("in bytes, that's %.0f bytes used out of a total of %.0f\n",
                ((double)buf.statfs_used_space * buf.statfs_blksize),
                ((double)buf.statfs_total_space * buf.statfs_blksize));
    }
}

Output:
each block in POSIX.ROOT.FS is 4096 bytes big
there are 2089 blocks in use out of a total of 2400
in bytes, that's 8556544 bytes used out of a total of 9830400

w_statvfs() — Get the file system status

Standards

<table>
<thead>
<tr>
<th>Standards / Extensions</th>
<th>C or C++</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS UNIX</td>
<td>both</td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#define _OPEN_SOURCE 2
#include <sys/statvfs.h>

int w_statvfs(const char *filesystem, struct statvfs *buffer, size_t buflen);
```

General description

The `w_statvfs()` function gets status about a specific file system.

- **filesystem**
  - The name of the file system for which status is being retrieved. This file system name can be one of the following:
    - The name specified in the FILESYSTEM parameter of the ROOT or MOUNT statements in the BPXPRMxx parmlib member.
    - The name specified in a TSO/E MOUNT command.
    - The name returned on a previous call to `w_getmntent()`.

- **buffer**
  - A buffer that the status information is put into. The information is returned in a `statvfs` structure, as defined in the `sys/statvfs.h` header file. The elements of this structure are described in [`statvfs()` — Get file system information](#).
  - If the buffer length is zero, only the return value is returned. A process can use a length of zero to detect if a file system exists or not.

Returned value

If successful, `w_statvfs()` returns the length of the data in the buffer.

If unsuccessful, `w_statvfs()` returns -1 and sets `errno` to one of the following values:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EINVAL</td>
<td>A parameter was specified incorrectly. For example, the file system name (filesystem) was not found.</td>
</tr>
</tbody>
</table>

Example

```c
#define _OPEN_SOURCE 2
#include <sys/statvfs.h>
#include <stdio.h>

main() {
  char fs[]="POSIX.ROOT.FS";
  struct statvfs buf;

  if (w_statvfs(fs, &buf, sizeof(buf)) == -1)
```
w_statvfs

```c
    perror("w_statvfs() error");
    else {
        printf("each block in %s is %d bytes big\n", fs,
               buf.f_bsize);
        printf("there are %d blocks available out of a total of %d\n",
               buf.f_bavail, buf.f_blocks);
        printf("in bytes, that's %.0f bytes free out of a total of %.0f\n",
               ((double)buf.f_bavail * buf.f_bsize),
               ((double)buf.f_blocks * buf.f_bsize));
    }
```

**Output:**

Each block in POSIX.ROOT.FS is 4096 bytes big.
There are 2089 blocks available out of a total of 2400.
In bytes, that's 8556544 bytes free out of a total of 9830400.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Format

```c
#include <math.h>

double y0(double x);
double y1(double x);
double yn(int n, double x);
```

Compiler option: LANGLVL(SAA), LANGLVL(SAA2), or LANGLVL(EXTENDED)

General description

Bessel functions are solutions to certain types of differential equations.

The y0(), y1(), and yn() functions are Bessel functions of the second kind, for orders 0, 1, and n, respectively. The argument x must be positive. The argument n should be greater than or equal to zero. If n is less than zero, there will be a negative exponent in the result.

Note: This function works in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See "IEEE binary floating-point" on page 94 for more information about IEEE Binary Floating-Point.

Returned value

If successful, the function returns the calculated value.

For y0(), y1(), or yn(), if x is negative, the function sets errno to EDOM and returns -HUGE_VAL.

For y0(), y1(), or yn(), if x causes overflow, the function sets errno to ERANGE and returns -HUGE_VAL.

Special behavior for IEEE: If x is negative, y0(), y1(), and yn() return the value NaNQ. If x is 0, y0(), y1(), and yn() return the value -HUGE_VAL. In all cases, errno remains unchanged.

Example

```c
CELEBY01
/
/* CELEBY01

This example computes y to be the order 0 Bessel function of the first kind for x and z to be the order 3 Bessel function of the second kind for x.

*/
#include <math.h>
#include <stdio.h>
```
int main(void)
{
    double x, y, z;
    x = 4.27;
    
    y = y0(x);    /* y = -0.3660 is the order 0 bessel */
    /* function of the first kind for x */
    z = yn(3,x);  /* z = -0.0875 is the order 3 bessel */
    /* function of the second kind for x */

    printf("x = %f\n y = %f\n z = %f\n", x, y, z);
}

Library functions for the system programming C (SPC) facilities

**Restriction:** The SPC facility is not supported in AMODE 64.

The library functions specific to the System Programming C (SPC) environment are described in [z/OS XL C/C++ Programming Guide](#). These system programming functions are as follows:

- `__xhotc()`
- `__xhotl()`
- `__xhott()`
- `__xhotu()`
- `__xregs()`
- `__xsacc()`
- `__xsrvc()`
- `__xusr()`
- `__xusr2()`
- `__24malc()`
- `__4kmalc()`
Appendix A. XL C/C++ Macros

You can use the macros listed in Table 60 to write programs that use built-in services of the z/OS XL C/C++ product. The general purpose macros, labelled *General*, are predefined macros that are either ANSI-standard macros or extensions to the Systems Application Architecture (SAA) definition. The internal-use-only macros, labelled *Internal*, are developed by IBM to provide you with additional z/OS XL C/C++ functionality. Internal macros are defined in corresponding include files.

Appendix B. Function support table

Preinitialized Environments for Authorized Programs

Preinitialized Environments for Authorized Programs is a new feature of z/OS Language Environment. It is intended to provide support for authorized components or products to create preinitialized environments that are capable of executing C, C++, and Language Environment-conforming assembler code in supervisor state, on a TCB or an SRB, or in cross-memory mode (with some restrictions).

Table 62 on page 2545 lists all the functions in the z/OS XL C/C++ Run-Time Library and their support of Preinitialized Environments for Authorized Programs.

Note: The function table does not include compiler built-in functions (builtin.h).

Enhanced ASCII support

Restriction: Enhanced ASCII and __LIBASCII are independent, and should not be used together. Using Enhanced ASCII and __LIBASCII together is not supported.

Enhanced ASCII support provides the means to write z/OS XL C/C++ applications which will execute with ASCII data representation.

Enhanced ASCII support makes it easier to port internationalized C/C++ applications developed on or for ASCII platforms to z/OS platforms by providing conversion from ASCII to EBCDIC and EBCDIC to ASCII.

In order to use Enhanced ASCII support, a C or C++ module must be compiled specifying ASCII as the data representation. Application compile units will be bound to ASCII versions of external variables and interfaces at compile time if they:
1. Use headers to declare external variables and interfaces used in compile unit source.
2. Are compiled with the ASCII option.

New ASCII function-versions and other support functions have been added to the z/OS XL C/C++ Run-Time Library to handle ASCII data in files, data manipulations, and conversions between ASCII and EBCDIC. The compile-time binding will determine which ASCII or EBCDIC function version is called during run-time execution.

Table 62 on page 2545 lists all the functions in the z/OS XL C/C++ Run-Time Library and their support of Enhanced ASCII processing.

Note: The function table does not include compiler built-in functions (builtin.h).

Table 61 lists all the External Variables and their support status in Enhanced ASCII. For other information about these variables, see “External variables” on page 96.

For a description of Limitations to the use of Enhanced ASCII, see [z/OS XL C/C++ Programming Guide](http://www.ibm.com). 

**Enhanced ASCII extensions**

Applications compiled ASCII were permitted to use library functions that did not have ASCII support for character data with the understanding that all ASCII to EBCDIC conversion was the responsibility of the application.

As service updates or new releases extend Enhanced ASCII to previously unsupported functions, it is necessary to protect the ASCII applications that have been calling those functions (with user-supplied character conversions).

A new feature test macro is defined to control the exposure of extensions to Enhanced ASCII. This feature test macro is `_ENHANCED_ASCII_EXT` and should be set to a non-zero, numeric value indicating the level of Enhanced ASCII support desired. Otherwise, the default value of 0x41020000 is assumed, which will limit exposure to only the Enhanced ASCII support provided in the z/OS V1R2 base. Numeric values less than the default will behave as if the default were specified. The special value 0xFFFFFFFF provides exposure to all Enhanced ASCII support, regardless of the service level, available for the TARGET release.

Functions whose Enhanced ASCII support exposure is controlled by values of this feature test macro, other than the default value or the special 0xFFFFFFFF value, will have the specific value documented in Table 62 on page 2545.

**Note:** Functions which are introduced in a release, and include Enhanced ASCII support, are not controlled using this macro. For example, getnameinfo() first appears in z/OS V1R4 base and has Enhanced ASCII support. It is always available in its ASCII form since there was no prior release containing the function.

Table 62 on page 2545 lists all the functions in the z/OS XL C/C++ Run-Time Library and their support of Enhanced ASCII processing.
Library function support

Table 62 shows all the z/OS XL C/C++ Run-Time Library functions in alphabetical order, their support of Enhanced ASCII processing and their support of Preinitialized Environments for Authorized Programs.

Enhanced ASCII

Each function is identified by the extent to which it supports Enhanced ASCII processing:
- Yes = supports Enhanced ASCII.
- No = does not support Enhanced ASCII.
- Neutral = not sensitive to the issue of ASCII/EBCDIC character encoding.

Following is a list of values for feature test macro _ENHANCED_ASCII_EXT:

- 0x41020000  
z/OS V1.2 base support plus all functions first introduced in subsequent releases. This is the default.
- 0x41020010  
Includes support added with APAR PQ63405
- 0x41060000  
Includes support added in z/OS V1.6.
- 0x41070000  
Includes support added in z/OS V1.7
- 0x410A0000  
Includes support added in z/OS V1.10
- 0xFFFFFFFF  
Exposes all Enhanced ASCII support regardless of service level for the TARGET release.

Each higher value includes all support exposed with the lesser values.

Functions which are used for conversion to ASCII or EBCDIC are labelled with those data types.

Preinitialized Environments for Authorized Programs

Each function is identified by the extent to which it supports Preinitialized Environments for Authorized Programs:
- Yes the function supports Preinitialized Environments for Authorized Programs.
- No the function does not support Preinitialized Environments for Authorized Programs.

</table>
Notes:
1. ASCII support provided only for XPG4 (or higher) interface.
2. ASCII support provided only for X/Open Sockets interface.
3. ASCII support is for the sun_path element of struct sockaddr_un when working with the AF_UNIX address family.
4. Preinitialized Environments for Authorized Programs support provided only for non-posix signals.
5. Preinitialized Environments for Authorized Programs support provided only if locale file resides in a dataset, not in a z/OS UNIX file system.
6. Preinitialized Environments for Authorized Programs support provided only for non-posix form of the function.
7. Preinitialized Environments for Authorized Programs support provided only for non z/OS UNIX file system DLLs.
8. Preinitialized Environments for Authorized Programs support provided only when dispatchable unit mode is task and cross memory mode is PASN=HASN=SASN. In addition, the RECOVERY=ESTAE parameter must be used on the CELAAUTH macro invocation.
9. This function table does not include compiler built-in functions (builtin.h).
Appendix C. Accessibility

Publications for this product are offered in Adobe Portable Document Format (PDF) and should be compliant with accessibility standards. If you experience difficulties when using PDF files, you may view the information through the z/OS Internet Library website or the z/OS Information Center. If you continue to experience problems, send an email to mhvrcfs@us.ibm.com or write to:

IBM Corporation
Attention: MHVRCFS Reader Comments
Department H6MA, Building 707
2455 South Road
Poughkeepsie, NY 12601-5400
USA

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use software products successfully. The major accessibility features in z/OS enable users to:

- Use assistive technologies such as screen readers and screen magnifier software
- Operate specific or equivalent features using only the keyboard
- Customize display attributes such as color, contrast, and font size

Using assistive technologies

Assistive technology products, such as screen readers, function with the user interfaces found in z/OS. Consult the assistive technology documentation for specific information when using such products to access z/OS interfaces.

Keyboard navigation of the user interface

Users can access z/OS user interfaces using TSO/E or ISPF. Refer to z/OS TSO/E Primer and z/OS ISPF User's Guide for information about accessing TSO/E and ISPF interfaces. These guides describe how to use TSO/E and ISPF, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

z/OS information

z/OS information is accessible using screen readers with the BookServer or Library Server versions of z/OS books in the Internet library at:

http://www.ibm.com/systems/z/os/zos/bkserv/

One exception is command syntax that is published in railroad track format, which is accessible using screen readers with the Information Center, as described in “Dotted decimal syntax diagrams.”

Dotted decimal syntax diagrams

Syntax diagrams are provided in dotted decimal format for users accessing the Information Center using a screen reader. In dotted decimal format, each syntax element is written on a separate line. If two or more syntax elements are always present together (or always absent together), they can appear on the same line, because they can be considered as a single compound syntax element.
Each line starts with a dotted decimal number; for example, 3 or 3.1 or 3.1.1. To hear these numbers correctly, make sure that your screen reader is set to read out punctuation. All the syntax elements that have the same dotted decimal number (for example, all the syntax elements that have the number 3.1) are mutually exclusive alternatives. If you hear the lines 3.1 USERID and 3.1 SYSTEMID, you know that your syntax can include either USERID or SYSTEMID, but not both.

The dotted decimal numbering level denotes the level of nesting. For example, if a syntax element with dotted decimal number 3 is followed by a series of syntax elements with dotted decimal number 3.1, all the syntax elements numbered 3.1 are subordinate to the syntax element numbered 3.

Certain words and symbols are used next to the dotted decimal numbers to add information about the syntax elements. Occasionally, these words and symbols might occur at the beginning of the element itself. For ease of identification, if the word or symbol is a part of the syntax element, it is preceded by the backslash (\) character. The * symbol can be used next to a dotted decimal number to indicate that the syntax element repeats. For example, syntax element *FILE with dotted decimal number 3 is given the format 3 \* FILE. Format 3* FILE indicates that syntax element FILE repeats. Format 3* \* FILE indicates that syntax element * FILE repeats.

Characters such as commas, which are used to separate a string of syntax elements, are shown in the syntax just before the items they separate. These characters can appear on the same line as each item, or on a separate line with the same dotted decimal number as the relevant items. The line can also show another symbol giving information about the syntax elements. For example, the lines 5.1*, 5.1 LASTRUN, and 5.1 DELETE mean that if you use more than one of the LASTRUN and DELETE syntax elements, the elements must be separated by a comma. If no separator is given, assume that you use a blank to separate each syntax element.

If a syntax element is preceded by the % symbol, this indicates a reference that is defined elsewhere. The string following the % symbol is the name of a syntax fragment rather than a literal. For example, the line 2.1 %OP1 means that you should refer to separate syntax fragment OP1.

The following words and symbols are used next to the dotted decimal numbers:

- ? means an optional syntax element. A dotted decimal number followed by the ? symbol indicates that all the syntax elements with a corresponding dotted decimal number, and any subordinate syntax elements, are optional. If there is only one syntax element with a dotted decimal number, the ? symbol is displayed on the same line as the syntax element, (for example 5? NOTIFY). If there is more than one syntax element with a dotted decimal number, the ? symbol is displayed on a line by itself, followed by the syntax elements that are optional. For example, if you hear the lines 5 ?, 5 NOTIFY, and 5 UPDATE, you know that syntax elements NOTIFY and UPDATE are optional; that is, you can choose one or none of them. The ? symbol is equivalent to a bypass line in a railroad diagram.

- ! means a default syntax element. A dotted decimal number followed by the ! symbol and a syntax element indicate that the syntax element is the default option for all syntax elements that share the same dotted decimal number. Only one of the syntax elements that share the same dotted decimal number can specify a ! symbol. For example, if you hear the lines 2? FILE, 2.1! (KEEP), and 2.1 (DELETE), you know that (KEEP) is the default option for the FILE keyword.
In this example, if you include the FILE keyword but do not specify an option, default option KEEP will be applied. A default option also applies to the next higher dotted decimal number. In this example, if the FILE keyword is omitted, default FILE(KEEP) is used. However, if you hear the lines 2? FILE, 2.1, 2.1.1! (KEEP), and 2.1.1 (DELETE), the default option KEEP only applies to the next higher dotted decimal number, 2.1 (which does not have an associated keyword), and does not apply to 2? FILE. Nothing is used if the keyword FILE is omitted.

* means a syntax element that can be repeated 0 or more times. A dotted decimal number followed by the * symbol indicates that this syntax element can be used zero or more times; that is, it is optional and can be repeated. For example, if you hear the line 5.1* data area, you know that you can include one data area, more than one data area, or no data area. If you hear the lines 3*, 3 HOST, and 3 STATE, you know that you can include HOST, STATE, both together, or nothing.

Notes:
1. If a dotted decimal number has an asterisk (*) next to it and there is only one item with that dotted decimal number, you can repeat that same item more than once.
2. If a dotted decimal number has an asterisk next to it and several items have that dotted decimal number, you can use more than one item from the list, but you cannot use the items more than once each. In the previous example, you could write HOST STATE, but you could not write HOST HOST.
3. The * symbol is equivalent to a loop-back line in a railroad syntax diagram.

+ means a syntax element that must be included one or more times. A dotted decimal number followed by the + symbol indicates that this syntax element must be included one or more times; that is, it must be included at least once and can be repeated. For example, if you hear the line 6.1+ data area, you must include at least one data area. If you hear the lines 2+, 2 HOST, and 2 STATE, you know that you must include HOST, STATE, or both. Similar to the * symbol, the + symbol can only repeat a particular item if it is the only item with that dotted decimal number. The + symbol, like the * symbol, is equivalent to a loop-back line in a railroad syntax diagram.
Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not give you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement, or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurement may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrates programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. You may copy, modify, and distribute these sample programs in any form without payment to IBM for the purposes of developing, using, marketing, or distributing application programs conforming to IBM's application programming interfaces.
Policy for unsupported hardware

Various z/OS elements, such as DFSMS, HCD, JES2, JES3, and MVS, contain code that supports specific hardware servers or devices. In some cases, this device-related element support remains in the product even after the hardware devices pass their announced End of Service date. z/OS may continue to service element code; however, it will not provide service related to unsupported hardware devices. Software problems related to these devices will not be accepted for service, and current service activity will cease if a problem is determined to be associated with out-of-support devices. In such cases, fixes will not be issued.

Programming interface information

This document contains intended Programming Interfaces that allow the customer to write programs to obtain the services of IBM z/OS XL C/C++ and IBM Language Environment in z/OS.

Standards

The Institute of Electrical and Electronics Engineers and The Open Group have granted IBM permission to reprint portions of their documentation.

In the following statement, the phrase "this text" refers to portions of the system documentation.

Portions of this text are reprinted and reproduced in electronic form in the z/OS, from IEEE Std 1003.1, 2004 Edition, Standard for Information Technology -- Portable Operating System Interface (POSIX), The Open Group Base Specifications Issue 6, copyright 2001-2004 by the Institute of Electrical and Electronics Engineers, Inc and The Open Group. In the event of any discrepancy between these versions and the original IEEE and The Open Group Standard, the original IEEE and The Open Group Standard is the referee document. The original Standard can be obtained online at http://www.opengroup.org/unix/online.html.

Portions of this text are derived from IEEE Std 1003.1—1990, IEEE Standard Information Technology—Portable Operating System Interface (POSIX)—Part 1: System Application Program Interface (API) [C language], copyright 1990 by the Institute of Electrical and Electronic Engineers, Inc. No further reproduction of this material is permitted without the written permission of the publisher.

Portions of this document are derived from IEEE P1003.1a Draft 6 July 1991, Draft Revision to Information Technology—Portable Operating System Interface (POSIX), Part 1: System Application Program Interface (API) [C Language], copyright 1992 by the Institute of Electrical and Electronic Engineers, Inc. No further reproduction of this material is permitted without the written permission of the publisher.

Portions of this document are derived from IEEE Std 1003.2—1992, IEEE Standard Information Technology—Portable Operating System Interface (POSIX)—Part 2: Shells and Utilities, copyright 1990 by the Institute of Electrical and Electronic Engineers, Inc.
