Fourteenth Edition, September 2009

This book replaces the previous edition, SA22-7772-12, which is now obsolete. Changes or additions to text and illustrations are indicated by a vertical line to the left of the change.

This edition applies to IBM SMP/E for z/OS, V3R5, program number 5655-G44, and to all subsequent releases and modifications, unless otherwise indicated in new editions.

Changes or additions to text and illustrations are indicated by a vertical line to the left of the change.

Order IBM publications through your IBM representative or the IBM branch office serving your locality. Publications are not stocked at the address given below.

IBM welcomes your comments. A form for readers’ comments may be provided at the back of this publication, or you may address your comments to the following address:

International Business Machines Corporation

About this document

Use this publication when you need to:
• Allocate SMP/E data sets
• Call SMP/E exit routines or service routines
• Code application programs that use SMP/E application programming interfaces
• Code SMP/E modification control statements
• Code SMPPARM members
• Define which utility programs SMP/E can call
• Transform data elements so that they can be packaged inline

Bibliography

This section tells you more about the SMP/E library.
• The IBM SMP/E for z/OS, V3R5 publications are available as printable PDF files and BookManager-viewable softcopy at [http://www.ibm.com/servers/eserver/zseries/zos/bserv/](http://www.ibm.com/servers/eserver/zseries/zos/bserv/)
• Table 1 lists the IBM SMP/E for z/OS, V3R5 publications and briefly describes each one.
• For information on z/OS® publications and more information on the IBM SMP/E for z/OS, V3R5 books, see [z/OS Information Roadmap](http://www.ibm.com/servers/eserver/zseries/zos/bserv/)

The z/OS Basic Skills Information Center

The z/OS Basic Skills Information Center is a Web-based information resource intended to help users learn the basic concepts of z/OS, the operating system that runs most of the IBM® mainframe computers in use today. The Information Center is designed to introduce a new generation of Information Technology professionals to basic concepts and help them prepare for a career as a z/OS professional, such as a z/OS system programmer.

Specifically, the z/OS Basic Skills Information Center is intended to:
• Provide basic education and information about z/OS without charge
• Shorten the time it takes for people to become productive on the mainframe
• Make it easier for new people to learn z/OS
To access the z/OS Basic Skills Information Center, open your Web browser to the following Web site, which is available to all users (no login required):

http://publib.boulder.ibm.com/infocenter/zos/basics/index.jsp
Summary of changes

Summary of Changes
for SA22-7772-13
SMP/E Version 3 Release 5

This document contains information relevant to previous releases of SMP/E, in addition to information supporting SMP/E Version 3 Release 5. A vertical bar ( | ) in the left margin indicates changes to the text and illustrations.

Changed information

In Chapter 2, “SMP/E modification control statements,” on page 5, the following sections have been updated for corrections:

- “Hierarchical file system element MCS” on page 26
- “++HOLD MCS” on page 37

You may notice changes in the style and structure of some content in this document—for example, headings that use uppercase for the first letter of initial words only, and procedures that have a different look and format. The changes are ongoing improvements to the consistency and retrievability of information in our documents.

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

Summary of Changes
for SA22-7772-12
SMP/E Version 3 Release 5

This document contains information relevant to previous releases of SMP/E, in addition to information supporting SMP/E Version 3 Release 5. A vertical bar ( | ) in the left margin indicates changes to the text and illustrations.

New information

- The following sections have been updated to include the new FIXCAT or HOLDFIXCAT subentry:
  - “++HOLD MCS” on page 37 and “++RELEASE MCS” on page 100
  - “HOLDDATA entry (global zone)” on page 239 and Table 17 on page 371
  - “OPTIONS entry (global zone)” on page 292 and Table 22 on page 375
  - Table 27 on page 378 and “SYSMOD entry (global zone)” on page 336
- A description of SMPHRPT has been added.
- The parameter COMPAT has been added to “EXEC statement” on page 443.

Changed information

- The UTILITY INPUT subentry of “LMOD entry (distribution and target zone)” on page 249 has been updated to state the proper UCLIN syntax when the file is located in the UNIX® file system.
The description for the SOURCEID operand has been updated in the following places to describe the long SOURCEID support:
- "++ASSIGN MCS" on page 8
- Table 27 on page 378 and Table 28 on page 381
- Table 61 on page 513

The SMPOUT DD and the PAGELEN entry "OPTIONS entry (global zone)" on page 292 and Table 22 on page 375 have been updated to include SMPRPT as one of the applicable data sets.

This document contains terminology, maintenance, and editorial changes, including changes to improve consistency and retrievability.

Summary of changes
for SA22-7772-11
SMP/E Version 3 Release 4

This revision reflects the deletion, addition, or modification of information to support miscellaneous maintenance items. A vertical bar ( | ) in the left margin indicates changes to the text and illustrations.

New information
- In Chapter 7, "Writing UNIX shell scripts," on page 413, a new environment variable (PATH) is added to the list of environment variables set by SMP/E in the Designing a shell script for SMP/E processing section.
- In Chapter 12, "GIMIAPI: Copy utility invocation program," on page 503, a description of the SMPJHOME DD statement is added to the JCL statements used in the DEIINST or HFSINST job section.

Changed information
- In Chapter 4, "SMP/E data sets and files," on page 141, the "Use" of the SMPJHOME DD statement is updated.
- In Chapter 2, "SMP/E modification control statements," on page 5, the "++ZAP MCS" usage note for the NAME statement is updated to add a third way to code the name statement.

This document contains terminology, maintenance, and editorial changes, including changes to improve consistency and retrievability.

Summary of changes
for SA22-7772-10
SMP/E Version 3 Release 4

This revision reflects the deletion, addition, or modification of information to support miscellaneous maintenance items.

The following statement in the list of syntax rules in Chapter 1, "Syntax notation and rules," on page 1, has been removed: "Include at least one blank between each operand." It is recommended but not required to do so.

In Chapter 4, "SMP/E data sets and files," on page 141, the data set descriptions for the SMPWRK1, SMPWRK2, SMPWRK3, SMPWRK4, and SMPWRK6 data sets have been updated.
In Chapter 5, “SMP/E data set entries,” on page 171, the ORDERRET option under the ORDER entry has been updated.

In Chapter 11, “Service routines,” on page 447, syntax notes in the GIMUNZIP and GIMZIP service routines have been updated to clarify that a comment may appear between a start-tag and its matching end-tag, but never within a tag; the example of using GIMZIP has been updated to include the comment.

This document contains terminology, maintenance, and editorial changes, including changes to improve consistency and retrievability.

Summary of changes
for SA22-7772-09
SMP/E Version 3 Release 4

This revision reflects the deletion, addition, or modification of information to support miscellaneous maintenance items.

These updates are made to support APAR IO03469.

New information
• Two new data sets, SMPCPATH and SMPJHOME, have been added in Chapter 4, “SMP/E data sets and files,” on page 141.

This document contains terminology, maintenance, and editorial changes, including changes to improve consistency and retrievability.
Chapter 1. Syntax notation and rules

This chapter explains the syntax notation and rules for SMP/E modification control statements (MCSs) and OPCODE members used by SMP/E. It describes:

• How to read the notation used to show how control statements should be coded
• The rules to follow when coding control statements

How to read the syntax diagrams

Throughout this publication, the structure defined below is used in describing syntax:

• Read the syntax diagrams from left to right, from top to bottom, following the path of the line.
  The ➞ symbol indicates the beginning of a statement.
  The → symbol indicates that the statement syntax is continued on the next line.
  The ← symbol indicates that a statement is continued from the preceding line.
  The ➞ symbol indicates the end of a statement.
• Required items appear on the horizontal line (main path).

▸—STATEMENT—required_item—▸

• Optional items appear below the main path.

▸—STATEMENT—optional_item

• If you can choose from two or more items, they appear in a vertical stack.
  If you must choose one of the items, one item of the stack appears on the main path.

▸—STATEMENT—required_choice1—required_choice2—▸

If choosing one of the items is optional, the entire stack appears below the main path.

▸—STATEMENT—optional_choice1—optional_choice2

If one of the optional items is the default, it appears above the main path and the remaining choices will be shown below.

▸—STATEMENT—default_choice1—optional_choice2—optional_choice3
Syntax notation and rules

- Keywords appear in uppercase (for example, PARM1). They must be spelled exactly as shown.
- Variables appear in lowercase italics (for example, parmx). They represent user-supplied names or values.

An arrow returning to the left above the main line indicates an item that can be repeated.

A repeat arrow above a stack indicates that you can make more than one choice from the stacked items, or repeat a single choice.
- A repeat arrow above a stack of keywords means that you can enter one or more of the keywords. However, each keyword can be entered only once.
- A repeat arrow above a variable means that you can enter one or more values for the variable. However, each value can be entered only once.
- If punctuation marks, parentheses, arithmetic operators, or other such symbols are shown, you must enter them as part of the syntax.
- Sometimes a single substitution represents a set of several parameters. For example, in the following diagram, the callout Parameter Block can be replaced by any of the interpretations of the subdiagram that is labeled Parameter Block:

Parameter Block:

Syntax rules for MCS and SMPPARM members

Follow these rules when you code SMP/E modification control statements (MCS) and SMPPARM member control statements:

- SMP/E input is case-sensitive. Use uppercase letters to enter all SMP/E keywords. Enter operands in the same case as the intended operand values. Enter the text within a comment in any case you prefer.
- Start each statement on a new logical 80-byte record.

For MCSs, do the following:
- Code the “++” for the MCS in columns 1 and 2.
- Code the MCS name on the same line as the “++”.

For OPCODE member control statements, do the following:
- Code the KEY=xxx operand first.
- Do not continue OPCODE member control statements on a subsequent record.
Syntax notation and rules

Note: Except for these restrictions, the SMP/E MCSs and OPCODE member control statements can begin and end anywhere up to and including column 72.

- You can code optional information in any order, except where noted in the syntax and operand descriptions.
- Separate operands and their values with a blank or comma.

Note: Although the syntax diagrams show only commas when indicating the allowable separator characters for repeating values, one or more blank characters may be used instead to separate repeating values.

- You can continue a statement on more than one line. SMP/E assumes a statement is continued if it did not find a period (.) before column 73.

Notes:
1. OPCODE members are an exception—they cannot span multiple records.
2. If an operand’s value must span multiple lines and that value is delimited by quotation marks, the value should extend up to and including column 72 and restart on column 1 of the next line. Put a quotation mark before the value and another after the value, but do not add extra quotation marks where the value spans lines. Blanks within the quoted value are considered to be part of the value, including any blanks at the beginning of a continuation line.

- Start comments with “/*” and end them with “*/”. The first “*/” encountered after the initial “/*” will end the comment. A comment can appear anywhere within or after a statement, but should not start before a statement, nor begin in column 1. (When “/*” starts in column 1, it indicates the end of an input data set.) A comment after the ending period must start on the same line as the period. You cannot specify any additional operands or comments after that final comment. For example, you can code a comment like this:

```plaintext
SET BDY(MVSTST1) /* Comment after period continued on subsequent records is okay. */
```

However, you should not code a comment like this:

```plaintext
SET BDY(MVSTST1) . /* Comment after period okay */ /* but this comment will give a syntax error */
```

This causes a syntax error at the start of the second comment after the period.

- Comments can be in single-byte characters (such as English alphanumeric characters) or in double-byte characters (such as Kanji).
- End each statement with a period.
- SMP/E completes processing for one statement before it starts processing the next one.
- SMP/E ignores columns 73 through 80. If data, such as a period, is specified beyond column 72, SMP/E ignores it and indicates an error in the statement after the one containing that data.

Syntax rules for XML statements

XML statements may be coded in the CLIENT, SERVER, SYSIN, file attribute, and package attribute files for use with the GIMZIP and GIMUNZIP service routines.

The following syntax rules apply to XML statements:
- SMP/E ignores columns 73 through 80.
Syntax notation and rules

- All tags have a starting and ending delimiter specified as <keyword> and </keyword>, respectively.
- Any tag that does not contain another tag (that is, nested tags) may have an ending delimiter of either </keyword> or just />.

```
<start-tag>
  attribute="attribute value"
</end-tag>
```

```
<start-tag>
  attribute="attribute value"
/>
```

- Comments must begin with "<!--" and end with "-->". All data between the "<!--" and the "-->" is ignored. Comments may not be placed inside a tag.
- Any text not contained within comment delimiters is syntax checked.
- Tags are case sensitive; attribute values may be mixed case.
- A tag is not required to start on a new line.
- XML tag names and attribute values may not contain the XML markup characters, '<', '>', and '&'.

Comments must begin with "<!--" and end with "-->". All data between the "<!--" and the "-->" is ignored. Comments may not be placed inside a tag.
Chapter 2. SMP/E modification control statements

Each SYSMOD processed by SMP/E is composed of two distinct types of data: instructions to SMP/E identifying the elements in the SYSMOD and how to install them, and the actual element replacements or updates. The instructions to SMP/E consist of a series of control statements, called modification control statements (or MCSs). This chapter describes the various MCSs that are processed by SMP/E.

Building SYSMODs (packaging)

Building SYSMODs (“packaging”) includes combining the appropriate MCS statements with software elements to create one or more SYSMODs. Depending on the type of SYSMODs you are building and how you plan to distribute them, packaging can also involve putting the SYSMODs in the proper format on the distribution medium.

Although this book describes the syntax of SMP/E MCS statements, it does not contain all the information you need to use these statements for packaging SYSMODs.

- To package function SYSMODs and the associated service (PTF SYSMODs and APAR SYSMODs), you must use this book along with z/OS Packaging Rules, which contains the rules, restrictions, and recommendations for packaging SYSMODs.
- To package USERMOD SYSMODs, use this book along with SMP/E User’s Guide, which steps you through building a USERMOD and provides USERMOD examples that you might find helpful.

Notes:

1. Each section describing an individual MCS has examples of SYSMODs containing that MCS. In the examples, the MCS being described is underlined. This is done only to make that MCS stand out; it does not imply that any special processing must be done to enter that data.

2. The examples of MCSs do not show the use of all the operands for each MCS. When you want to know how to use a particular operand for a specific MCS, first check the section describing that MCS. If the operand is not shown in an example there, check the index entry for the desired operand to see which other MCSs also contain that operand. Then check the examples under those MCSs. Examples of the use of an operand for one MCS can often illustrate its use for another MCS.
The ++APAR MCS identifies a service SYSMOD. This type of SYSMOD is a temporary corrective fix to the elements of target system and distribution libraries. All other MCSs for this SYSMOD follow this header MCS. For more information about packaging an APAR fix, see z/OS Packaging Rules.

**Syntax**

```
++APAR MCS
 ++APAR(sysmod_id) DESCRIPTION(description) FILES(number)
 RFDSNPFX(relfile_prefix) REWORK(level)
```

**Operands**

**DESCRIPTION**
specifies a descriptive name to be associated with this SYSMOD.
- DESCRIPTION can also be specified DESC.
- The DESCRIPTION value can be in single-byte characters (such as English alphanumeric) or double-byte characters (such as Kanji).
- The DESCRIPTION value can contain up to 64 bytes of data, including blanks. Extra blanks, as well as leading and trailing blanks, are deleted. (For double-byte data, the 64-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters. Shift-in and shift-out pairs with only blanks between are compressed).
- The DESCRIPTION value can span multiple 80-byte records. Data must continue up to and including column 72 and begin in column 1 of the next line. All data past column 72 is ignored. For single-byte data, the break does not translate to a blank unless a blank is explicitly coded in column 72 of the first line or in column 1 of the second line. For double-byte data, each line must contain both the shift-out and shift-in characters.
- If DESCRIPTION is specified, it must contain at least one non-blank character.
- If parentheses are included in the text, they must be in matched pairs.

**FILES**
specifies the number of relative files belonging to this APAR fix. It can be a decimal number from 1 to 9999. For information about packaging SYSMODs in relative files, see z/OS Packaging Rules

**Notes:**
1. Although SMP/E allows you to package APAR fixes in relative files, they are not generally packaged in this format.
2. If a packager uses a high-level qualifier on RELFILE data sets, the RFDSNPFX operand on the header MCS (not the RFPREFIX operand on the RECEIVE command) must be used to identify that high-level qualifier.
++APAR MCS

REWORK
specifies the level of this SYSMOD, which was reworked for minor changes. Up to eight numeric characters can be specified.

For SYSMODs supplied by IBM, the REWORK level is yyyyddd, where yyyy is the year the SYSMOD was reworked and ddd is the Julian date.

REWORK allows an updated SYSMOD to be automatically received again, as long as it is more recent than the version that has already been received. This takes the place of rejecting the SYSMOD and receiving it again.

Note: If a SYSMOD appears more than once in the SMPPTFIN data set, the first occurrence may be received. However, none of the subsequent versions of the SYSMOD are received, even if their rework level is higher than the one for the first version of the SYSMOD. (Message GIM40001E is issued for each of the subsequent versions of the SYSMOD.)

RFDSNPFX
identifies to SMP/E the prefix used in the relative file data set names for this SYSMOD. SMP/E uses this prefix when allocating data set names for the SYSMOD’s relative files during RECEIVE processing.

• This operand can be specified only if the FILES operand is also specified.
• The RFDSNPFX value specified on the MCS statement must match the actual prefix used in the data set names for the associated relative files.

For example, if the names of the relative files created for a SYSMOD start with “IBM”, as in IBM.sysmod_id.F1, the header MCS statement for the SYSMOD must specify RFDSNPFX(IBM) so SMP/E knows which prefix to use when allocating the data set names for the SYSMOD’s relative files during RECEIVE processing.

• Following standard data set naming conventions, the prefix can be from 1 to 8 alphanumeric or national ($, #, @) characters or a dash (–).

To enable full Security Server protection for tape data sets and to keep the tape header within the 17-character limit (including periods), you should limit the prefix to 1 to 3 characters. If the name exceeds the 17-character limit, only the rightmost 17 characters are written to the tape header label.

sysmod_id
specifies a unique 7-character system modification identifier for the APAR fix. See “Naming conventions for SYSMODs” on page 517 for more information.

Examples
Here is an example of a SYSMOD containing a ++APAR statement for a temporary fix to module IFBMOD01. As the example shows, this fix is needed to answer APAR AZ12345 on an MVS™ system. The module must be at the service level provided by PTF UZ00004 for function FXY1040.

++APAR(AZ12345) /* APAR type fix */.
++VER(2038) FMID(FXY1040) /* for MVS product FXY1040 */
      PRE(UZ00004) /* at this service level. */.
++ZAP(IFBMOD01) /* Change to one module */.
      DISTLIB(AOSFB) /* in this DLIB. */.
...
... IMASPZAP control statements
...

Chapter 2. SMP/E modification control statements 7
++ASSIGN MCS

++ASSIGN MCS

The ++ASSIGN MCS assigns a source identifier (source ID) to one or more specified SYSMODs, as long as those SYSMODs are in the SMPPTS data set by the end of RECEIVE processing.

Syntax

```
++ASSIGN MCS
  SOURCEID(source_id) TO(sysmod_id)
```

Operands

**SOURCEID**

is a 1- to 64-character string identifying the source of the SYSMODs being processed. SMP/E associates the SOURCEID value with the SYSMODs named on the ++ASSIGN MCS. The SOURCEID value can consist of any nonblank character (X'41' through X'FE') except single quotation mark ('), asterisk (*), percent (%), comma (,), left parenthesis (() and right parenthesis ()).

**TO**

specifies the SYSMODs with which the source ID is to be associated.

Usage Notes

- The source ID specified on the ++ASSIGN statement is added to any source ID that was assigned to a specified SYSMOD by the RECEIVE command. It is also added to any source IDs currently associated with a specified SYSMOD that has already been received.

- ++ASSIGN statements are processed only when the SMPPTFIN data set is processed.
  - If the whole SMPPTFIN data set is processed, all ++ASSIGN statements are processed.
  - If only selected SYSMODs are processed, the ++ASSIGN statements for those SYSMODs are processed.

- ++ASSIGN statements are not processed when only the SMPHOLD data set is being processed.

- The SOURCEID and TO values must be validly specified and cannot be blank or null. For more information about source ID naming conventions, see "Naming conventions for source IDs" on page 516.

- The source ID is not assigned to any SYSMODs that are not in the global zone.

- The same SYSMOD cannot appear more than once on a single ++ASSIGN MCS.

- If the same SYSMOD appears on more than one ++ASSIGN MCS, all the source IDs are associated with the SYSMOD.

- The ++ASSIGN MCS is used in the SMPPTFIN data set and can be placed between, before, or after SYSMODs, ++FEATURE MCS, or ++PRODUCT MCS. It must be followed by one of the following: a ++APAR, ++FEATURE, ++FUNCTION, ++PRODUCT, ++PTF, or ++USERMOD MCS; another
**++ASSIGN MCS**

++ASSIGN MCS; or an end-of-file. If one of these does not follow, SMP/E does not receive the SYSMOD being processed, and it skips the ++ASSIGN MCS.

**Examples**

Here are some examples of ++ASSIGN statements for SYSMODs from several preventive service levels that have been merged into the same ESO tape. A ++ASSIGN MCS has been placed between the groups of SYSMODs to identify their source:

```plaintext
++ASSIGN SOURCEID(PUT0701) /* service level 0701. */
TO(UZ12345,UZ12346).
++PTF(UZ12345) /* PTF UZ12345 */.
++VER(Z038) FMID(HXP1100) /* for MVS function HXP1100. */.
++MOD(A) DISTLIB(DN554) /* Update module A. */.
A
++PTF(UZ12346) /* PTF UZ12346 */.
++VER(Z038) FMID(HXP1200) /* for MVS function HXP1200. */.
++MOD(C) DISTLIB(DN554) /* Update module C. */.
C
++ASSIGN SOURCEID(PUT0702) /* service level 0702. */
TO(UZ12347,UZ12348).
++PTF(UZ12347) /* PTF UZ12347 */.
++VER(Z038) FMID(HXP1100) /* for MVS function HXP1100. */.
++IF FMID(HXP1200) THEN REQ(UZ12348).
++MOD(D) DISTLIB(DN554) /* Update module D. */.
D
++MOD(D) DISTLIB(AOS12) /* Update module D. */.
++MOD(A) DISTLIB(AOS12) /* Update module A. */.
A
++MOD(B) DISTLIB(AOS12) /* Update module B. */.
B
```
Data element MCSs describe elements that are not macros, modules, or source. Data elements have the following characteristics:

- A data element must be a member of a PDS or PDSE (DSORG=PO) or reside in a sequential data set (DSORG=PS).
- The record format (RECFM) must be F, FA, FM, FS, FB, FBA, FBM, FBS, V, VA, VM, VB, VBA, VBM, VS, or VBS.
- The LRECL for a data element must be from 1 to 32,654.
- The records can be numbered or unnumbered.
- A VSAM data set can be a data element if it is in REPRO format. However, after the data is installed by SMP/E, you must run an AMS REPRO job to create the original form of the VSAM data.

Any type of data element may be installed in any distribution or target library that meets these requirements. For example, CLIST data elements can be installed into variable block target libraries.

When copying a data element during APPLY, ACCEPT, or RESTORE processing, it may be necessary for SMP/E to perform the copy itself, rather than invoking the copy utility. SMP/E performs the copy when:

- The target library or distribution library is a sequential data set.
- The data element must be reformatted to be compatible with the target or distribution library. (For more information on the reformattting of data elements, see the section on reformattting data elements in the APPLY command chapter in [SMP/E Commands](#).

There are MCSs to replace data elements, just as there are MCSs to replace other types of elements. (There are no MCSs to update data elements.) Table 2 shows the MCSs that can be used for data elements.

**Table 2. MCS statements for data elements.** If an element is provided in only one language, the x’s can be left off the MCS. If an element is provided in more than one language, replace the x’s with the appropriate value from Table 3 on page 13.

| ++UTINxxx     | General utility input                                                       |
| ++UTOUTxxx    | General utility output                                                      |

**Supporting several languages**

Some types of elements, such as panels, messages, or text, may have to be translated into several languages. In these cases, the corresponding MCSs contain xxx to indicate which language is supported by a given element. Figure 1 on page 12 shows an example where product XX1 must provide both English and French support for a message module, a panel, a panel message, and a sample element.
Data element MCS

| ++FUNCTION(FXX1101). | ++FUNCTION(FXX1102). |

| SYSLIB(SZZZSAME). | SYSLIB(SZZZSAME). |

Figure 1. Example of using data element MCSs

Notes:
1. The message modules can be in the same distribution library, because the element names are different.
2. For the panels, dialog messages, and samples, there is a different element type for each language version of an element. Therefore, the element name can remain the same for all the languages in which the element is supported. However, elements with the same name must be installed in different libraries. (SMP/E does not check whether different types of data elements have the same name. Likewise, SMP/E does not prevent elements with the same name from being installed in the same libraries.)

Table 3 on page 13 shows the xxx values that can be used when the MCS indicates the language being supported.

Syntax

The syntax to be used depends on the processing to be done for the element:
- Adding or replacing the element
- Deleting the element

Adding or replacing a data element
Data element MCS

Deleting a data element

Data element MCS

ALIAS
specifies the alias names for the data element in both the target and distribution libraries.

You can use ALIAS when data elements of the same type must be defined in the same zone and must have the same name for programming access. In this case, you can specify the common name on ALIAS and a unique name as the data element name.

DELETE
indicates that the element and all of its alias names are to be removed from the target libraries, the distribution libraries, and the SMP/E data sets.

Notes:
1. DELETE is mutually exclusive with all other operands except DISTLIB and VERSION.
2. If the element statement is in a base function, you may want to use the DELETE operand on the ++VER MCS to delete the previous release, rather than on the element statement to delete a specific element.
3. Specification of the DELETE operand results in all alias names of the data element being deleted along with the data element identified.

DISTLIB
specifies the ddname of the distribution library for the data element.

Notes:
1. DISTLIB must be specified if the element has not been previously recorded on the target zone or distribution zone.
2. If a data element entry already exists in the target zone or distribution zone and the value currently in that entry does not match that specified in the DISTLIB operand, the SYSMOD is not applied or accepted.

element
specifies the type of element. Table 2 on page 10 shows the MCSs used for the various element types.

FROMDS
identifies the partitioned data set that contains this element.

Note: The FROMDS operand and its DSN, NUMBER, VOL, and UNIT suboperands are included in the MCS generated by the BUILDMCS command. IBM does not intend the FROMDS operand to be used in manually coded MCS.

DSN
specifies the dsname of the FROMDS data set. The specified data set name
must conform to standard data set naming conventions and cannot contain parentheses. The maximum length of the entire name is 44 characters (including the periods).

**NUMBER**
specifies a number that SMP/E is to use when assigning a name to the SMPTLIB data set associated with this FROMDS data set. (This is similar to the way the relative file number is used in RELFILE processing.)

**VOL**
specifies, for an uncataloged data set, the volume serial number of the volume containing the FROMDS data set. If specified, this volume identifier must be from 1 to 6 alphanumeric characters.

VOL may be omitted for a cataloged data set.

**UNIT**
specifies, for an uncataloged data set, the UNIT type containing the FROMDS data set. If specified, the UNIT value must be from 1 to 8 characters and must conform to standard UNIT naming conventions.

SMP/E accepts any nonblank characters specified between the open and close parentheses, up to a maximum length of 8.

UNIT may be omitted for a cataloged data set.

**Note:** FROMDS is mutually exclusive with DELETE, RELFILE, and TXLIB.

**name**
specifies the name of the element to be replaced. The name can contain any alphanumeric characters and $, #, @, or hex C0.

**RELFILE**
specifies which relative file associated with the SYMMOD contains this element. This operand is required if you provide the element in RELFILE format, rather than inline or in a TXLIB data set.

**Note:** RELFILE is mutually exclusive with DELETE, FROMDS, and TXLIB.

**RMID**
specifies the last PTF that replaced this data element. This operand can be used only in a service-updated function, and the specified PTF must be integrated into the function.

**Note:** RMID is mutually exclusive with DELETE.

**SYSLIB**
specifies the ddname of the target library for the specified element.

**Note:** SYSLIB is mutually exclusive with DELETE.

**TXLIB**
specifies the ddname of the partitioned data set containing the element. This operand is required if the element is provided in a TXLIB data set rather than inline or in RELFILE format.

**Notes:**
1. SMPTLIB cannot be used as a value on the TXLIB operand.
2. TXLIB is mutually exclusive with DELETE, FROMDS, and RELFILE.

**VERSION**
specifies one or more function SYMMODs that currently contain the element.
Data element MCS

The function containing the data element statement takes over ownership of the element from the specified functions.

When VERSION is specified on an element statement, it overrides any VERSION operand values specified on the ++VER MCS.

Usage Notes

- If the element is packaged inline, it must immediately follow the data element MCS and must not contain any records that start with the characters ++. Neither FROMDS, nor RELFILE, nor TXLIB can be specified on the data element MCS.
- To be packaged inline, a data element must contain fixed-block-80 records. If the original format of the element is not fixed-block-80 records, you can use GIMDTS to transform the element into the required format before packaging it. Later, when SMP/E installs the element, it is changed back to its original format. For more information about using GIMDTS, see “GIMDTS: Data transformation service routine” on page 450.
- If the data element is packaged in a TXLIB data set, the ddname specified on the TXLIB operand is required during APPLY and ACCEPT processing.
- For information about packaging SYSMODs in RELFILE, TXLIB, or inline format, see “z/OS Packaging Rules”.

Examples

The following examples are provided to help you use the data element MCS:

Example 1: Packaging a CLIST in a function

Here is an example of a SYSMOD containing a ++CLIST statement to install your CLIST and have SMP/E track any changes to it. It can be packaged as a function, as shown below:

```clist
++FUNCTION(MYCLSTI)          /* Function.              */.
++CLIST(CLIXI)               /* Install this CLIST */.
    TXLIB(NEWSMP)/* from this TXLIB */.
    DISTLIB(AMACLIB) /* into this DLIB and */.
    SYSLIB(ISPCLIB) /* this target library. */.
```

Example 2: Packaging a renamed CLIST

Suppose that, for some reason, you need to rename CLIST1, which was introduced in “Example 1: Packaging a CLIST in a function.” The new name is to be CLISTX. You do not need to change anything else about the CLIST. Here is an example of a SYSMOD containing the data element statements needed to package this renamed CLIST:

```clist
++USERMOD(USR0001)          /* User modification */.
++CLIST(CLIXI)               /* to user application. */.
    DELETE                  /* CLIST. */.
    ++CLIST(CLIXI)           /* Add the renamed CLIST */.
        TXLIB(NEWSMP)/* from this TXLIB */.
        DISTLIB(AMACLIB) /* into this DLIB and */.
    SYSLIB(ISPCLIB) /* this target library. */.
```

You must ensure that the renamed CLIST is in the TXLIB library (NEWSMP) used to provide SMP/E with the element.
++DELETE MCS

During APPLY processing, the ++DELETE MCS deletes a load module and any known alias or symbolic link names from a target library and the associated target zone. It can also delete alias or symbolic link names without deleting the load module itself.

During ACCEPT processing, if inline JCLIN was processed, the distribution zone’s entries are updated to reflect the ++DELETE changes. The target libraries and target zone entries are not updated.

Note: This change is not reversible. You cannot restore the SYSMOD containing the ++DELETE MCS; therefore, you cannot recreate the deleted load module.

Syntax

```
++DELETE MCS
```

```
++DELETE{name} SYSLIB(ALL) ALIAS{alias} SYSLIB{ddname}
```

Operands

ALIAS

specifies that only the indicated alias or symbolic link names are to be deleted, but not the load module.

- An alias name can have up to 1023 characters.

  Although a load module residing in a PDSE can have an alias name greater than 8 characters, the ++DELETE statement cannot be used to delete such an alias value. To delete such an alias value without deleting the load module, you need to resupply JCLIN to define the load module without providing an ALIAS statement for the alias value to be deleted. Make sure to also include a ++MOD statement for a module in the load module to force SMP/E to relink the load module.

- Single apostrophes must be used as delimiters for an alias name in these cases:
  - The alias name contains a character that is not uppercase alphabetic, numeric, national ($, #, or @), slash (/), plus (+), hyphen, period, or ampersand (&).
  - The alias name is continued on another line in the control statement. Apostrophes used as delimiters do not count as part of the 1023-character limit.

- If an apostrophe is part of the alias name and is not a delimiter, it needs to be doubled. These two apostrophes count as 2 characters in the 1023-character limit.
++DELETE MCS

- Characters specified must be in the range X'41' through X'FE'. Unlike the binder, SMP/E does not support shift-in (X'0F') and shift-out (X'0E') characters.
- When processing the ++DELETE statement, SMP/E uses the alias name as is, and does not enforce any rules the binder might be using as a result of the CASE execution parameter.

**Notes:**

1. **Do not** specify this operand if you also want to delete the load module.
   ++DELETE without the ALIAS operand automatically deletes any alias or symbolic link names associated with the load module.
2. When **ALIAS** is specified, SMP/E checks the ALIAS control statements in the LMOD entry to verify that the specified name is actually an alias or symbolic link of the load module. For copied load modules, instead of looking for ALIAS control statements, SMP/E checks the corresponding MOD entry's TALIAS subentries.
3. If a valid **ALIAS** value is specified, SMP/E deletes the alias from all known target libraries, including any associated side deck library, no matter what was coded for SYSLIB. SMP/E overrides the SYSLIB value with SYSLIB(ALL).
4. When you specify **ALIAS** to delete an alias for a load module, you must reflect this change using JCLIN. To do this, include a ++JCLIN statement with JCLIN data containing a link-edit step for the load module, with the alias deleted from the list of aliases on the link-edit ALIAS statement. This causes SMP/E to replace the alias list in the LMOD entry.

**name**

specifies the name of the load module to be deleted.

**SYSLIB**

specifies the ddname of the target library where the load module resides.

- If **ALL** is specified, the load module is deleted from all target libraries defined in the target zone.
- If a single ddname is specified, the load module is deleted only from the indicated target library.

If the load module or alias is to be deleted from two target libraries, a second ddname can be specified. However, to make sure the module is deleted from both libraries, you should use **ALL** instead.

- For load modules with a SYSLIB allocation (or load modules having a CALLLIBS subentry), specifying **ALL** or deleting the load module from all the target libraries in which it resides, deletes the base version of the load module from the SMPLTS library.
- For load modules with a side deck library, specifying **ALL** or deleting the load module from all the target libraries in which it resides, deletes the associated definition side deck from the side deck library.

**Note:** If **ALIAS** is specified, SMP/E deletes the alias from all known target libraries, including any associated side deck library, no matter what was coded for SYSLIB. SMP/E overrides the SYSLIB value with SYSLIB(ALL).

**Usage Notes**

- **SYSLIB** must always be specified to identify the affected target libraries.
++DELETE MCS

- **ALIAS** should be specified only if alias names, and not load modules, are to be deleted.
- ++DELETE statements must follow any ++VER and ++IF statements and must precede any ++JCLIN or element MCSs.
- Regardless of the order in which ++MOVE, ++RENAME, and ++DELETE statements are coded in a SYSMOD, they are always processed in this order for APPLY and ACCEPT:
  1. ++MOVE
  2. ++RENAME
  3. ++DELETE

Afterwards, the ++JCLIN statements are processed, and then the element statements are processed.

**Note:** You cannot restore the SYSMOD containing the ++DELETE MCS.

**Examples**

The following examples are provided to help you use the ++DELETE MCS:

**Example 1: Deleting a single load module**

Here is an example of a SYSMOD containing a ++DELETE statement that deletes load module LMODA from SYS1.LINKLIB:

```language-none
++PTF(UR01234) /* Identify the PTF number. */.
++VER(2038) FMID(HXY1300) /* For MVS function HXY1300. */.
++IF (ESY1300) THEN /* If ESY1300 is installed */.
  REQ(UR12399) /* UR12399 is required. */.
++HOLD(UR01234) /* Hold UR01234. */.
  FMID(HXY1300) /* For MVS function HXY1300. */.
  SYSTEM /* System hold */.
  REASON(DELETE) /* because of ++DELETE. */.
  COMMENT(THIS DELETION OF LMODA FROM LINKLIB IS IRREVERSIBLE).
++DELETE (LMODA) /* Delete load module LMODA */.
SYSLIB(LINKLIB) /* from LINKLIB. */.
++JCLIN /* JCLIN follows. */.
  *
  *
++MOD(MODAA) DISTLIB(AOSXX) /* Element MCS statements. */.
```

**Example 2: Deleting an alias from a load module**

Assume that IBM has shipped you a PTF that deletes an alias for load module LMODA. Here is an example of a SYSMOD containing a ++DELETE statement that deletes an alias from LMODA:

```language-none
++PTF(UR01235) /* Identify the PTF number. */.
++VER(2038) FMID(HXY1300) /* For MVS function HXY1300. */.
++HOLD(UR01235) /* Hold UR01235. */.
  FMID(HXY1300) /* For MVS function HXY1300. */.
  SYSTEM /* System hold */.
  REASON(DELETE) /* because of ++DELETE. */.
  COMMENT( THE DELETION OF THE ALIAS FOR LMODA IS IRREVERSIBLE).
++DELETE (LMODA) /* Identify LMOD LMODA. */.
SYSLIB(ALL) /* Process all SYSLIBs. */.
ALIAS(OTHNAME) /* Identify alias. */.
++JCLIN /* JCLIN to delete alias. */.
  *
  *
++MOD(MODAAA) DISTLIB(AOSXX) /* Element MCS statements. */.
```

Chapter 2. SMP/E modification control statements 19
Example 3: Deleting an alias from a load module in a UNIX file system

Assume that IBM has shipped you a PTF that deletes an alias for load module BPXLMODB, which resides in a UNIX file system. Here is an example of a SYSMOD containing a ++DELETE statement that deletes an alias from BPXLMODB:

```plaintext
++PTF(UZ00440) /* Identify the PTF number. */
++VER(Z838) FMID(HOP1101) /* For MVS function HOP1101. */
++HOLD(UZ00440) /* Hold UZ00440. */
   FMID(HOP1101) /* For MVS function HOP1101. */
   SYSTEM /* System hold */
   REASON(DELETE) /* because of ++DELETE. */
   COMMENT(THE DELETION OF THE ALIAS FROM BPXLMODB IS IRREVERSIBLE).
++DELETE (BPXLMODB) /* Identify LMOD BPXLMODB. */
  SYSLIB(ALL) /* Process all SYSLIBs. */
  ALIAS('..nicename') /* Identify alias. */
++JCLIN /* JCLIN follows. */
  
++MOD(BPXMODAA) DISTLIB(AOSXX) /* Element MCS statements. */
```
**++FEATURE MCS**

++FEATURE MCS is used to describe a set of function SYSMODs that are collectively referred to as a FEATURE. It introduces descriptive information about a new or replacement set of functions into the global zone. A ++FEATURE MCS may be associated with an orderable software feature.

**Syntax**

```
++FEATURE MCS

++FEATURE(name) DESCRIPTION(description)

FMID(fmId)

PRODUCT(prodId,vv.rr.mm) REWORK(level)
```

**Operands**

*name* is a 1- to 8-character feature name. It can contain uppercase alphabetic, numeric, or national characters ($, #, @).

**DESCRIPTION**

describes the feature that represents this collection of function SYSMODs.

- DESCRIPTION can also be specified as DESC.
- The DESCRIPTION value can be in single-byte characters (such as English alphanumeric) or double-byte characters (such as Kanji).
- The DESCRIPTION value can contain up to 64 bytes of data, including blanks. (For double-byte data, the 64-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters.) Extra blanks as well as leading and trailing blanks are deleted.
- The DESCRIPTION value can span multiple 80-byte records. Data must continue up to and including column 72 and begin in column 1 of the next line. All data past column 72 is ignored. The break does not translate to a blank unless a blank is explicitly coded in column 72 of the first line or in column 1 of the second line.
- The DESCRIPTION value cannot be only blanks.
- If parentheses are included in the text, they must be in matched pairs.

**FMID**

specifies the list of all function SYSMODs that make up this feature. Each FMID is 7 characters long and must be a valid SYSMOD ID. That is, it must contain uppercase alphabetic, numeric, or national characters ($, @, #). If multiple FMIDs are specified, they must be separated by commas.

**PRODUCT**

identifies the *prodId* and *vv.rr.mm* of the product with which this feature is associated.

**REWORK**

is the level of this feature, which was reworked for minor changes. Up to eight numeric characters can be specified.
++FEATURE MCS

For IBM features, the REWORK level is yyyyddd, which is the year followed by the Julian date (for example, 2008110).

REWORK allows an updated feature to be automatically received again, as long as it is more recent than the version that has already been received. This takes the place of rejecting the feature and receiving it again.

Note: If a ++FEATURE statement appears more than once in the SMPPTFIN data set, the first occurrence may be received. However, none of the subsequent versions of the ++FEATURE statement are received, even if their rework level is higher than the one for the first version of the ++FEATURE statement.

Usage Notes

- The ++FEATURE statements are processed only when the SMPPTFIN data set is processed.
  - If the whole SMPPTFIN data set is processed, all ++FEATURE statements are processed.
  - If only selected SYSMODs are processed, SMP/E processes the ++FEATURE statements that name at least one of the selected SYSMODs in their FMID operand list.
++FEATURE statements are not processed when only the SMPHOLD data set is being processed.
- The name, DESCRIPTION, and PRODUCT values are required and cannot be blank or null.
- The ++FEATURE MCS is used in the SMPPTFIN data set and can be placed between, before, or after SYSMODs, ++FEATURE MCS, or ++PRODUCT MCS. If the function SYSMODs identified in the FMID operand of the ++FEATURE statement have not been previously received, the ++FEATURE statement must follow these function SYSMODs in the SMPPTFIN data set.
The ++FEATURE statement must be followed by one of the following: a ++APAR, ++ASSIGN MCS, ++FUNCTION, ++PRODUCT, ++PTF, ++USERMOD, another ++FEATURE MCS, or an end-of-file. If one of these does not follow, SMP/E skips the ++FEATURE MCS.

Example

Here is an example of a ++FEATURE MCS for the OS/390® product.

```++FEATURE( 05325BAS )  /* Feature definition */
DESCRIPTION( OS/390 Base Feature )  /* Description */
FMID(HBB6605,HMP1000,JBB66C5,....)  /* FMID List */
PRODUCT (5647-A01,2.5.0)  /* Owning Product */ .```
**++FUNCTION MCS**

The ++FUNCTION MCS identifies a SYSMOD as a base function or dependent function. This type of SYSMOD introduces a new or replacement function into target system and distribution libraries. All other MCSs follow this header MCS statement. For more information about packaging a function, see z/OS Packaging Rules.

### Syntax

```
++FUNCTION MCS

++FUNCTION(sysmod_id) DESCRIPTION(description)

FESN(fe_service_number) FILES(number) RFDSNFPFX(relfile_prefix)

REWORK(level)
```

### Operands

**DESCRIPTION**

specifies a descriptive name to be associated with this SYSMOD. z/OS Packaging Rules manual.
- DESCRIPTION can also be specified DESC.
- The DESCRIPTION value can be in single-byte characters (such as English alphanumeric) or double-byte characters (such as Kanji).
- The DESCRIPTION value can contain up to 64 bytes of data, including blanks. (For double-byte data, the 64-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters.) Extra blanks, as well as leading and trailing blanks are deleted.
- The DESCRIPTION value can span multiple 80-byte records. Data must continue up to and including column 72 and begin in column 1 of the next line. All data past column 72 is ignored. The break does not translate to a blank unless a blank is explicitly coded in column 72 of the first line or in column 1 of the second line.
- If DESCRIPTION is specified, it must contain at least one non-blank character.
- If parentheses are included in the text, they must be in matched pairs.

**FESN**

is a 7-character field engineering (FE) service number.

**FILES**

specifies the number of relative files belonging to this function. It can be a decimal number from 1 to 9999, and is used only if the function is packaged in relative files, rather than inline or in indirect libraries. For information about packaging SYSMODs in relative files, see z/OS Packaging Rules.
++FUNCTION MCS

Notes:
1. Functions are generally packaged in relative files to improve SMP/E’s performance when applying and accepting the SYSMOD.
2. If a packager uses a high-level qualifier on RELFILE data sets, the RFDSNPFX operand on the header MCS (not the RFPPREFIX operand on the RECEIVE command) must be used to identify that high-level qualifier.

REWORK
is the level of this SYSMOD, which was reworked for minor changes. Up to eight numeric characters can be specified.

REWORK is generally used only for SYSMODs supplied by IBM that have been reworked for minor changes, such as for a service update or to use a ++MOVE, ++RENAME, or ++DELETE MCS. For these SYSMODs, the REWORK level is yyyyddd, which is the year followed by the Julian date (for example, 20081110).

REWORK allows an updated SYSMOD to be automatically received again, as long as it is more recent than the version that has already been received. This takes the place of rejecting the SYSMOD and receiving it again.

Note: If a SYSMOD appears more than once in the SMPPTFIN data set, the first occurrence may be received. However, none of the subsequent versions of the SYSMOD are received, even if their rework level is higher than the one for the first version of the SYSMOD. (Message GIM40001E is issued for each of the subsequent versions of the SYSMOD.)

RFDSNPFX
identifies to SMP/E the prefix used in the relative file data set names for this SYSMOD. SMP/E uses this prefix when allocating data set names for the SYSMOD’s relative files during RECEIVE processing.
• This operand can be specified only if the FILES operand is also specified.
• The RFDSNPFX value specified on the MCS statement must match the actual prefix used in the data set names for the associated relative files. For example, if the names of the relative files created for a SYSMOD start with "IBM", as in IBM.sysmod_id.F1, the header MCS statement for the SYSMOD must specify RFDSNPFX(IBM) so SMP/E knows which prefix to use when allocating the data set names for the SYSMOD’s relative files during RECEIVE processing.
• Following standard data set naming conventions, the prefix can be from 1 to 8 alphanumeric or national (@, #, &@) characters or a dash (–).
To enable full Security Server protection for tape data sets and to keep the tape header within the 17-character limit (including periods), you should limit the prefix to 1 to 3 characters. If the name exceeds the 17-character limit, only the rightmost 17 characters are written to the tape header label.

sysmod_id
is a unique 7-character name, or SYSMOD ID, for the function. This ID is also called a function modification identifier (FMID). For more information, see “Naming conventions for SYSMODs” on page 517.

Usage Notes
A function cannot contain statements that update elements (++MACUPD, ++SRCUPD, and ++ZAP).
Examples

Here is an example of a function SYSMOD to be created with a SYSMOD ID of JXY1040 that is dependent on function JXY1000. The elements and JCL input data are members of three unloaded partitioned data sets on a tape created using the relative file method:

```+FUNCTION(JXY1040)
  /* New function SYSMOD */
  FILES(3) /* in RELFILE format. */
  RFDSNPFX(IBM) /* RELFILE prefix for IBM. */
  ++VER(Z038) FMID(JXY1000) /* For MVS function JXY1000. */
  ++JCLIN RELFILE(1) /* JCLIN in RELFILE 1. */
  ++MOD(IFBMOD01) /* This module */
    DISTLIB(AOSFB) /* for this DLIB */
    RELFILE(2) /* is in RELFILE 2. */
  ++MOD(IFBMOD02) /* This module */
    DISTLIB(AOSFB) /* for this DLIB */
    RELFILE(2) /* is in RELFILE 2. */
  ++MAC(IFBMAC01) /* This macro */
    DISTLIB(AOSMAC) /* for this DLIB */
    RELFILE(3) /* is in RELFILE 3. */
```
Hierarchical file system element MCS

The hierarchical file system element MCSs describe elements located in a UNIX file system. Hierarchical file system elements can have any of the following characteristics:

- The record format (RECFM) must be F, FA, FM, FB, FBA, FB, V, VA, VM, VB, VBA, or VBM.
- Elements with variable-length records cannot contain spanned records.
- The maximum LRECL is 32,654.
- The records can be numbered or unnumbered.

There are MCSs to replace hierarchical file system elements, just as there are MCSs to replace other types of elements. (There are no MCSs to update hierarchical file system elements.) [Table 4] shows the MCSs that can be used for hierarchical file system elements. [Table 5 on page 27] shows the xxx values that can be used when the MCS indicates the language being supported.

Table 4. MCS statements for hierarchical file system elements. If an element is provided in only one language, the xxx can be left off the MCS. If an element is provided in more than one language, replace the xxx with the appropriate value from [Table 5 on page 27].

<table>

Syntax

The syntax to be used depends on the processing to be performed for the element:
- Adding or replacing the element
- Deleting the element
Hierarchical file system element MCS

Adding or replacing a hierarchical file system element

Deleting a hierarchical file system element

Operands

**BINARY** indicates that the hierarchical file system copy utility should install the element into a UNIX file system in binary mode. This means that the element is installed in its entirety as a data stream, with no breaks for logical records.

**Notes:**

1. BINARY is mutually exclusive with TEXT.
2. When BINARY is specified on the element MCS, SMP/E sets the BINARY mode indicator in the hierarchical file system element entry. When TEXT is specified on the element MCS, SMP/E sets the TEXT mode indicator in the hierarchical file system element entry.
Hierarchical file system element MCS

If neither BINARY nor TEXT is specified on the element MCS, SMP/E uses the mode indicator in the hierarchical file system element entry to tell the HFS copy utility how to install the element.

If neither BINARY nor TEXT is specified on the element MCS and there is no mode indicator in the hierarchical file system element entry, the HFS copy utility determines how to install the element.

3. SMP/E recommends the appropriate value BINARY or TEXT be specified to ensure that the HFS copy utility uses the correct mode. If no value is specified, the HFS copy utility chooses either binary or text mode based on the RECFM of the element to be copied, and it might choose incorrectly.

DELETE
specifies that the hierarchical file system element and all of its link names and symbolic link names are to be removed from the “target library” (UNIX file system) and the distribution library.

Notes:
1. DELETE is mutually exclusive with all other operands except DISTLIB and VERSION.
2. If the element statement is in a base function, you may want to use the DELETE operand on the ++VER MCS to delete the previous release, rather than on the element statement to delete a specific element.
3. Specification of the DELETE operand results in all link names and symbolic link names of the element being deleted along with the element identified.

DISTLIB
specifies the ddbname of the distribution library for the specified hierarchical file system element. During ACCEPT processing, SMP/E installs the hierarchical file system element into the distribution library as a member. (The distribution library must be a PDS or PDSE; it cannot be part of a UNIX file system.)

Notes:
1. DISTLIB must be specified when the hierarchical file system element is first installed.
2. If an element entry already exists in the target zone or distribution zone and the value currently in that entry does not match that specified in the DISTLIB operand, the SYSMOD is not applied or accepted.

 element
specifies the type of element. Table 4 on page 26 shows the MCSs used for the various hierarchical file system element types.

FROMDS
identifies the partitioned data set that contains this element.

Note: The FROMDS operand and its DSN, NUMBER, VOL, and UNIT suboperands are included in the MCS generated by the BUILDMCS command. IBM does not intend the FROMDS operand to be used in manually coded MCS.

DSN specifies the dname of the FROMDS data set. The specified data set name must conform to standard data set naming conventions and cannot contain parentheses. The maximum length of the entire name is 44 characters (including the periods).

NUMBER specifies a number that SMP/E is to use when assigning a
Hierarchical file system element MCS

name to the SMPTLIB data set associated with this FROMDS data set. (This is similar to the way the relative file number is used in RELFILE processing.)

VOL specifies, for an uncataloged data set, the volume serial number of the volume containing the FROMDS data set. If specified, this volume identifier must be from 1 to 6 alphanumeric characters.

VOL may be omitted for a cataloged data set.

UNIT specifies, for an uncataloged data set, the UNIT type containing the FROMDS data set. If specified, the UNIT value must be from 1 to 8 characters and must conform to standard UNIT naming conventions. SMP/E accepts any nonblank characters specified between the open and close parentheses, up to a maximum length of 8.

UNIT may be omitted for a cataloged data set.

Note: FROMDS is mutually exclusive with DELETE, RELFILE, and TXLIB.

LINK specifies the alternative names by which this hierarchical file system element can be known in a UNIX file system. The full name is produced by concatenating the specified linkname with the UNIX file system directory identified by the SYSLIB subentry. Each linkname is passed to the HFS copy utility as an execution parameter.

Notes:
1. The linkname can be from 1 to 1023 characters.
2. A linkname can be enclosed in single apostrophes ('). A linkname must be enclosed in single apostrophes if any of the following is true:
   - The linkname contains lowercase alphabetic characters.
   - The linkname contains a character that is not uppercase alphabetic, numeric, national ($, #, @), slash (/), plus (+), hyphen, period, or ampersand (&).
   - The linkname spans more than one line in the control statement.

   The single apostrophes used to enclose a linkname (the delimiters) do not count as part of the 1023-character limit.
3. Any apostrophes specified as part of a linkname (not the delimiters) must be doubled.

   Double apostrophes count as two characters in the 1023-character limit.
4. The linkname can include characters X'40' through X'FE'.
5. LINK values are saved and passed to the HFS copy utility as follows:
   - If LINK is specified on the element MCS, any values previously saved in the element entry are overlaid.
   - If LINK is not specified on the element MCS and saved values exist in the hierarchical file system element entry, the saved values are passed to the HFS copy utility as execution parameters.

   If LINK is not specified on the element MCS and there are no saved values in the hierarchical file system element entry, no linknames are passed to the HFS copy utility.
Hierarchical file system element MCS

**name**

specifies the name of the hierarchical file system element member. The name can contain any uppercase alphabetic, numeric, or national ($, #, @) character and can be 1 to 8 characters long.

**PARM**

specifies a character string that is to be passed to the hierarchical file system copy utility as an execution-time parameter. (The values that can be specified on the PARM operand, such as PATHMODE, are those accepted by the BPXCOPY utility. See [z/OS UNIX System Services Command Reference](https://publib.boulder.ibm.com/infocenter/zos/v2r12/topic/com.ibm.zos.r12.doc/TOC.htm) for a description of BPXCOPY and the values it accepts.) The maximum length of this character string is 300 bytes of nonblank data. If any blanks are specified in the PARM value, they are deleted by SMP/E during processing and do not count toward the 300-byte maximum.

**Notes:**

1. PARM is an optional operand.
2. The character string can be entered free-form, without regard to blanks (which are compressed out of the string), and can span multiple 80-byte records.
3. If parentheses are specified in the PARM value, there must always be a pair (left and right); otherwise, the results are unpredictable.
4. PARM values are saved and passed to the HFS copy utility as follows:
   - If PARM is specified on the element MCS, any values previously saved in the hierarchical file system element entry are overlaid.
   - If PARM is not specified on the element MCS and saved values exist in the hierarchical file system element entry, the saved values are passed to the HFS copy utility as execution parameters.
   - If PARM is not specified on the element MCS and there are no saved values in the hierarchical file system element entry, no parameters are saved from the element MCS or passed from the hierarchical file system element entry to the HFS copy utility.
5. If the UTILITY entry for the HFS copy utility specifies a PARM value, those parameters are passed to the utility in addition to any parameters saved in the hierarchical file system element entry.

**RELFILE**

identifies which relative file associated with the SYSMOD contains this element. This operand is required if you provide the element in RELFILE format, rather than inline or in a TXLIB data set.

**Notes:**

1. The RELFILE value must be a decimal number from 1 to 9999.
2. RELFILE is mutually exclusive with FROMDS and TXLIB.

**RMID**

specifies the last SYSMOD that replaced this element. This operand can be used only in a service-updated function, and the specified PTF must be integrated into the function.

**SHSCRIPT**

specifies a UNIX shell script, *scriptname*, to be invoked when the element is installed in (or deleted from) a directory of a UNIX file system. *scriptname* can contain any uppercase alphabetic, numeric, or national ($, #, @) character and can be 1 to 8 characters long.
Hierarchical file system element MCS

A shell script is commonly used to complete the installation of an element. For example, if the hierarchical file system element is a TAR or PAX file, you can provide a shell script that performs the necessary steps to restore the file. 

`scriptname` must be the first value to follow the SHSCRIPT operand.

You define the shell script to SMP/E through a `++SHELLSCR` statement, which can be within the same SYSMOD as the hierarchical file system element, or within a SYMOD that was processed previously. When the element is itself a SHELLSCR type, the SHSCRIPT operand must match the name of the element.

You cannot define more than one shell script for an element.

You can follow `scriptname` with either of two optional values, **PRE** and **POST**, to specify the point in SMP/E processing when the shell script is to be invoked. The following examples show how you can use the **PRE** and **POST** values:

- To run the shell script before the element is copied to a UNIX file system directory, specify:
  
  `SHSCRIPT(scriptname, PRE)`

- To run the shell script after the element is copied to a UNIX file system directory, specify:
  
  `SHSCRIPT(scriptname, POST)`

or specify no value after `scriptname` to use POST by default.

- To run the shell script both before and after the element is copied to a UNIX file system directory, specify:
  
  `SHSCRIPT(scriptname, PRE, POST)`

If you do not specify a **PRE** or **POST** value for the shell script, SMP/E invokes the shell script after the element is installed in the directory.

When the element is a shell script, **PRE** is not valid. Also, you cannot specify the SHSCRIPT operand with the **DELETE** operand.

**SYMLINK**

specifies a list of one or more symbolic links, which are file names that can be used as alternate names for referring to this element in a UNIX file system. Each linkname listed here is associated with a pathname listed in the SYMPATH operand. For more information on how the linknames and pathnames are associated, see the description of the SYMPATH operand and "Example 3: Packaging a SYMOD with a symbolic link" on page 36.

The SYMLINK value specified should be a relative path value (that is, it does not start with a slash `"/"`). When the symbolic link is created, it is created relative to the pathname of the element’s SYSLIB ddname.

**SYMLINK** must be specified if the **SYMPATH** operand is specified, otherwise it must be omitted.

A symbolic linkname can be from one to 1023 characters. Any characters in the range `X’40’ through `X’FE’ may be specified.

The value may be enclosed in single apostrophes. It **must** be enclosed in single apostrophes if:

- it is continued to the next line in the MCS, or
- it contains a character that is not uppercase alphabetic, numeric, national ($, #, @), slash (/), plus (+), hyphen, period, or ampersand (&).

If an apostrophe is a part of the symbolic linkname and is not a delimiter, then it must be doubled. These two apostrophes count as two characters against the
Hierarchical file system element MCS

1023 character limit for a symbolic linkname. The single apostrophes used to enclose a symbolic linkname do not count against the 1023 character limit.

SYMPATH
specifies a list of one or more pathnames that are associated with symbolic links identified by the SYMLINK operand. The first pathname in the SYMPATH operand is associated with the first symbolic link in the SYMLINK operand, the second pathname with the second symbolic link, and so on. If there are more symbolic links listed than there are pathnames, then the last listed pathname is used for the remaining symbolic links. If more pathnames are specified than symbolic linknames, then the excess pathnames (at the end of the list) are ignored.

The SYMPATH value specified should be a relative path value. When the symbolic link is accessed, the system assumes the destination of that link (the SYMPATH value) is relative to that symbolic link (the SYMLINK value). For more information on how the pathnames and linknames are associated, see "Example 3: Packaging a SYSMOD with a symbolic link" on page 36.

SYMPATH must be specified if the SYMLINK operand is specified, otherwise it must be omitted.

A symbolic pathname can be one to 1023 characters. Any characters in the range 'X'40' through 'X'7E' may be specified.

The value may be enclosed in single apostrophes. It must be enclosed in single apostrophes, if:
• it is continued to the next line in the MCS, or
• it contains a character that is not uppercase alphabetic, numeric, national ($, #, @), slash (/), plus (+), hyphen, period, or ampersand (&).

If an apostrophe is a part of the symbolic pathname and is not a delimiter, then it must be doubled. These two apostrophes count as two characters against the 1023 character limit for a symbolic pathname. The single apostrophes used to enclose a symbolic linkname do not count against the 1023 character limit.

SYSLIB
specifies the ddname of the “target library” within the UNIX file system for the element.

During APPLY processing, the HFS copy utility installs the hierarchical file system element into a UNIX file system. During RESTORE processing, the HFS copy utility copies the hierarchical file system element from the distribution library member into a UNIX file system.

Note: SYSLIB must be specified when the hierarchical file system element is first installed.

TEXT
indicates that the hierarchical file system copy utility should install the element into a UNIX file system in text mode. This means that the element is installed with breakpoints for logical records.

Notes:
1. TEXT is mutually exclusive with BINARY.
2. When TEXT is specified on the element MCS, SMP/E sets the TEXT mode indicator in the hierarchical file system element entry. When BINARY is specified on the element MCS, SMP/E sets the BINARY mode indicator in the hierarchical file system element entry.
Hierarchical file system element MCS

If neither BINARY nor TEXT is specified on the element MCS, SMP/E uses the mode indicator in the hierarchical file system element entry to tell the HFS copy utility how to install the element.

If neither BINARY nor TEXT is specified on the element MCS and there is no mode indicator in the hierarchical file system element entry, the HFS copy utility determines how to install the element.

3. SMP/E recommends the appropriate value BINARY or TEXT be specified to ensure that the HFS copy utility uses the correct mode. If no value is specified, the HFS copy utility chooses either binary or text mode based on the RECFM of the element to be copied, and it might choose incorrectly.

TXLIB
is the ddname of the partitioned data set containing the hierarchical file system element. This operand is required if the hierarchical file system element is provided in a data set that the users have access to, rather than inline or in RELFILE format.

Notes:
1. SMPTLIB cannot be used as a value on the TXLIB operand.
2. TXLIB is mutually exclusive with FROMDS and RELFILE.

VERSION
specifies one or more function SYSMODs that currently contain the element. The function containing the element MCS takes over ownership of the element from the specified functions.

When VERSION is specified on an element statement, it overrides any VERSION operand values that might be specified on the ++VER MCS.

Usage Notes

• If the hierarchical file system element is packaged inline, it must immediately follow the hierarchical file system element MCS and must not contain any records starting with ++. Neither FROMDS, nor RELFILE, nor TXLIB can be specified on the hierarchical file system element MCS.
• To be packaged inline, a hierarchical file system element must contain fixed-block–80 records. If the original format of the element is not fixed-block–80 records, you can use GIMDTS to transform the element into the required format before packaging it. Later, when SMP/E installs the element, it is changed back to its original format. For more information about using GIMDTS, see "GIMDTS: Data transformation service routine" on page 450.
• If the hierarchical file system element is packaged in a TXLIB data set, the ddname specified in the TXLIB operand is required during APPLY and ACCEPT processing.
• For information about elements packaged in RELFILE format, see z/OS Packaging Rules.
• A ++HFS MCS can be used to supply a pre-built program object to be placed into a UNIX file system. A user can do an OGET for an existing program object in the file system to cause the program object to be placed into an MVS data set as fixed length records. This data can then be packaged as a ++HFS element with the BINARY operand. The HFS copy utility can then copy the element into the file system as a binary entity, which can then be executed.

Examples
The following examples are provided to help you use the hierarchical file system element MCS:
Hierarchical file system element MCS

- “Example 1: Packaging a hierarchical file system element in a function”
- “Example 2: Packaging a renamed hierarchical file system Element”
- “Example 3: Packaging a SYSMOD with a symbolic link” on page 36

Example 1: Packaging a hierarchical file system element in a function

Here is an example of a SYSMOD containing a hierarchical file system element statement to install your element and have SMP/E track any changes to it. The element:

- Uses the Japanese language
- Is to be installed in BINARY mode
- Can also be known by its linkname “USERHFS”
- Is to be processed by shell script “UNTAR” after the element is copied to a UNIX file system directory.

The element can be packaged in a function, as shown below:

```c
++FUNCTION(MYHFS)
++VER(Z038)
++HFSJPN(HFSELEMX)
/FUNCTION(MYHFSEL)
/TXLIB(NEWHFS) */ from this TXLIB */
/DISTLIB(ABPLIB) */ into this DLIB and */
/SYSLIB(BPXLIB) */ this target library. */
/BINARY */ Use BINARY mode. */
/LINK('..USERHFS') */ Define linkname. */
/SYSLIB(BPXLIB1)

++VER(Z038) FMID(MYHFS) */ to user application. */
++HFSJPN(HFSELEMX) /* Delete the original */
/DELETE */ HFS element. */
++HFSJPN(HFSELEMX) /* Add the renamed element*/
/TXLIB(NEWHFS) */ from this TXLIB */
/DISTLIB(ABPLIB) */ into this DLIB and */
/SYSLIB(BPXLIB) */ this target library. */
/TEXT */ Use TEXT mode. */
/LINK('..USERHFS') /* Define linkname. */

/* Untar the file with the UNTRAN exec. */
```

To install the function, you need to specify DDDEF entries or DD statements for the TXLIB, DISTLIB, and SYSLIB data sets. Remember that the SYSLIB data set is actually a pathname in a UNIX file system. For an example of defining a pathname in a DDDEF entry, see “Example 10: Defining pathnames in a UNIX file system” on page 209.

Example 2: Packaging a renamed hierarchical file system Element

Suppose that, for some reason, you need to rename HFSELEMX, which was introduced in “Example 1: Packaging a hierarchical file system element in a function.” The new name is to be HFSELEMX. You do not need to change anything else about the hierarchical file system element. Here is an example of a SYSMOD containing the hierarchical file system element statements needed to package this renamed hierarchical file system element:

```c
++USERMOD(USR0001) */ User modification */
++VER(Z038) FMID(MYHFS) */ to user application. */
++HFSJPN(HFSELEMX) /* Delete the original */
/DELETE */ HFS element. */
++HFSJPN(HFSELEMX) /* Add the renamed element*/
/TXLIB(NEWHFS) */ from this TXLIB */
/DISTLIB(ABPLIB) */ into this DLIB and */
/SYSLIB(BPXLIB) */ this target library. */
/TEXT */ Use TEXT mode. */
/LINK('..USERHFS') /* Define linkname. */
```

To install the USERMOD, you need to specify DDDEF entries or DD statements for the TXLIB, DISTLIB, and SYSLIB data sets. Remember that the SYSLIB data set is actually a pathname in a UNIX file system. For an example of defining a pathname in a DDDEF entry, see “Example 10: Defining pathnames in a UNIX file system” on page 209.
Hierarchical file system element MCS

You must also ensure that the renamed hierarchical file system element is in the TXLIB library used to provide SMP/E with the element.

**Example 3: Packaging a SYSMOD with a symbolic link**

Here is an example of a SYSMOD containing a hierarchical file system element statement to install your element with a symbolic link. The element:

- Is to be installed in TEXT mode
- Can be known by its linkname “/usr/lpp/gskssl/include/gskssl.h”
- Can also be known by its symbolic link “/usr/include/gskssl.h”

The element can be packaged in a function, as shown below:

```c
++FUNCTION(SAMPLE) /* Function. */
++VER(Z83B) /* For MVS SRELs. */
++HFS(GSKAH010) /* Install this element */
RELFILE(2) /* from a RELFILE */
DISTLIB(AGSKHFS) /* into this DLIB and */
SYSLIB(SGSKHFS) /* this target library. */
LINK("../include/gskssl.h")
  /* Define linkname. */
SYMLINK("../include/gskssl.h")
  /* Define symbolic link */
SYMPATH("../lpp/gskssl/include/gskssl.h")
  /* Define path name. */
PARM(PATHMODE(0,6,4,4)) /* HFS copy utility parameters */
TEXT /* Use TEXT mode. */
```

To install the function, you need to specify DDDEF entries or DD statements for the DISTLIB and SYSLIB data sets. Remember that the SYSLIB data set is actually a pathname in a UNIX file system. In this example, the DDDEF for SYSLIB must be defined as follows:

```c
UCLIN.
ADD DDDEF(SGSKHFS) PATH('/service/usr/lpp/gskssl/IBM/').
ENDUCLIN.
```

When SMP/E installs file GSKAH010 into the directory specified on the given DDDEF entry, the LINK and SYMLINK values will be resolved relative to the DDDEF directory. The file will then be known by the following absolute path names in a UNIX file system:

<table>
<thead>
<tr>
<th>Source</th>
<th>Resolved absolute pathname</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMP/E element name</td>
<td>/service/usr/lpp/gskssl/IBM/GSKAH010</td>
</tr>
<tr>
<td>LINK name</td>
<td>/service/usr/lpp/gskssl/include/gskssl.h</td>
</tr>
<tr>
<td>SYMLINK name</td>
<td>/service/usr/include/gskssl.h</td>
</tr>
</tbody>
</table>

The contents of a symbolic link (SYMLINK) is its associated SYMPATH. In this case, the contents of the symbolic link is “../../../usr/lpp/gskssl/include/gskssl.h”. When a symbolic link is resolved, its content is resolved relative to the symbolic link itself. That is, the SYMPATH value is relative to the SYMLINK value. Therefore, in this case, the SYMPATH value resolves to the LINK name, “/service/usr/lpp/gskssl/include/gskssl.h”.
The ++HOLD MCS identifies a SYSMOD to be placed into exception SYSMOD status (signifying that special SMP/E processing is required before it can be applied or accepted). ++HOLD statements can occur within a SYSMOD (internal HOLDDATA), or they can be read directly from the SMPHOLD file during RECEIVE processing (external HOLDDATA). For additional information on processing the ++HOLD statements, see [SMP/E Commands](#).

### SYSTEM reason IDs used by IBM:

- ACTION
- AO
- DB2BIND
- DOD
- DELETE
- DEP
- DOC
- DOWNLD
- EC
- ENH
- EXIT
- EXRF
- FULLGEN
- IOGEN
- IPL
- MSGSKEL
- MULTSYS
- RESTART
Operands

CATEGORY
a 1- to 64-character string that specifies a Fix Category. There can be one or more Fix Category values. A Fix Category value associates the reason ID APAR to a particular category of fixes. A Fix Category might be used to identify a group of APAR fixes required to support a particular hardware device, or to provide a particular software capability, similar to how a Preventive Service Planning Bucket (PSP-Bucket) identifies a group of APARs. Examples of Fix Categories used by IBM are
IBM.Device.2094.z/OS and IBM.HealthChecker.

The Fix Category values are used during RECEIVE command processing to create source IDs for the SYSMODs that will resolve the specified reason ID APAR. During APPLY and ACCEPT command processing the Fix Category values are used to determine if the HOLDDATA is applicable to the current command by comparing the values in the HOLDDATA to those in the active Fix Category interest list. The active Fix Category interest list is specified on the APPLY and ACCEPT command, or within the active OPTIONS entry.

A category value might contain any nonblank character in the range X'41' - X'FE' except single quotation mark ('), asterisk (*), percent (%), comma (,), left parenthesis ((), and right parenthesis ()).

CLASS
a 1- to 7-character string indicating an alternative reason to release an exception SYSMOD for processing. A class name is specified along with a reason ID to identify a condition when the reason ID need not be resolved. The same class name can be specified on any number of ++HOLD statements in any number of SYSMODs.

These are the specific values currently used by IBM:

<table>
<thead>
<tr>
<th>Class</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERREL</td>
<td>The SYSMOD is held for an error reason ID but should be installed anyway. IBM has determined that the problem the SYSMOD resolves is significantly more critical than the error reflected by the holding APAR.</td>
</tr>
<tr>
<td>HIPER</td>
<td>The SYSMOD is held with a hold class of HIPER (High Impact)</td>
</tr>
<tr>
<td>PE</td>
<td>The SYSMOD is held with a hold class of “PTF in Error”.</td>
</tr>
<tr>
<td>UCLREL</td>
<td>UCLIN needed for the SYSMOD has been handled by IBM and no longer requires your attention.</td>
</tr>
<tr>
<td>YR2000</td>
<td>Identifies PTFs that provide Year 2000 function, or fix a Year 2000-related problem.</td>
</tr>
</tbody>
</table>
For additional information, see “Naming conventions for HOLD reason IDs and HOLD classes” on page 514.

COMMENT(text)
free-form text to be used to describe the problem identified by the REASON operand. The comments supplied are associated only with the reason ID supplied. The comments can be in single-byte characters (such as English alphanumeric characters) or double-byte characters (such as Kanji).

COMMENT(Enhanced HOLDDATA)
contains IBM–supplied Enhanced HOLDDATA, as follows:

SMRTDATA
indicates that the COMMENT operand contains Enhanced HOLDDATA.

CHGDT
specifies the date that the ++HOLD statement was last updated with Enhanced HOLDDATA. The date is specified as yymmdd, where yy is the last two digits of the year, mm is the month and dd is the date of the month.

FIX identifies the SYSMOD that resolves the held SYSMOD.

SYMP contains a description of the hold. The description might include symbols representing symptoms of the problem, a description of the problem in text form, or a combination of both. The symbols that represent symptoms identify how the problem affects the held SYSMOD.

Here is a list of symbols that might appear and their meanings. For a complete list of the symbols, see Enhanced HOLDDATA for z/OS and OS/390 (http://service.software.ibm.com/holdata/390holddata.html).

DAL Data loss
DST2007 Daylight Saving Time support
EURO99 Euro currency symbol support
FUL Major function loss
IPL System outage (Requires IPL)
PRF Performance
PRV Pervasive
SYSPLXDS SYSPLEX data sharing
XSYS Cross-system migration, compatibility, or toleration
YR2000 Year 2000

The SYMP field can be no more than 30 characters in length. Parentheses can be used within the field, but they must be matched pairs.

DATE
specifies the date that the ++HOLD statement was generated. The date is specified as yymmdd, where yy is the last two digits of the year and ddd is the Julian date.

ERROR, FIXCAT, SYSTEM, or USER
specifies the hold category into which the SYSMOD is to be put. At least one of the values must be specified.
++HOLD MCS

<table>
<thead>
<tr>
<th>ERROR</th>
<th>An APAR reported an error in the SYSMOD. The SYSMOD should not be applied or accepted until the APAR is resolved. A PTF held for this reason is also called a program error PTF, or PE-PTF. SMP/E automatically resolves the APAR and allows the SYSMOD to be applied or accepted when a SYSMOD that either matches or supersedes the APAR is also applied or accepted. Error holds can be read only from the SMPHOLD data set.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note: ERROR can also be specified as ERR.</td>
<td></td>
</tr>
<tr>
<td>FIXCAT</td>
<td>An APAR provides a fix for the held SYSMOD and the fix is associated with one or more Fix Categories. It is optional whether the APAR will affect processing for the held SYSMOD, based on the APAR's Fix Categories and the Fix Categories of interest specified by the user. If any one or more Fix Categories for the APAR match any of those of interest to the user, then the held SYSMOD will not be applied or accepted until the APAR is resolved. The APAR is resolved when a SYSMOD that matches the APAR name, or a SYSMOD that supersedes the APAR, is applied or accepted. FIXCAT holds can be read only from the SMPHOLD data set.</td>
</tr>
<tr>
<td>See the FIXCAT operand for APPLY and ACCEPT command processing for details of specifying the Fix Categories of interest.</td>
<td></td>
</tr>
<tr>
<td>SYSTEM</td>
<td>Special action outside normal SMP/E processing is required for the SYSMOD. Examples are SYSMODs requiring a SYSGEN after they are installed, or SYSMODs requiring the installation of an associated engineering change (EC) level. System holds can appear in the SYSMOD itself or in the SMPHOLD data set.</td>
</tr>
<tr>
<td>Note: SYSTEM can also be specified as SYS.</td>
<td></td>
</tr>
<tr>
<td>USER</td>
<td>The SYSMOD requires special processing because of a decision you have made. User holds can be read only from the SMPHOLD data set.</td>
</tr>
<tr>
<td>FMID</td>
<td>specifies the FMID to which the held SYSMOD is applicable. For external HOLDDATA (a ++HOLD statement not within a SYSMOD), this information allows SMP/E to receive only those statements associated with FMIDs defined in the user's global zone. This operand is required.</td>
</tr>
<tr>
<td>REASON</td>
<td>a 1- to 7-character string used to help users identify the reason why the SYSMOD is being put into exception SYSMOD status. The reason IDs that can be specified depend on the type of hold.</td>
</tr>
<tr>
<td>Note: A SYSMOD can contain only one ++HOLD MCS for each required reason ID.</td>
<td></td>
</tr>
<tr>
<td>^</td>
<td>- An error reason ID is the APAR number that caused the SYSMOD to be placed in exception status.</td>
</tr>
</tbody>
</table>
| ^ | - A system reason ID identifies some special processing the SYSMOD requires. Although SMP/E accepts any 1- to 7-character alphanumeric string as a system reason ID, these are the values currently used by IBM on ++HOLD statements:
<table>
<thead>
<tr>
<th>ID</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTION</td>
<td>The SYSMOD needs special handling before or during APPLY processing, ACCEPT processing, or both.</td>
</tr>
<tr>
<td>AO</td>
<td>The SYSMOD may require action to change automated operations procedures and associated data sets and user exits in products or in customer applications. The PTF cover letter describes any changes (such as to operator message text, operator command syntax, or expected actions for operator messages and commands) that can affect automation routines.</td>
</tr>
<tr>
<td>DB2BIND</td>
<td>A DB2® application REBIND is required for the SYSMOD to become effective.</td>
</tr>
<tr>
<td>DDDEF</td>
<td>Data set changes or additions as required.</td>
</tr>
<tr>
<td>DELETE</td>
<td>The SYSMOD contains a ++DELETE MCS, which deletes a load module from the system.</td>
</tr>
<tr>
<td>DEP</td>
<td>The SYSMOD has a software dependency.</td>
</tr>
<tr>
<td>DOC</td>
<td>The SYSMOD has a documentation change that should be read before the SYSMOD is installed.</td>
</tr>
<tr>
<td>DLWLD</td>
<td>Code that is shipped with maintenance that needs to be downloaded.</td>
</tr>
<tr>
<td>DYNACT</td>
<td>The changes supplied by the SYSMOD may be activated dynamically without requiring an IPL. The HOLD statement describes the instructions required for dynamic activation. If those instructions are not followed, then an IPL is required for the SYSMOD to take effect.</td>
</tr>
<tr>
<td>EC</td>
<td>The SYSMOD needs a related engineering change.</td>
</tr>
<tr>
<td>ENH</td>
<td>The SYSMOD contains an enhancement, new option or function. The HOLD statement provides information to the user regarding the implementation and use of the enhancement.</td>
</tr>
<tr>
<td>EXIT</td>
<td>The SYSMOD contains changes that may affect a user exit. For example, the interface for an exit may be changed, an exit may need to be reassembled, or a sample exit may be changed.</td>
</tr>
<tr>
<td>EXRF</td>
<td>The SYSMOD must be installed in both the active and the alternative Extended Recovery Facility (XRF) systems at the same time to maintain system compatibility. (If you are not running XRF, you should bypass this reason ID.)</td>
</tr>
<tr>
<td>FULLGEN</td>
<td>The SYSMOD needs a complete system or subsystem generation to take effect.</td>
</tr>
<tr>
<td>IOGEN</td>
<td>The SYSMOD needs a system or subsystem I/O generation to take effect.</td>
</tr>
<tr>
<td>IPL</td>
<td>The SYSMOD requires an IPL to become effective. For example, the SYSMOD may contain changes to LPA or NUCLEUS, the changes may require a CLPA, or a failure to perform an IPL might lead to catastrophic results, such as could be caused by activation of a partial fix.</td>
</tr>
</tbody>
</table>
++HOLD MCS

Note: If you plan to perform an IPL with CLPA after the SYSMOD has been applied, then no further investigation of the HOLD is required; simply bypass the IPL reason ID. However, if you are not planning to perform an IPL with CLPA, then the details of the HOLD statement must be investigated to determine what kind of actions are required to activate the SYSMOD.

MSGSKEL This SYSMOD contains message changes that must be compiled for translated versions of the message changes to become operational on extended TSO consoles.

If you want to use translated versions of the messages, you must run the message compiler once for the library containing the English message outlines, and once for each additional language you want to be available on your system. For details, see /OS MVS Planning: Operations.

If you want to use only the English version of the messages, you do not need to run the message compiler. You should bypass this reason ID.

MULTSYS Identifies fixes that need to be applied to multiple systems, in one of three cases: preconditioning, coexistence, or exploitation.

RESTART To become effective, the SYSMOD requires a special subsystem restart operation. The HOLD statement contains information regarding the required restart actions.

- A user reason ID is defined by the user.
- A Fix Category reason ID is the SYSMOD ID for the APAR that caused the SYSMOD to be placed into exception status. The APAR reason ID is associated to one or more categories of fixes.

For additional information, see “Naming conventions for HOLD reason IDs and HOLD classes” on page 514

RESOLVER Identifies the SYSMOD that resolves the held SYSMOD. More specifically, the resolving SYSMOD supersedes the reason ID APAR that caused the SYSMOD to be held.

sysmod_id

If the ++HOLD is being processed from the SMPHOLD data set, sysmod_id specifies the name of the SYSMOD to be placed into exception SYSMOD status.

If the ++HOLD is internal to a SYSMOD, then sysmod_id specifies either the SYSMOD that contains the ++HOLD or the originating SYSMOD that contained the ++HOLD and is now superseded by the current SYSMOD.

This operand is required.

Usage Notes

- If the text within the COMMENT operand contains parentheses, they must be in matched pairs. For example:

  COMMENT ( ADD 'PARM(COND(5))' ON THE EXEC )

  This works, but the following statements result in an error:

  COMMENT ( ADD OPENING PARENTHESES '(' )
or

```
COMMENT ( ADD CLOSING PARENTHESES ' ) ' )
```

- The following restrictions apply only to ++HOLD MCSs packaged within a SYSMOD:
  - The only HOLD type allowed is SYSTEM.
  - ++HOLD statements must be placed after all ++VER and ++IF statements and before the first ++JCLIN or element statement.
  - The SYSMOD ID on the ++HOLD MCS must match either the SYSMOD containing the ++HOLD MCS, or the originating SYSMOD that contained the ++HOLD MCS and is now superseded by the current SYSMOD.

**Examples**

The following examples are provided to help you use the ++HOLD MCS:

**Example 1: Noting a special documentation change**

Here is an example of a SYSMOD containing a ++HOLD statement. PTF UZ12345, which is applicable to function FX1040, introduces a documentation change that the system operator should know about.

```
++PTF(UZ12345) /* PTF modification. */
++VER(Z038) FMID(FX1040) /* For MVS product FX1040. */
           /* No prerequisites. */
++HOLD   (UZ12345) /* Hold this PTF */
          FMID(FX1040) /* for this function */
          SYSTEM /* for system processing and*/
          REASON(DOC) /* for doc change. */
          COMMENT(this PTF changes operator console
          message xxx1233. A reply of U is
          required to this message ).
++MOD(IFBMOD01) /* Change this module */
DISTLIB(A0512) /* in this DLIB. */
```

**Example 2: Marking a PTF that is in error**

When IBM discovers errors in PTFs it has already shipped, it provides information about these program error PTFs (PE-PTFs) in RETAIN®. To make sure these PTFs are held, you can use the RETAIN information to build ++HOLD statements for the PTFs.

**Note:** In this example, because only ++HOLD statements are being shown, none of them are underlined.

```
++HOLD   (UZ12345) /* Hold this PTF */
          FMID(FX1040) /* for this function */
          ERROR  /* for APAR fix. */
          REASON(AZ00001) /* APAR is AZ00001. */
          COMMENT(this APAR causes loop) /* */
++HOLD   (UZ12345) /* Hold this PTF */
          FMID(FX1040) /* for this function */
          ERROR  /* for APAR fix. */
          REASON(AZ00002) /* APAR is AZ00002. */
          COMMENT(this APAR causes OC4) /* */
++HOLD   (UZ12346) /* Hold this PTF */
          FMID(FX1040) /* for this function */
          ERROR  /* for APAR fix. */
          REASON(AZ00003) /* APAR is AZ00003. */
          COMMENT(incorrect output on console) /* */
++HOLD   (UZ12347) /* Hold this PTF */
          FMID(FX1040) /* for this function */
          ERROR  /* for APAR fix. */
          REASON(AZ00004) /* APAR is AZ00004. */
```

Chapter 2. SMP/E modification control statements  43
**Example 3: Specifying a hold class**

Here is an example of a SYSMOD containing a ++HOLD statement for a PTF requiring a change that applies only if a Year 2000-related fix is desired.

```plaintext
++PTF(UZ12345)  /* PTF modification. */
++VER(Z038)  FMID(FXY1040)  /* For MVS product FXY1040. */
               /* No prerequisites. */
++HOLD(UZ12345)  /* Hold this PTF */
               FMID(FXY1040)  /* for this function */
               ERROR    /* for APAR fix. */
               REASON(AQ19558)  /* APAR is AQ19558. */
               CLASS(YR2000)  /* This change is required */
               SYMP(YR2000)  CHGDT(981019))
++MOD(IFBMOD01)  /* Change this module */
               DISTLIB(AOS12)  /* in this DLIB. */
```

**Example 4: Identifying APARs and their associated fix categories**

Here are some examples of using the ++HOLD FIXCAT MCS to identify APARs and their associated fix categories.

```plaintext
++HOLD(HBB7730)  /* Held FMID */
FMID(HBB7730)  FIXCAT  /* Associates an APAR to a fix category */
               REASON(AA15968)  /* The APAR */
               CATEGORY(IBM.Device.2094)  /* A fix category */
               RESOLVER(UA27113)  /* The fixing PTF */
```
+++IF MCS

The +++IF MCS specifies requisites that must be installed with a SYSMOD if a certain function is installed. If the specified function is installed in the zone that SMP/E is trying to install this SYSMOD into, the requisite must also be installed in that zone; otherwise SMP/E does not install the SYSMOD containing the +++IF MCS. If the specified function is not yet installed in the zone where SMP/E is trying to install this SYSMOD, SMP/E saves the information from the +++IF MCS in case the specified function is installed later.

+++IF statements are interpreted, reformatted, and placed in the target zone data set during APPLY processing and in the distribution zone data set during ACCEPT processing.

+++IF statements can describe dependencies between two products, even if those products have different SRELs and are defined in different zones. The information from these statements is used by the REPORT command to identify cross-zone requisites—that is, conditional requisites needed in one zone because of +++IF statements in a SYSMOD installed in another zone.

A +++IF statement is associated with the +++VER MCS preceding it in the SYSMOD. Multiple +++IF statements can be specified following each +++VER MCS.

Syntax

```
++IF MCS
+++IF FMID(sysmod_id) THEN REQ(sysmod_id)
```

Operands

<table>
<thead>
<tr>
<th>FMID</th>
<th>Specifies the function that is to be checked to determine whether it is installed in one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• The target libraries (for APPLY processing)</td>
</tr>
<tr>
<td></td>
<td>• The distribution libraries (for ACCEPT processing)</td>
</tr>
<tr>
<td></td>
<td>This operand is required. It is not satisfied by superseded FMIDs.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>REQ</th>
<th>Specifies the SYSMODs that are needed if the function SYSMOD specified on the FMID operand of the +++IF MCS is installed. This operand is required.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>THEN</th>
<th>Specifies that the requisite for the +++IF MCS follows.</th>
</tr>
</thead>
</table>

Usage Notes

- The operands must be specified in the order shown in the syntax.
- The function specified for FMID must be different from the SYSMOD ID on the header statement.
Examples

PTF UZ00004 contains service for elements belonging to function FXY1040. If function FXY1050 is installed in the same zone, PTF UZ00005 must also be installed in that zone in order for PTF UZ00004 to be installed successfully. If function FXY1050 is not presently installed, PTF UZ00005 is not required; however, SMP/E saves the ++IF MCS in case function FXY1050 is installed in the future. Then, when FXY1050 is installed, PTF UZ00005 is considered an unsatisfied conditional requisite that must also be installed.

Here is an example of a SYSMOD containing a ++IF statement to define UZ00005 as a conditional requisite:

```
++PTF(UZ00004) /* PTF SYSMOD. */
++VER(Z038) FMID(FXY1040) /* For MVS product FXY1040. */
++IF FMID(FXY1050) /* If FXY1050 is on, or */
    THEN /* when it's put on later, */
        REQ(UZ00005) /* UZ00005 is required. */
++MOD(IFBMOD01) /* Replace this module */
    DISTLIB(AOSFB) /* Replace this module */
++MACUPD(IFBMAC01) /* Update this macro */
    DISTLIB(IFBMACS) /* in this DLIB. */
```
The ++JAR MCS describes a Java™ ARchive (JAR) file. The Java jar command is used to construct and update such files in a UNIX file system. JAR elements can have any of the following characteristics:

- The record format (RECFM) must be F, FA, FM, FB, FBA, FBM, V, VA, VM, VB, VBA, or VBM.
- Elements with variable-length records cannot contain spanned records.
- The maximum LRECL is 32,654.
- The records can be numbered or unnumbered.

There are MCS statements to replace JAR elements, just as there are MCS statements to replace other types of elements. The ++JARPD MCS can be used to update JAR elements.

**Syntax**

The syntax to be used depends on the processing to be performed for the element:

- Adding or replacing the element
- Deleting the element
Adding or replacing a JAR element

++JAR MCS

- ++JAR(name)
  - DISTLIB(ddname)
  - JARPARM(character_string)

- LINK(linkname)
  - PARM(character_string)
  - RELFILE(number)
  - TXLIB(ddname)
  - FROMDS

- RMID(sysmod_id)
  - SHSCRIPT(scriptname)
    - PRE
    - POST

- SYMLINK
  - SYSLIB(ddname)
    - URID(sysmod_id)

- VERSION(sysmod_id)

FROMDS

- FROMDS(DSN(dsn)NUMBER(n)
  - VOL(vol)
  - UNIT(unit)

SYMLINK

- SYMLINK(symlinkname)
  - SYMPATH(sympathname)

Deleting a JAR element

++JAR MCS

- ++JAR(name)
  - DELETE
  - DISTLIB(ddname)
  - VERSION(sysmod_id)

Operands

DELETE specifies that the JAR element and all of its link names and symbolic link names are to be removed from the “target library” (UNIX file system) and the distribution library.
+JAR MCS

Notes:
1. DELETE is mutually exclusive with all other operands except DISTLIB and VERSION.
2. If the element statement is in a base function, you may want to use the DELETE operand on the +VER MCS to delete the previous release, rather than on the element statement to delete a specific element.
3. Specification of the DELETE operand results in all link names and symbolic link names of the element being deleted along with the element identified.

DISTLIB
specifies the ddname of the distribution library for the specified JAR element. During ACCEPT processing, SMP/E installs the JAR element into the distribution library as a member. (The distribution library must be a PDS or PDSE; it cannot be part of a UNIX file system.)

Notes:
1. DISTLIB must be specified when the JAR element is first installed.
2. If an element entry already exists in the target zone or distribution zone and the value currently in that entry does not match that specified in the DISTLIB operand, the SYSMOD is not applied or accepted.

FROMDS
identifies the partitioned data set that contains this element.

Note: The FROMDS operand and its DSN, NUMBER, VOL, and UNIT suboperands are included in the MCS generated by the BUILDMCS command. IBM does not intend the FROMDS operand to be used in manually coded MCS.

DSN specifies the dsname of the FROMDS data set. The specified data set name must conform to standard data set naming conventions and cannot contain parentheses. The maximum length of the entire name is 44 characters (including the periods).

NUMBER specifies a number that SMP/E is to use when assigning a name to the SMPTLIB data set associated with this FROMDS data set. (This is similar to the way the relative file number is used in RELFILE processing.)

VOL specifies, for an uncataloged data set, the volume serial number of the volume containing the FROMDS data set. If specified, this volume identifier must be from 1 to 6 alphanumeric characters.

VOL may be omitted for a cataloged data set.

UNIT specifies, for an uncataloged data set, the UNIT type containing the FROMDS data set. If specified, the UNIT value must be from 1 to 8 characters and must conform to standard UNIT naming conventions. SMP/E accepts any nonblank characters specified between the open and close parentheses, up to a maximum length of 8.

UNIT may be omitted for a cataloged data set.

Note: FROMDS is mutually exclusive with DELETE, RELFILE, and TXLIB.
++JAR MCS

JARPARM
specifies a character string that is to be passed to the jar command as a
command option when updating the JAR file. The maximum length of this
character string is 300 bytes of data.

Only those jar command options that require only the option indicator to be
specified are supported, such as 0 and M. Options requiring additional input
over and above the option indicator are not supported. Examples of
unsupported options are the m and -C options.

Notes:
1. The character string can include any non-blank characters (characters x’41’
through x’FE’).
2. The JARPARM value is saved and passed to the jar command as follows:
   • If JARPARM is specified on the element MCS, any value previously
     saved in the JAR element entry is overlaid and the new value is passed
to the jar command.
   • If JARPARM is not specified on the element MCS and a saved value
     exists in the JAR element entry, then the saved value is passed to the jar
command.
   • If JARPARM is not specified on the element MCS and there is no saved
     value in the JAR element entry, then no value is saved in the element
entry and no value is passed to the jar command.

LINK
specifies the alternative names by which this JAR element can be known in a
UNIX file system. The full name is produced by concatenating the specified
linkname with a UNIX file system directory identified by the SYSLIB subentry.
Each linkname is passed to the HFS copy utility as an execution parameter.

Notes:
1. The linkname can be from 1 to 1023 characters.
2. A linkname can be enclosed in single apostrophes (’). A linkname must be
   enclosed in single apostrophes if any of the following is true:
   • The linkname contains lowercase alphabetic characters.
   • The linkname contains a character that is not uppercase alphabetic,
     numeric, national ($, #, @), slash (/), plus (+), hyphen, period, or
     ampersand (&).
   • The linkname spans more than one line in the control statement.
   The single apostrophes used to enclose a linkname (the delimiters) do not
   count as part of the 1023-character limit.
3. Any apostrophes specified as part of a linkname (not the delimiters) must
   be doubled.
   Double apostrophes count as two characters in the 1023-character limit.
4. The linkname can include characters X’40’ through X’FE’.
5. LINK values are saved and passed to the HFS copy utility as follows:
   • If LINK is specified on the element MCS, any values previously saved in
     the element entry are overlaid.
   • If LINK is not specified on the element MCS and saved values exist in
     the JAR element entry, the saved values are passed to the HFS copy
utility as execution parameters.
   If LINK is not specified on the element MCS and there are no saved
values in the JAR element entry, no linknames are passed to the HFS
copy utility.
++JAR MCS

name

specifies the name of the JAR element member. The name can contain any uppercase alphabetic, numeric, or national ($) # @ character and can be 1 to 8 characters long.

PARM

specifies a character string that is to be passed to the hierarchical file system copy utility as an execution-time parameter. (The values that can be specified on the PARM operand, such as PATHMODE, are those accepted by the BPXCOPY utility. See z/OS UNIX System Services Command Reference for a description of BPXCOPY and the values it accepts.) The maximum length of this character string is 300 bytes of nonblank data. If any blanks are specified in the PARM value, they are deleted by SMP/E during processing and do not count toward the 300-byte maximum.

Notes:

1. PARM is an optional operand.
2. The character string can be entered free-form, without regard to blanks (which are compressed out of the string), and can span multiple 80-byte records.
3. If parentheses are specified in the PARM value, there must always be a pair (left and right); otherwise, the results are unpredictable.
4. PARM values are saved and passed to the HFS copy utility as follows:

   • If PARM is specified on the element MCS, any values previously saved in the JAR element entry are overlaid.

   • If PARM is not specified on the element MCS and saved values exist in the JAR element entry, the saved values are passed to the HFS copy utility as execution parameters.

   If PARM is not specified on the element MCS and there are no saved values in the JAR element entry, no parameters are saved from the element MCS or passed from the JAR element entry to the HFS copy utility.

5. If the UTILITY entry for the HFS copy utility specifies a PARM value, those parameters are passed to the utility in addition to any parameters saved in the JAR element entry.

RELFILE

identifies which relative file associated with the SYSMOD contains this element. This operand is required if you provide the element in RELFILE format, rather than inline or in a TXLIB data set.

Notes:

1. The RELFILE value must be a decimal number from 1 to 9999.
2. RELFILE is mutually exclusive with FROMDS and TXLIB.

RMID

specifies the last SYSMOD that replaced this element. This operand can be used only in a service-updated function, and the specified PTF must be integrated into the function.

SHSCRIPT

specifies a UNIX shell script, scriptname, to be invoked when the element is installed in (or deleted from) a directory of a UNIX file system. scriptname can contain any uppercase alphabetic, numeric, or national ($) # @ character and can be 1 to 8 characters long.
A shell script is commonly used to complete the installation of an element. For example, if the JAR element requires an external link, you can provide a shell script that performs the necessary steps to create the external link for the JAR element.

`scriptname` must be the first value to follow the SHSCRIPT operand.

You define the shell script to SMP/E through a `++SHELLSCR` statement, which can be within the same SYSMOD as the JAR element, or within a SYSMOD that was processed previously.

You cannot define more than one shell script for an element.

You can follow `scriptname` with either of two optional values, PRE and POST, to specify the point in SMP/E processing when the shell script is to be invoked. The following examples show how you can use the PRE and POST values:

- To run the shell script before the element is copied to a UNIX file system directory, specify:
  ```
  SHSCRIPT(scriptname,PRE)
  ```

- To run the shell script after the element is copied to a UNIX file system directory, specify:
  ```
  SHSCRIPT(scriptname,POST)
  ```

or specify no value after `scriptname` to use POST by default.

- To run the shell script both before and after the element is copied to a UNIX file system directory, specify:
  ```
  SHSCRIPT(scriptname,PRE,POST)
  ```

If you do not specify a PRE or POST value for the shell script, SMP/E invokes the shell script after the element is installed in the directory.

You cannot specify the SHSCRIPT operand with the DELETE operand.

**SYMLINK**

specifies a list of one or more symbolic links, which are file names that can be used as alternate names for referring to this element in a UNIX file system. Each linkname listed here is associated with a pathname listed in the SYMPATH operand. For more information on how the linknames and pathnames are associated, see the description of the SYMPATH operand and  

"Example 3: Packaging a SYSMOD with a symbolic link" on page 36.

The SYMLINK value specified should be a relative path value (that is, it does not start with a slash "/"). When the symbolic link is created, it is created relative to the pathname of the element’s SYSLIB ddname.

**SYMLINK** must be specified if the **SYMPATH** operand is specified, otherwise it must be omitted.

A symbolic linkname can be from one to 1023 characters. Any characters in the range X’40’ through X’FE’ may be specified.

The value may be enclosed in single apostrophes. It **must** be enclosed in single apostrophes if:

- it is continued to the next line in the MCS, or
- it contains a character that is not uppercase alphabetic, numeric, national ($, #, @), slash (/), plus (+), hyphen, period, or ampersand (&).

If an apostrophe is a part of the symbolic linkname and is not a delimiter, then it must be doubled. These two apostrophes count as two characters against the
++JAR MCS

1023 character limit for a symbolic linkname. The single apostrophes used to
enclose a symbolic linkname do not count against the 1023 character limit.

**SYMPATH**
specifies a list of one or more pathnames that are associated with symbolic
links identified by the SYMLINK operand. The first pathname in the
SYMPATH operand is associated with the first symbolic link in the SYMLINK
operand, the second pathname with the second symbolic link, and so on. If
there are more symbolic links listed than there are pathnames, then the last
listed pathname is used for the remaining symbolic links. If more pathnames
are specified than symbolic linknames, then the excess pathnames (at the end
of the list) are ignored.

The SYMPATH value specified should be a relative path value. When the
symbolic link is accessed, the system assumes the destination of that link (the
SYMPATH value) is relative to that symbolic link (the SYMLINK value). For
more information on how the pathnames and linknames are associated, see
“Example 3: Packaging a SYSMOD with a symbolic link” on page 36.

**SYMPATH** must be specified if the SYMLINK operand is specified, otherwise
it must be omitted.

A symbolic pathname can be one to 1023 characters. Any characters in the
range ‘X’40’ through ‘X’FE’ may be specified.

The value may be enclosed in single apostrophes. It must be enclosed in single
apostrophes, if:
• it is continued to the next line in the MCS, or
• it contains a character that is not uppercase alphabetic, numeric, national ($,
  #, @), slash (/), plus (+), hyphen, period, or ampersand (&).

If an apostrophe is a part of the symbolic pathname and is not a delimiter,
then it must be doubled. These two apostrophes count as two characters
against the 1023 character limit for a symbolic pathname. The single
apostrophes used to enclose a symbolic linkname do not count against the 1023
character limit.

**SYSLIB**
specifies the ddname of the “target library” within the UNIX file system for
the element.

During APPLY processing, the HFS copy utility installs the JAR element into a
UNIX file system. During RESTORE processing, the HFS copy utility copies the
JAR element from the distribution library member into a UNIX file system.

**Note:** SYSLIB must be specified when the JAR element is first installed.

**TXLIB**
is the ddname of the partitioned data set containing the JAR element. This
operand is required if the JAR element is provided in a data set that the users
have access to, rather than inline or in RELFILE format.

**Notes:**
1. SMPTLIB cannot be used as a value on the TXLIB operand.
2. TXLIB is mutually exclusive with FROMDS and RELFILE.

**UMID**
specifies the SYSMODs that have updated this JAR file since it was last
replaced. This operand can be used only in a service-updated function, and the
specified SYSMODs must be integrated into the function.
++JAR MCS

VERSION
specifies one or more function SYSMODs that currently contain the element.
The function containing the element MCS takes over ownership of the element
from the specified functions.

When VERSION is specified on an element statement, it overrides any
VERSION operand values that might be specified on the ++VER MCS.

Usage Notes

• If the JAR element is packaged inline, it must immediately follow the ++JAR
  MCS and must not contain any records starting with ++. Neither FROMDS, nor
  RELFILE, nor TXLIB can be specified on the ++JAR MCS when the element is
  packaged inline.
• To be packaged inline, a JAR file element must contain fixed-block-80 records. To
  achieve this, the original element can be extracted from a UNIX file system into
  a data set (using the TSO command OGET for example), and then GIMDTS can
  be used to transform the element into fixed-block-80 records.

Examples

Here is an example of the ++JAR MCS.

++JAR(ABCTTT) DISTLIB(AABCBIN) SYSLIB(SABCBIN) RELFILE(2)
  PARM(PATHMODE(0,6,4,4))
  LINK('./TicTacToe.jar')
  SYMLINK('./../usr/lib/TicTacToe.jar')
  SYMPATH('./../../../usr/lpp/abc/bin/TicTacToe.jar').
++JARUPD MCS

The ++JARUPD MCS describes an update to a Java ARchive (JAR) file in a UNIX file system. The Java jar command is used to construct and update such files in a UNIX file system. A JARUPD element is itself a Java Archive file, but it contains only the component files to be added to or replaced in an existing JAR file, as opposed to a complete replacement for an existing JAR file.

Notes:
1. To update JAR files, SMP/E must use the update (u) option of the jar command, which is provided in version 1.2 of the Java Development Kit (JDK). Therefore, in order to perform APPLY or ACCEPT command operations for a SYSMOD that contains JARUPD elements, SMP/E requires the IBM Developer Kit for OS/390, Java 2 Technology Edition, or its successor. Java 2 Technology Edition is a no-charge product available for users of OS/390 Version 2 Release 8 and above, or z/OS Version 1 Release 1 and above.

Java must be available in the execution environment for SMP/E. The SMPJHOME DD statement or DDDEF entry should be used to specify the directory where Java resides. For example, if Java 1.4, which has been installed in the /usr/lpp/java/J1.4 directory, should be used, then the following DD statement should be specified:

```
//SMPJHOME DD PATH='/usr/lpp/java/J1.4/',PATHDISP=KEEP
```

For additional information about how to set the SMPJHOME value, see Chapter 4, “SMP/E data sets and files,” on page 141.

2. There is no way to delete component files from a JAR file. ++JARUPD can be used only to add or replace component files in a JAR file. If component files must be deleted, then the entire JAR file must be replaced with another JAR file from which those component files have been removed.

Syntax
++JARUPD MCS

Operands

JARPARM

specifies a character string that is to be passed to the jar command as a
command option when updating the JAR file. The maximum length of this
character string is 300 bytes of data.

Only those jar command options that require only the option indicator to be
specified are supported, such as 0 and M. Options requiring additional input
over and above the option indicator are not supported. Examples of
unsupported options are the m and -C options.

Notes:
1. The character string can include any non-blank characters (characters x‘41’
through x‘FE’).
2. The JARPARM value is saved and passed to the jar command as follows:
   • If JARPARM is specified on the ++JARUPD, any value previously saved
     in the JAR element entry is overlaid and the new value is passed to the
     jar command.
   • If JARPARM is not specified on the ++JARUPD and a saved value exists
     in the JAR element entry, then the saved value is passed to the jar
     command.
   • If JARPARM is not specified on the ++JARUPD and there is no saved
     value in the JAR element entry, then no value is saved in the element
     entry and no value is passed to the jar command.

LINK

specifies the alternative names by which this JAR element can be known in a
UNIX file system. The full name is produced by concatenating the specified
linkname with a UNIX file system directory identified by the SYSLIB subentry.
Each linkname is passed to the HFS copy utility as an execution parameter.

Notes:
1. The linkname can be from 1 to 1023 characters.
2. A linkname can be enclosed in single apostrophes (‘). A linkname must be
   enclosed in single apostrophes if any of the following is true:
   • The linkname contains lower case alphabetic characters.
   • The linkname contains a character that is not upper case alphabetic,
     numeric, national ($, #, @), slash (/), plus (+), hyphen, period, or
     ampersand (&).
   • The linkname spans more than one line in the control statement.
   The single apostrophes used to enclose a linkname (the delimiters) do not
   count as part of the 1023-character limit.
3. Any apostrophes specified as part of a linkname (not the delimiters) must
   be doubled.
   Double apostrophes count as two characters in the 1023-character limit.
4. The linkname can include characters X‘40’ through X‘FE’.
5. LINK values are saved and passed to the HFS copy utility as follows:
   • If LINK is specified on the ++JARUPD, any values previously saved in
     the element entry are overlaid.
   • If LINK is not specified on the ++JARUPD and saved values exist in the
     JAR element entry, the saved values are passed to the HFS copy utility as
     execution parameters.
++JARUPD MCS

If LINK is not specified on the ++JARUPD and there are no saved values in the JAR element entry, no linknames are passed to the HFS copy utility.

name

specifies the name of the JAR element member. The name can contain any uppercase alphabetic, numeric, or national ($, #, @) character and can be 1 to 8 characters long.

PARM

specifies a character string that is to be passed to the hierarchical file system copy utility as an execution-time parameter. (The values that can be specified on the PARM operand, such as PATHMODE, are those accepted by the BPXCOPY utility. See [z/OS UNIX System Services Command Reference](#) for a description of BPXCOPY and the values it accepts.) The maximum length of this character string is 300 bytes of nonblank data. If any blanks are specified in the PARM value, they are deleted by SMP/E during processing and do not count toward the 300-byte maximum.

Notes:
1. PARM is an optional operand.
2. The character string can be entered free-form, without regard to blanks (which are compressed out of the string), and can span multiple 80-byte records.
3. If parentheses are specified in the PARM value, there must always be a pair (left and right); otherwise, the results are unpredictable.
4. PARM values are saved and passed to the HFS copy utility as follows:
   • If PARM is specified on the ++JARUPD, any values previously saved in the JAR element entry are overlayd.
   • If PARM is not specified on the ++JARUPD and saved values exist in the JAR element entry, the saved values are passed to the HFS copy utility as execution parameters.
      If PARM is not specified on the ++JARUPD and there are no saved values in the JAR element entry, no parameters are saved from the ++JARUPD or passed from the JAR element entry to the HFS copy utility.
5. If the UTILITY entry for the HFS copy utility specifies a PARM value, those parameters are passed to the utility in addition to any parameters saved in the JAR element entry.

RELFILE

identifies which relative file associated with the SYSMOD contains this element. This operand is required if you provide the element in RELFILE format, rather than inline or in a TXLIB data set.

Notes:
1. The RELFILE value must be a decimal number from 1 to 9999.
2. RELFILE is mutually exclusive with TXLIB.

SYMLINK

specifies a list of one or more symbolic links, which are file names that can be used as alternate names for referring to this element in a UNIX file system. Each linkname listed here is associated with a pathname listed in the SYMPATH operand. For more information on how the linknames and pathnames are associated, see the description of the SYMPATH operand and "Example 3: Packaging a SYSMOD with a symbolic link" on page 36.
The SYMLINK value specified should be a relative path value (that is, it does not start with a slash ["/"]). When the symbolic link is created, it is created relative to the pathname of the element’s SYSLIB ddname.

**SYMLINK** must be specified if the **SYMPATH** operand is specified, otherwise it must be omitted.

A symbolic linkname can be from one to 1023 characters. Any characters in the range X’40’ through X’FE’ may be specified.

The value may be enclosed in single apostrophes. It must be enclosed in single apostrophes if:

- it is continued to the next line in the MCS, or
- it contains a character that is not uppercase alphabetic, numeric, national ($, #, @), slash (/), plus (+), hyphen, period, or ampersand (&).

If an apostrophe is a part of the symbolic linkname and is not a delimiter, then it must be doubled. These two apostrophes count as two characters against the 1023 character limit for a symbolic linkname. The single apostrophes used to enclose a symbolic linkname do not count against the 1023 character limit.

**SYMPATH** specifies a list of one or more pathnames that are associated with symbolic links identified by the SYMLINK operand. The first pathname in the SYMPATH operand is associated with the first symbolic link in the SYMLINK operand, the second pathname with the second symbolic link, and so on. If there are more symbolic links listed than there are pathnames, then the last listed pathname is used for the remaining symbolic links. If more pathnames are specified than symbolic linknames, then the excess pathnames (at the end of the list) are ignored.

The SYMPATH value specified should be a relative path value. When the symbolic link is accessed, the system assumes the destination of that link (the SYMPATH value) is relative to that symbolic link (the SYMLINK value). For more information on how the pathnames and linknames are associated, see "Example 3: Packaging a SYMMD with a symbolic link” on page 36.

**SYMPATH** must be specified if the **SYMLINK** operand is specified, otherwise it must be omitted.

A symbolic pathname can be one to 1023 characters. Any characters in the range X’40’ through X’FE’ may be specified.

The value may be enclosed in single apostrophes. It must be enclosed in single apostrophes if:

- it is continued to the next line in the MCS, or
- it contains a character that is not uppercase alphabetic, numeric, national ($, #, @), slash (/), plus (+), hyphen, period, or ampersand (&).

If an apostrophe is a part of the symbolic pathname and is not a delimiter, then it must be doubled. These two apostrophes count as two characters against the 1023 character limit for a symbolic pathname. The single apostrophes used to enclose a symbolic linkname do not count against the 1023 character limit.

**TXLIB**

is the ddname of the partitioned data set containing the JAR element. This operand is required if the JAR element is provided in a data set that the users have access to, rather than inline or in RELFILE format.
++JARUPD MCS

Notes:
1. SMPLIB cannot be used as a value on the TXLIB operand.
2. TXLIB is mutually exclusive with RELFILE.

Usage Notes

- If the JAR update file is packaged inline, it must immediately follow the
++JARUPD MCS and must not contain any records starting with ++. Neither
RELFILE nor TXLIB can be specified on the MCS when the element is packaged
inline.

- To be packaged inline, a JAR file element must contain fixed-block-80 records. To
do this, the original element can be extracted from a UNIX file system into a
data set (using, for example, the TSO command OGET), and then GIMDTS can
be used to transform the element into fixed-block-80 records.

Examples

Here is an example of the ++JARUPD MCS.

++JARUPD(ABCTTT) JARPARM(OM)
PARM(PATHMODE(0,6,4,4))
LINK('../TicTacToe.jar')
SYMLINK('.../usr/lib/TicTacToe.jar')
SYMPATH('.../usr/lpp/abc/bin/TicTacToe.jar').
++JCLIN MCS

The ++JCLIN MCS identifies the start of the job control language (JCL) input that must be processed as part of installing the SYMMOD. The JCLIN input is used to identify the structure of the target system libraries to SMP/E so that the modules, macros, and source code being replaced can be installed correctly. Processing of ++JCLIN input during APPLY or ACCEPT is similar to the processing done for the JCLIN command. For an additional description of JCLIN processing, see SMP/E Commands.

Note: The ++JCLIN MCS does not cause SMP/E to update the target or distribution libraries; only the entries in the target and distribution zones are updated. These libraries are updated when SMP/E processes the elements in the SYMMOD. The element statements in the SYMMOD determine which elements should be installed and cause SMP/E to invoke the utilities that install the elements.

Syntax

```plaintext
++JCLIN MCS

ASM(PGM=asmpgm)

CALLLIBS

COPY(PGM=copypgm)

/LKED(PGM=lkedpgm)

UPDATE(PGM=updpgm)

/RELFILE(number)

/TXLIB(ddname)

/FROMDS(DSN(dsn)NUMBER(n)

/VOL(vol)

/UNIT(unit)
```

Operands

**ASM**

specifies the name of the assembler program or procedure that is used in the JCLIN data. This operand must be specified if the name is different from those recognized by SMP/E, which are the program names ASMBLR, ASMA90, IEUASM, IEV90, and IFOX00, and procedure name ASMS.

**CALLLIBS**

specifies that SMP/E is to process SYSLIB DD statements in JCLIN link-edit steps. SYSLIB DD statements are processed only if the CALLLIBS operand is specified on the JCLIN command or ++JCLIN MCS, or if */CALLLIBS=YES is encountered after a job card preceding a link-edit step. If the CALLLIBS operand or the CALLLIBS comment is not specified, SMP/E ignores any SYSLIB DD statements it encounters.

**COPY**

specifies the name of the copy program or procedure that is used in the JCLIN
++JCLIN MCS

data. This operand must be specified if the name is different from that recognized by SMP/E, which is the program name IEBCOPY.

FROMDS
identifies the partitioned data set that contains this element.

Note: The FROMDS operand and its DSN, NUMBER, VOL, and UNIT suboperands are included in the MCS generated by the BUILDMCS command. IBM does not intend the FROMDS operand to be used in manually coded MCS.

DSN
specifies the dsname of the FROMDS data set. The specified data set name must conform to standard data set naming conventions and cannot contain parentheses. The maximum length of the entire name is 44 characters (including the periods).

NUMBER
specifies a number that SMP/E is to use when assigning a name to the SMPTLIB data set associated with this FROMDS data set. (This is similar to the way the relative file number is used in RELFILE processing.)

VOL
specifies, for an uncataloged data set, the volume serial number of the volume containing the FROMDS data set. If specified, this volume identifier must be from 1 to 6 alphanumeric characters.

UNIT may be omitted for a cataloged data set.

UNIT
specifies, for an uncataloged data set, the UNIT type containing the FROMDS data set. If specified, the UNIT value must be from 1 to 8 characters and must conform to standard UNIT naming conventions. SMP/E accepts any nonblank characters specified between the open and close parentheses, up to a maximum length of 8.

UNIT may be omitted for a cataloged data set.

Note: FROMDS is mutually exclusive with DELETE, RELFILE, and TXLIB.

LKED
specifies the name of the link-edit program or procedure that is used in the JCLIN data. This operand must be specified if the name is different from those recognized by SMP/E, which are the program names HEWL, HEWLH096, HEWLKED, IEWBLINK, IEWL, and LINKEDIT, and procedure name LINKS.

OPCODE
identifies an OPCODE member containing control statements identifying character strings to be treated as OPCODEs or macros.

PGM
specifies a program name (instead of a procedure name) for a utility.

RELFILE
specifies the relative position, within the files associated with this SYSMOD, of the file containing the JCLIN data as one of its members.

The member in the RELFILE data set containing the JCLIN input data must match the SYSMOD’s SYSMOD ID; for example, the JCLIN for ++PTF(UZ11111) is supplied in member UZ11111 of the unloaded PDS identified by the RELFILE operand.
Note: RELFILE is mutually exclusive with FROMDS and TXLIB.

TXLIB

specifies the ddname of a partitioned data set containing the JCLIN data as one of its members.

The member of the TXLIB data set containing the JCLIN input data must match the SYSMOD's SYSMOD ID; for example, the JCLIN for ++PTF(UZ11111) is supplied in member UZ11111 of the data set identified by the TXLIB operand.

Notes:
1. SMPTLIB cannot be used as a value on the TXLIB operand.
2. TXLIB is mutually exclusive with FROMDS and RELFILE.

UPDATE

specifies the name of the update program or procedure that is used in the JCLIN data. This operand must be specified if the name is different from that recognized by SMP/E, which is the program name IEBUPDTE.

Usage Notes

- If the JCLIN data is packaged inline, it must immediately follow the ++JCLIN MCS and must not contain any records that start with ++. Neither FROMDS, nor RELFILE, nor TXLIB can be specified on the ++JCLIN MCS.
- If the JCLIN data is packaged in a TXLIB data set, the ddname specified on the TXLIB operand is required during APPLY and ACCEPT processing.
- For information about packaging SYSMODs in RELFILE format, see z/OS Packaging Rules.

Examples

For these examples, assume function JXY1040 contains some inline JCLIN, one module (IFBMOD01), and one macro (IFBMAC01). The same format was used to package the JCLIN and the elements.

Note: Even though the examples are for a function, they are equally valid for PTFs, APARs, and USERMODs.

The following examples are provided to help you use the ++JCLIN MCS:

Example 1: ++JCLIN data packaged inline

Here is an example of a SYSMOD containing a ++JCLIN statement for packaging JCLIN inline:

```plaintext
++FUNCTION(JXY1040) /* Function SYSMOD. */.
++VER(Z838) /* For MVS, no requisites. */.
++JCLIN /* JCLIN is required. */.
//JOB JOB 'accounting info',MSGLEVEL=(1,1)
//STEP1 EXEC PGM=IEWL
//SYSLMOD DD DSN=SYS1.LINKLIB,DISP=SHR
//A0S12 DD DSN=SYS1.A0S12,DISP=SHR
//SYSLIN DD *
INCLUDE A0S12(IFBMOD01)
ENTRY IFBMOD01
ALIAS IFBMOD01A
NAME IFBMOD01(R)
/*
++MOD(IFBMOD01) /* This module */.
DISTLIB(A0S12) /* for this DLIB. */.
...
... object deck for IFBMOD01
```
No special DD statements, other than those for the target and DLIBs, are required to process this SYSMOD.

During APPLY, SMP/E processes the ++JCLIN data, determines that module IFBMOD01 gets linked into load module IFBMOD01 (which has an alias), stores information in the target zone, and then invokes the proper utilities to install the module and macro.

**Example 2: ++JCLIN data packaged in a RELFILE**

Here is an example of a SYSMOD containing a ++JCLIN statement for packaging JCLIN in relative files. No special ++JCLIN operands are required.

```plaintext
++FUNCTION(JXY1040) /* Function SYSMOD */
FILES(3) /* in RELFILE format. */
++VER(2038) /* For MVS, no requisites. */
++JCLIN /* JCLIN is required. */
  RELFILE(1) /* Data is in first RELFILE. */
++MOD(IFBMOD01) /* This module */
  DISTLIB(AOS12) /* for this DLIB */
  RELFILE(2) /* is in second RELFILE. */
++MAC(IFBMAC01) /* This macro */
  DISTLIB(AMACLIB) /* for this DLIB */
  RELFILE(3) /* is in third RELFILE. */
```

The SMPTLIB DD statement is required for the RECEIVE command to load the RELFILE data sets from tape onto DASD, and at APPLY and ACCEPT, in order to access the data in the unloaded partitioned data sets on DASD.

**Note:** Different RELFILE data sets are required for the module and macro, because they are in different formats (modules must be in load module format, RECFM=U, while macros are RECFM=FB). Although a separate RELFILE data set was used to contain the ++JCLIN data, that data could have been put into the data set with the macros, because both have the same attributes (LRECL=80, RECFM=FB).

**Example 3: ++JCLIN data packaged in a TXLIB with a user utility program name**

Here is an example of a SYSMOD containing a ++JCLIN statement for packaging JCLIN in text libraries. The JCLIN contains assembly steps using a special link-edit utility, ALTIEWL.

```plaintext
++FUNCTION(JXY1040) /* Function SYSMOD */
++VER(2038) /* For MVS, no requisites. */
++JCLIN /* JCLIN is required. */
  TXLIB(LIB1040) /* Data is in text library. */
  LKED(PGM=ALTIEWL) /* Use other link-edit. */
++MOD(IFBMOD01) /* This module */
  DISTLIB(AOS12) /* for this DLIB */
  TXLIB(LIB1040) /* is in text library. */
++MAC(IFBMAC01) /* This macro */
  DISTLIB(AMACLIB) /* for this DLIB */
  TXLIB(LIB1040) /* is in text library. */
```
A DD statement for LIB0104 is required during APPLY and ACCEPT in order for SMP/E to call the utilities to get the replacements installed into the operating system libraries. An example of the DD statement is:

```
//LIB1040  DD DSN=...
```

**Note:** In this case, the replacements for all three elements were put in one data set. That data set must contain three members: member JXY1040 must be the JCLIN data, member IFBMOD01 must contain the object deck for module IFBMOD01, and member IFBMAC01 must contain the replacement for macro IFBMAC01. Because all have the same formats (that is, RECFM=FB LRECL=80) they can be packaged in one data set.

Member JXY1040 looks as follows:

```
//JOB       JOB 'accounting info',MSGLEVEL=(1,1)
//STEP1     EXEC PGM=ALTIEWL
//SYSLMOD   DD DSN=SYS1.LINKLIB,DISP=SHR
//AOS12     DD DSN=SYS1.AOS12,DISP=SHR
//SYSLIN    DD *
  INCLUDE AOS12(IFBMOD01)
  ENTRY IFBMOD01
  ALIAS IFBMOD01A
  NAME IFBMOD01(R)
/*
```

Note the use of ALTIEWL on the EXEC statement.
The ++MAC MCS describes a single macro replacement. It must immediately precede the macro definition statements when they are within the SYSMOD.

**Syntax**

The syntax to be used depends on the processing to be done for the element:
- Adding or replacing the element
- Deleting the element

**Adding or replacing a macro**

**Deleting a macro**

**Operands**

**ASSEM**

specifies the names of modules to be assembled in addition to those modules named as GENASM subentries in the MAC entry. The source for the assemblies is the ASSEM entry, SRC entry, or DISTSRC member whose name matches the specified ASSEM value. SMP/E looks for a match—first with an ASSEM entry, then with a SRC entry, and finally with an entry in the DISTSRC data set—and uses the first match it finds. The source must either be known to

---

Chapter 2. SMP/E modification control statements 65
++MAC MCS

SMP/E at the time the ASSEM operand is encountered on the ++MAC statement, or be included in the same SYSMOD.

Notes:
1. APPLY and ACCEPT processing place the specified names into the SYSMOD entry created on the target zone and distribution zone.
2. If the object deck for the element specified on the ASSEM operand is also provided by the SYSMOD, the assembly may not occur. (See [SMP/E](#) for more information.)

DELETE
specifies that the macro and alias names are to be removed from the target libraries, distribution libraries, and SMP/E data sets.

Notes:
1. DELETE is mutually exclusive with all other operands except DISTLIB and VERSION.
2. If the element statement is in a base function, you may want to use the DELETE operand on the ++VER MCS to delete the previous release, rather than on the element statement to delete a specific element.

DISTLIB
specifies the ddname of the distribution library for the specified macro.

Notes:
1. DISTLIB must be specified if the macro has not been previously recorded on the target zone or distribution zone. If a MAC entry already exists in the target zone or distribution zone and the value currently in that entry does not match that specified in the DISTLIB operand, the SYSMOD is not applied or accepted, unless that SYSMOD also used the ++MOVE MCS to change the DISTLIB to that new value.
2. You cannot use SYSPUNCH as the DISTLIB. It is used by SMP/E and other products to process assembled modules.

DISTMOD
specifies the ddname of the link-edit distribution library for those modules specified in the ASSEM operand. During ACCEPT processing, the object code from the assembler is link-edited to the library specified.

DISTSRC
specifies the ddname of the library containing the additional assembly or source to be assembled. The additional assembly or source must be specified in the ASSEM operand.

FROMDS
identifies the partitioned data set that contains this element.

Note: The FROMDS operand and its DSN, NUMBER, VOL, and UNIT suboperands are included in the MCS generated by the BUILDMCS command. IBM does not intend the FROMDS operand to be used in manually coded MCS.

DSN specifies the dsname of the FROMDS data set. The specified data set name must conform to standard data set naming conventions and cannot contain parentheses. The maximum length of the entire name is 44 characters (including the periods).

NUMBER specifies a number that SMP/E is to use when assigning a name to the
++MAC MCS

SMPTLIB data set associated with this FROMDS data set. (This is similar to the way the relative file number is used in RELFILE processing.)

VOL specifies, for an uncataloged data set, the volume serial number of the volume containing the FROMDS data set. If specified, this volume identifier must be from 1 to 6 alphanumeric characters.

VOL may be omitted for a cataloged data set.

UNIT specifies, for an uncataloged data set, the UNIT type containing the FROMDS data set. If specified, the UNIT value must be from 1 to 8 characters and must conform to standard UNIT naming conventions. SMP/E accepts any nonblank characters specified between the open and close parentheses, up to a maximum length of 8.

UNIT may be omitted for a cataloged data set.

Note: FROMDS is mutually exclusive with DELETE, RELFILE, SSI, and TXLIB.

MALIAS specifies the alias names for the macro in both the target system and the distribution libraries.

Note: MALIAS must be specified on the ++MAC MCS even if ALIAS was specified on the COPY SELECT statement. MALIAS is required for the RECEIVE command to properly handle aliases in RELFILEs. During RECEIVE processing, SMP/E copies RELFILEs to SMPTLIB data sets. All element members and their associated aliases are copied. Because JCLIN is not processed during RECEIVE, the aliases must be identified on the MCS to get RECEIVE to copy the aliases.

You can use MALIAS when two or more macros that must be defined in the same zone must have the same name for programming access. For example, you can use MALIAS if several products have a help macro whose name must match the name of the command processing module it describes. You can specify HELP on MALIAS and a unique element name as the macro name.

name specifies the name of the macro member in the distribution library and, optionally, in the target system library. The name can contain any alphanumeric characters and $, #, @, or hex C0.

PREFIX specifies the first characters (prefix) of the names of modules to be assembled in addition to those modules named as GENASM subentries in the target zone MAC entry. The prefix values must contain no more than 7 characters.

The full module names are determined by comparing the prefix with the target zone or distribution zone MOD entry names.

The source for the assembly is the ASSEM entry, SRC entry, or DISTSRC member whose name matches a MOD entry name beginning with one of the specified prefixes. SMP/E looks for a match—first with an ASSEM entry, then with a SRC entry, finally with an entry in the DISTSRC data set—and uses the first match it finds. The source must either be known to SMP/E at the time the PREFIX operand is encountered on the ++MAC statement, or be included in the same SYSMOD.

Chapter 2. SMP/E modification control statements 67
++MAC MCS

**Note:** If the object deck for an element selected by the PREFIX operand is also provided by the SYSMOD, the assembly may not occur. (See S/390 **Commands** for more information.)

**RELFILE**
identifies which relative file associated with the SYMOD contains this element. This operand is required if you provide the element in RELFILE format, rather than inline or in a TXLIB data set.

**Note:** RELFILE is mutually exclusive with FROMDS and TXLIB.

**RMID**
specifies the last SYSMOD that replaced this macro. This operand may be used only in a service-updated function, and the specified PTF must be integrated into the function.

**SSI**
specifies eight hexadecimal digits of system status information. This information is placed in the directory of the target system library or SMPMTS or SMPSTS during APPLY processing, and in the distribution library during ACCEPT processing, as four packed hexadecimal bytes of user data. See the IEBUPDTE program description in [S/390 DFSMSdfp Utilities, SC26-7414](#).

**Note:** This operand is ignored if text is located in a library, as is the case when either the FROMDS, RELFILE, or TXLIB operand is specified.

**SYSLIB**
specifies the ddname of the target library, if the macro exists in one. APPLY and RESTORE processing update this library.

**Note:** If a MAC entry already exists in the target zone or distribution zone and the value currently in that entry does not match that specified in the SYSLIB operand, S/390 ignores the SYSLIB value in the SYMOD being installed, unless that SYMOD also used the ++MOVE MCS to change the SYSLIB to that new value.

**TXLIB**
is the ddname of the partitioned data set containing the macro. This operand is required if the macro is provided in a data set that the users have access to, rather than inline or in RELFILE format.

**Notes:**
1. SMPTLIB cannot be used as a value on the TXLIB operand.
2. TXLIB is mutually exclusive with FROMDS and RELFILE.

**UMID**
specifies the SYSMODs that have updated this macro since it was last replaced. This operand can be used only in a service-updated function, and the specified PTFs must be integrated into the function.

**VERSION**
specifies one or more function SYSMODs that currently contain the element. The function containing the ++MAC MCS will take over ownership of the element from the specified functions.

When **VERSION** is specified on an element statement, it overrides any VERSION operand values that might be specified on the ++VER MCS.
Usage Notes

- If the macro is packaged inline, it must immediately follow the ++MAC MCS and must not contain any records that start with ++. Neither FROMDS, nor RELFILE, nor TXLIB can be specified on the ++MAC MCS.
- If the macro is packaged in a TXLIB data set, the ddname specified in the TXLIB operand is required during APPLY and ACCEPT processing.
- For information about elements packaged in RELFILE format, see "Rules".
- If the ++MAC MCS is for an inner macro (a macro referred to by another macro instruction that resides in the macro library), the modules that require reassembly must be specified in the ASSEM operand list.
- If the macro resides in a target library (rather than the SMPMTS), the target library should be included in the SYSLIB DD concatenation for assemblies during APPLY processing. For additional information on SYSLIB requirements, see "SMP/E User’s Guide" and "SMP/E Commands".

Examples

The following examples are provided to help you use the ++MAC MCS.

Example 1: Replacing a macro through a USERMOD

Assume you want to replace a macro, named YOURMAC, that is part of a product you own, named YOURPROD. You have updated a copy of the macro in a text library, TSO.NEWSMP.MACLIB. Here is an example of a SYSMOD containing a ++MAC statement to build a USERMOD that installs the changes:

```
++USERMOD(USR0001)      /* User modification */.
++VER(Z038) FMID(HUSR003) /* for your product */.
++MAC(YOURMAC)          /* to replace this macro. */.
TXLIB(NEWSMP)           /* Macro is in this TXLIB. */.
```

In this example, you have just applied another piece of service to the YOURPROD macro, but YOURPROD is still the owner of the macro. If you attempt to install some vendor-supplied service (that is, a PTF) to that macro, SMP/E issues an error message indicating that your user modification will be regressed, and will not install that service until the BYPASS(ID) operand is used.

Another method of installing the new macro is for you to assume ownership for the macro by using the VERSION operand. Assume you already have a user function, JXY1040, installed, and you want to transfer ownership of the SMP/E macro to your function. The following SYSMOD contains a ++MAC statement to do that:

```
++USERMOD(USR0001)      /* User modification */.
++VER(Z038) FMID(JXY1040) /* for user application */.
++MAC(GIMOPCDE)          /* to replace this macro. */
    VERSION(HMP1E00) /* Version SMP/E. */.
    TXLIB(NEWSMP) /* Macro is in this TXLIB. */.
```

If after the installation of this SYSMOD any subsequent IBM service modifies this macro, the replacement or update from the IBM service is not selected. It is your responsibility to provide continued modifications for the macro. Thus, this method of updating an element should be used carefully.

In both examples, because the new macro exists in a TXLIB, the following DD statement is required during APPLY and ACCEPT:

```
//NEWSMP DD DSN=TSO.NEWSMP.MACLIB,DISP=SHR
```
Example 2: Deleting a macro
Assume you have installed one of your application programs as function HUSR001. The function contains macro USRMAC01, which is no longer required. Here is an example of a SYSMOD containing a ++MAC statement to delete the macro from the target and distribution libraries:

```clike
++USERMOD(USR0001) /* User modification */.
++VER(Z038) FMID(HUSR001) /* for user application. */.
++MAC(USRMAC01) /* Delete this macro. */.
DELETE /*.*/.
```

Example 3: Adding a new macro
Assume you have installed one of your application programs as function HUSR001. A new macro USRMAC02 is required, and it has these requirements:

- The macro is to be put into SYS1.USRMACS in the target zone.
- The macro is to be put into SYS1.AUSRMACS in the distribution zone.
- The macro is to be installed with an alias of TERMINAL.
- After being installed, modules USRASM01, USRASM02, USRSRC01, and USRSRC02 are to be assembled. USRASM01 and USRASM02 already exist as assembler entries in the CSI, and USRSRC01 and USRSRC02 exist as source entries in the CSI.

Here is an example of a SYSMOD containing a ++MAC statement defining all this information:

```clike
++USERMOD(USR0002) /* User modification */.
++VER(Z038) FMID(HUSR001) /* for user application. */.
++MAC(USRMAC02) /* Add this macro */.
DISTLIB(AUSRMACS) /* to this DLIB */.
SYSLIB(USRMACS) /* and to this tgt lib */.
MALIAS(TERMINAL) /* with this alias. */.
ASSEM(USRASM01, /* Assemble these modules. */.
USRASM02, /* */.
USRSRC01, /* */.
USRSRC02) /* */.
/* Inline text follows. */.
```

```
... macro USRMAC02 goes here
...
```
Example 4: Packaging a renamed macro

Suppose that, for some reason, you need to rename macro USRMAC02, which was introduced in “Example 3: Adding a new macro” on page 70. The new name is to be USRMACXX. You do not need to change anything else about the macro. Here is an example of a SYSMOD containing the ++MAC statements needed to package this renamed macro:

```+MAC MCS
++USERMOD(USR0003) /* User modification */.
++VER(Z038) Fomid(HUSR001) /* to user application. */.
PRE(USR0002) /* Base on previous USERMOD. */.
++MAC(USRMAC02) /* Delete the original */.
DELETE /* macro. */.
++MAC(USRMACXX) /* Add the renamed macro */.
DISTLIB(AUSRMACS) /* to this DLIB */.
SYSLIB(USRMACS) /* and to this tgt lib */.
MALIAS(TERMINAL)/* with this alias. */.
ASSEM(USRASM01, /* Assemble these modules. */
    USRASM02, /*
    USRSRC01, /*
    USRSRC02)/*
/* Inline text follows. */.
```

... macro USRMACXX goes here
...
The ++MACUPD MCS describes a single macro update within a PTF, an APAR fix, or a USERMOD. It must immediately precede the macro update statements within the SYSMOD.

Syntax

++MACUPD MCS

++MACUPD(name)

ASSEM(module)

DISTMOD(ddname)

DISTSRC(ddname)

DISTLIB(ddname)

MALIAS(alias)

PREFIX(prefix)

SYSLIB(ddname)

Operands

ASSEM
specifies the names of modules to be assembled in addition to those named as GENASM subentries in the MAC entry. The source for the assemblies is the ASSEM entry, SRC entry, or DISTSRC member whose name matches the specified ASSEM value. SMP/E looks for a match—first with an ASSEM entry, then with a SRC entry, and finally with an entry in the DISTSRC data set—and uses the first match it finds. The source must either be known to SMP/E at the time the ASSEM operand is encountered on the ++MACUPD statement, or be included in the same SYSMOD.

Notes:
1. APPLY and ACCEPT processing place the specified names into the SYSMOD entry created on the target zone and distribution zone.
2. If the object deck for the element specified on the ASSEM operand is also provided by the SYSMOD, the assembly may not occur. For more information, see the section on assemblies in the APPLY command chapter in SMP/E Commands.

DISTLIB
specifies the ddname of the distribution library for the specified macro.

Notes:
1. DISTLIB must be specified if the macro has not been previously recorded on the target zone or distribution zone. If a MAC entry already exists in the target zone or distribution zone, and the value currently in that entry does not match that specified in the DISTLIB operand, the SYSMOD is not applied or accepted.
++MACUPD MCS

2. You cannot use SYSPUNCH as the DISTLIB. It is used by SMP/E and other products to process assembled modules.

DISTMOD
specifies the ddname of the link-edit distribution library for the modules specified in the ASSEM operand. During ACCEPT processing, the object code from the assembler is link-edited to the library specified.

DISTSRC
specifies the ddname of the library containing the additional assembly or source to be assembled. The additional assembly or source must be specified in the ASSEM operand.

MALIAS
specifies the alias names for the macro in both the target system and distribution libraries.

You can use MALIAS when two or more macros that must be defined in the same zone must have the same name for programming access. For example, you can use MALIAS if several products have a help macro whose name must match the name of the command processing module it describes. You can specify HELP on MALIAS and a unique element name as the macro name.

name
specifies the name of the macro member in the distribution library and, optionally, in the target system library. The name can contain any alphanumeric characters and $, #, @, or hex C0.

PREFIX
specifies the first characters (prefix) of the names of modules to be assembled in addition to those modules named as GENASM subentries in the target zone MAC entry. The prefix values must be 7 characters or less.

The full module names are determined by comparing the prefix with the target zone or distribution zone MOD entry names.

The source for the assembly is the ASSEM entry, SRC entry, or DISTSRC member whose name matches a MOD entry name beginning with one of the specified prefixes. SMP/E looks for a match—first with an ASSEM entry, then with a SRC entry, and finally with an entry in the DISTSRC data set—and uses the first match it finds. The source must be either known to SMP/E at the time the PREFIX operand is encountered on the ++MACUPD statement, or be included in the same SYSMOD.

Note: If the object deck for the element specified on the PREFIX operand is also provided by the SYSMOD, the assembly may not occur. For more information, see the section on assemblies in the APPLY command chapter in SMP/E Commands.

SYSLIB
specifies the ddname of the target library, if the macro exists in one. APPLY and RESTORE processing update this library.

Usage Notes
- If a SYSMOD containing a ++MACUPD statement attempts to change the ownership (FMID) of the element (with the VERSION operand), the SYSMOD cannot be installed.
- The changes for the macro must immediately follow the ++MACUPD MCS and must not contain any records that start with ++.
++MACUPD MCS

- If the macro resides in a target library (rather than the SMPMTS), that target library should be included in the SYSLIB DD concatenation for assemblies during APPLY processing. For additional information on SYSLIB requirements, see SMP/E User's Guide and SMP/E Commands.
- The only IEBUPDTE control statements allowed in a SYSMOD are ./ CHANGE and ./ ENDUP.
- The only IEBUPDTE CHANGE operand SMP/E checks is NAME, which must specify the same element as the ++MACUPD MCS. Other CHANGE operands may produce undesired results and are used at your own risk. For example, if you code UPDATE=INPLACE, SMP/E may update the distribution library. Once the distribution libraries are changed, there is no way to remove the updates.
- SMP/E does not support a continuation of the ./ CHANGE statement.
- SMP/E generates any ./ ALIAS statements needed and places them in the IEBUPDTE input data following the last text statement. The ./ ALIAS control statements are generated only for macro updates.
- When processing multiple updates to the same lines in a given macro, SMP/E uses the ./ CHANGE statement from the last update to the lines.
- If an APAR fix or USERMOD updates a macro that causes an assembly, SMP/E sets the ASSEMBLY indicator in the MOD entry for the assembled module. This can cause a problem when additional service that does not know about the macro change is installed at the same time as the APAR or USERMOD—for example, if you are installing your own USERMOD and IBM-supplied PTFs with the same APPLY command. In such cases, because the ASSEMBLY indicator is set, the module is reassembled, but does not contain the macro changes from the APAR or USERMOD. To prevent these assemblies, you can reset the ASSEMBLY indicator using UCLIN after installing the APAR or USERMOD.

Examples

Assume you want to update macro IFBMAC02, which resides in distribution library IFBMACS. Because of this change, module IFBSRC01 must be reassembled. Module IFBSRC01 exists as a source in distribution library SYS1.IFBSRC, and as an object module in distribution library SYS1.AOS23. The macro and the modules are part of JXY1040, a user-written function. Here is an example of a SYSMOD containing a ++MACUPD statement to make the necessary changes:

```
++PTF(USR0001)    /* Preventive service */.
++VER(Z938) FMID(JXY1040) /* for user product. */.
++MACUPD(IFBMAC02) /* Update this macro */.
   DISTLIB(IFBMACS) /* in this DLIB. */.
   ASSEM(IFBSRC01) /* Assemble this source. */.
   DISTSRC(IFBSRC) /* Source is here. */.
   DISTMOD(AOS23) /* Assembled SRC goes here. */.

./ CHANGE name=IFBMAC02
   ... IEBUPDTE control cards and data
   ...
```

In this example, DD statements are required when the SYSMOD is applied to define the target libraries for the macro and the load module to be updated as a result of the assembly. For example, if the modules in SYS1.AOS23 (the assembled module’s distribution library) were copied to SYS1.LINKLIB and the source in SYS1.IFBSRC (the source element’s distribution library) were copied to SYS1.CHGLIB, the following DD statements are needed:

```
/LINKLIB DD DSN=SYS1.LINKLIB...
/CHGLIB DD DSN=SYS1.CHGLIB...
```
++MACUPD MCS

In this example, the following DD statements are needed when the SYSMOD is being accepted to define the distribution libraries:

//IFBMACS  DD  DSN=SYS1.IFBMACS...  (macro DLIB)
//IFBSRC    DD  DSN=SYS1.IFBSRC...  (source DLIB for assembly)
//AOS23     DD  DSN=SYS1.AOS23...  (DLIB for module assembled)
The ++MOD MCS describes a single module replacement. It must immediately precede the module definition statements when they are within the SYSMOD. You should use the ++MOD MCS when you want to provide the object form of a module. If you want to provide the source form and have it assembled when the SYSMOD is installed, use the ++SRC MCS instead.

Syntax
The syntax to be used depends on the processing to be done for the element:
- Adding or replacing the element
- Deleting the element

Adding or replacing a module

Deleting a module
++MOD MCS

Operands

CSECT

lists all the CSECTs contained in the module. This operand is required if the module contains more than one CSECT or if the CSECT name is different from the module name on the ++MOD MCS.

- If no CSECT name is specified, SMP/E assumes that the module contains only one CSECT, whose name matches the module name on the ++MOD MCS.
- If CSECT is specified, it must include all the CSECTs contained in the module, even if one of them has the same name as the module.

Notes:
1. A CSECT name can contain from 1 to 8 characters. The name can contain any characters except the following:
   - Comma ,
   - Left parenthesis (,  Right parenthesis )
   - Blank
2. Comments are not allowed within a CSECT name. For example, the following is not allowed:
   ```
   CSECT ( /* this is a csect name */ CSECT01)
   ```
   The comment is interpreted as part of the CSECT name, instead of a comment.
3. Even if CSECT is not specified on the ++MOD MCS used to create a MOD entry, CSECT information is saved if CSECT is specified on subsequent ++MOD statements that update the MOD entry.

DALIAS

is the alias name of a module that has an alias in the distribution library, but not in the target library. This might be used if the module is included under its alias name during system generation.

Note: DALIAS is mutually exclusive with TALIAS.

DELETE

indicates that the module and alias names are to be removed from the target libraries, distribution libraries, and SMP/E data sets.

In order to DELETE a module, the FMID on the SYSMOD must match the FMID of the module. If the module has no FMID associated with it, then the SYSMOD will delete the module. If the FMID of the module does not match the FMID on the SYSMOD, then the SYSMOD will not delete the module, because the specified FMID does not own the module.

Note: DELETE is mutually exclusive with all other operands except CSECT, DISTLIB, and VERSION.

DISTLIB

specifies the ddname of the distribution library for the specified module.

Notes:
1. This operand must be specified if the module has not been previously recorded on the target zone or distribution zone. If a MOD entry already exists in the target zone or distribution zone and the value currently in that entry does not match that specified in the DISTLIB operand, the SYSMOD
++MOD MCS

is not applied or accepted, unless that SYSMOD also used the ++MOVE MCS to change the DISTLIB to that new value.

2. You cannot use SYSPUNCH as the DISTLIB. It is used by SMP/E and other products to process assembled modules.

FROMDS
identifies the partitioned data set that contains this element.

Note: The FROMDS operand and its DSN, NUMBER, VOL, and UNIT suboperands are included in the MCS generated by the BUILDMCS command. IBM does not intend the FROMDS operand to be used in manually coded MCS.

DSN specifies the dsname of the FROMDS data set. The specified data set name must conform to standard data set naming conventions and cannot contain parentheses. The maximum length of the entire name is 44 characters (including the periods).

NUMBER
specifies a number that SMP/E is to use when assigning a name to the SMPTLIB data set associated with this FROMDS data set. (This is similar to the way the relative file number is used in RELFILE processing.)

VOL specifies, for an uncataloged data set, the volume serial number of the volume containing the FROMDS data set. If specified, this volume identifier must be from 1 to 6 alphanumeric characters. VOL may be omitted for a cataloged data set.

UNIT specifies, for an uncataloged data set, the UNIT type containing the FROMDS data set. If specified, the UNIT value must be from 1 to 8 characters and must conform to standard UNIT naming conventions. IBM SMP/E for z/OS, V3R5 accepts any nonblank characters specified between the open and close parentheses, up to a maximum length of 8. UNIT may be omitted for a cataloged data set.

Note: FROMDS is mutually exclusive with DELETE, LKLIB, RELFILE, and TXLIB.

LEPARM
specifies link-edit utility attributes for the module. Any of the following values can be specified:
++MOD MCS

Notes:
1. The LPARM values from the ++MOD MCS are associated with a load module entry only if the module was copied, not link-edited, into the target libraries. (The COPY indicator is set in the load module entry.) If the load module was link-edited, JCLIN must be used to change its link-edit utility attributes.

2. During APPLY processing of a ++MOD MCS with LPARMs, the LPARM options are saved not in the MOD entry created, but in the LMOD entry. During ACCEPT processing, the MOD entry is created with the LPARMs present. The target zone MOD entry can contain the LPARM options through either UCLIN or the copying of the distribution zone to a target zone.

3. All LPARM attributes may also be specified in the format 'attribute=value'. For example, FILL(nn) may also be specified as FILL=nn.

4. The previously listed link-edit attributes are the only attributes that can be specified on the LPARM operand. If any other attributes are specified, a syntax error will result during RECEIVE processing.

5. The LPARM values of DCBS, LET, LIST, XCAL, and XREF are recognized by SMP/E, but are not saved. Specifying them on the ++MOD MCS does not cause them to be passed to the link-edit utility.

For more information on how the LPARM operand is processed, see the chapters on ACCEPT and APPLY processing in SMP/E Commands. These attributes are described in full in "MOD entry (distribution and target zone)" on page 275.

LKLIB
is the ddname of the partitioned data set containing the link-edited format of the object module. This operand is required if the module is provided in a data set, rather than inline or on a tape.

Note: LKLIB is mutually exclusive with FROMDS, RELFILE, and TXLIB.
**LMOD**

lists existing load modules that are to contain the module. If any of the names specified are not already LMOD subentries in the target zone MOD entry, they are added during APPLY processing.

**Notes:**
1. LMOD can be used only to add a module to an existing load module.
2. LMOD cannot be used to create a new load module. Nor can it be used if any link-edit control statements must be added or changed to add the module to an existing load module. However, you can use JCLIN data to create a new load module and to add or change link-edit control statements.
3. If an LMOD entry does not exist for one of the load modules specified, sufficient information is not available to create one. Thus, when the MOD is to be link-edited during APPLY processing, an error message is issued, and no link-edit is performed for that load module.

**name**

specifies the name of the module in the distribution library and, optionally, in the target library. The name can contain any alphanumeric characters and $, #, @, or hex C0.

**RELFILE**

identifies which relative file associated with the SYSMOD contains this module. This operand is required if you provide the element in RELFILE format, rather than inline or in a LKLIB or TXLIB data set.

**Notes:**
1. RELFILE is mutually exclusive with FROMDS, LKLIB, and TXLIB.
2. If an object module is provided in RELFILE format, it must be in link-edited format.

**RMID**

specifies the last SYSMOD that replaced this module. This operand can be used only in a service-updated function, and the specified PTF must be integrated into the function.

**TALIAS**

specifies one or more alias names for the module. The aliases exist in the distribution library and the target library.

You can use TALIAS for a module that was copied from a distribution library into a target library (defined by JCLIN data as a copied module), but not for one that is link-edited (defined by JCLIN data as a link-edited module).

**Note:** TALIAS must be specified on the ++MOD MCS even if ALIAS was specified on the COPY SELECT statement. TALIAS is required for the RECEIVE command to properly handle aliases in RELFILEs. During RECEIVE processing, SMP/E copies RELFILEs to SMPTLIB data sets. All element members and their associated aliases are copied. Because JCLIN is not processed during RECEIVE, the aliases must be identified on the MCS to get RECEIVE to copy the aliases.

Likewise, to specify an alias for a copied load module, you must use the TALIAS operand on the ++MOD statement for that load module. (To specify an alias for a link-edited load module, do not use TALIAS. You must identify that alias using an ALIAS link-edit control statement in the JCLIN that defined the load module. For more information, see [SMP/E Commands](#).)
++MOD MCS

**Note:** TALIAS is mutually exclusive with DALIAS.

**TXLIB**

is the ddname of the partitioned data set containing an object module that has not been link-edited. This operand is required if the module is provided in a TXLIB data set rather than inline, in a FROMDS data set, in a LKLIB data set, or in RELFILE format.

**Notes:**

1. SMPTLIB cannot be used as a value on the TXLIB operand.
2. TXLIB is mutually exclusive with FROMDS, LKLIB, and RELFILE.

**UMID**

specifies the SYSMODs that have updated this module since it was last replaced. This operand can be used only in a service-updated function, and the specified PTFs must be integrated into the function.

**VERSION**

specifies one or more function SYSMODs that currently contain the element. The function containing the ++MOD MCS takes over ownership of the element from the specified functions.

When VERSION is specified on an element statement, it overrides any VERSION operand values specified on the ++VER MCS.

**Usage Notes**

- If the module is packaged inline, it must immediately follow the ++MOD MCS and must not contain any records that start with ++. Neither FROMDS, LKLIB, RELFILE, nor TXLIB may be specified.
- If the module is packaged in a TXLIB data set, the ddname specified on the TXLIB operand is required during APPLY and ACCEPT processing.
- If the module is in an LKLIB data set, the ddname specified in the LKLIB operand is required during APPLY and ACCEPT processing. Module replacements in an LKLIB data set must be in load module format (that is, processed by the link-edit utility).
- For information about packaging SYSMODs in RELFILE, TXLIB, or inline format, see [z/OS Packaging Rules](#).
- There are several ways to associate a module with a load module:
  - The DISTLIB library can be totally copied into the target library.
  - JCLIN can identify the module as part of one or more load modules.
  - The LMOD operand on the ++MOD MCS can indicate the associated load module.

If SMP/E cannot identify the load module associated with a given module, it does not update the target libraries during APPLY processing. Instead, it issues warning message GIM43401W.

**Examples**

The following examples are provided to help you use the ++MOD MCS:

**Example 1: Adding a new module to an existing load module**

Module IFBMOD01 is a new module that is to be placed in the distribution library SYS1.AOSFB and is to be link-edited with the existing load module IEEFRQ in the target system library SYS1.LINKLIB. Module IFBMOD01 contains two CSECTs, IFBCST01 and IFBCST02. Here is an example of a SYSMOD containing a ++MOD statement to do this:
++USERMOD(USR0001) /* User modification */.
++VER(Z038) FMID(JXY1040) /* to user application. */.
++MOD(IFBMOD01) /* Add this module */.
DISTLIB(AOSFB) /* to this DLIB at ACCEPT, */.
LMOD(IEEFRQ) /* to this LMOD at apply. */.
CSECT(IFBCST01 /* Module has two CSECTs. */.
IFBCST02) /* */.

... object deck for IFBMOD01...

The following DD statement is needed at APPLY time to define the operating system load module library:

//LINKLIB DD DSN=SYS1.LINKLIB,DISP=OLD

When the SYSMOD is accepted, the following DD statement is needed to define the distribution library for this module:

//AOSFB DD DSN=SYS1.AOSFB,DISP=OLD

Example 2: Specifying link-edit utility attributes with LEPARM
For this example, assume you have installed a product, FXY1040, packaged in RELFILE format. The package contained a module, IFBMOD01, that was identified by inline JCLIN as being installed as follows:

1. It was copied from the distribution library, AOS12, to the target system library, LPALIB.
2. It was linked with several other modules to form a load module, IFBLMDXX, in LINKLIB.
3. It was linked, by itself, to form a load module, named IFBLMDX1, in LINKLIB.

The JCLIN in the initial function was as follows:

//JOB JOB 'accounting info',MSGLEVEL=(1,1)
//COPY1 EXEC PGM=IEBCOPY
//AOS12 DD DSN=SYS1.AOS12,DISP=SHR
//LPALIB DD DSN=SYS1.LPALIB,DISP=SHR
//SYSSIN DD *
COPY INDD=AOS12,OUTDD=LPALIB
SELECT M=(IFBMOD01)
/*
//LINK1 EXEC PGM=IEWL,PARM='REUS'
//AOS12 DD DSN=SYS1.AOS12,DISP=SHR
//SYSLMOD DD DSN=SYS1.LINKLIB,DISP=SHR
//SYSLIN DD *
INCLUDE AOS12(IFBMOD01)
INCLUDE AOS12(IFBMOD0A,IFBMOD0B,IFBMOD0C)
ENTRY IFBMOD01
NAME IFBLMDXX(R)
/*
//LINK2 EXEC PGM=IEWL
//AOS12 DD DSN=SYS1.AOS12,DISP=SHR
//SYSLMOD DD DSN=SYS1.LINKLIB,DISP=SHR
//SYSLIN DD *
INCLUDE AOS12(IFBMOD01)
NAME IFBLMDX1(R)
/*

The target zone now contains the following entries:

1. MOD entry for IFBMOD01, having LMOD subentries of IFBMOD01 (from the copy step), IFBLMDXX (from the first link step), and IFBLMDX1 (from the second link step).
2. LMOD entry for IFBMOD01, (created from the SELECT statement of the copy step), indicating that the load module was copied during installation. The LMOD entry does not have any link-edit utility parameters yet, because SMP/E copied IFBMOD01 from the RELFILE data sets, and, thus, had no need to obtain the link parameters.

3. LMOD entry for IFBLMDXX (created from the first link step), with link-edit attributes of REUS.

4. LMOD entry for IFBLMDX1 (created from the second link step), with link-edit attributes of STD (because no special parameters were specified).

Now assume a PTF to replace module IFBMOD01 is required. Module IFBMOD01 has link-edit utility attributes of REUS and RENT. Here is an example of a SYSMOD containing a ++MOD statement to do this:

```
++PTF(UZ12345)    /* PTF */
++VER(Z0038)       /* for this function. */
++MOD(IFBMOD01)    /* Replace IFBMOD01 */
       DISTLIB(A0152) /* in this DLIB. */
       LEPARM(RENT)   /* Reentrant */
       LEPARM(REUS)   /* and reusable. */
```

... object deck for IFBMOD01 ...

When the PTF is applied, SMP/E processes the LEPARM as follows:

1. Because LMOD IFBMOD01 was copied from the DLIB module, it is updated using the LEPARM values from the ++MOD MCS.

2. LMOD IFBLMDXX link-edit attributes remain as they are. This is because the link-edit utility attributes of each module within the load module have no bearing on the link-edit utility attributes of the load module; and, in this case, they are not the same. One of the other modules in IFBLMDXX must have a more restrictive set of link-edit attributes, thus forcing the load module to have that restrictive set of attributes.

3. LMOD IFBLMDX1 link-edit attributes remain as they are, for the same reason that load module IFBLMDXX attributes did not change. This is true even though load module IFBLMDX1 is composed of only the one DLIB module. As long as the load module was identified by a link-edit step, SMP/E assumes that the load module may contain multiple DLIB modules.

**Note:** The only way to change the link-edit attributes of a load module that was link-edited during initial installation is to provide JCLIN input to identify the new link-edit attributes.

**Example 3: Packaging a renamed module**

Suppose that, for some reason, you need to rename module IFBMOD01, which was introduced in "Example 1: Adding a new module to an existing load module" on page 81. The new name is to be IFBMODXX. You do not need to change anything else about the module. Here is an example of a SYSMOD containing the ++MOD statements needed to package this renamed module:

```
++USERMOD(USR0002)    /* User modification */
++VER(Z0038)          /* to user application. */
       PRE(USR0001)     /* Base on previous USERMOD. */
++MOD(IFBMOD01)       /* Delete the original */
       DELETE           /* module. */
++MOD(IFBMODXX)       /* Add the renamed module */
       DISTLIB(AOSFB)   /* to this DLIB at ACCEPT, */
       LMOD(IEEFRQ)     /* to this LMOD at apply. */
       CSECT(IFBCST01)  /* Module has two CSECTs. */
```

Chapter 2. SMP/E modification control statements  83
Note: When packaging a renamed module, you must ensure that this module is included in the appropriate load modules, either through JCLIN or the LMOD operand on the ++MOD statement, as in this example.

The following DD statement is needed at APPLY time to define the operating system load module library:

```
//LINKLIB DD DSN=SYS1.LINKLIB,DISP=OLD
```

When the SYSMOD is accepted, the following DD statement is needed to define the distribution library for this module:

```
//AOSFB DD DSN=SYS1.AOSFB,DISP=OLD
```

### Example 4: Deleting a module

If you need to delete a module, here is an example of a SYSMOD containing the ++MOD statement:

```
++USERMOD(USR0004) /* User modification */.
++VER(Z038) FMID(JXY1040) /* to user application. */.
++MOD(IFBMOD0Z) /* Delete the module */.
   DELETE /* from DLIB AOSFB - entry */.
   DISTRIB(AOSFB) /* for DLIB must be AOSFB. */.
```

Note: When packaging a SYSMOD to delete a module, no object deck is required. The previous example is a complete SYSMOD, and does not require any other SMP/E elements in the SYSMOD.

For more information on the processing done when a module is deleted, see “Deleting Elements” in [SMP/E Commands](#).
++MOVE MCS

++MOVE MCS
The ++MOVE MCS moves a macro, a module, a source, or a load module (and any known aliases) from one library to another. The associated target or distribution zone is automatically updated to show that the entry has been deleted from the old library and added to the new one.

Note: You cannot use ++MOVE to move a load module from one path to another path in a UNIX file system if symbolic links have been defined for that load module.

Syntax
The syntax to be used depends on the type of library involved:
- Moving to a different distribution library (DISTLIB)
- Moving to a different target library (SYSLIB)

Moving to another DISTLIB

++MOVE MCS

++MOVE (name) DISTLIB(ddname) TODISTLIB(ddname) 

FMID(sysmod_id)

Moving to another SYSLIB

++MOVE MCS

++MOVE (name) SYSLIB(ddname) TOSYSLIB(ddname) 

FMID(sysmod_id)

Operands

DISTLIB
specifies the ddname of the distribution library in which the member resides.

FMID
specifies the FMID that owns the element. This is used when the current owner of the element is different from the FMID specified on the ++VER MCS. Up to 10 SYSMOD IDs can be specified.

Note: FMID is mutually exclusive with LMOD.
**++MOVE MCS**

MAC, MOD, SRC, or LMOD

specifies the type of member to be moved.

- If DISTLIB and TODISTLIB are specified, MAC, MOD, or SRC is valid.
- If SYSLIB and TOSYSLIB are specified, MAC, SRC, or LMOD is valid.

**Note:** LMOD is mutually exclusive with FMID.

`name`

specifies the name of the element or load module to be moved.

**SYSLIB**

specifies the ddname of the target library in which the member resides.

**TODISTLIB**

specifies the ddname of the distribution library to which the member is to be moved. This must be specified if DISTLIB is specified.

**TOSYSLIB**

specifies the ddname of the target library to which the member is to be moved. This must be specified if SYSLIB is specified.

**Usage Notes**

- The member and library operands are required. You must specify the member name, the set of libraries affected by the move, and the member type.
- ++MOVE statements must follow any ++VER and ++IF statements and must precede any element MCSs.
- Regardless of the order in which ++MOVE, ++RENAME, and ++DELETE statements are coded in a SYSMOD, they are processed in the following order:
  - APPLY and ACCEPT
    1. ++MOVE
    2. ++RENAME
    3. ++DELETE
  - RESTORE
    1. ++RENAME
    2. ++MOVE

Afterwards, ++JCLIN statements are processed, and then element statements.

- You must use the FMID operand to identify all possible owners of an element to be moved.

Using the FMID operand does not imply that the owner of the element is being changed. You can change ownership only by specifying the VERSION operand on the ++VER MCS or on the element statement. Even if you are changing the owner of the element, you must specify the FMID operand, because the element is moved before its ownership is changed. For more information about the VERSION operand, see ["++VER MCS" on page 118].

- A ++MOVE MCS can move a member to a given library from one library at a time. If a member exists in more than one library, you must use additional ++MOVE or ++DELETE statements to process the additional copies. For more information about ++DELETE statements, see ["++DELETE MCS" on page 17].

- If a ++MOVE MCS changes the DLIB for an element that is also being replaced, the element MCS must specify the new DLIB.

**Examples**

Assume IBM ships you a PTF that moves module MODAA from its current distribution library to a new library, and also moves load module LMODA from its
current target library to a new one. Here is an example of a SYSMOD containing ++MOVE statements that makes these changes:

```
++PTF(UR01234)        /* Identify the PTF number */.
++VER(Z038) FMID(HXY1300) /* for MVS function HXY1300 */.
++IF (ESY1300) THEN /* If ESY1300 is installed */
   REQ(UR12399) /* UR12399 is required. */.
++MOVE (MODAA) /* Move module MODAA */
   DISTLIB(AOS11) /* from DLIB AOS11 */
   TODISTLIB(AOSXX) MOD /* to DLIB AOSXX. */.
++MOVE (LMODA) /* Move load module LMODA */
   SYSLIB(LINKLIB) /* from LINKLIB */
   TOSYSLIB(LPALIB) LMOD /* to LPALIB. */.
```

++MOD(MODAA) DISTLIB(AOSXX) /* Element MCS statements. */.
++NULL MCS

++NULL MCS
The ++NULL MCS is valid only in the SMPHOLD data set. It provides no SMP/E function other than allowing all service tapes to be built with the same format, even though a function may have no exception SYSMOD data for a particular month.

Syntax

```
++NULL MCS
```

++NULL MCS
++PRODUCT MCS

The ++PRODUCT MCS is used to describe information about a product. It introduces descriptive information about a new or replacement product into the global zone.

Syntax

++PRODUCT MCS

++PRODUCT(prodid,vv.rr.mm)---DESCRIPTION(description)---SREL(srel)

PRODSUP((prodid,vv.rr.mm))

URL(product_url)

VENDOR(vendor_name)---REWORK(level)

Operands

The PRODUCT is identified by the combination of the prodid and the vv.rr.mm values.

prodid

is a 1- to 8-character product identifier. It can contain uppercase alphabetic, numeric, and national ($) characters. It may also contain one or more dashes (-). For IBM products, the prodid is assumed to be the IBM program product number (5647-A01, for example).

vv.rr.mm

specifies the version, release, and modification level of this PRODUCT. It is 5 to 8 characters long in the form vv.rr.mm. The version (vv), release (rr), and modification (mm) values must be one or two numeric characters separated by a period ('). SMP/E will insert leading zeros to each section of the vv.rr.mm value that is one character long. That is, 2.5.0 will become 02.05.00 when stored.

DESCRIPTION

a text description of the product.

- DESCRIPTION can also be specified as DESC.
- The DESCRIPTION value can be in single-byte characters (such as English alphanumeric) or double-byte characters (such as Kanji).
- The DESCRIPTION value can contain up to 64 bytes of data, including blanks. (For double-byte data, the 64-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters.) Extra blanks as well as leading and trailing blanks are deleted.
- The DESCRIPTION value can span multiple 80-byte records. Data must continue up to and including column 72 and begin in column 1 of the next record.
++PRODUCT MCS

line. All data past column 72 is ignored. The break does not translate to a blank unless a blank is explicitly coded in column 72 of the first line or in column 1 of the second line.

- The DESCRIPTION value cannot be only blanks.
- If parentheses are included in the text, they must be in matched pairs.

SREL

specifies the system or subsystem releases on which the PRODUCT can be installed. Each SREL value must be four alphanumeric characters, usually one alphabetic character followed by three numeric characters. These are the systems and subsystems defined by IBM, with their SRELs:

<table>
<thead>
<tr>
<th>System</th>
<th>SREL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2</td>
<td>P115</td>
</tr>
<tr>
<td>CICS°</td>
<td>C150</td>
</tr>
<tr>
<td>IMS™</td>
<td>P115</td>
</tr>
<tr>
<td>MVS</td>
<td>Z038</td>
</tr>
<tr>
<td>NCP</td>
<td>P004</td>
</tr>
</tbody>
</table>

The list of SRELs is used during RECEIVE processing to determine whether a PRODUCT should be received.

PRODSUP

indicates which PRODUCTS are superseded (replaced) by this PRODUCT. It is a list of prodid,vv.rr.mm values for the PRODUCTS being superseded. The combination of prodid and vv.rr.mm determines the uniqueness of an entry in the PRODSUP operand list.

The PRODSUP operand must not specify a prodid,vv.rr.mm combination matching the prodid,vv.rr.mm combination of the ++PRODUCT statement on which it is specified.

URL

specifies a uniform resource locator (URL) that can be used to obtain additional information about this product.

- The URL can be in single-byte characters (such as English alphanumeric) or double-byte characters (such as Kanji).
- The URL can contain up to 256 bytes of data, excluding blanks. (For double-byte data, the 256-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters.) All blanks including leading and trailing blanks are deleted.
- The URL can span multiple 80-byte records. Data must continue up to and including column 72 and begin in column 1 of the next line. All data past column 72 is ignored, including blanks. The break does not translate to a blank.
- The URL cannot be only blanks.
- If parentheses are included in the text, they must be in matched pairs.

VENDOR

specifies the name of the vendor supplying the product.

- The VENDOR can be in single-byte characters (such as English alphanumeric) or double-byte characters (such as Kanji).
- The VENDOR can contain up to 64 bytes of data, including blanks. (For double-byte data, the 64-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters.) Extra blanks as well as leading and trailing blanks are deleted.
+++PRODUCT MCS

- The VENDOR can span multiple 80-byte records. Data must continue up to and including column 72 and begin in column 1 of the next line. All data past column 72 is ignored. The break does not translate to a blank unless a blank is explicitly coded in column 72 of the first line or in column 1 of the second line.
- The VENDOR cannot be only blanks.
- If parentheses are included in the text, they must be in matched pairs.

REWORK

is the level of this +++PRODUCT MCS, which was reworked for minor changes. Up to eight numeric characters can be specified.

REWORK is generally used only for +++PRODUCT statements supplied by IBM that have been reworked for minor changes. For these +++PRODUCT statements, the REWORK level is yyyyddd, which is the year followed by the Julian date (for example, 20081110).

REWORK allows an updated +++PRODUCT MCS to be automatically received again, as long as it is more recent than the version that has already been received. This takes the place of rejecting the +++PRODUCT MCS and receiving it again.

Note: If a +++PRODUCT MCS appears more than once in the SMPPTFIN data set, the first occurrence may be received. However, none of the subsequent versions of the +++PRODUCT MCS are received, even if their rework level is higher than the one for the first version of the +++PRODUCT MCS.

Usage Notes

- The +++PRODUCT statements are processed whenever the SMPPTFIN data set is processed. This is true whether only selected SYSMODs are being processed or the entire SMPPTFIN data set is being processed.
- +++PRODUCT statements are not processed when only the SMPHOLD data set is being processed.
- The prodid, v0.rr.mm, DESCRIPTION, and SREL values are required and cannot be blank or null.
- The +++PRODUCT MCS is used in the SMPPTFIN data set and can be placed between, before, or after SYSMODs, +++FEATURE MCS, or +++PRODUCT MCS. It must be followed by one of the following: a +++APAR, +++ASSIGN MCS, +++FEATURE MCS, +++FUNCTION, +++PTF, +++USERMOD, another +++PRODUCT MCS, or an end-of-file. If one of these does not follow, SMP/E does not receive the SYSMOD being processed and it skips the +++PRODUCT MCS.

Example

Here is an example of a +++PRODUCT MCS for a product called OS/390.

```plaintext
+++PRODUCT(5647-A01,2.5.0)  /* Product definition */
DESCRIPTION(OS/390)    /* Description */
URL(http://www.s390.ibm.com/os390/) /* URL */
SREL(Z038)         /* SREL value */
PRODSUP((5645-001,01.04.00)) /* Product supers */
VENDOR(IBM)         /* Product Vendor */.
```
+++PROGRAM MCS

+++PROGRAM MCS

The +++PROGRAM MCS describes a program element (a pre-built load module or a program object). It must immediately precede the load module or program object when they are within the SYSMOD. Use the +++PROGRAM when you want to ship executables as program parts. If you want to provide the object form of the module, use the +++MOD MCS instead. JCLIN is not used to define the program element.

Syntax

The syntax to be used depends on the processing to be performed for the element:

- Adding or replacing the element
- Deleting the element

Adding or replacing a program element

Deleting a program element

Operands

ALIAS

specifies an alternate name for the program object or load module.

DELETE

specifies that the program element and all aliases are to be removed from the target library and the distribution library.
++PROGRAM MCS

Notes:
1. DELETE is mutually exclusive with all other operands except DISTLIB and VERSION.
2. If the element statement is in a base function, you may want to use the DELETE operand on the ++VER MCS to delete the previous release, rather than on the element statement to delete a specific element.
3. Specification of the DELETE operand results in all aliases of the program element being deleted along with the program element identified.

DISTLIB
specifies the ddname of the distribution library for the specified program element. During ACCEPT processing, SMP/E installs the program element into the distribution library as a member. (The distribution library must be a PDS or PDSE; it cannot be part of a UNIX file system.)

Notes:
1. DISTLIB must be specified when the program element is first installed.
2. If a program element entry already exists in the target zone or distribution zone and the value currently in that entry does not match that specified in the DISTLIB operand, the SYSMOD is not applied or accepted.

FROMDS
identifies the partitioned data set that contains this element.

Note: The FROMDS operand and its DSN, NUMBER, VOL, and UNIT suboperands are included in the MCS generated by the BUILDMCS command. IBM does not intend the FROMDS operand to be used in manually coded MCS.

DSN
specifies the dsname of the FROMDS data set. The specified data set name must conform to standard data set naming conventions and cannot contain parentheses. The maximum length of the entire name is 44 characters (including the periods).

NUMBER
specifies a number that SMP/E is to use when assigning a name to the SMPTLIB data set associated with this FROMDS data set. (This is similar to the way the relative file number is used in RELFILE processing.)

VOL
specifies, for an uncataloged data set, the volume serial number of the volume containing the FROMDS data set. If specified, this volume identifier must be from 1 to 6 alphanumeric characters.

VOL may be omitted for a cataloged data set.

UNIT
specifies, for an uncataloged data set, the UNIT type containing the FROMDS data set. If specified, the UNIT value must be from 1 to 8 characters and must conform to standard UNIT naming conventions. SMP/E accepts any nonblank characters specified between the open and close parentheses, up to a maximum length of 8.

UNIT may be omitted for a cataloged data set.

Note: FROMDS is mutually exclusive with DELETE, RELFILE, and LKLIB.

LKLIB
is the ddname of the partitioned data set containing the program element. This
++PROGRAM MCS

operand is required if the program element is provided in a data set to which
the users have access, rather than inline or in RELFILE format.

Notes:
1. SMPTLIB cannot be used as a value on the LKLIB operand.
2. LKLIB is mutually exclusive with FROMDS and RELFILE.

name
specifies the name of the program element member. The name can contain any
uppercase alphabetic, numeric, or national ($, #, @) character and can be 1 to 8
characters long.

RELFILE
identifies which relative file associated with the SYSMOD contains this
element. This operand is required if you provide the element in RELFILE
format, rather than inline or in a LKLIB data set.

Notes:
1. The RELFILE value must be a decimal number from 1 to 9999.
2. RELFILE is mutually exclusive with FROMDS and LKLIB.

RMID
specifies the last SYSMOD that replaced this program element. This operand
can be used only in a service-updated function, and the specified PTF must be
integrated into the function.

SYSLIB
specifies the ddname of the target library for the program element. (The target
library must be a PDS or PDSE; it cannot be part of a UNIX file system.)

During APPLY processing, the copy utility installs the program element into
the target library. During RESTORE processing, the copy utility copies the
program element from the distribution library member into the target library.

Note: SYSLIB must be specified when the program element is first installed.

VERSION
specifies one or more function SYSMODs that currently contain the element.
The function containing the element MCS takes over ownership of the element
from the specified functions.

When VERSION is specified on an element statement, it overrides any
VERSION operand values that might be specified on the ++VER MCS.

Usage Notes

- The target and distribution libraries for a program element must be a PDS (for
  pre-built load module) or a PDSE (for a program object).
- If the program element is packaged inline, it must immediately follow the
  ++PROGRAM MCS and must not contain any records starting with ++. Neither
  FROMDS, nor RELFILE, nor LKLIB can be specified on the ++PROGRAM
  MCS.
- To be packaged inline, a program element must be unloaded along with its
  aliases into a sequential data set and then transformed into the required
  fixed-block-80 record format before it is packaged (see "Examples" on page 95
  for a discussion of doing this). Later, when SMP/E installs the element, it is
  changed back to its original format. For more information about using GIMDTS,
  see "GIMDTS: Data transformation service routine" on page 450.
If the program element is packaged in a LKLIB data set, the ddname specified in the LKLIB operand is required during APPLY and ACCEPT processing.
For information about packaging program objects or pre-built load modules, see z/OS Packaging Rules.

Examples
Suppose you have a partitioned data set whose members contain a pre-built load module (LMODABC) and two aliases (ALIAS1 and ALIAS2). Further, suppose that you want to package LMODABC and its aliases inline in a PTF. The steps to package and install pre-built load module LMODABC in a PTF are as follows:

Step 1: Unload the partitioned data set member LMODABC and its aliases to create a sequential, VS format, data set.
```assembly
//JOBx JOB ...
//STEP1 EXEC PGM=IEBCOPY,REGION=512K
//SYSPRINT DD SYSOUT=*
//SYSUT3 DD UNIT=SYSDA,SPACE=(TRK,(5,1))
//SYSUT4 DD UNIT=SYSDA,SPACE=(TRK,(5,1))
//INPUT DD DSN=userid.TEST.LOAD,DISP=SHR
//OUTPUT DD DSN=userid.UNLOAD.DATA,DISP=(NEW,CATLG),
// SPACE=(CYL,(20,10),RLSE),UNIT=SYSDA
//SYSIN DD *
COPY OUTDD=OUTPUT,INDD=INPUT
SELECT MEMBER=LMODABC
SELECT MEMBER=ALIAS1
SELECT MEMBER=ALIAS2
/*
```

Step 2: Transform the unloaded data set into fixed-block-80 type records by using the SMP/E provided service routine GIMDTS.
```assembly
//JOBx JOB ...
//TFORM EXEC PGM=GIMDTS
//* ----- GIMDTS IS AN SMP/E LOAD MODULE.
//SYSPRINT DD SYSOUT=*
//*
//* ----- INPUT TO BE TRANSFORMED - RECFM=VS
//*
//SYSUT1 DD DSN=userid.UNLOAD.DATA,DISP=SHR
//*
//* ----- OUTPUT - RECFM=FB
//*
//SYSUT2 DD DSN=userid.FB80.DATA,DISP=OLD
```

Step 3: Place the fixed block 80 records inline in the PTF following the ++PROGRAM MCS that identifies the element and its aliases to SMP/E.
```assembly
++PTF(PTF0001).
++VER(ZO38) FMID(00001).
++PROGRAM(LMODABC) ALIAS(ALIAS1,ALIAS2) DISTLIB(TGTLIB)
     SYSLIB(VEND001).
:
  Place the data transformed by GIMDTS here.
:
```

Step 4: APPLY the PTF to install LMODABC and its aliases into the appropriate target library.
```assembly
SET BDY(TGT1).
APPLY PTF(PTF0001).
```
During the APPLY step, SMP/E retransforms the inline data back into a variable spanned (VS) sequential data set. SMP/E then invokes the copy utility to copy the retransformed data into the target library. The program element and aliases are copied using a COPYMOD and SELECT statements.

After the APPLY, the target library contains LMODABC and its aliases.
++PTF MCS

The ++PTF MCS identifies a service SYSMOD. This type of SYSMOD can replace or update elements in target and distribution libraries, such as for a permanent correction, or it can add new elements. All other MCSs for this SYSMOD follow this header MCS. For more information about packaging a PTF, see z/OS Packaging Rules.

Syntax

++PTF MCS

++PTF(sysmod_id) DESCRIPTION(description)

FILES(number) RFDSNPFX(relfile_prefix) REMORK(level)

Operands

DESCRIPTION specifies a descriptive name to be associated with this SYSMOD. z/OS Packaging Rules manual.

- DESCRIPTION can also be specified DESC.
- The DESCRIPTION value can be in single-byte characters (such as English alphanumeric) or double-byte characters (such as Kanji).
- The DESCRIPTION value can contain up to 64 bytes of data, including blanks. (For double-byte data, the 64-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters.) Extra blanks, as well as leading and trailing blanks are deleted.
- The DESCRIPTION value can span multiple 80-byte records. Data must continue up to and including column 72 and begin in column 1 of the next line. All data past column 72 is ignored. The break does not translate to a blank unless a blank is explicitly coded in column 72 of the first line or in column 1 of the second line.
- If DESCRIPTION is specified, it must contain at least one non-blank character.
- If parentheses are included in the text, they must be in matched pairs.

FILES specifies the number of relative files belonging to this PTF. It can be a decimal number from 1 to 9999. For information about packaging SYMODs in relative files, see z/OS Packaging Rules.

Notes:

1. Although SMP/E allows you to package PTFs in relative files, they are not generally packaged in this format.
2. If a packager uses a high-level qualifier on RELFILE data sets, the RFDSNPFX operand on the header MCS (not the RFPREFIX operand on the RECEIVE command) must be used to identify that high-level qualifier.
++PTF MCS

REWORK

specifies the level of this SYSMOD, which has been reworked for minor changes. Up to eight numeric characters can be specified.

For SYSMODs supplied by IBM, the REWORK level is yyyyddd, where yyyy is the year the SYSMOD was reworked and ddd is the Julian date.

REWORK allows an updated SYSMOD to be automatically received again, as long as it is more recent than the version that has already been received. This takes the place of rejecting the SYSMOD and receiving it again.

Note: If a SYSMOD appears more than once in the SMPPTFIN data set, the first occurrence may be received. However, none of the subsequent versions of the SYSMOD are received, even if their rework level is higher than the one for the first version of the SYSMOD. (Message GIM40001E is issued for each of the subsequent versions of the SYSMOD.)

RFDSNPFX

identifies to SMP/E the prefix used in the relative file data set names for this SYSMOD. SMP/E uses this prefix when allocating data set names for the SYSMOD’s relative files during RECEIVE processing.

- This operand can be specified only if the FILES operand is also specified.
- The RFDSNPFX value specified on the MCS statement must match the actual prefix used in the data set names for the associated relative files.

For example, if the names of the relative files created for a SYSMOD start with “IBM”, as in IBM.sysmod_id.F1, the header MCS statement for the SYSMOD must specify RFDSNPFX(IBM) so SMP/E knows which prefix to use when allocating the data set names for the SYSMOD’s relative files during RECEIVE processing.

- Following standard data set naming conventions, the prefix can be from 1 to 8 alphanumeric or national ($, #, @) characters or a dash (-).

To enable full Security Server protection for tape data sets and to keep the tape header within the 17-character limit (including periods), you should limit the prefix to 1 to 3 characters. If the name exceeds the 17-character limit, only the rightmost 17 characters are written to the tape header label.

sysmod_id

specifies a unique 7-character system modification identifier for the PTF. For more information, see “Naming conventions for SYSMODs” on page 517

Usage Notes

If you want to update IBM-supplied code, you should use the ++USERMOD MCS rather than the ++PTF MCS. For more information, see “++USERMOD MCS” on page 115

Examples

A PTF is required that replaces module IFBMOD01 for function FXY1040. The prerequisite service SYSMOD for the module is PTF UZ00004. The APAR incident fixed by this PTF is AZ12345. Here is an example of a SYSMOD containing a ++PTF statement to accomplish this:

```c
++PTF(UZ00006) /* Identify the PTF number. */
++VER(Z038) FMID(FXY1040) /* for MVS function FXY1040 */
    PRE(UZ00004) /* with a prerequisite. */
    SUP(AZ12345) /* Fixes one APAR. */
++MOD(IFBMOD01) /* This module */
```
++PTF MCS

DISTLIB(AOSFB) /* from this DLIB. */
...
... object deck for IFBMOD01
...
The **++RELEASE MCS** removes a previously held SYSMOD from exception SYSMOD status. **++RELEASE** statements are processed by the RECEIVE command.

**Syntax**

```
++RELEASE MCS

++RELEASE(sysmod_id) ERROR(REASON(reason_id)) FMID(fmid)

DATE(yyddd)
```

**SYSTEM reason IDs used by IBM:**

- ACTION
- AD
- DB2BIND
- DQDEF
- DELETE
- DEP
- DOC
- DOWNL0
- FC
- ENH
- EXIT
- EXRF
- FULLGEN
- IGEN
- IPL
- MSGSKEL
- MULTSYS
- RESTART

**Operands**

**ERROR, FIXCAT, SYSTEM, or USER**

specifies the hold category from which the SYSMOD is to be removed. You must specify one of these categories.

**ERROR**

An APAR reported an error in the SYSMOD. The SYSMOD should not be applied or accepted until the APAR is resolved. A PTF held for this reason is also called a program error PTF, or PE-PTF. SMP/E automatically resolves the APAR and allows the SYSMOD to be applied or accepted when a SYSMOD that either matches or supersedes the APAR is also applied or accepted. Error holds can be read only from the SMFHOLD data set.
++RELEASE MCS

Note: ERROR can also be specified as ERR.

**FIXCAT**  
An APAR provides a fix for the held SYSMOD and the fix is associated with one or more Fix Categories. It is optional whether the APAR will affect processing for the held SYSMOD, based on the APAR’s Fix Categories and the Fix Categories of interest specified by the user. If any one or more Fix Categories for the APAR match any of those of interest to the user, then the held SYSMOD will not be applied or accepted until the APAR is resolved. The APAR is resolved when a SYSMOD that matches the APAR name, or a SYSMOD that supersedes the APAR, is applied or accepted. FIXCAT holds can be read only from the SMPHOLD data set.

See the FIXCAT operand for APPLY and ACCEPT command processing for details of specifying the Fix Categories of interest.

**SYSTEM**  
Special action outside normal SMP/E processing is required for the SYSMOD. Examples are SYSMODs requiring a SYSGEN after they are installed, or SYSMODs requiring the installation of an associated engineering change (EC) level. System holds can appear in the SYSMOD itself or in the SMPHOLD data set.

Note: SYSTEM can also be specified as SYS.

**USER**  
The SYSMOD requires special processing because of a decision you have made. User holds can be read only from the SMPHOLD data set.

**DATE**  
specifies the date that the ++HOLD MCS was generated.

**FMID**  
specifies the FMID to which the held SYSMOD is applicable. For external HOLDDATA (a ++HOLD statement not within a SYSMOD), this information allows SMP/E to receive only those statements associated with FMIDs defined in the user’s global zone. This operand is required.

**REASON**  
identifies the HOLD reason ID that is to be removed from the SYSMOD. This field is required.

- An *error reason ID* is the number of the APAR that caused the SYSMOD to be placed in exception status.
- A *fix category reason ID* is the SYSMOD ID for the APAR that caused the SYSMOD to be placed into exception status.
- A *system reason ID* is a 1- to 7-character string used to identify some special processing the SYSMOD requires. These are the specific values currently used by IBM:

<table>
<thead>
<tr>
<th>ID</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTION</td>
<td>The SYSMOD needs special handling before or during APPLY processing, ACCEPT processing, or both.</td>
</tr>
<tr>
<td>AO</td>
<td>The SYSMOD may require action to change automated operations procedures and associated data sets and user exits in products or in customer applications. The PTF cover letter describes any changes (such as to operator messages</td>
</tr>
</tbody>
</table>
++RELEASE MCS

text, operator command syntax, or expected actions for operator messages and commands) that can affect automation routines.

<table>
<thead>
<tr>
<th>DB2BIND</th>
<th>A DB2 application REBIND is required for the SYSMOD to become effective.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDDEF</td>
<td>Data set changes or additions as required.</td>
</tr>
<tr>
<td>DELETE</td>
<td>The SYSMOD contains a ++DELETE MCS, which deletes a load module from the system.</td>
</tr>
<tr>
<td>DEP</td>
<td>The SYSMOD has a software dependency.</td>
</tr>
<tr>
<td>DOC</td>
<td>The SYSMOD has a documentation change that should be read before the SYSMOD is installed.</td>
</tr>
<tr>
<td>DOWNLD</td>
<td>Code that is shipped with maintenance that needs to be downloaded.</td>
</tr>
<tr>
<td>DYNACT</td>
<td>The changes supplied by the SYSMOD may be activated dynamically without requiring an IPL. The HOLD statement describes the instructions required for dynamic activation. If those instructions are not followed, then an IPL is required for the SYSMOD to take effect.</td>
</tr>
<tr>
<td>EC</td>
<td>The SYSMOD needs a related engineering change.</td>
</tr>
<tr>
<td>ENH</td>
<td>The SYSMOD contains an enhancement, new option or function. The HOLD statement provides information to the user regarding the implementation and use of the enhancement.</td>
</tr>
<tr>
<td>EXIT</td>
<td>The SYSMOD contains changes that may affect a user exit. For example, the interface for an exit may be changed, an exit may need to be reassembled, or a sample exit may be changed.</td>
</tr>
<tr>
<td>EXRF</td>
<td>The SYSMOD must be installed in both the active and the alternative Extended Recovery Facility (XRF) systems at the same time to maintain system compatibility. (If you are not running XRF, you should bypass this reason ID.)</td>
</tr>
<tr>
<td>FULLGEN</td>
<td>The SYSMOD needs a complete system or subsystem generation to take effect.</td>
</tr>
<tr>
<td>IOGEN</td>
<td>The SYSMOD needs a system or subsystem I/O generation to take effect.</td>
</tr>
<tr>
<td>IPL</td>
<td>The SYSMOD requires an IPL to become effective. For example, the SYSMOD may contain changes to LPA or NUCLEUS, the changes may require a CLPA, or a failure to perform an IPL might lead to catastrophic results, such as could be caused by activation of a partial fix.</td>
</tr>
</tbody>
</table>

**Note:** If you plan to perform an IPL with CLPA after the SYSMOD has been applied, then no further investigation of the HOLD is required; simply bypass the IPL reason ID. However, if you are not planning to perform an IPL with CLPA, then the details of the HOLD statement must be investigated to determine what kind of actions are required to activate the SYSMOD.
**MSGSKEL**

This SYSMOD contains message changes that must be compiled for translated versions of the message changes to become operational on extended TSO consoles.

If you want to use translated versions of the messages, you must run the message compiler once for the library containing the English message outlines, and once for each additional language you want to be available on your system. For details, see [z/OS MVS Planning: Operations](#).

If you want to use only the English version of the messages, you do not need to run the message compiler. You should bypass this reason ID.

**MULTSYS**

Identifies fixes that need to be applied to multiple systems, in one of three cases: preconditioning, coexistence, or exploitation.

**RESTART**

To become effective, the SYSMOD requires a special subsystem restart operation. The HOLD statement contains information regarding the required restart actions.

- A user reason ID is defined by the user.

For additional information, see "Naming conventions for HOLD reason IDs and HOLD classes" on page 514.

**sysmod_id**

specifies that SMP/E is to remove the identified SYSMOD from exception SYSMOD status. This operand is required.

**Usage Notes**

- ++RELEASE statements are not allowed within a SYSMOD. They are allowed only in SMFHOLD.
- ++RELEASE statements unconditionally remove a SYSMOD from exception status and should, therefore, be used with caution. To install a SYSMOD that is currently in exception status, you should probably not create and process a ++RELEASE statement, but rather use the appropriate BYPASS operand of the APPLY or ACCEPT command.
- ++RELEASE statements do not affect ++HOLD statements within a SYSMOD (internal HOLDDATA). However, SMP/E can ignore this internal HOLDDATA during APPLY or ACCEPT processing if BYPASS(HOLDSYS) or BYPASS(HOLDUSER) is specified.

**Examples**

The following examples are provided to help you use the ++RELEASE MCS:

**Example 1: Removing a SYSMOD from HOLDUSER status**

Here is an example of a ++HOLD statement that holds the PTF until after some event (such as new hardware) occurs:

```
++HOLD (UZ12345) /* Put this PTF until after some event (such as new hardware) occurs: */
FMID(FXY1040) /* for this function */
USER /* into hold user status */
REASON(CPU0A) /* for CPU 0A update. */
COMMENT(I DO NOT WANT THIS TO GO ON UNTIL AFTER THE CPU CHANGE) /* */
```

When the CPU change is made, the following sample ++RELEASE statement allows the PTF to be installed:
++RELEASE MCS

++RELEASE (UZ12345) /* Remove this PTF */
   FMID(FXY1040) /* for this function */
   USER /* from hold user status */
   REASON(CPU0A) /* for CPU 0A update. */
/

That PTF is now eligible for normal installation.

Example 2: Incorrect use of ++RELEASE
Assume the following +++HOLD MCS was processed as part of the normal preventive service installation:

+++HOLD (UZ12345) /* Put this PTF */
   FMID(FXY1040) /* for this function */
   ERROR /* into hold error status */
   REASON(AZ12345) /* for the APAR. */
   COMMENT(WHEN RUNNING PRODUCT XYZ and OC4
      ABEND MAY OCCUR) /* */
/

You are running one system with product XYZ installed and one without product XYZ. The PTF provides a fix for another problem you are encountering on the system without product XYZ; so you want to install this PTF on that system. Here is an example of a ++RELEASE statement that lets you apply PTF UZ12345 without having to use the BYPASS operand:

++RELEASE (UZ12345) /* Remove this PTF */
   FMID(FXY1040) /* for this function */
   ERROR /* from hold error status */
   REASON(AZ12345) /* for the APAR. */
/

The risk with this method of processing is that SMP/E no longer has any record of PTF UZ12345 being in exception status. Therefore, the next time any modifications are installed on the system with product XYZ installed, the PTF is installed, introducing a potential 0C4 problem into that system.

The correct way to install the PTF on the system without product XYZ is to use the following command:

SET BDY(MVSTST1) /* Process MVSTST1 tgt zone. */.
APPLY S(UZ12345) /* Process the PTF. */
   BYPASS(HOLDERR(AZ12345)) /* Bypass known error. */.
/

Now the PTF is installed on one system, but SMP/E still remembers that it is in hold error status and does not allow it to be installed on any other system.

Note: Any other applicable operand (FORFMID, SOURCEID, and so on) can be used in place of the SELECT or S operand.

Example 3: A ++RELEASE statement with a FIXCAT HOLD
Here is an example of the use of the FIXCAT hold category on a ++RELEASE statement:

++RELEASE (HBB7720) /* Remove this PTF */
   FMID(HBB7720) /* for this function */
   REASON(AK18603) /* for this APAR */
   FIXCAT /* from fix category hold status */
   DATE(06231) /* on this date */.
/

++RELEASE MCS
++RENAME MCS

During APPLY processing, the ++RENAME MCS renames a load module in all the target libraries and the LMOD entry in the target zone. It also updates the LMOD subentry of the MOD entry for each module in the load module. For load modules having a CALLLIBS subentry (or having a SYSLIB allocation), SMP/E also renames the base version of the load module in the SMPLTS library. For load modules having a side deck library subentry, SMP/E also renames the definition side deck in the side deck library.

During ACCEPT processing, if inline JCLIN was processed, the distribution zone entries are updated to reflect the ++RENAME changes. The target libraries and target zone entries are not updated.

Notes:
1. You cannot use ++RENAME to rename a load module for which symbolic links have been defined.
2. You cannot use ++RENAME to rename macros, modules, source, or other elements. SMP/E does, however, support these ways to rename an element:
   - For elements other than modules, you must use an element MCS statement to delete the original element, and another element MCS statement to reintroduce it using the new name. You can do both of these steps in the same SYMMD. For examples, see the descriptions of the various element MCS statements in this chapter.
   - For modules, you must use a ++MOD statement to delete the original module, and another ++MOD statement to reintroduce it using the new name. In addition, you must ensure that the renamed module is included in the appropriate load modules, either through JCLIN or the LMOD operand on the ++MOD statement. You can do all of these steps in the same SYMMD. For an example, see "Example 3: Packaging a renamed module" on page 83 in this chapter.

Syntax

++RENAME MCS

++RENAME (old_name) TONAME (new_name)

Operands

old_name
    specifies the name of the load module to be renamed.

TONAME
    specifies the new name for the load module.

Usage Notes

- There are no optional operands. You must specify the load module name and its new name.
- ++RENAME statements must follow any ++VER and ++IF statements, and must precede any element MCSs.
++RENAME MCS

- Regardless of the order in which ++MOVE, ++RENAME, and ++DELETE statements are coded in a SYSMOD, they are processed in the following order:
  - APPLY and ACCEPT
    1. ++MOVE
    2. ++RENAME
    3. ++DELETE
  - RESTORE
    1. ++RENAME
    2. ++MOVE

++JCLIN statements are processed next, followed by element statements.

Examples

Here is an example of a SYSMOD containing a ++RENAME statement renaming load module LMODA:

```plaintext
++PTF(UR01234) /* Identify the PTF number. */.
++VER(Z038) FMID(HXY1300) /* For MVS function HXY1300. */.
++IF (ESY1300) THEN /* If ESY1300 is installed */.
  REQ(UR12399) /* UR12399 is required. */.
++RENAME (LMODA) /* Rename load module LMODA */.
  TONAME(LMODBB) /* to LMODBB. */.
++JCLIN /* JCLIN follows. */.
```

```plaintext
++MOD(MODAA) DISTLIB(AOSXX) /* Element MCS statements. */.
```
++SRC MCS

The ++SRC MCS describes a single source replacement. It must immediately precede the source definition statements when they are within the SYSMOD.

You should use the ++SRC MCS when you want to provide the source form of a module and have it get assembled when the SYSMOD is installed. If you want to provide the object form of the module, use the ++MOD MCS instead.

Syntax

The syntax to be used depends on the processing to be done for the element:
- Adding or replacing the element
- Deleting the element

Adding or replacing source

![Adding or replacing source diagram]

Deleting source

![Deleting source diagram]

Operands

DELETE indicates that the source is to be removed from the target libraries, distribution libraries, and SMP/E data sets.

Note: DELETE is mutually exclusive with all other operands except DISTLIB and VERSION.

DISTLIB specifies the ddname of the distribution library for the specified source.
Note: **DISTLIB** must be specified if the source has not been previously recorded on the target zone or distribution zone. If a SRC entry already exists in the target zone or distribution zone, and the value currently in that entry does not match that specified in the DISTLIB operand, the SYSMOD is not applied or accepted, unless that SYSMOD also used the ++MOVE MCS to change the DISTLIB to that new value.

**DISTMOD**

specifies the ddname of the link-edit distribution library for the assembled source code. During ACCEPT processing, the object code from the assembler is link-edited to the library specified.

**FROMDS**

identifies the partitioned data set that contains this element.

Note: The FROMDS operand and its DSN, NUMBER, VOL, and UNIT suboperands are included in the MCS generated by the BUILDMCS command. IBM does not intend the FROMDS operand to be used in manually coded MCS.

**DSN**

specifies the dsname of the FROMDS data set. The specified data set name must conform to standard data set naming conventions and cannot contain parentheses. The maximum length of the entire name is 44 characters (including the periods).

**NUMBER**

specifies a number that SMP/E is to use when assigning a name to the SMPTLIB data set associated with this FROMDS data set. (This is similar to the way the relative file number is used in RELFILE processing.)

**VOL**

specifies, for an uncataloged data set, the volume serial number of the volume containing the FROMDS data set. If specified, this volume identifier must be from 1 to 6 alphanumeric characters.

VOL may be omitted for a cataloged data set.

**UNIT**

specifies, for an uncataloged data set, the UNIT type containing the FROMDS data set. If specified, the UNIT value must be from 1 to 8 characters and must conform to standard UNIT naming conventions. IBM SMP/E for z/OS, V3R5 accepts any nonblank characters specified between the open and close parentheses, up to a maximum length of 8.

UNIT may be omitted for a cataloged data set.

Note: FROMDS is mutually exclusive with DELETE, RELFILE, SSI, and TXLIB.

**name**

specifies the name of the source in the distribution library and, optionally, in the target library. The name can contain any alphanumeric characters and $, #, @, or hex C0.

**RELFILE**

identifies which relative file associated with the SYSMOD contains this element. This operand is required if you provide the element in RELFILE format, rather than inline or in a TLIB data set.
Notes:
1. SMPTLIB cannot be used as a value on the TXLIB operand.
2. RELFILE is mutually exclusive with FROMDS and TXLIB.

RMID
specifies the last SYSMOD that replaced this source. This operand can be used only in a service-updated function, and the specified PTF must be integrated into the function.

SSI
specifies eight hexadecimal digits of system status information. This information is placed in the directory of the target system library or SMPMTS or SMPSTS during APPLY processing, and in the distribution library during ACCEPT processing, as four packed hexadecimal bytes of user data. See the IEBUPDTE program description in z/OS DFSMSdfp Utilities, SC26-7414.

Note: This operand is ignored if text is located in a library, as is the case when either the FROMDS, RELFILE, or TXLIB operand is specified.

SYSLIB
specifies the ddname of the target library, if the source module exists in one. APPLY and RESTORE processing update this library.

Note: If a SRC entry already exists in the target zone or distribution zone and the value currently in that entry does not match that specified in the SYSLIB operand, SMP/E ignores the SYSLIB value in the SYSMOD being installed, unless that SYSMOD also used the ++MOVE MCS to change the SYSLIB to that new value.

TXLIB
is the ddname of the partitioned data set containing the source. This operand is required if the module is provided in a data set the users have access to, rather than inline or in RELFILE format.

Notes:
1. SMPTLIB cannot be used as a value on the TXLIB operand.
2. TXLIB is mutually exclusive with FROMDS and RELFILE.

UMID
specifies the UMIDs of the source. This operand can be used only in function SYSMODs and specifies the PTF service level of the source (the set of SYSMODs that have updated this source since it was last replaced).

VERSION
specifies one or more function SYSMODs that currently contain the element. The function containing the ++SRC MCS takes over ownership of the element from the specified functions.

When VERSION is specified on an element statement, it overrides any VERSION operand values that might be specified on the ++VER MCS.

Usage Notes

- If the source is packaged inline, it must immediately follow the ++SRC MCS and must not contain any records starting with ++. Neither FROMDS, nor RELFILE, nor TXLIB can be specified.
- If the source is in a TXLIB data set, the ddname specified on the TXLIB operand is required during APPLY and ACCEPT processing.
For information about packaging SYSMODs in RELFILE, TXLIB, or inline format, see [z/OS Packaging Rules](#).

Examples

The following examples are provided to help you use the ++SRC MCS:

**Example 1: Adding a new source to the system**

A replacement for the source IFBSRC01 is in a partitioned data set referred to by the ddname REPLACE. The distribution library for the source is SYS1.IFBSRC; SYS1.AOS23 is the distribution library for the module, IFBSRC01, resulting from the assembly of the source, IFBSRC01.

Here is an example of a SYSMOD containing a ++SRC statement that causes SMP/E to install the source code, assemble it, and save the resulting module in the DLIBs:

```plaintext
++USERMOD(USR0001)   /* User modification */
++VER(Z038) FMID(FXY1040) /* for user function in MVS. */
++SRC(IFBSRC01)       /* Replace source */
   DISTLIB(IFBSRC)    /* in this DLIB. */
   DISTMOD(AOS23)     /* MOD goes in this DLIB. */
   TXLIB(REPLACE)     /* Replacement SRC is here. */
```

The following DD statements are required when the SYSMOD is applied:

```plaintext
//REPLACE  DD DSN=...
//SMPSTS   DD DSN=SYS1.SMPSTS,DISP=OLD
```

plus whatever other DD statements are required based on which load modules the assembled source is to be linked to. These load modules should be identified by JCLIN, either as a separate step or within the SYSMOD itself. Assuming the load module was composed of only this one module, the following ++JCLIN MCS can be added to the SYSMOD after the ++VER statement.

```plaintext
++JCLIN.        /* JCLIN to get SRC linked. */
   //JOB1          JOB 'accounting info',MSGLEVEL=(1,1)
   //STEP1         EXEC PGM=IEBCOPY
   //AOS23         DD DSN=SYS1.AOS23,DISP=SHR
   //LPALIB        DD DSN=SYS1.LPALIB,DISP=SHR
   //SYSIN         DD *
      COPY INDD=AOS23,OUTDD=LPALIB
      SELECT M=(IFBSRC01)
   /*
```

In this case, you also need the following DD statement when the SYSMOD is applied:

```plaintext
//LPALIB        DD DSN=SYS1.LPALIB,DISP=OLD
```

The following DD statements are required when the SYSMOD is accepted:

```plaintext
//REPLACE  DD DSN=...
//IFBSRC   DD DSN=SYS1.IFBSRC,DISP=OLD
//AOS23    DD DSN=SYS1.AOS23,DISP=OLD
```

**Example 2: Packaging renamed source**

Suppose that, for some reason, you need to rename source IFBSRC01, which was introduced in [“Example 1: Adding a new source to the system.”](#) The new name is to be USRSRCXX. You do not need to change anything else about the source. Because the original source was linked by JCLIN, you must provide updated
JCLIN to link the renamed version of the source. Here is an example of a SYSMOD containing the ++SRC statements and JCLIN needed to package this renamed source:

```plaintext
++USERMOD(USR0002) /* User modification */.
++VER(Z038) FMID(FXY1040) /* for user function in MVS. */.
  PRE(USR0001) /* Base on previous USERMOD. */.
++SRC(IFBSRC01) /* Delete the original */.
  DELETE /* source. */.
++SRC(USR5SRCXX) /* Add renamed source */.
  DISTLIB(IFBSRC) /* to this DLIB. */.
  DISTMOD(A0523) /* MOD goes in this DLIB. */.
  TXLIB(REPLACE) /* Replacement SRC is here. */.
...
++JCLIN. /* JCLIN to get SRC linked. */.
//JOB1 JOB 'accounting info',MSGLEVEL=(1,1)
//STEP1 EXEC PGM=IEBCOPY
//A0523 DD DSN=SYS1.A0523,DISP=SHR
//LPALIB DD DSN=SYS1.LPALIB,DISP=SHR
//SYSIN DD *
COPY INDD=A0523,OUTDD=LPALIB

SELECT M=(USR5SRCXX)
/*

You must ensure that the renamed source is in the TXLIB library (REPLACE) used to provide SMP/E with the element.

The following DD statements are required when the SYSMOD is applied:

//REPLACE DD DSN=...
//SMPSTS DD DSN=SYS1.SMPSTS,DISP=OLD
//LPALIB DD DSN=SYS1.LPALIB,DISP=OLD

The following DD statements are required when the SYSMOD is accepted:

//REPLACE DD DSN=...
//IFBSRC DD DSN=SYS1.IFBSRC,DISP=OLD
//A0523 DD DSN=SYS1.A0523,DISP=OLD
```
++SRCUPD MCS

++SRCUPD MCS
The ++SRCUPD MCS describes a single set of source update statements within a
PTF, an APAR fix, or a USERMOD. It must immediately precede the source update
statements within the SYSMOD.

Syntax

++SRCUPD MCS
   ++SRCUPD(name)
   DISTLIB(ddname)
   DISTMOD(ddname)
   SYSLIB(ddname)

Operands

name
specifies the name of the source in the distribution library and, optionally, in
the target library. The name can contain any alphanumeric characters and $, #,
@, or hex C0.

DISTLIB
specifies the ddname of the distribution library for the specified source.

Note: DISTLIB must be specified if the source has not been previously
recorded on the target zone or distribution zone. If a SRC entry already
exists in the target zone or distribution zone, and the value currently in
that entry does not match that specified in the DISTLIB operand, the
SYSMOD is not applied or accepted.

DISTMOD
specifies the ddname of the link-edit distribution library for the assembled
source code. During ACCEPT processing, the object code from the assembler is
link-edited to the library specified.

SYSLIB
specifies the ddname of the target library, if the source exists in one. APPLY
and RESTORE processing update this library.

Usage Notes

• If a SYSMOD containing a ++SRCUPD statement attempts to change the
  ownership (FMID) of the element (with the VERSION operand), the SYSMOD
cannot be installed.
• The changes for the source must immediately follow the ++SRCUPD MCS and
  must not contain any records starting with ++.
• The only IEBUPDTE control statements allowed in a SYSMOD are ./ CHANGE
  and ./ ENDUP.
• The only IEBUPDTE CHANGE operand that SMP/E checks is NAME, which
  must specify the same element as the ++SRCUPD MCS. Other CHANGE
  operands may produce undesired results and are used at your own risk. For
  example, if you code UPDATE=INPLACE, SMP/E may update the distribution
  library. Once the distribution libraries are changed, there is no way to remove
  the updates.
• When processing multiple updates to the same lines in a given source module, SMP/E uses the ./ CHANGE statement from the last update to the lines.
• SMP/E does not support a continuation of the ./ CHANGE statement.

Examples

The following examples are provided to help you use the ++SRCUPD MCS:

Example 1: Updating an existing source

Here is an example of a SYSMOD containing a ++SRCUPD statement to make a modification to an IBM source module, in this case module JESMOD01, which is part of product EJS1102:

```
++USERMOD(MY00001)     /* User modification     */.
++VER(Z038)  FMID(EJS1102)     /* for MVS JES.            */.
      PRE(UZ12345)  /* Current service level. */.
++SRCUPD(JESMOD01)     /* Update this JES MOD.     */.
      /* DISTLIB already known. */.
./ CHANGE NAME=JESMOD01
   LA         R1, MYPARM     00001000
   BALR      MYPGM    00001100
MYPGM  EQU   *         00500080
         ...       00500100
         ...       00500200
       B       R14   00500300
```

Example 2: Making subsequent source updates

Assume that, after installing the modification given in the first example, you need to make another modification. Assume the following lines had to be changed:

```
...                                 00500150
   BALR      MYPGM2    00500160
MYPGM2  EQU   *         00600000
         ...       00600100
         ...       00600200
       B       R14   00600300
```

You have two choices as to the method of building the second modification:
1. The first method is to build the second SYSMOD to contain only the newly changed lines of code, and then specify the PRE operand in both the current IBM service level and the previous user modification.
2. The second method is to build the second SYSMOD to contain all the user modifications to this module; then specify the PRE operand in the current IBM service level and supersede the previous user modification.

Here is an example of a SYSMOD for the first method:

```
++USERMOD(MY00002)     /* User modification     */.
++VER(Z038)  FMID(EJS1102)     /* for MVS JES.            */.
      PRE(UZ12345)  /* Current service level. */.
      MY00001     /* plus previous USERMOD. */.
++SRCUPD(JESMOD01)     /* Update this JES MOD.     */.
      /* DISTLIB already known. */.
./ CHANGE NAME=JESMOD01
   ...                                 00500150
   BALR      MYPGM2    00500160
MYPGM2  EQU   *         00600000
         ...       00600100
         ...       00600200
       B       R14   00600300
```

Here is an example of a SYSMOD for the second method:
++SRCUPD MCS

++USERMOD(MY00002) /* User modification */.
++VER(Z038) FMID(EJS1102) /* for MVS JES. */
PRE(UZ12345) /* Current service level. */
SUP(MY00001) /* Supersede previous usermod. */.
++SRCUPD(JESMOD01) /* Update this JES MOD. */
/* DISTLIB already known. */.

./ CHANGE NAME=JESMOD01
   LA R1,MYPARM 00001000
   BALR MYPGM 00001100
MYPGM EQU * 00500000
   ... 00500100
   BALR MYPGM2 00500160
   ... 00500200
   B R14 00500300
   ... 00500150
MYPGM2 EQU * 00600000
   ... 00600100
   ... 00600200
   B R14 00600300

The advantages to the second method are that all modifications to one source are contained in a single SYSMOD, and if that SYSMOD has to be restored or re-applied, processing is much more efficient.

Note: The SMP/E ++SRCUPD MCS is the same for both methods; only the ++VER MCS and the actual update control cards change.
++USERMOD MCS

The ++USERMOD MCS identifies a user modification. This type of SYSMOD can be used to add user-defined functions or to replace or update elements for IBM-supplied code in the target or distribution libraries. All other MCSs for this SYSMOD follow this header MCS. For more information about packaging a USERMOD, see SMP/E User's Guide.

Syntax

```
++USERMOD MCS
   ++USERMOD(sysmod_id)            DESCRIPTION(description)
       FILES(number)               RFDSNFPFX(relfile_prefix)
       REMORK(level)               ...
```

Operands

DESCRIPTION

specifies a descriptive name to be associated with this SYSMOD. z/OS Packaging Rules manual.

- DESCRIPTION value can also be specified DESC.
- The DESCRIPTION value can be in single-byte characters (such as English alphanumeric) or double-byte characters (such as Kanji).
- The DESCRIPTION value can contain up to 64 bytes of data, including blanks. (For double-byte data, the 64-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters.) Extra blanks, as well as leading and trailing blanks are deleted.
- The DESCRIPTION value can span multiple 80-byte records. Data must continue up to and including column 72 and begin in column 1 of the next line. All data past column 72 is ignored. The break does not translate to a blank unless a blank is explicitly coded in column 72 of the first line or in column 1 of the second line.
- If DESCRIPTION is specified, it must contain at least one non-blank character.
- If parentheses are included in the text, they must be in matched pairs.

FILES

specifies the number of relative files belonging to this USERMOD. It can be a decimal number from 1 to 9999. For information about packaging SYSMODs in relative files, see z/OS Packaging Rules

Notes:

1. Although SMP/E allows you to package USERMODs in relative files, they are not generally packaged in this format.
2. If a packager uses a high-level qualifier on RELFILE data sets, the RFDSNFPFX operand on the header MCS (not the RFPREFIX operand on the RECEIVE command) must be used to identify that high-level qualifier.
++USERMOD MCS

REWORK
specifies the level of this SYSMOD, which was reworked for minor changes.
Up to eight numeric characters can be specified.
For SYSMODs supplied by IBM, the REWORK level is yyyyddd, where yyyy is
the year the SYSMOD was reworked and ddd is the Julian date.
REWORK allows an updated SYSMOD to be automatically received again, as
long as it is more recent than the version that has already been received. This
takes the place of rejecting the SYSMOD and receiving it again.

Note: If a SYSMOD appears more than once in the SMPPTFIN data set, the
first occurrence may be received. However, none of the subsequent
versions of the SYSMOD are received, even if their rework level is
higher than the one for the first version of the SYSMOD. (Message
GIM40001E is issued for each of the subsequent versions of the
SYSMOD.)

RFDSNPFX
identifies to SMP/E the prefix used in the relative file data set names for this
SYSMOD. SMP/E uses this prefix when allocating data set names for the
SYSMOD’s relative files during RECEIVE processing.
• This operand can be specified only if the FILES operand is also specified.
• The RFDSNPFX value specified on the MCS statement must match the
actual prefix used in the data set names for the associated relative files.
For example, if the names of the relative files created for a SYSMOD start
with “IBM”, as in IBM.sysmod_id.F1, the header MCS statement for the
SYSMOD must specify RFDSNPFX(IBM) so SMP/E knows which prefix to
use when allocating the data set names for the SYSMOD’s relative files
during RECEIVE processing.
• Following standard data set naming conventions, the prefix can be from 1 to
8 alphanumeric or national ($) # @) characters or a dash (-).
To enable full Security Server protection for tape data sets and to keep the
tape header within the 17-character limit (including periods), you should
limit the prefix to 1 to 3 characters. If the name exceeds the 17-character
limit, only the rightmost 17 characters are written to the tape header label.

sysmod_id
specifies a unique 7-character system modification identifier for the
USERMOD. For more information, see “Naming conventions for SYSMODs”
on page 517.

Usage Notes
If you have updated an element, SYSMODs other than functions cannot replace it
unless you explicitly allow them to by bypassing MODID checking. However, if
you install a function, it may overlay your user modifications. SMP/E issues a
warning message when it detects this condition.

Examples
A source (IFBSRC02) owned by function SYSMOD FXY1040 is to be modified. Your
modification requires a service level provided UZ00007; you are only updating, not
replacing, the source. You have chosen a SYSMOD ID of MY00001. Here is an
example of a SYSMOD containing a ++SRCUPD statement that accomplishes this:

++USERMOD(MY00001) /* USERMOD number */.
++VER(Z0938) FMID(FXY1040) /* for function FXY1040 */.
PRE(UZ00007) /* at this service level. */.
++SRCUPD(IFBSRC02) /* Update this source */
DISTLIB(IFBSRC) /* in this DLIB. */
./ CHANGE NAME=IFBSRC02
... update control cards
...

For additional examples of USERMODs, see "++SRCUPD MCS" on page 112 and "SMP/E User’s Guide"
The ++VER MCS describes the environment required for receiving and installing a SYSMOD. A SYSMOD must contain a separate ++VER MCS for each environment to which it applies. At least one ++VER MCS must be present in a SYSMOD, and a maximum of 255 ++VER statements are allowed for each SYSMOD.

**Syntax**

++VER MCS

++VER MCS

**Operands**

**DELETE**

indicates which function SYSMODs should be deleted when this function is installed. These functions are permanently deleted and cannot be restored.

**DELETE** can be specified only in function SYSMODs.

The same SYSMOD can be specified on both DELETE and SUP. This cleans up entries for the deleted function, and, at the same time, allows SYSMODs that name the deleted function as a requisite to still be installed.

SYSMODs specified in the DELETE operand do not have to be specified in VERSION operands of ++VER, ++MAC, ++SRC, or ++MOD statements.

For additional information on the effect of DELETE during APPLY and ACCEPT processing, see SMP/E Commands.

**FMID**

FMID identifies the function to which a SYSMOD applies. **FMID** must be specified for all SYSMODs except base functions.

The following considerations relate to the FMID operand:

- Unlike prerequisites specified by the PRE operand, the functional prerequisite specified by the FMID operand is satisfied only by the specified SYSMOD. It is not satisfied by another SYSMOD that supersedes that function.
++VER MCS

- When specified on the ++VER MCS for a function, FMID defines the function as a dependent function. In this case, FMID indicates that the elements supplied by the dependent function SYSMOD are functionally higher than the specified base function.
  A function cannot be both a base function and a dependent function. Therefore, if a base function contains more than one ++VER MCS, none of them can specify the FMID operand. Likewise, if a dependent function contains more than one ++VER MCS, all of them must specify the FMID operand.
- When specified on the ++VER MCS for a non-function SYSMOD, FMID indicates the functional level of all elements in the SYSMOD.
- SMP/E RECEIVE processing does not receive a dependent function unless the FMID of the base is already present in the global zone or BYPASS(FMID) is specified. For more information on packaging of dependent SYSMODs, refer to RECEIVE processing in [SMP/E Commands](#).

NPRE

indicates which function SYSMODs cannot exist in the same zone as this function. These are negative prerequisite SYSMODs. The current SYSMOD cannot be applied or accepted if any of the listed SYSMODs are already present.

This operand has no effect on RECEIVE eligibility.

NPRE can only be specified within a function SYSMOD.

PRE

indicates which SYSMODs are prerequisites for this SYSMOD. A prerequisite SYSMOD must either be already installed, or must be installed concurrently with this SYSMOD. For additional information on how prerequisites are resolved during APPLY and ACCEPT processing, see [SMP/E Commands](#).

If a SYSMOD replaces an existing element, the PRE operand must specify the previous SYSMOD that replaced the element (RMID) and all the SYSMODs that have updated the element (UMIDs) since it was last replaced.

If a SYSMOD updates an existing element, the PRE operand must specify the previous SYSMOD that replaced the element. It should also specify the last SYSMOD that updated the element since then.

This operand has no effect on RECEIVE eligibility.

REQ

indicates which SYSMODs are requisites for this SYSMOD. The specified SYSMOD must either be already installed, or must be installed concurrently with this SYSMOD. If the specified SYSMOD also specifies this SYSMOD as a requisite, these two SYSMODs are corequisites, and neither can be installed independently; they must be installed within the same APPLY and ACCEPT command. For additional information on how requisites are resolved during APPLY and ACCEPT processing, see [SMP/E Commands](#).

This operand has no effect on RECEIVE eligibility.

srel

specifies the system or subsystem release on which the SYSMOD can be installed. The SREL must contain four alphanumeric characters, usually one alphabetic character followed by three numeric characters. These are the systems and subsystems defined by IBM, with their SRELS:

<table>
<thead>
<tr>
<th>System</th>
<th>SREL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2</td>
<td>P115</td>
</tr>
</tbody>
</table>
++VER MCS

<table>
<thead>
<tr>
<th>CICS</th>
<th>C150</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMS</td>
<td>P115</td>
</tr>
<tr>
<td>MVS</td>
<td>Z038</td>
</tr>
<tr>
<td>NCP</td>
<td>P004</td>
</tr>
</tbody>
</table>

The SREL is used during RECEIVE processing to determine whether a SYSMOD should be received. For more information on how the SREL operand is processed, see the [SMP/E Commands](#).

**SUP**

indicates which SYSMODs are superseded (contained in and replaced) by this SYSMOD. For example, it may specify one or more APARs fixed in the element modifications supplied with this SYSMOD.

For functions, the same SYSMOD can be specified on both DELETE and SUP. This cleans up entries for the deleted function, and, at the same time, allows SYSMODs that name the deleted function as a requisite to still be installed.

For PTFs, APARs, and USERMODs to properly supersede another SYSMOD, all the elements in the superseded SYSMOD must be contained in either the superseding SYSMOD or a SYSMOD from the requisite set for the superseding SYSMOD (unless the element is being deleted by the superseding SYSMOD).

**VERSION**

indicates functions whose elements should be considered functionally lower than the elements contained in this SYSMOD. It specifies one or more function SYSMODs that currently contain the element. The function containing the ++VER MCS takes over ownership of all the elements from the specified functions.

When VERSION is specified on an element statement, it overrides any VERSION operand values specified on the ++VER MCS.

**Note:** A SYSMOD containing an element update (++MACUPD, ++SRCUPD, or ++ZAP) cannot change the ownership of the element. The ownership can be changed (with the ++VER VERSION operand) only if the SYSMOD provides a replacement for the element.

**Usage Notes**

- You can build a SYSMOD that can be processed by previous versions of SMP/E, as well as this version of SMP/E. For service SYSMODs, this construction requires at least two ++VER statements, one processable by previous versions of SMP/E and the other processable by this version of SMP/E. The SRELs in these ++VER statements must be different, so the SYSMOD can be processed correctly by the applicable version of SMP/E.

- A SYSMOD cannot contain multiple ++VER statements that have identical SREL and FMID values, because SMP/E would not be able to determine which ++VER MCS to use in doing the remaining applicability checking during APPLY and ACCEPT processing.

- You cannot specify the same SYSMOD more than once on a single ++VER operand. Likewise, you generally cannot specify the same SYSMOD on more than one operand. However, you can specify the same SYSMOD on VERSION and another operand (except FMID). You can also specify the same SYSMOD on the DELETE and SUP operands.

- Corequisite SYSMODs (which are related through the REQ operand) that are applicable to the same FMID cannot have elements in common. Because the REQ operand implies no service hierarchy, SMP/E cannot determine which SYSMOD has the highest service level of the common elements. When the
Examples

The following examples are provided to help you use the ++VER MCS:

Example 1: Defining base and dependent functions
Assume you want to package one of your user applications as a function so you can use SMP/E in installing and maintaining it. You also have an optional enhancement to that product you want to package. The base function has two modules, USRMOD01 and USRMOD02, which are in link-edit format and reside in the library pointed to by the USRLIBXX DD statement. The optional enhancement changes USRMOD02 and depends on the base application being present. Here are examples of SYSMODs for these functions:

```c
++FUNCTION(EUSR001) /* Base application */.
++VER(Z038) /* for MVS version. */.
++MOD(USRMOD01) /* Has this MOD */.
  DISTLIB(AOS12) /* in this DLIB. */.
  LKLIB(USRLIBXX) /* Replacement is here */.
++MOD(USRMOD02) /* Has this MOD */.
  DISTLIB(AOS12) /* in this DLIB. */.
  LKLIB(USRLIBXX) /* Replacement is here */.
++FUNCTION(FUSR011) /* Dependent function */.
++VER(Z038) /* for MVS version. */.
  FMID(EUSR001) /* Base function must be present. */.
++MOD(USRMOD02) /* Has this MOD */.
  DISTLIB(AOS12) /* in this DLIB. */.
  LKLIB(USRLIBXX) /* Replacement is here */.
++MOD(USRMOD03) /* Has this MOD */.
  DISTLIB(AOS12) /* in this DLIB. */.
  LKLIB(USRLIBXX) /* Replacement is here */.
```

The dependent function, FUSR011, specifies the base function on its FMID operand. This means the base function must be present in order for the dependent function to be installed. The FMID operand also indicates that if the two functions have any elements in common, the version in the dependent product is the one that is to be installed. The dependent product has now assumed ownership of those elements.

Example 2: Defining intersecting dependent functions
Assume you want to add another dependent function for the base function defined in the preceding example. It works whether or not the other dependent function is installed. Here is an example of a SYSMOD containing a ++VER statement to define the relationship between the dependent functions:

```c
++FUNCTION(FUSR012) /* Dependent function */.
++VER(Z038) /* for MVS version. */.
  FMID(EUSR001) /* Base function must be present. */.
```

Chapter 2. SMP/E modification control statements 121
After this function is installed, module USRMOD02 is the version from function FUSR012, no matter what the former functional level was.

Example 3: Deleting a previous level of a function

Assume you want to provide a new level of the base function defined in the first example. It includes both of the dependent functions for the original base function. Here is an example of a SYSMOD containing a ++VER statement deleting the previous level of the function:

```c
++FUNCTION(EUSR002) /* New base application */.
++VER(Z038) /* for MVS version. */.
DELETE(EUSR001) /* Delete prev level. */.
++MOD(USRMOD01) /* Has this MOD */.
  DISTLIB(AOS12) /* in this DLIB. */.
  LKLIB(USRLIBXX) /* Replacement is here. */.
++MOD(USRMOD02) /* Has this MOD */.
  DISTLIB(AOS12) /* in this DLIB. */.
  LKLIB(USRLIBXX) /* Replacement is here. */.
++MOD(USRMOD03) /* Has this MOD */.
  DISTLIB(AOS12) /* in this DLIB. */.
  LKLIB(USRLIBXX) /* Replacement is here. */.
++MOD(USRMOD04) /* Has this MOD */.
  DISTLIB(AOS12) /* in this DLIB. */.
  LKLIB(USRLIBXX) /* Replacement is here. */.
```

After the new function is installed, all references to SYSMODs EUSR001, FUSR011, and FUSR012 are deleted from the target zone and distribution zone (except the SYSMOD entry for EUSR001, which indicates it was deleted by EUSR002).

This SYSMOD does not require the previous level of the base function to be installed. The DELETE operand just says that if that previous function was installed, SMP/E should delete it before installing the new level. For more information on delete processing for the APPLY and ACCEPT commands, see SMP/E Commands.

Example 4: Deleting a function without replacing it (dummy delete)

Assume you no longer need a particular function, and you want to delete it from your system. First, you must make sure that no other functions depend on the function you want to delete. Once you have done this, you need to define a dummy function SYSMOD that deletes the function you want to delete. You then receive, apply, and accept the dummy function, and run UCLIN to delete the SYSMOD entries for the deleted function and for the dummy function.

For example, assume you are ready to delete function MYFUNC1 using dummy function DELFUNC. MYFUNC1 is applicable to SREL Z038 and is installed in target zone TGT1 and distribution zone DLIB1. Here is an example of the dummy function:

```c
++FUNCTION(DELFUNC) /* Any valid unique SYSMOD ID. */.
++VER(Z038) /* For SREL Z038 (MVS products). */.
DELETE(MYFUNC1) /* Deletes MYFUNC1. */.
```
These are the commands you use to receive and install the dummy function, and to delete the SYSMOD entries for the dummy function and the deleted function:

```
SET BDY(GLOBAL) /* Set to global zone. */.
RECEIVE S(DELFUNC) /* Receive the function. */.
SET BDY(TGT1) /* Set to applicable target. */.
APPLY S(DELFUNC) /* Apply to delete old */
    /* function. */.
SET BDY(DLIB1) /* Set to applicable DLIB. */.
ACCEPT S(DELFUNC) /* Accept to delete old */
    /* function. */.
SET BDY(TGT1) /* Set to applicable target. */.
UCLIN.
DEL SYSMOD(DELFUNC) /* Delete SYSMOD entries for */.
DEL SYSMOD(MYFUNC1) /* dummy and old function. */.
ENDUCL.
```

When you accept the dummy function, SMP/E automatically deletes the associated SYSMOD entry from the global zone and the MCS entry from the SMPPTS.

To complete the cleanup, you should also use the REJECT command to delete any SYSMODs and HOLDDATA applicable to the dummy function and the old function. In addition, you should delete the FMIDs from the GLOBALZONE entry to prevent SMP/E from receiving any SYSMODs or HOLDDATA applicable to either of those functions. Here are examples of the commands you can use to do this.

```
SET BDY(GLOBAL) /* Set to global zone. */.
REJECT HOLDDATA NOFMID /* Reject SYSMODs, HOLDDATA */
    /* PRODUCT information */
DELETEFMID /* for the deleted functions. */
(DELFUNC MYFUNC1) /* Delete the FMIDs from the */
    /* GLOBALZONE entry. */.
```

**Note:** If you delete a function that used totally copied libraries, there will be DLIB entries left in the zone after the deletion, which may cause problems if this function is later reinstalled. You should run UCLIN to delete the leftover DLIB entries to ensure that SMP/E will create new DLIB entries that point to the proper libraries when a new copy of the function is installed.
The ++ZAP MCS describes a module update within a PTF, APAR fix, or USERMOD. It must precede the IMASPZAP statements within the SYSMOD.

Syntax

```
++ZAP
   ++ZAP(name)
       DALIAS(alias)
       DISTLIB(ddname)
       TALIAS(alias)
```

Operands

**DALIAS**

is the alias name of a module that has an alias in the distribution library, but not in the target library. This might be used if the module is included under its alias name during system generation.

*Note:* DALIAS is mutually exclusive with TALIAS.

**DISTLIB**

specifies the ddname of the distribution library for the specified module.

*Note:* This operand must be specified if the module has not been previously recorded on the target zone or distribution zone. If a MOD entry already exists in the target zone or distribution zone and the value currently in that entry does not match that specified in the DISTLIB operand, the SYSMOD is not applied or accepted.

**name**

specifies the name of the module member in the distribution library and, optionally, in the target system library. The name can contain any alphanumeric characters and $, #, @, or hex C0.

*Note:* If the module to be updated has been assembled, specify the name of the assembled module, not the CSECT name.

**TALIAS**

identifies all the alias names of a module that has aliases in both the target and distribution libraries.

You can use TALIAS for a module that was copied from a distribution library into a target library (defined by JCLIN data as a copied module), but not for one that is link-edited (defined by JCLIN data as a link-edited module). TALIAS must be specified on the ++MOD MCS even if ALIAS was specified on the COPY SELECT statement.

*Note:* TALIAS is mutually exclusive with DALIAS.
++ZAP MCS

Usage Notes

- If a SYSMOD containing a ++ZAP statement attempts to change the ownership (FMID) of the element (with the VERSION operand), the SYSMOD cannot be installed.
- The changes for the module must immediately follow the ++ZAP MCS and must not contain any records that start with ++.
- The only IMASPZAP control statements allowed in a SYSMOD are:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABSDUMP</td>
<td>DUMP</td>
</tr>
<tr>
<td>ABSDUMPT</td>
<td>DUMPT</td>
</tr>
<tr>
<td>BASE</td>
<td>IDRDATA</td>
</tr>
<tr>
<td></td>
<td>SETSSI</td>
</tr>
</tbody>
</table>

- An EXPAND control statement in link-edit utility format can be placed within IMASPZAP input to allow lengthening of control sections. The EXPAND statement must follow the NAME statement. For the syntax and description of the EXPAND statement, see [IBM MVS Program Management: User’s Guide and Reference, SA22-7643](https://www.example.com). All control statements must begin in or after column 2.
- Expand type IMASPZAP processing cannot be performed against a noneditable (NE) module.
- Any SETSSI statements placed in the input stream for expand-type IMASPZAP processing must be in a form acceptable to both IMASPZAP and the link-edit utility; that is, they must begin in column 2 or after. The SSI statements must follow the EXPAND statements.
- The name specified on the ++ZAP MCS must be the same as the name of the distribution library module. The CSECT value on the IMASPZAP NAME statement must be the same as the load module’s CSECT name. That CSECT name is usually the same as the distribution library name, but it can be different. For example, if the module to be updated has been assembled, the ++ZAP statement should specify the name of the assembled module, not the CSECT name.
- The LIST LMOD statement produces a target zone listing of link-edit utility control statements that might have changed the CSECT name of the member. A link-edit map may be helpful in other cases where the names differ.
- The IMASPZAP NAME statement can optionally be coded as follows:

  ```
  NAME  csect-name
  or
  NAME  lmod-name  csect-name
  or
  NAME  lmod-name  csect-name  class-name
  ```

The coding of one operand assumes that operand to be a CSECT name for the module referred to in the ++ZAP statement. In this case, all load modules containing the module named in the ++ZAP statement are processed by IMASPZAP.

Two operands can be specified, in which case the second operand is assumed to be a CSECT name. The first operand is assumed to be a valid load module containing the module named in the ++ZAP statement. In this case, only the indicated load module is processed by IMASPZAP.

Three operands can also be specified, in which case the first two operands are as described in the previous paragraphs. The third operand indicates, for program objects only, the class of text that you want to modify. The default is B_text. If
++ZAP MCS

you want to omit the CSECT name and supply a class-name, code a single asterisk for the CSECT name, followed by the class-name.

- When using IMASPZAP on an assembled module, be careful: The modification identifier is updated, but not the modification of any associated macros.

It is not recommended that you use IMASPZAP to modify assembled modules. An assembled module modified by IMASPZAP does not cause updating of the distribution library during accept processing; therefore, a subsequently generated system does not contain the IMASPZAP modification.

A more satisfactory method of updating assembled modules is to update the macros that generate them.

- SMP/E processing does not save a backup copy of the nucleus during apply processing when the nucleus is modified by a SYSMOD containing a non-expand-type IMASPZAP modification.

- Only one ZAP can be applied to a module by a single APPLY command. If you need to install several ZAPs for a given module, each one must be packaged separately and installed by a separate APPLY command.

- If you need to install a ++ZAP change on a live system library and that library uses library lookaside (LLA), virtual lookaside facility (VLF), or both, you must do some setup work before installing the change. Otherwise, the change might not take effect, even after installation. See [z/OS MVS Initialization and Tuning Guide](#) for guidance on:
  - Removing libraries from LLA and VLF control
  - Refreshing LLA and VLF

Note: Installing a change on a live system is not recommended.

**Examples**

The examples in this section are based on the load module structure shown in [Figure 2](#).

<table>
<thead>
<tr>
<th>Load Module Name</th>
<th>Load Module Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Module Name</td>
<td>Module Name</td>
</tr>
<tr>

**Figure 2. Load module structure for ++ZAP examples**

The following examples show how ++ZAP statements can be used to update modules, load modules, and CSECTs within modules:
Example 1: Changing all load modules that contain the same module
Assume you want to change CSECT2 in module MOD1, which is in both LMODA and LMODB. Here is an example of a SYSMOD that accomplishes this by specifying the CSECT name on the NAME statement without including any load module names:

++USERMOD(MYMOD01).
++VER(Z038) FMID(FXY1000).
++ZAP(MOD1).
    NAME CSECT2
    VER 0000 FF4160
    REP 0000 FE4160

Example 2: Changing the only load module that contains a given module
Assume you want to change CSECT MOD3 in module MOD3, which is only in LMODA. Here is an example of a SYSMOD that accomplishes this by specifying the CSECT name on the NAME statement without including any load module names:

++USERMOD(MYMOD02).
++VER(Z038) FMID(FXY1000).
++ZAP(MOD3).
    NAME MOD3
    VER 000A 00
    REP 000A FF

Example 3: Changing one of several load modules that contain a given module
Assume you want to change CSECT2 in module MOD1, which is in both LMODA and LMODB. You want to update only the version in LMODB. Here is an example of a SYSMOD that accomplishes this by specifying both the load module name and the CSECT name on the NAME statement.

++USERMOD(MYMOD03).
++VER(Z038) FMID(FXY1000).
++ZAP(MOD1).
    NAME LMODB CSECT2
    VER 0000 00
    REP 0000 FF

Example 4: Expanding a module
Assume you want to update CSECT3 with an EXPAND request. CSECT3 is in module MOD1, which is in both LMODA and LMODB. Here is an example of a SYSMOD that accomplishes this by specifying the CSECT name on the NAME statement and on an EXPAND statement.

++USERMOD(MYMOD04).
++VER(Z038) FMID(FXY1000).
++ZAP(MOD1).
    NAME CSECT3
    VER 0000 FF
    REP 0000 FE
    EXPAND CSECT3(4)
Chapter 3. Defining control statements in SMPPARM members

The SMPPARM data set can contain members that allow you to customize SMP/E as follows:

<table>
<thead>
<tr>
<th>Member name</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>GIMDDALC</td>
<td>Defines data sets to be dynamically allocated</td>
</tr>
<tr>
<td>GIMEXITS</td>
<td>Defines exit routines</td>
</tr>
<tr>
<td>GIMOPCDE</td>
<td>Defines macro and assembler operation codes</td>
</tr>
</tbody>
</table>

### GIMDDALC control statements

SMPPARM member GIMDDALC is used to specify data sets that are to be dynamically allocated by SMP/E. The following types of data sets may be specified in GIMDDALC:

- Data sets to be allocated to a SYSOUT class (or to the terminal for foreground execution)
- Data sets to be allocated as temporary data sets
- SMPTLIB data sets

During any attempt to allocate a data set, SMP/E first looks for a DD statement specified in the job. If no DD statement was specified, SMP/E then looks for a DDDEF entry in the zone. If no DDDEF entry was found, SMP/E then checks to see if there is an SMPPARM data set. If so, and there is a GIMDDALC member within it, SMP/E looks for a GIMDDALC control statement for the corresponding ddname.

### Syntax

**SYSOUT data sets**

```plaintext
DD(ddname) SYSDOUT(class,TERM)
```

**SMPWRKn and SYSUTn data sets**

```plaintext
DD(ddname) DDDEF

- BLOCK(size)
- SPACE(primary,secondary)
- CYLINDERS
- TRACKS
- UNIT(type)
- VOLUME(volid)
- DATAclas(name)
- MGMTCLASS(name)

- STORAGE(name)
- DSNAME(LIBRARY)
- PDS
```

© Copyright IBM Corp. 1986, 2009
GIMDDALC statements

- **SMPTLIB data sets**

<table>
<thead>
<tr>
<th>DD(SMPTLIB)</th>
<th>TRACKS</th>
<th>DIR(nnn)</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPACE(primary,secondary)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Operands**

- **DD**
  identifies the ddname of the data set to be allocated.
  - *ddname* can be from 1 to 8 alphanumeric (A through Z, and 0 through 9), or national characters (@,#, or $), and must start with an alphabetic or national character.
  - The DD operand must be the first operand specified on a GIMDDALC control statement.

- **BLOCK(size)**, **CYLINDERS**, or **TRACKS**
  specifies the space units to be used in allocating the data set: blocks, cylinders, or tracks. *size* is the size of each block to be allocated, and can be from 1 to 5 decimal digits. To specify the number of these units, use the **SPACE** operand.
  - **BLOCK** can be specified as BLK, **CYLINDERS** can be specified as CYL, and **TRACKS** can be specified as TRK.

- **DATACLA**
  specifies the name of a data class to be used for allocating a data set managed by SMS.
  - The data class can be from 1 to 8 alphanumeric characters (A through Z and 0 through 9) or national characters (@, #, $).

- **DIR**
  specifies the number of directory blocks to allocate.
  - The number can contain from 1 to 4 decimal digits.

- **DSN TYPE**
  specifies the type of partitioned data set to be created.
  - **LIBRARY** indicates a PDSE is to be created.
  - **PDS** indicates a PDS is to be created.

- **MGMTCLA**
  specifies the name of a management class to be used for allocating a data set managed by SMS.
  - The management class can be from 1 to 8 alphanumeric characters (A through Z and 0 through 9) or national characters (@, #, $).

- **SPACE**
  specifies the primary and secondary space allocation for a data set. To specify the units for the space allocation, use one of the **BLOCK**, **CYLINDERS**, or **TRACKS** operands.
  - The *primary* and *secondary* values can contain from 1 to 4 decimal digits, and the two values must be separated by a comma or a blank.
  - The units of *primary* and *secondary* space allocation for SMPTLIB data sets is always tracks.
GIMDDALC statements

STORCLAS
specifies the name of a storage class to be used for allocating a data set managed by SMS.

The storage class can be from 1 to 8 alphanumeric characters (A through Z and 0 through 9) or national characters (@, #, $).

SYSOUT
specifies the output class for SYSOUT data sets.
- The class value must be 1 alphabetic or numeric character (A through Z and 0 through 9).
- An asterisk (*) indicates the class from the OUTPUT DD statement is to be used. If no OUTPUT DD statement is found, the system default message class is used.
- TERM indicates if SMP/E is executing in the foreground, the data set is to be allocated to the terminal.
- SYSOUT is mutually exclusive with all other operands except DD.
- You can not specify SYSOUT for SMPTLIB data sets.

UNIT
specifies the UNIT type the data set is to reside on.
UNIT can be any nonblank 1 to 8 character string.

VOLUME
specifies the volume serial number of the volume the data set is to reside on.

The volume serial number can be from 1 to 6 alphanumeric characters (A through Z and 0 through 9).

Syntax notes

1. GIMDDALC control statements must each start on a new line.
2. GIMDDALC control statements may be continued on more than one line. SMP/E assumes a statement is continued if it did not find a period (.) before column 73.
3. SMP/E ignores columns 73 through 80. If data, such as a period, is specified beyond column 72, SMP/E will ignore it and indicate an error in the control statement following the one containing the data.
4. GIMDDALC control statements may contain comments. Comments start with /* and end with */. The first */ encountered after the initial /* will end the comment. A comment can appear anywhere within a statement. A comment after the ending period must start on the same line as the period, and you cannot start any additional comments after that final comment. For example, you can code a comment like this:
   DD(SMPTLIB) SPACE(5,5) DIR(20). /* Comment after period continued
   on subsequent lines is OK. */

   However, you cannot code a comment like this:
   DD(SMPTLIB) SPACE(5,5) DIR(20). /* Comment after period OK,
   */ but starting another comment
   causes a syntax error. */

   This causes a syntax error at the start of the second comment after the period.
5. Only one GIMDDALC control statement is allowed for a single data set.
6. At least one operand (other than DD) must be specified on each GIMDDALC control statement.
7. For SMPTLIB, only the **SPACE**, **TRACKS**, and **DIR** operands are allowed.

**Sample GIMDDALC member**

The following is a sample GIMDDALC member. The member is named GIMDDALC and is shipped with SMP/E in the SAMPLIB target library.

```c
/*

*                                                                            *
* GIMDDALC -- Sample GIMDDALC member for the SMPPARM data set               *
*                                                                            *
*******************************************************************************

This sample member is a model to assist the SMP/E user in constructing a GIMDDALC member specifically for their use. A user should copy this sample into the GIMDDALC member of a data set. That data set is then defined to SMP/E using the SMPPARM ddname either using a DD statement in the SMP/E job, or using a DDDEF entry.

The GIMDDALC member contains information used to dynamically allocate three kinds of data sets:

1. Data sets to be allocated to a SYSOUT class (or to the terminal for foreground execution),
2. Data sets to be allocated as temporary data sets, and
3. SMPTLIB data sets.

During any attempt to allocate a ddname, SMP/E will first look for a DD statement specified in the job. If no DD statement was specified, SMP/E will look for a DDDEF entry in the zone. If no DDDEF entry was found, SMP/E will then go to member GIMDDALC in the SMPPARM data set. If there is an SMPPARM data set, and there is a GIMDDALC member within it, SMP/E will look for an appropriate control statement.

**NOTE:** The allocation values in the control statements of this sample member are not intended to be recommendations for the actual values you should use and will not be appropriate for all users and all environments.

See the "SMP/E Reference" for details on the syntax of the control statements and on the use of member GIMDDALC.

Figure 3. Sample GIMDDALC member provided in SAMPLIB (Part 1 of 2)
GIMEXITS control statements

SMP/E provides support for two exit points in SMP/E command processing. You can write exit routine programs that receive control at those exit points to:
• process statements from SMPPTFIN during the RECEIVE command, and
• control retry processing when data sets run out of space during ACCEPT, APPLY, GZONEMERGE, LINK LMODS, LINK MODULE, RECEIVE, or RESTORE processing.

Figure 3. Sample GIMDDALC member provided in SAMPLIB (Part 2 of 2)
GIMEXITS Statements

The GIMEXITS member of the SMPPARM data set contains control statements used to identify the exit routine programs to be given control at those SMP/E exit points. It is the presence of the control statement that indicates to SMP/E that an exit routine program is to be called at the appropriate exit point during SMP/E processing. The statements not only identify the exit routine program, but also allow you to identify the data set that contains the exit routine program. This eliminates the need to copy the exit routines into the new MIGLIB or LINKLIB data sets; the exit routines can reside in almost any authorized data set you desire.

Syntax

```
GIMEXITS control statement

EXIT(RECEIVE,RTRY,MODNAME(name),DATASET(dataset)).
```

Operands

EXIT identifies the SMP/E exit point that will pass control to the exit routine defined on the MODNAME operand of this control statement. Valid values are:

- RECEIVE indicates the RECEIVE command exit point will pass control to the exit routine.
- RETRY indicates the RETRY exit point will pass control to the exit routine.

The EXIT operand must be the first operand specified on a GIMEXITS control statement.

MODNAME specifies the name of the exit routine to receive control during SMP/E execution at the identified exit point. The exit routine must be a load module residing in an authorized library. If the DATASET operand is not specified, SMP/E uses the system search order for programs to locate the exit routine. See the topic “The Search Order the System uses for Programs” in z/OS MVS Initialization and Tuning Guide for more information.

The name can be from 1 to 8 alphanumeric characters (A through Z and 0 through 9) or national characters (@, #, $). MODNAME is a required operand.

DATASET specifies the data set name of a load library in which the exit routine resides. The data set must be cataloged and it must be an authorized library. If the DATASET operand is not specified, SMP/E uses the system search order for programs to locate the exit routine. See the topic “The Search Order the System uses for Programs” in z/OS MVS Initialization and Tuning Guide for more information.

The data set name must conform to standard naming conventions for data sets. Each part of the name must contain from 1 to 8 alphanumeric characters (A through Z and 0 through 9) or dash (-), separated from the other parts by a period (.), with no intervening blanks. The first character of each part must not be numeric or dash, and the maximum length of the entire name is 44 characters (including the periods).
GIMEXITS Statements

Syntax notes

1. GIMEXITS control statements must each start on a new line.
2. GIMEXITS control statements may be continued on more than one line. SMP/E assumes a statement is continued if it did not find a period (.) before column 73.
3. SMP/E ignores columns 73 through 80. If data, such as a period, is specified beyond column 72, SMP/E will ignore it and indicate an error in the control statement following the one containing the data.
4. GIMEXITS control statements may contain comments. Comments start with /* and end with */. The first */ encountered after the initial /* will end the comment. A comment can appear anywhere within a statement. A comment after the ending period must start on the same line as the period, and you cannot start any additional comments after that final comment. For example, you can code a comment like this:
   
   EXIT(RECEIVE) MODNAME(MYRECEX). /* Comment after period continued on subsequent lines is OK. */

   However, you cannot code a comment like this:
   
   EXIT(RECEIVE) MODNAME(MYRECEX). /* Comment after period OK, */ /* but starting another comment causes a syntax error. */

   This causes a syntax error at the start of the second comment after the period.
5. Only one GIMEXITS control statement is allowed for a single exit point.

Sample GIMEXITS member

The following is a sample GIMEXITS member. The member is named GIMEXITS and is shipped with SMP/E in the SAMPLIB target library.
This sample member is a model to assist the SMP/E user in constructing a GIMEXITS member specifically for their use. A user should copy this sample into the GIMEXITS member of a data set. That data set is then defined to SMP/E using the SMPPARM ddname either using a DD statement in the SMP/E job, or using a DDDEF entry.

The GIMEXITS member contains information used to identify the exit routines which are to get control during SMP/E processing at specific exit points:

RECEIVE  The RECEIVE exit point allows you to scan statements in the SMPPFTIN data set during RECEIVE command execution.

RETRY    The RETRY exit point enables you to control SMP/E's RETRY processing when a data set runs out of space during APPLY, ACCEPT, RESTORE, and LINK command execution.

See the "SMP/E Reference" for details on the syntax of the control statements and on the use of member GIMEXITS.

**OPCODE control statements**

During JCLIN processing, SMP/E scans the SMP/JCLIN input, which consists of various job steps calling system utilities. To determine the structure of the target system, SMP/E specifically looks at copy steps, link-edit steps, and assembly steps.

As SMP/E scans inline assembly steps, it looks at each assembler instruction to determine whether the instruction is a macro invocation or an OPCODE. If SMP/E determines that this is a macro invocation, it builds a MAC entry in the target zone and defines the connection between the macro and the assembly in which the macro was found. As a result, when that macro is later changed by the installation of a SYSMOD, SMP/E can cause all the assemblies that used that macro to be redone.

SMP/E uses GIMOPCDE members to determine whether an assembler instruction is a macro invocation or an OPCODE.

SMP/E provides you with a default set of OPCODE definitions that identifies all the known standard assembler OPCODEs. You can define your own members to identify additional OPCODE values or macro names by using the sample GIMOPCDE member SMP/E supplied for you. If you define your own member, you must allocate the SMPPARM data set. You can specify the name of one of these user-defined GIMOPCDE members on the JCLIN command or on the ++JCLIN statement to have SMP/E pick up this additional information. The data from this other GIMOPCDE member is merged with the data from the default set of OPCODE definitions. If duplicate data is specified, the user-specified member has priority.

SMP/E uses the following method to determine whether an assembler instruction is an OPCODE or a macro:

- SMP/E looks for a user-allocated SMPPARM data set.
- If SMPPARM is not found, SMP/E uses the default set of OPCODE definitions.
  
  If SMPPARM is found and there is a user-defined GIMOPCDE member specified on the JCLIN statement or in the ++JCLIN MCS, then SMP/E searches for the specified member in SMPPARM. If it finds that member, it will look first in that member for a definition of the character string.

- If the user-defined GIMOPCDE member specified is not found, SMP/E searches SMPPARM for the GIMOPCDE member. If it finds the GIMOPCDE member, it will look only in that member for a definition of the character string. (The GIMOPCDE member, if it exists in SMPPARM, will completely override SMP/E’s default set of OPCODE definitions.)

- If the GIMOPCDE member is not found, SMP/E uses the default set of OPCODE definitions.

- If the character string is not defined in either the SMPPARM data set or the default set, SMP/E considers it to be a macro.

For additional information about how SMP/E processes assembler input as JCLIN, see “++JCLIN MCS” on page 60.
**OPCODE statements**

**Syntax**

```
GIMOPCDE member control statements

KEY=name
    TYPE=OPCODE
    TYPE=MACRO
```

**Operands**

**KEY**
identifies a character string for SMP/E to check for when scanning assembler entries during JCLIN processing, either during the JCLIN command or when applying a SYSMOD with inline JCLIN.

*name* can be any alphanumeric character string from one to eight characters in length.

**TYPE**
specifies how SMP/E treats that character string when it is encountered. The following values may be specified:

- **OPCODE**
specifies that SMP/E treats the specified character string as a valid assembler OPCODE.

  **Note:** OPCODE can also be specified as OP.

- **MACRO**
indicates that SMP/E treats the specified character string as the name of a macro.

  **Note:** MACRO can also be specified as MAC.

**Notes:**
1. The TYPE operand can be specified only once per control statement.
2. If the TYPE operand is not specified, the default is TYPE=OPCODE.

**Usage notes**

- Either a blank or a comma can be used to separate the operands.
- Comments are permitted, subject to the next restriction.
- An OPCODE control statement cannot span multiple lines. The complete control statement, including comments, must be contained on a single line.
- If, during JCLIN processing, SMP/E encounters a string specified in one of the OPCODE control statements, and the OPCODE control statement specifies that the string is to be treated as a macro, SMP/E builds a MAC entry in the target zone and connects that MAC entry to the ASSEM entry built for the current assembly. For a further description of JCLIN processing as related to the GIMOPCDE members, see [SMP/E Commands](#).

**Examples**
The following examples are provided to help you use OPCODE statements.
Example 1: Defining a new OPCODE for special assemblers

Some licensed programs use a version of the assembler supplied with their product rather than the standard assembler. Often, this assembler recognizes special OPCODEs. When SMP/E is processing JCLIN containing assembler steps that use these OPCODEs, you do not want SMP/E creating target zone macro entries for them. To avoid this situation, create a special GIMOPCDE member containing appropriate control statements to define those OPCODEs to SMP/E.

The following is an example of a GIMOPCDE member containing three control statements to define the three-character strings, \textit{OP1}, \textit{OPCD1}, and \textit{OPCODE01} as special assembler OPCODEs:

\begin{verbatim}
KEY=OP1    TYPE=OPCODE.
KEY=OPCD1   TYPE=OP.
KEY=OPCODE01    TYPE=OPCODE.
\end{verbatim}

Example 2: Overriding an SMP/E-defined OPCODE

You may provide your own GIMOPCDE member to override SMP/E’s default set of OPCODE definitions by using the sample GIMOPCDE member provided for you. This sample member contains a control statement identifying \textit{PUNCH} as a character string that should be treated as an assembler OPCODE. You may have constructed a \textit{PUNCH} macro and now want SMP/E to recognize \textit{PUNCH} as a macro name. This can be done by adding the following control statement to an GIMOPCDE member and then specifying that member on the JCLIN command or ++JCLIN statement:

\begin{verbatim}
KEY=PUNCH    TYPE=MACRO /* override type to macro */.
\end{verbatim}
OPCODE statements
Chapter 4. SMP/E data sets and files

This chapter describes the data sets that are used to process SMP/E commands. These data sets are listed by the ddnames for the data sets required by each SMP/E command. According to the type of data set, you can define it with a DDDEF entry, a DD statement, or with GIMDDALC control statements in SMPPARM member GIMDDALC. For more information on DDDEF entries, see "DDDEF entry (distribution, target, and global zone)" on page 197. For more information on SMPPARM member GIMDDALC, see Chapter 3, “Defining control statements in SMPPARM members,” on page 129. For more information on dynamic allocation, see SMP/E User’s Guide.

CLIENT

ddbname Specified by the user.

Use The CLIENT data set contains information about the local z/OS system such as how to navigate a local FTP firewall and HTTP proxy server, in addition to the location of Java application classes and Java debug options. This information is used by the RECEIVE FROMNETWORK and RECEIVE ORDER commands, as well as the GIMGTPKG service routine. The contents of the CLIENT data set are described in the RECEIVE chapter in SMP/E Commands.

Attributes Sequential or member of a partitioned data set; LRECL=80, RECFM=F or FB.

Device Direct access.

Note: This data set may reside in a UNIX file system. Specify PATHOPTS(ORDONLY) and either FILEDATA=TEXT or FILEDATA=BINARY on the DD statement if it is to reside in a UNIX file system. For simplicity, FILEDATA=TEXT is preferred, and ensure the newline character (X'15') marks the end of each line. If you use FILEDATA=BINARY, you must ensure that each line is padded with blanks to the 80-byte record length because there is no end of record marker in binary data.

Distribution library (DLIB)

ddbname The ddname for a distribution library should match the low-level qualifier of the data set name. For example, the ddname for SYS1.AMACLIB should be AMACLIB.

Use Distribution libraries (DLIBs) contain updated versions of macros, source, and modules that were shipped by IBM and stored during ACCEPT processing. They are used during system generation to build the target libraries, so you should keep them at a tested functional and service level. They are also used during RESTORE processing to replace elements in the target libraries. You must provide a DDDEF entry or DD statement for each distribution library that is being processed.

Attributes Partitioned.
INFILE

**ddname**
The ddname for an INFILE data set cannot be the same as the ddname for any other data sets used by SMP/E. Other than this, there are no restrictions.

**Use**
The INFILE data set is a sequential data set containing a zone that is to be loaded by the ZONEIMPORT command. The ddname of this sequential data set is specified on the INFILE operand of the ZONEIMPORT command. The zone in the INFILE data set can be used in two ways:
- To recreate a zone that was destroyed
- To recreate a zone on another CSI data set

You must use the ZONEEXPORT command to create the INFILE data set. (This same data set is called the OUTFILE data set when it is created by the ZONEEXPORT command.)

**Attributes**
Sequential; no DCB parameters are required.
If the INFILE data set is on tape, there may be more than one volume for an exported data set. Remember to specify all the volume serial numbers on the INFILE DD statement.

**Device**
Tape or direct access.

**Note:** BLKSIZE must not exceed 32760.

Link library (LKLIB)

**ddname**
The ddname for a link library must match the LKLIB value on the element MCS. For example, the ddname for the link library on statement `++MOD(MODA) LKLIB(LIBX)` must be LIBX.

**Use**
Link libraries contain replacements for object modules in link-edited format. They are used when the modules are provided in partitioned data sets rather than inline or in relative files.

**Attributes**
Partitioned.

**Device**
Direct access only.

ORDERSERVER

**ddname**
Specified by the user.

**Use**
The ORDERSERVER data set contains information about the IBM Automated Delivery Request server used by the RECEIVE ORDER command. The contents of the ORDERSERVER are described in the RECEIVE chapter in [SMP/E Commands, SA22-7771](#).

**Attributes**
Sequential or member of a partitioned data set; LRECL=80, RECFM=F or FB.

**Device**
Direct access.

**Note:** This data set may reside in a UNIX file system. Specify `PATHOPTS(ORDONLY)` and either `FILEDATA=TEXT` or `FILEDATA=BINARY` on the DD statement if it is to reside in a UNIX file.
system. For simplicity, \texttt{FILEDATA=TEXT} is preferred, and ensure the newline character (X'15') marks the end of each line. If you use \texttt{FILEDATA=BINARY}, you must ensure that each line is padded with blanks to the 80-byte record length because there is no end of record marker in binary data.

**OUTFILE**

- **ddname**: The ddname for an OUTFILE data set cannot be the same as the ddname for any other data sets used by SMP/E. Other than this, there are no restrictions.

**Use**

The OUTFILE data set is a sequential data set containing a zone copied by the ZONEEXPORT command. The ddname of this sequential data set is specified on the OUTFILE operand. The zone in the OUTFILE data set can be used in two ways:

- As a backup copy, to recreate a zone that was destroyed
- As a transportable copy, to recreate a zone on another CSI data set

You must use the ZONEIMPORT command to process the OUTFILE data set. (This same data set is called the INFILE data set when it is processed by the ZONEIMPORT command.)

**Attributes**: Sequential; no DCB parameters are required.

**Device**: Tape or direct access.

**Note**: BLKSIZE must not exceed 32760.

**SERVER**

- **ddname**: Specified by the user.

**Use**

The SERVER data set contains information about a TCP/IP connected host running an FTP server.

**Attributes**: Sequential or member of a partitioned data set; LRECL=80, RECFM=F or FB.

**Device**: Direct access.

**Note**: This data set may reside in a UNIX file system. Specify \texttt{PATHOPTS(ORDONLY)} and either \texttt{FILEDATA=TEXT} or \texttt{FILEDATA=BINARY} on the DD statement if it is to reside in a UNIX file system. For simplicity, \texttt{FILEDATA=TEXT} is preferred, and ensure the newline character (X'15') marks the end of each line. If you use \texttt{FILEDATA=BINARY}, you must ensure that each line is padded with blanks to the 80-byte record length because there is no end of record marker in binary data.

**SMPCLNT**

- **ddname**: SMPCLNT

**Use**

The SMPCLNT data set contains information about the local z/OS system such as how to navigate a local FTP firewall, the location of Java application classes and Java debug options. This information is used by the GIMGTPKG service routine, and has the same
SMPCNTL

ddname  SMPCNTL.
Use     The SMPCNTL data set contains the SMP/E commands to be processed.
Attributes  Sequential; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB.
Device   Card, tape, direct access, or terminal.
Notes:  
1. BLKSIZE must not exceed 32760.
2. This data set may reside in a UNIX file system. Specify
   PATHOPTS(ORDONLY) and either FILEDATA=TEXT or
   FILEDATA=BINARY on the DD statement if it is to reside in a UNIX file
   system. For simplicity, FILEDATA=TEXT is preferred, and ensure the
   newline character (X'15') marks the end of each line. If you use
   FILEDATA=BINARY, you must ensure that each line is padded with blanks
   to the 80-byte record length because there is no end of record marker in
   binary data.

SMPCPATH

ddname  SMPCPATH
Use     The SMPCPATH (SMP/E classpath) is a directory in the UNIX file
        system that contains SMP/E Java application classes. The classes
        are used by RECEIVE ORDER processing to communicate with the
        IBM Automated Delivery Request server, and by the RECEIVE
        command and GIMGTPKG, GIMZIP, and GIMUNZIP service
        routines to calculate SHA-1 hash values when ICSF is not
        available. The default location for SMPCPATH is
        /usr/lpp/smp/classes/.
Attributes  Existing directory in the UNIX file system.
Device     Direct access only.
Notes:  
1. SMPCPATH can be specified using a DD statement or a DDDEF entry. If a
        value is not specified, the default path of /usr/lpp/smp/classes/ is used.
2. For additional information about how to specify the location of the Java runtime, see “Options that affect Java,” in the “Preparing to use Internet service retrieval” chapter in SMP/E User’s Guide.

**SMPCSI**

**ddname**

SMPCSI.

**Use**

The data set specified by the ddname SMPCSI is the CSI containing the global zone. (This data set is also known as the master CSI.) The CSI is the database used by SMP/E to record status and other information about the various target and distribution libraries being supported.

**Attributes**

VSAM; RECORDSIZE(24 143), KEYS(24 0).

**Device**

Direct access only.

**Notes:**

1. The low-level qualifier of the data set name must be CSI.
2. If you have used IBM SMP/E for z/OS, V3R5 to update a CSI data set, you might not be able to process that data set with previous releases of SMP/E. For more information, see the “Migration” section in SMP/E User’s Guide.
3. When running on systems with the required level of Data Facility Product (DFP), SMP/E automatically takes advantage of the local shared resource (LSR) feature of VSAM. This reduces the number of times SMP/E must access data when it is reading CSI data sets. As a result, SMP/E performance is improved for commands such as APPLY, APPLY CHECK, ACCEPT, ACCEPT CHECK, and especially LIST.
4. CSI data sets should usually be allocated dynamically. However, you may want to use the batch local shared resources (BLSR) subsystem with expanded storage hiperspaces (instead of SMP/E’s implementation of LSR) to improve SMP/E performance during APPLY and ACCEPT processing for a large number of changes.
   To do this, you use JCL statements instead of dynamic allocation to define the CSI data sets containing the zones required for processing. For each CSI data set, you need to provide two DD statements:
   • The first DD statement is used by SMP/E to enqueue on the data set (to protect it from simultaneous updates) and to trigger batch LSR. This DD statement uses the DDNAME parameter to point to the second DD statement.
   • The second DD statement is used by batch LSR to open the CSI data set.
   Both DD statements must specify the same DSN value. The following example shows how this can be done:

   ```
   //SMPCSI DD DSN=dataset1.CSI,DISP=SHR,
   //     SUBSYS=(BLSR,'DDNAME=MYSMPCSI',
   //             'HBUFND=value','HBUFNI=value')
   //MYSMPCSI DD DSN=dataset1.CSI,DISP=SHR
   //
   //tgtzone DD DSN=dataset2.CSI,DISP=SHR,
   //     SUBSYS=(BLSR,'DDNAME=MYTGT1',
   //             'HBUFND=value','HBUFNI=value')
   //MYTGT1 DD DSN=dataset2.CSI,DISP=SHR
   ```

   In this example, note that:
   • If the target zone and global zone exist in the same CSI, dataset1 and dataset2 refer to the same data set.
HBUFND and HBUFNI are used instead of BUFND and BUFNI to indicate the use of hyperspace in expanded storage (if available).

*tgtzone* is the name of the target zone specified on the SET BDY command to be processed.

The DSN parameter must be specified on all DD statements to ensure internal enqueue protection.

5. For more information about using the [EXEC statement](SMP/E User’s Guide) to specify the CSI data set containing the global zone, see "Zone statement" on page 169.

6. For information about the target and distribution zones in a CSI data set, see "Zone statement" on page 169.

---

**SMPDATA1**

**ddname** SMPDATA1.

**Use** The SMPDATA1 data set is used to store library change file records. The library change file records are written by SMP/E during APPLY or RESTORE processing when the CHANGEFILE subentry of the OPTIONS entry is set to YES. For more information on library change file records, see Chapter 8, “Library change file records.”

**Attributes** Sequential; BLKSIZE=1069–32670, RECFM=VB, DISP=MOD.

- To have the system determine the optimal block size for the data set, specify BLKSIZE=0.
- If you specify a non-zero BLKSIZE that is less than 1069, SMP/E uses a default of 8800.
- **DISP=MOD** must be specified to maintain a cumulative history of SMP/E ‘delta’ processing.
- If a **DISP** other than **MOD** is specified by the user, SMP/E uses it.
- SMP/E uses LRECL=1065 in allocating the SMPDATA1 data set.

**Device** Direct access only.

**Notes:**
1. The SMPDATA1 data set can only be defined to SMP/E with a DD statement or a DDDEF.
2. The SMPDATA1 DD statement or DDDEF must be defined to each target zone to enable ‘delta’ processing to occur for that target zone.
3. Do not concatenate SMPDATA1 data sets.
4. Do not allocate the SMPDATA1 data set as a path in a UNIX file system.

The SMPDATA1 DDDEF can also be defined with the SMP/E Administration dialogs.

**SMPDATA2**

**ddname** SMPDATA2.

**Use** The SMPDATA2 data set is used to store the library change file records when the SMPDATA1 data set becomes full. This type of processing is called *spill processing*. The library change records are...
SMPDATA2

Written by SMP/E during APPLY or RESTORE processing. For more information on library change file records, see Chapter 8, "Library change file records."

Attributes  Sequential; BLKSIZE=1069–32760, RECFM=VB, DISP=MOD.

- To have the system determine the optimal block size for the data set, specify BLKSIZE=0.
- If you specify a non-zero BLKSIZE that is less than 1069, SMP/E uses a default of 8800.
- DISP=MOD must be specified.
- If a DISP other than MOD is specified, SMP/E will use it.
- SMP/E will use LRECL=1065 in allocating the SMPDATA2 data set.

Device  Direct access only.

Notes:
1. The SMPDATA2 data set can only be defined to SMP/E with a DD statement or a DDDEF.
2. The SMPDATA2 DD statement or DDDEF must be defined to each target zone to enable spill processing to occur for that target zone.
3. Do not concatenate SMPDATA2 data sets.
4. Do not allocate the SMPDATA2 data set as a path in a UNIX file system.
5. The size of the SMPDATA2 data set will vary depending on how the user intends to manage it.
6. As is the case with SMPLOG data set, the user is responsible for managing the contents and space.

The SMPDATA2 DDDEF can also be defined with the SMP/E Administration dialogs.

SMPDEBUG

ddname  SMPDEBUG.

Use  The SMPDEBUG data set contains a dump that was requested by the DEBUG command. Depending on the operands specified, it may contain (1) a dump of SMP/E control blocks and storage areas associated with the specified dump points, or (2) a dump of the VSAM RPL control block and additional RPL information for the specified SMP/E function.

Attributes  Sequential; LRECL=121, BLKSIZE=multiple of 121, RECFM=FBA, DISP=MOD.

Device  SYSOUT, printer, direct access, tape, or terminal.

Notes:
1. BLKSIZE must not exceed 32760.
2. This data set may reside in a UNIX file system. Specify FILEDATA=TEXT and PATHOPTS(OWRONLY,OAPPEND) on the DD statement for this data set, if it is to reside in a UNIX file system.

SMPDIR

ddname  SMPDIR.
## SMPDIR

**Use**

The SMPDIR directory identifies the name of a path to be allocated in a UNIX file system. The name is not a complete pathname; it is the directory under which the files produced by GIMZIIP are stored.

**Attributes**

Existing directory within a UNIX file system.

**Device**

Direct access.

**Notes:**

1. The SMPDIR directory must be defined with a DD statement.
2. The SMPDIR directory must be defined as a directory in a UNIX file system.
3. The size of the SMPDIR directory depends on the size of the package files produced by GIMZIIP.

## SMPDUMMY

**ddname**

SMPDUMMY

**Use**

SMPDUMMY is intended for use as the definition side deck library for a load module when the IMPORT statements associated with a DLL are not wanted. It allows the SYSDEFSD DD statement to be allocated as a DUMMY data set.

When any of the following SYSDEFSD DD statements is encountered in the link edit JCLIN input stream:

- //SYSDEFSD DD DSN=SMPDUMMY,DISP=xxx
  (where SMPDUMMY may be the lowest-level qualifier of a multi-qualifier data set name)
- or-
  //SYSDEFSD DD DSN=NULLFILE
  (where NULLFILE must be a single-word parameter)
- or-
  //SYSDEFSD DD DUMMY

the SIDE DECK LIBRARY subentry for the load module will be set to SMPDUMMY. When needed for processing, SMP/E will dynamically allocate SMPDUMMY as a DUMMY data set. Any existing SMPDUMMY DDDEF entry or GIMDDALC statement will be ignored. If SMPDUMMY was previously allocated outside of SMP/E, SMP/E will free the SMPDUMMY DD and reallocate it as a DUMMY data set.

**Attributes**

DUMMY.

**Device**

None.

**Note:** The SMPDUMMY ddname is intended only for association with the SIDE DECK LIBRARY subentry for load modules. SMP/E does not prohibit its specification for other library ddnames with the various input methods (MCS, UCLIN, JCLIN, and so on). However, SMPDUMMY will always be allocated by SMP/E as "DD DUMMY". Therefore, the results are unpredictable, in that they depend on each utility’s ability to handle a DUMMY data set.

## SMPHOLD

**ddname**

SMPHOLD.
**SMPJCLIN**

**ddname** SMPJCLIN.

**Use**
The SMPJCLIN data set contains a job stream of assembly, link-edit, and copy job steps. This data is typically the stage 1 output from the most recent full or partial system generation, but it may be other data in a similar format, such as output from the SMP/E GENERATE command. This job stream is used as input to the JCLIN command to update or create entries in a target zone.

**SMPHRPT**

**ddname** SMPHRPT

**Use**
The SMPHRPT data set is an alternate report data set. If SMPHRPT is allocated, the HOLD reports that are generated during RECEIVE, APPLY, and ACCEPT processing are directed to this data set while other reports are directed to Smprpt.

**Attributes**
Sequential; LRECL=121, BLKSIZE=multiple of 121, RECFM=FBA, DISP=MOD.

**Device**
SYSOUT, printer, direct access, tape, or terminal.

**Notes:**
1. BLKSIZE cannot exceed 32760.
2. If SMPHRPT is not allocated, all report output goes to the Smprpt data set. If Smprpt is not allocated, all report output goes to the Smpout data set.
3. If SMPHRPT is allocated to a data set, the disposition must be MOD, because SMP/E opens and closes the SMPHRPT DD statement at each SET command. If the disposition is SHR or OLD, SMPHRPT contains only the reports from the last set of commands that is processed before the end of SMP/E processing.
4. The SMPHRPT ddname can be allocated to a file in the UNIX file system. Specify FILEDATA=TEXT and PATHOPTS=OWRONLY, OAPPEND) on the DD statement if the SMPHRPT ddname is allocated to a file in the UNIX file system. If OAPPEND is not specified, SMPHRPT contains only the reports from the last set of commands that is processed before the end of SMP/E processing.

**SMPHOLD**

This may refer to an actual data set, or it may refer to a file on a tape (such as file 4 on an ESO tape).

**Use**
SMPHOLD contains ++HOLD and ++RELEASE statements to be processed by the RECEIVE command.

**Attributes**
Sequential; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB.

**Device**
Direct access or tape.

**Notes:**
1. BLKSIZE must not exceed 32760.
2. This data set may reside in a UNIX file system. Specify PATHOPTS=ORDONLY and either FILEDATA=TEXT or FILEDATA=BINARY on the DD statement if it is to reside in a UNIX file system. For simplicity, FILEDATA=TEXT is preferred, and ensure the newline character (X'15') marks the end of each line. If you use FILEDATA=BINARY, you must ensure that each line is padded with blanks to the 80-byte record length because there is no end of record marker in binary data.
SMPJCLIN

Attributes  Sequential; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB.
Device  Card, tape, direct access, or terminal.
Notes:
1. BLKSIZE must not exceed 32760.
2. This data set may reside in a UNIX file system. Specify
   PATHOPTS(ORDONLY) and either FILEDATA=TEXT or FILEDATA=BINARY
   on the DD statement if it is to reside in a UNIX file system. For simplicity,
   FILEDATA=TEXT is preferred, and ensure the newline character (X'15') marks
   the end of each line. If you use FILEDATA=BINARY, you must ensure that
   each line is padded with blanks to the 80-byte record length because there is no
   end of record marker in binary data.

SMPJHOME

ddbname  SMPJHOME
Use  SMPJHOME (SMP/E JAVAHOME) is a directory in the UNIX file
system that contains the Java runtime. SMP/E uses Java classes
during RECEIVE ORDER processing to communicate with the IBM
Automated Delivery Request server, and by the RECEIVE
command and GIMGTPKG, GIMZIP, and GIMUNZIP service
routines to calculate SHA-1 hash values when ICSF is not
available.

SMP/E requires the Java runtime directory when either of the
following conditions applies.

- When SMP/E is installing ++JARUPD elements, or
- When a UNIX shell script is invoked during the installation of a
  file system element, and the shell script issues a Java command.

No default location is assumed by SMP/E for SMPJHOME.

Attributes  Existing directory in the UNIX file system.
Device  Direct access only.
Notes:
1. SMPJHOME can be specified using a DD statement or a DDDEF entry.
2. For additional information about how to specify the location of the SMP/E
   application classes, see “Establishing access to Java runtime environment and
   application classes,” in the “Preparing to use internet service retrieval” chapter
   in SMP/E User’s Guide.

SMPLIST

ddbname  SMPLIST.
Use  The SMPLIST data set contains the output of all LIST commands.
Attributes  Sequential; LRECL=121, BLKSIZE=multiple of 121, RECFM=FBA,
            DISP=MOD.
Device  SYSOUT, printer, direct access, tape, or terminal.
Notes:
1. BLKSIZE must not exceed 32760.
2. If SMPLIST is not defined, all LIST output goes to the SMPOUT data set.
3. If SMPLIST is allocated to a data set, the disposition must be MOD, because SMP/E opens and closes the SMPLIST DD statement at each SET command. If the disposition is SHR or OLD, SMPLIST contains only the output from the last set of commands processed before the end of SMP/E processing.

4. This data set may reside in a UNIX file system. Specify FILEDATA=TEXT and PATHOPTS(OWRONLY,OAPPEND) on the DD statement for this data set, if it is to reside in a UNIX file system. If OAPPEND is not specified, SMPLIST contains only the output from the last set of commands processed before the end of SMP/E processing.

<th>ddname</th>
<th>SMPLOGA.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use</td>
<td>SMPLOGA is a backup LOG data set. If SMPLOGA is defined, it is used automatically when the SMPLOG data set is full. The LOG data set contains time-stamped records of SMP/E processing. The records in this data set can be written automatically by SMP/E or added by the user through the LOG command. The data set also</td>
</tr>
</tbody>
</table>
SMPOGA

contains messages issued by SMP/E, as well as detailed information about data set allocation.

Attributes  Sequential; BLKSIZE=514-32000, RECFM=VB, DISP=MOD.

- The BLKSIZE value determines how many records are written to the LOG at one time. As a block is filled, it is written to SMPLOG.

  If BLKSIZE is less than 514, SMP/E uses the BLKSIZE in effect for the SMPLOG data set.

  The BLKSIZE for the SMPOGA data set must match the BLKSIZE for the related SMPLOG data set.

- **DISP=MOD** must be specified to maintain a cumulative history of SMP/E processing.

- SMP/E uses LRECL=510 in allocating the SMPOGA data set.

Device  Tape or direct access.

Notes:

1. **Important:** If the data set allocated to the SMPOGA DD statement has the wrong data set attributes, SMP/E will open the data set for output processing with acceptable attributes. This action will overlay the contents of the data set.

2. Each zone should have its own SMPOGA data set.

3. If the SMPOGA data set is full, the extra log data is written to the SMPOUT data set, with the date and time stamp encrypted.

4. SMPOGA should be updated only by the LOG command or by processing for other SMP/E commands.

5. Because some messages are longer than in earlier releases of SMP/E, you may need to increase the size of any data sets used for SMP/E messages (such as SMPOUT). How much more space you need depends on the current size of these data sets and which messages are issued. To start, you may want to allocate new data sets twice the size of the old ones.

SMPLTS

ddbname  SMPLTS.

Use  The SMPLTS data set is used to maintain the base versions of load modules and program objects for which SYSLIB allocations have been specified. A base version of each load module or program object includes only the modules that were explicitly defined for it by SMP/E MCS statements and JCLIN. Other modules that might be implicitly included in the execution-time load modules and program objects when they are bound are not stored in the base version copy in the SMPLTS.

SMP/E saves the base version of a load module or program object in SMPLTS only when the load module or program object is defined to SMP/E with CALLLIBS and the JCLIN specifies SYSLIB allocations (which are used to create the CALLLIBS subentry lists in the corresponding LMOD entries) and:

- the load module or program object contains XZMOD subentries (indicating cross-zone modules), or

- the target zone was created before SMP/E V3R2 and the UPGRADE command has not yet been used to upgrade it.
SMP/E uses the load modules and program objects in the SMPLTS as input when binding the execution-time load modules and program objects into their specified target libraries.

In some cases, SMP/E may also need to create a temporary member in the SMPLTS to resolve certain warning conditions identified by the binder. This temporary member (if created) is deleted from the SMPLTS after a successful link-edit into the target library.

**Attributes**

Partitioned (DSNTYPE=PDS or DSNTYPE=LIBRARY); RECFM=U, DISP=OLD, BLKSIZE greater than or equal to 6144.

If you allocate the SMPLTS as a PDS, IBM recommends a block size of 32760 to minimize the use of DASD space for this data set.

**Device**

Direct access only.

**Notes:**

1. Each target zone must have its own SMPLTS data set that is not shared by any other target zone.
2. The SMPLTS data set is required for APPLY, LINK LMODS, LINK MODULE, and RESTORE processing.
3. The BLKSIZE of the SMPLTS data set needs to be 1024 or greater to support load modules that specify the SCTR attribute. A large BLKSIZE is recommended to provide maximum space efficiency.
4. The SMPLTS data set is eligible for RETRY processing, in the same manner as other target libraries, after an x37 ABEND. The size of an SMPLTS data set varies depending on the number of load modules that specify a CALLLIBS subentry list in the target zone associated with the SMPLTS.
5. If the SMPLTS data set is to contain program objects, it needs to be allocated as a PDSE.

---

**SMPMTS**

**ddname**

SMPMTS.

**Use**

The SMPMTS data set (MTS) is a target library for macros that exist only in a distribution library (such as macros in SYS1.AMODGEN). This data set allows the current version of these macros to be used for assemblies during APPLY processing. For more information about MTS entries, see "MTSMAC entry (SMPMTS)" on page 290.

**Attributes**

Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB, DISP=OLD.

**Device**

Direct access only.

**Notes:**

1. Each target zone must have its own SMPMTS data set that is not shared by any other target zone. This SMPMTS data set may be used with the related distribution zone.
2. For APPLY processing, the SMPMTS data set must be allocated with enough space to hold all the system generation macros, as well as any other macros that do not reside in a target library. This is because functions are now packaged with a complete set of system generation macros.
3. The SMPMTS data set must be in the SYSLIB concatenation for APPLY and RESTORE processing. It can be in the SYSLIB concatenation for ACCEPT processing. For information on SYSLIB concatenation requirements, see SMP/E User’s Guide.

**SMPNTS**

**ddname**

SMPNTS.

**Use**

The SMPNTS (SMP/E Network Temporary Store) is a directory of UNIX file system files that are used for temporary storage of network transported packages that were received during SMP/E RECEIVE processing.

**Attributes**

Existing directory within a UNIX file system. A UNIX file system directory name is concatenated with the appropriate subdirectories and file names to create complete pathnames.

- The directory name can be from 1 to 255 characters.
- The directory name must begin and end with a slash (/).
- In addition to the required delimiters (/), a directory name must also be enclosed in single apostrophes (') if any of the following is true:
  - The directory name contains lowercase alphabetic characters
  - The directory name contains a character that is not uppercase alphabetic, numeric, or national ($, #, or @), slash (/), plus (+), hyphen, period, or ampersand (&).
- The apostrophes must be outside the required delimiters, as in '/directory name/', not '/directory name'/.
- The single apostrophes used to enclose the directory name (the delimiters) do not count as part of the 255-character limit.
- Any apostrophes specified as part of the directory (not the delimiters) must be doubled. Double apostrophes count as two characters in the 255-character limit.
- The directory name can include characters through X’40’ and X’FE’.
- Do not use symbolic substitution.

**Device**

Direct access only.

**Notes:**

1. The SMPNTS can be defined to SMP/E only with a DD statement or a DDDEF.
2. Do not allocate the SMPNTS as anything other than a directory in a UNIX file system.

3. The size of the SMPNTS directory depends on the size of the packages received from the network and stored there.

**SMPOBJ**

**ddname**

SMPOBJ.

**Use**

The SMPOBJ data set is used primarily for source-maintained products. It contains preassembled modules that can be used instead of reassembling those modules. These modules must be in...
load module format—that is, in the same format as modules residing in the distribution library.

Attributes  Partitioned; RECFM=U, DISP=SHR.
Device       Direct access only.

**SMPOUT**

<table>
<thead>
<tr>
<th>ddname</th>
<th>SMPOUT.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use</td>
<td>The SMPOUT data set contains messages issued during SMP/E processing, as well as dumps of the VSAM RPL, if any dumps were taken. It might also contain LIST output and reports if the SMPHRPT, SMPLIST, and SMPRPT data sets are not defined.</td>
</tr>
<tr>
<td>Attributes</td>
<td>Sequential; LRECL=121, BLKSIZE=multiple of 121, RECFM=FBA, DISP=MOD.</td>
</tr>
<tr>
<td>Device</td>
<td>SYSOUT, printer, direct access, tape, or terminal.</td>
</tr>
</tbody>
</table>
| Notes:    | 1. BLKSIZE must not exceed 32760.  
2. If SMPOUT is allocated to a data set, the disposition must be MOD, because SMP/E opens and closes the SMPOUT DD statement at each SET command. If the disposition is SHR or OLD, SMPOUT contains only the output from the last set of commands processed before the end of SMP/E processing.  
3. If SMPOUT is being allocated for the GIMGTPKG, GIMUNZIP, GIMXSID, or GIMZIP service routine, and you want the resulting SMP/E messages to be formatted to an 80-character length for easier browsing on a terminal, then specify LRECL=81 and BLKSIZE as a multiple of 81.  
4. This data set may reside in a UNIX file system. Specify FILEDATA=TEXT and PATHOPTS(OWRONLY,OAPPEND) on the DD statement for this data set, if it is to reside in a UNIX file system. If OAPPEND is not specified, SMPOUT contains only the output from the last set of commands processed before the end of SMP/E processing. |

**SMPPARM**

<table>
<thead>
<tr>
<th>ddname</th>
<th>SMPPARM.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use</td>
<td>The SMPPARM data set contains members that allow you to customize SMP/E as follows:</td>
</tr>
<tr>
<td></td>
<td><strong>Member name</strong></td>
</tr>
<tr>
<td></td>
<td>GIMDDALC</td>
</tr>
<tr>
<td></td>
<td>GIMEXITS</td>
</tr>
<tr>
<td></td>
<td>GIMOPCDE</td>
</tr>
<tr>
<td>Note:</td>
<td>The File Allocation Reports for the APPLY and ACCEPT commands include status information for the SMPPARM data set, even if an SMPPARM data set is not allocated. SMP/E does this as a reminder to users who may have intended to supply one or more SMPPARM members. If you do not intend to supply any SMPPARM members, you may ignore this status information for the SMPPARM data set.</td>
</tr>
<tr>
<td></td>
<td>• For the GIMDDALC member:</td>
</tr>
</tbody>
</table>
SMPPARM

During SET processing, SMP/E determines whether SMPPARM member GIMDDALC was provided. If so, it processes the GIMDDALC control statements contained within the member. For more information about GIMDDALC members, see Chapter 3, “Defining control statements in SMPPARM members,” on page 129.

- For the GIMEXIT member:
  During RECEIVE, APPLY, ACCEPT, RESTORE and LINK processing, SMP/E will determine if SMPPARM member GIMEXIT has been provided. If so, it will process the EXITS control statements contained within the member. For more information about GIMEXIT members, see Chapter 3, “Defining control statements in SMPPARM members,” on page 129.

- For the GIMOPCDE member:
  During JCLIN processing, SMP/E determines whether assembler instructions are macro invocations or OPCODEs. SMP/E contains a default set of OPCODE definitions, which identify standard assembler OPCODEs. If you do not want to use this default set, you can define your own by using the sample GIMOPCDE member supplied to you. For more information about GIMOPCDE members, see Chapter 3, “Defining control statements in SMPPARM members,” on page 129.

Attributes
Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB.

Device
Direct access only.

SMPPTFIN

**ddname** SMPPTFIN.

This ddname can refer to an actual data set or to a file on a tape (such as file 1 on an ESO tape).

**Use** The SMPPTFIN data set contains SYSMODs and ++ASSIGN statements to be processed by the RECEIVE command.

**Attributes** Sequential; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB.

**Device** Card, tape, direct access, or terminal.

**Notes:**
1. BLKSIZE must not exceed 32760.
2. If the SMPPTFIN data set is inline, you must make sure that the combination of characters used for the delimiter does not occur in the input itself.
   For example, if DD * is specified for SYSIN and the SMPPTFIN data set contains the characters $S$, then $S$ cannot be used as the default delimiter for the input or for the delimiter specified on the DLM parameter. (The output of SMP/E service routine GIMDTS contains the characters $S$.)
3. If you want to receive from multiple product tapes, you cannot concatenate them on a single SMPPTFIN DD statement. Instead, you must process each tape in a separate step, using separate SMPPTFIN DD statements.
   Refer to the documentation supplied with the tape for exact information on how to code the SMPPTFIN DD statement. For example, with a product tape, the program directory contains this information.
4. This data set may reside in a UNIX file system. Specify PATHOPTS(ORDONLY) and either FILEDATA=TEXT or FILEDATA=BINARY.
on the DD statement if it is to reside in a UNIX file system. For simplicity, `FILEDATA=TEXT` is preferred, and ensure the newline character (X'15') marks the end of each line. If you use `FILEDATA=BINARY`, you must ensure that each line is padded with blanks to the 80-byte record length because there is no end of record marker in binary data.

<table>

</tr>
<tr>
<td><strong>Device</strong></td>
<td>Direct access only.</td>
</tr>
</tbody>
</table>

Chapter 4. SMP/E data sets and files  157
SMPPTS spill data set

SMPPTS spill data set

**ddname** SMPPTS1 through SMPPTS99.

**Use** SMPPTS spill data sets can be used to store SYSMODs when the SMPPTS data set becomes full. This type of processing is called *spill processing*. SMPPTS spill data sets are used by SMP/E in the same way as the primary SMPPTS data set is used. For more information, see “SMPPTS” on page 157.

**Attributes** Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB, DISP=OLD.

It is recommended that SMPPTS spill data sets be allocated as a PDSE (DSNTYPE=LIBRARY).

If you plan to run concurrent jobs, specify **DISP=SHR** instead of **DISP=OLD**.

Do not concatenate SMPPTS spill data sets.

The first SMPPTS spill data set must be specified with a ddname of **SMPPTS1**, the second **SMPPTS2**, and so on, up to a maximum of **SMPPTS99**. Do not skip any ddnames in this sequence; if a spill data set is omitted, SMP/E ignores any data sets that may follow the omitted data set. (For example, if you specify only **SMPPTS1** and **SMPPTS3**, then SMP/E uses only **SMPPTS1** and ignores **SMPPTS3**.)

You **must** specify a valid data set name for an SMPPTS data set. **NULLFILE** and **DD DUMMY** are invalid for SMPPTS spill data sets.

**Device** Direct access only.

---

SMPPUNCH

**ddname** SMPPUNCH.

**Use** The SMPPUNCH data set contains output from various SMP/E commands. This output generally consists of commands or control statements.

- For BUILDMCS, it contains the complete superseding function SYSMODs.
- For GENERATE, it contains a job stream for building target libraries.
- For REPORT CROSSZONE, it contains commands for installing cross-zone requisites.
- For REPORT ERRSYSMODS, it contains commands for installing SYSMODs that resolve the error hold reason IDs for exception SYSMODs.
- For REPORT SOURCEID, it contains commands for listing SYSMODs associated with the source IDs that were found in the specified zones.
- For REPORT SYMSMODS, it contains commands for installing SYSMODs from the input zone that are applicable to the comparison zone.
SMPPUNCH

- For UNLOAD, it contains UCLIN statements for recreating the entries that were unloaded.

Attributes  Sequential; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB, DISP=MOD.

Device        Card, tape, or direct access.

Notes:
1. BLKSIZE must not exceed 32760.
2. If SMPPUNCH is allocated to a data set, the disposition must be MOD, because SMP/E opens and closes the SMPPUNCH DD statement at each SET command. If the disposition is SHR or OLD, SMPPUNCH contains only the output from the last set of commands processed before the end of SMP/E processing.
3. For the UNLOAD command, SMPPUNCH should be allocated to a direct access data set or to tape, because the volume of output is large. You may also want a large BLKSIZE; the larger the BLKSIZE, the fewer the times SMP/E must do I/O.
4. This data set may reside in a UNIX file system. Specify FILEDATA=TEXT and PATHOPTS(OWRONLY,OAPPEND) on the DD statement for this data set, if it is to reside in a UNIX file system. If OAPPEND is not specified, SMPPUNCH contains only the output from the last set of commands processed before the end of SMP/E processing.

SMPRPT

<table>
<thead>
<tr>
<th>ddname</th>
<th>SMPRPT.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use</td>
<td>The SMPRPT data set contains the reports produced during SMP/E processing.</td>
</tr>
<tr>
<td>Attributes</td>
<td>Sequential; LRECL=121, BLKSIZE=multiple of 121, RECFM=FBA, DISP=MOD.</td>
</tr>
<tr>
<td>Device</td>
<td>SYSOUT, printer, direct access, tape, or terminal.</td>
</tr>
</tbody>
</table>

Notes:
1. BLKSIZE must not exceed 32760.
2. If SMPRPT is not defined, all report output goes to the SMPOUT data set.
3. If SMPRPT is allocated to a data set, the disposition must be MOD, because SMP/E opens and closes the SMPRPT DD statement at each SET command. If the disposition is SHR or OLD, SMPRPT contains only the reports from the last set of commands processed before the end of SMP/E processing.
4. This data set may reside in a UNIX file system. Specify FILEDATA=TEXT and PATHOPTS(OWRONLY,OAPPEND) on the DD statement for this data set, if it is to reside in a UNIX file system. If OAPPEND is not specified, SMPRPT contains only the reports from the last set of commands processed before the end of SMP/E processing.

SMPSCDS

<table>
<thead>
<tr>
<th>ddname</th>
<th>SMPSCDS.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use</td>
<td>The SMPSCDS data set (SCDS) contains backup copies of target zone entries that are created during APPLY processing. These backup copies are made before the entries are (1) changed by inline JCLIN, a ++MOVE MCS, or a ++RENAME MCS, or (2) deleted by</td>
</tr>
</tbody>
</table>
**SMPSCDS**

an element MCS with the DELETE operand. The backup copies are used during RESTORE processing to return the entries to the way they were before APPLY processing. For more information about BACKUP entries, see “BACKUP entries (SMPSCDS)” on page 188.

**Attributes**
Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB, DISP=OLD.

**Device**
Direct access only.

**Note:** Each target zone must have its own SMPSCDS data set; that data set must be unique to that target zone. This SMPSCDS data set must also be used with the related distribution zone.

---

**SMPSNAP**

**ddname** SMPSNAP.

**Use**
The SMPSNAP data set is used for snap dump output. When a severe error occurs, such as an abend or severe VSAM return code, SMP/E requests a snap dump of its storage before doing any error recovery. In addition, the DEBUG command may request a snap dump of SMP/E storage when specified messages are issued, or it may request a snap dump of control blocks and storage areas associated with a specified dump point.

**Attributes**
Sequential.

**Device**
SYSOUT, printer, direct access, tape, or terminal.

**Note:** BLKSIZE must not exceed 32760.

---

**SMPSRVR**

**ddname** SMPSRVR.

**Use**
The SMPSRVR data set contains information about a TCP/IP connected host running an FTP server. It is used by the GIMGTPKG service routine.

**Attributes**
Sequential or member of a partitioned data set; LRECL=80, RECFM=F or FB.

**Device**
Direct access.

**Note:** This data set may reside in a UNIX file system. Specify PATHOPTS(ORDERONLY) and either FILEDATA=TEXT or FILEDATA=_BINARY on the DD statement if it is to reside in a UNIX file system. For simplicity, FILEDATA=TEXT is preferred, and ensure the newline character (X'15') marks the end of each line. If you use FILEDATA=BINARY, you must ensure that each line is padded with blanks to the 80-byte record length because there is no end of record marker in binary data.

---

**SMPSTS**

**ddname** SMPSTS.

**Use**
The SMPSTS data set (STS) is a target library for source that exists
only in a distribution library. This data set allows the current version of these modules to be used for assemblies during APPLY processing.

Attributes        Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB, DISP=OLD.

Device           Direct access only.

Note: Each target zone must have its own SMPSTS data set, which may not be shared by any other target zone. This SMPSTS data set can also be used with the related distribution zone.

---

**SMPTLIB**

<table>
<thead>
<tr>
<th>ddname</th>
<th>SMPTLIB.</th>
</tr>
</thead>
</table>

Use        SMPTLIB data sets (TLIBs) are used as temporary storage for relative files that are loaded from SMPTFIN during RECEIVE processing. They are deleted when the associated SYSMOD is deleted by REJECT, RESTORE, or ACCEPT processing.

You can have SMP/E dynamically allocate the TLIB data sets, or you can allocate them yourself before RECEIVE processing. For information about how SMP/E allocates the TLIBs, see the RECEIVE Command chapter in *SMP/E Commands* (Regardless of how the SMPTLIB data sets are allocated, they do not appear in the File Allocation report.)

Notes:

1. No DD statement or DDDEF entry is required for the SMPTLIB data sets if they are preallocated and cataloged.
2. If you allocate and catalog the SMPTLIB data sets yourself, make sure they are allocated on the volume specified in the catalog.
3. If you allocate the SMPTLIB data sets yourself but do not catalog them, make sure they are allocated on the volume specified in the SMPTLIB DD statement or DDDEF entry being used for the command you are processing.
4. If you need to specify a unit that is not SYSALLDA, and the unit is not set by use of a STORCLAS or an ACS filter routine, then you must use a DDDEF entry instead of a DD statement to allocate SMPTLIB data sets and specify the unit value in the DDDEF entry.
5. If you are using SMS to manage your data sets, you can set up the unit, volume, and space allocation through a STORCLAS or an ACS filter routine, instead of specifying them on a DD statement or DDDEF entry.
6. If you are using SMS to manage your data sets, do not specify dummy volumes on a DD statement or in a DDDEF entry for the SMPTLIB allocation. Dummy volumes used as indicators to ACS routines for SMS class selection can cause operator mount messages to be issued for the non-existent dummy volumes. This is because SMP/E first attempts to allocate the SMPTLIB data sets as if they already exist on the volume, which can cause operator mount messages to be issued for the dummy volume.
7. SMPTLIB data sets should not be allocated as PDSEs, because IEBCOPY does not support copying an unloaded PDS load library from tape to a PDSE load library on DASD.

8. DDDEFs are not required in target or distribution zones for SMPTLIB data sets, unless you have uncataloged the SMPTLIB data sets from the global zone (this is not recommended). In this case, only the VOLUME and UNIT subentries are accepted as input on UCLIN statements for target or distribution zone SMPTLIB DDDEFs.

Attributes

Partitioned. Here are two examples of SMPTLIB DD statements:

/SMPTLIB DD UNIT=SYSALLDA, VOL=SER=SMPVOL
/ //SMPTLIB DD UNIT=SYSALLDA,
/     VOL=SER=(SMPVL1,SMPVL2)

If you use DDDEFs to have SMP/E dynamically allocate the SMPTLIB data sets, you cannot specify the initial or final disposition. SMP/E determines the disposition based on the command it is processing.

Device

Direct access only.

SMPTLOAD

dname

SMPTLOAD.

Use

SMP/E may need to use an SMPTLOAD data set when installing program elements that were packaged inline. SMPTLOAD is required when applying or accepting a program element and either:

- the destination data set (target or distribution library) is a PDS and the unloaded inline data represents a PDSE that contains program elements
- the destination data set is a PDSE and the unloaded inline data set has RECFM=U and is not a PDSE.

SMP/E dynamically allocates a new SMPTLOAD data set whenever one is needed.

Attributes

Partitioned (DSNTYPE=PDS or DSNTYPE=LIBRARY), DISP=(NEW,DELETE).

Device

Direct access.

Notes:

1. If the unloaded inline data represents a PDSE, SMP/E allocates SMPTLOAD with DSNTYPE=LIBRARY. Otherwise, SMP/E allocates SMPTLOAD with DSNTYPE=PDS.

2. All other allocation information for the SMPTLOAD is obtained from the SMPTLOAD DDDEF or, if a DDDEF does not exist, from GIMDDALC control statements found in SMPPARM member GIMDDALC. If a DD statement is supplied for SMPTLOAD, it is freed and the allocation for SMPTLOAD is done using the DDDEF or the GIMDDALC control statement found in SMPPARM member GIMDDALC.

SMP/E uses the following information, if it is supplied by the user, to dynamically allocate an SMPTLOAD data set:
• Primary and secondary space amounts
• Allocation units for primary and secondary space
• Number of directory blocks
• A unit designation
• A volume designation
• A STORCLAS designation
• A MGMTCLAS designation
• A DATACLAS designation

If SMP/E cannot get the required allocation information from a DDDEF or a GIMDDALC control statement in the GIMDDALC member of SMPPARM, then the allocation fails.

3. If there is an SMPTLOAD DDDEF, SMP/E tries to allocate the SMPTLOAD data set, even if the DDDEF does not supply any of the previously listed information. This is because SMP/E always tries to allocate the SMPTLOAD data set new with either a DSNTYPE of PDS or LIBRARY, which may be sufficient if an ACS routine exists to supply other needed allocation values.

5. SMP/E will not use an SMPTLOAD data set specified with JCL. If an SMPTLOAD DD statement is specified, SMP/E dynamically frees the SMPTLOAD ddname prior to allocating a new SMPTLOAD data set.

SMPWKDIR

ddname SMPWKDIR.

Use The SMPWKDIR directory identifies the name of a directory in a UNIX file system. SMPWKDIR is used to store temporary files created during SMP/E processing. If SMPWKDIR is not specified, SMP/E will use one of the following directories for temporary files, depending on the command or service:
• APPLY and ACCEPT commands: the system /tmp directory
• RECEIVE command: the system /tmp directory and the package directory of the SMPNTS directory specified on a DD statement or DDDEF entry.
• GIMZIP and GIMUNZIP service routines: the package directory specified on the SMPDIR DD statement.

Attributes Existing directory in a UNIX file system.

Device Direct access only.

Note: The SMPWKDIR can be defined for the RECEIVE, APPLY, and ACCEPT commands using either a DD statement or a DDDEF entry. It can be defined for the GIMZIP and GIMUNZIP service routines using a DD statement only.

SMPWRK1

ddname SMPWRK1.

Use The SMPWRK1 data set is used as temporary storage for macro updates and replacements that will be processed by the IEBUPDTE and IEBCOPY programs. During APPLY and ACCEPT processing, SMP/E places the input in this data set before calling the utility.
SMPWRK1

Attributes
Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB, DISP=(NEW,DELETE).

Specifying DISP=(NEW,DELETE) minimizes space loss problems. SMPWRK1 is generally needed only for the duration of the SMP/E job step. To keep the data set longer than that, you must use a different DISP value and compress the data set to reclaim space.

The SMS-related options DATACLAS, MGMTCLAS, STORCLAS, and DSNTYPE provide additional data set support. For more information, refer to z/OS DFSMS Using Data Sets

Device
Direct access only.

Notes:
1. BLKSIZE must not exceed 32760.
2. If the BLKSIZE value is omitted or inapplicable, SMP/E uses a default of 0 which allows the system to determine the most appropriate block size.

SMPWRK2

ddname
SMPWRK2.

Use
The SMPWRK2 data set is used as temporary storage for source updates and source replacements that will be processed by the IEBUPDTE and IECOPY programs. During APPLY and ACCEPT processing, SMP/E places the input in this data set before calling the utility.

Attributes
Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB, DISP=(NEW,DELETE).

Specifying DISP=(NEW,DELETE) minimizes space loss problems. SMPWRK2 is generally needed only for the duration of the SMP/E job step. To keep the data set longer than that, you must use a different DISP value and compress the data set to reclaim space.

The SMS-related options DATACLAS, MGMTCLAS, STORCLAS, and DSNTYPE provide additional data set support. For more information, refer to z/OS DFSMS Using Data Sets

Device
Direct access only.

Notes:
1. BLKSIZE must not exceed 32760.
2. If the BLKSIZE value is omitted or inapplicable, SMP/E uses a default of 0 which allows the system to determine the most appropriate block size.

SMPWRK3

ddname
SMPWRK3.

Use
The SMPWRK3 data set is used as temporary storage for object modules supplied by a SYMMOD, object modules created by assemblies, and IMASZPZAP control cards following ++ZAP statements.

Attributes
Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB, DISP=(NEW,DELETE).
Specifying \texttt{DISP=(NEW,DELETE)} minimizes space loss problems. SMPWRK3 is generally needed only for the duration of the SMP/E job step. To keep the data set longer than that, you must use a different \texttt{DISP} value and compress the data set to reclaim space.

If you want to save assembled object modules until SMP/E has successfully applied or accepted the SYSMODs that caused the assemblies, specify \texttt{DISP=(NEW,KEEP)}. This allows SMP/E to reuse the assembled object modules if the APPLY or ACCEPT command fails. For more information on reusing assemblies, see \texttt{SMP/E Commands}.

\textbf{Note:} If SMPWRK3 is a permanent data set, make sure to specify \texttt{OLD} as the initial disposition. Do not specify \texttt{SHR}. An initial disposition of \texttt{SHR} may cause an abend.

The SMS-related options DATACLAS, MGMTCLAS, STORCLAS, and DSNTYPE provide additional data set support. For more information, refer to \texttt{z/OS DFSMS Using Data Sets}.

Device: Direct access only

Notes:
1. BLKSIZE must not exceed 32760.
2. If the BLKSIZE value is omitted or inapplicable, SMP/E uses a default of 0 which allows the system to determine the most appropriate block size.

**SMPWRK4**

<table>
<thead>
<tr>
<th>ddname</th>
<th>SMPWRK4.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use</td>
<td>The SMPWRK4 data set is used as temporary storage for IMASPZAP and link-edit input containing EXPAND control statements.</td>
</tr>
<tr>
<td>Attributes</td>
<td>Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB, DISP=(NEW,DELETE).</td>
</tr>
</tbody>
</table>

Specifying \texttt{DISP=(NEW,DELETE)} minimizes space loss problems. SMPWRK4 is generally needed only for the duration of the SMP/E job step. To keep the data set longer than that, you must use a different \texttt{DISP} value and compress the data set to reclaim space.

The SMS-related options DATACLAS, MGMTCLAS, STORCLAS, and DSNTYPE provide additional data set support. For more information, refer to \texttt{z/OS DFSMS Using Data Sets}.

Device: Direct access only.

Notes:
1. BLKSIZE must not exceed 32760.
2. If the BLKSIZE value is omitted or inapplicable, SMP/E uses a default of 0 which allows the system to determine the most appropriate block size.

**SMPWRK6**

<table>
<thead>
<tr>
<th>ddname</th>
<th>SMPWRK6.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use</td>
<td>The SMPWRK6 data set is used during APPLY and ACCEPT processing as temporary storage for inline replacements for data</td>
</tr>
</tbody>
</table>
SMPWRK6

elements. It is also used as temporary storage for inline updates for JAR elements. SMP/E places the input in this data set so it can be directly accessed and installed by the copy utility or SMP/E.

Attributes

Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB, DISP=(NEW,DELETE).

Specifying DISP=(NEW,DELETE) minimizes space loss problems. SMPWRK6 is generally needed only for the duration of the SMP/E job step. To keep the data set longer than that, you must use a different DISP value and compress the data set to reclaim space.

The SMS-related options DATACLAS, MGMTCLAS, STORCLAS, and DSNTYPE provide additional data set support. For more information, refer to z/OS DFSMS Using Data Sets.

Device

Direct access only.

Notes:
1. BLKSIZE must not exceed 32760.
2. If the BLKSIZE value is omitted or inapplicable, SMP/E uses a default of 0 which allows the system to determine the most appropriate block size.

SMPnnnnn

ddname SMPnnnnn, where nnnnn is a number from 00000 through 99999.

Use SMP/E allocates SMPnnnnn data sets for its own internal processing. To avoid processing errors, do not assign such a ddname to any data set.

SYSIN

ddname SYSIN.

Use Contains package control statements used as input to the GIMZIP and GIMUNZIP service routines.

Attributes Sequential or a member of a partitioned data set; LRECL=80

Device Direct access or SYSIN file.

Notes:
1. SYSIN can be defined to GIMZIP and GIMUNZIP only with a DD statement.
2. The size of the input data set will vary depending on how you intend to manage it.
3. You are responsible for managing the contents and space of the input data set.
4. This data set may reside in a UNIX file system. Specify PATHOPTS(ORDONLY) and either FILEDATA=TEXT or FILEDATA=BINARY on the DD statement if it is to reside in a UNIX file system. For simplicity, FILEDATA=TEXT is preferred, and ensure the newline character (X'15') marks the end of each line. If you use FILEDATA=BINARY, you must ensure that each line is padded with blanks to the 80-byte record length because there is no end of record marker in binary data.

SYSLIB

ddname SYSLIB.
Use

The SYSLIB data set is a concatenation of macro libraries that are to be used by the assembler utility.

For APPLY and RESTORE processing, the data sets should be concatenated in this order:
1. SMPMTS
2. MACLIB
3. MODGEN
4. Target system macro libraries (such as libraries specified for SYSLIB on the ++MAC statement)
5. Distribution macro libraries (such as libraries specified for DISTLIB on the ++MAC statement)

For more information about the proper SYSLIB concatenation for ACCEPT processing, see SMP/E User’s Guide.

Attributes

Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB.

Device

Direct access only.

SYSPRINT

ddname

SYSPRINT.

You can specify different SYSPRINT data sets for each of the utilities that SMP/E calls. This can be done with the PRINT value in the appropriate UTILITY entry. For more information, see “UTILITY entry (global zone)” on page 350.

Use

The SYSPRINT data set contains output from the utilities called by SMP/E.

Attributes

Sequential; DISP=MOD.

Do not specify LRECL, BLKSIZE, or RECFM unless they are compatible with the attributes used by the utilities called.

If SYSPRINT is allocated to a data set, the disposition must be MOD, because SMP/E opens and closes the SYSPRINT DD statement at each SET command. If the disposition is SHR or OLD, SYSPRINT contains only the output from the last set of commands processed before the end of SMP/E processing.

Device

SYSOUT, printer, direct access, or tape.

SYSOUT or a tape is recommended, because SYSPRINT might be opened with different DCB attributes by the various utilities and service aids called by SMP/E.

Notes:

1. BLKSIZE must not exceed 32760.
2. How you specify the SYSPRINT data set can affect whether a listing of the utility output is produced. For example, no listing is produced if the PRINT value in the UTILITY entry specifies either of the following:
   • A DDDEF for a DUMMY data set
   • A DDDEF for a data set that is sent to a SYSOUT class that suppresses output
SYSPUNCH

**ddname** SYSPUNCH.

**Use** The SYSPUNCH data set is a temporary data set containing object modules assembled by running the job stream produced by system generation or the GENERATE command. These modules are not installed in the distribution libraries at ACCEPT time.

**Attributes** Partitioned; LRECL=80, BLKSIZE=multiple of 80, RECFM=FB.

Do not specify a DISP value. Instead, let SMP/E use its defaults:
- DISP=(NEW,PASS) for the first job generated
- DISP=(OLD,PASS) for any subsequent jobs

**Device** Direct access only.

---

**SYSUT1, SYSUT2, and SYSUT3**

**ddname** SYSUT1, SYSUT2, and SYSUT3.

**Use** These are scratch data sets for SMP/E and the utilities it calls. They can be used instead of the following data sets when certain utilities are called:
- SYSTIN for invocations of the copy utility
- For some invocations of the update utility
- For some invocations of the x37 RETRY COMPRESS utility
- SYSLIN for invocations of the link-edit utility
- SYSUT2 for invocations of the assembler utility

SYSUT1 and SYSUT2 are also used by the GIMDTS service routine:
- SYSUT1 points to the data set containing the input in its original format.
- SYSUT2 points to the data set containing the transformed output.

**Attributes** Sequential; DISP=(NEW,DELETE)

**Device** Direct access only.

**Notes:**
1. BLKSIZE must not exceed 32760.
2. Do not specify BLKSIZE=0. SMP/E does not support system-determined block size (SDB) for this data set.
3. If the BLKSIZE value is omitted or invalid, SMP/E uses a default of 3200.

---

**SYSUT4**

**ddname** SYSUT4.

**Use** This data set can be used instead of the SYSIN data sets when certain utilities are called:
- For invocations of the x37 RETRY COMPRESS utility
- For some invocations of the assembler utility
- For RECEIVE FROMNETWORK and RECEIVE FROMNTS command processing
Attributes | Sequential; DISP=(NEW,DELETE)
---|---
Device | Direct access only.

Notes:
1. BLKSIZE must not exceed 32760.
2. Do not specify BLKSIZE=0. SMP/E does not support system-determined block size (SDB) for this data set.
3. If the BLKSIZE value is omitted or invalid, SMP/E uses a default of 3200.

Target library

ddname | The ddname for a target library should match the low-level qualifier of the data set name. For example, the ddname for SYS1.LINKLIB should be LNKLIB.
---|---
Use | Target libraries contain updated versions of macros, source modules, and load modules that were stored during APPLY or RESTORE processing. They are the libraries used for your running system. You must provide a DDDEF entry or DD statement for each target library that is being processed.

Attributes | Partitioned.
---|---
Device | Direct access only.

Text library (TXLIB)

ddname | The ddname for a text library must match the TXLIB value on the ++JCLIN or element MCS. For example, the ddname for the text library on statement ++MOD(MODA) TXLIB(LIBX) must be LIBX.
---|---
Use | Text libraries contain JCLIN input or replacements for macros, source, or object modules that have not been link-edited. They are used when the JCLIN or elements are provided in partitioned data sets rather than inline or in relative files.

Attributes | Partitioned.
---|---
Device | Direct access only.

Zone statement

ddname | The ddname must match the name of the target or distribution zone.
---|---
Use | The zone DD statement is used by SMP/E to access an individual target or distribution zone in a CSI data set. For example, to have SMP/E access target zone MVSTGT1, you can provide a DD statement like this:

```
//MVSTGT1 DD DSN=SMPE.SMPCSI.CSI,DISP=SHR
```

If you do not provide a DD statement for a target or distribution zone, SMP/E allocates the zone dynamically using the ZONEINDEX information in the GLOBALZONE entry. Also note that, while DD statements may be used to override the ZONEINDEX information, they are not a substitute for a zoneindex. A zoneindex is always required for a zone.

Attributes | VSAM; RECORDSIZE(24 143), KEYS(24 0).
Zone statement

Device Direct access only.

Notes:
1. The low-level qualifier of the data set name must be CSI.
2. If you have used IBM SMP/E for z/OS, V3R5 to update a zone, you might not be able to process that zone with previous releases of SMP/E. For more information, see the "Migration" section in SMP/E User’s Guide.
3. When running on systems with the required level of DFP, SMP/E automatically takes advantage of the local shared resource (LSR) feature of VSAM. This reduces the number of times SMP/E must access data when it is reading CSI data sets. As a result, SMP/E performance is improved for commands such as APPLY, APPLY CHECK, ACCEPT, ACCEPT CHECK, and especially LIST.
4. CSI data sets should usually be allocated dynamically. However, you may want to use the batch local shared resources (BLSR) subsystem with expanded storage hiperspaces (instead of SMP/E’s implementation of LSR) to improve SMP/E performance during APPLY and ACCEPT processing for a large number of changes. For more information about BLSR, see the Notes® in “SMPCSI” on page 145.
5. For information about the CSI data set containing the global zone, see “SMPCSI” on page 145.
Chapter 5. SMP/E data set entries

This chapter describes the entries in the various data sets SMP/E uses. It discusses the following:

- How these data sets are organized
- How the entries in these data sets are organized
- How to create, update, and obtain information about these entries

Note: The LIST, UCLIN, and UNLOAD commands used to process these entries are described in [SMP/E Commands].

How the data sets are organized

SMP/E uses the following data sets as a database for its processing: the CSI, PTS, SCDS, MTS, and STS. It is important to understand how SMP/E uses each of these data sets and how they are related.

The following is a description of each data set:

- The CSI data set is a VSAM data set that serves as the primary data set for SMP/E. SMP/E divides the CSI into multiple partitions using the VSAM key structure. Each partition is referred to as a zone.

  There are three types of zones:

  1. Global zone. A single global zone is used to record information about SYSMODs that have been received. The global zone also contains information enabling SMP/E to access the other two types of zones, and information allowing you to tailor parts of SMP/E processing.
  2. Target zones. One or more target zones are used to record information about the status and structure of the operating system (or target) libraries.
  3. Distribution zones. One or more distribution zones are used to record information about the status and structure of the distribution libraries.

In Figure 5 on page 172 the CSI is pictured as one data set. In fact, you can group all your zones within one VSAM data set (up to 32766 zones per data set), or divide them up into multiple VSAM data sets, even one zone per data set. The choice is yours; it is based on such factors as:

- Which packs the associated target and distribution libraries are on. It is advisable to keep the associated zone on the same pack as the libraries controlled from the zone, so when the pack is dumped, the data and description are kept synchronized.
- The organization of your shop. Totally separate service organizations for different products may require many separate data sets.

Figure 6 on page 173 illustrates the same zone relationship as Figure 5 on page 172 with the CSI spread across multiple VSAM data sets.

- The PTS is used strictly as a storage data set for SYSMODs. A SYSMOD is read from the SMPPTFIN data set and stored directly on the PTS without any modifications or SMP/E information. It is, therefore, related to the global zone in that both data sets contain information about the received SYSMODs. You can, therefore, look at the global zone and the PTS as a pair of data sets that must be processed (such as scratched, saved, or modified) concurrently.
Data set entries

- The **SCDS** is used by SMP/E to store backup copies of modified target zone entries during apply processing of a SYSMOD with inline JCLIN. Thus, the SCDS is directly related to a specific target zone, and each target zone must have its own SCDS.

- The **MTS** is a library in which SMP/E stores updated copies of macros during apply when no other target macro library is identified. The MTS is, therefore, related to a specific target zone, and each target zone must have its own MTS data set.

- The **STS** is a library in which SMP/E stores updated copies of source during APPLY when no other target source library is identified. The STS is, therefore, related to a specific target zone, and each target zone must have its own STS data set.

The relationships among SMP/E data sets and zones are shown in Figure 5 for a single CSI data set, and in Figure 6 on page 173 for multiple CSI data sets.

```
//SMPCSI DD DSN=SMPE.SMPCSI.CSI,DISP=SHR
//TGT1 DD DSN=SMPE.SMPCSI.CSI,DISP=SHR
//TGT2 DD DSN=SMPE.SMPCSI.CSI,DISP=SHR
//DLB1 DD DSN=SMPE.SMPCSI.CSI,DISP=SHR
//DLB2 DD DSN=SMPE.SMPCSI.CSI,DISP=SHR
```

![Diagram](Figure 5. Single-CSI structure)
How data set entries are organized

Within the global zone, target zone, and distribution zone, SMP/E keeps many types of entries. These can be divided into two categories:

- Those that are used to control SMP/E processing. These consist of:
  - GLOBALZONE definition entry
  - TARGETZONE definition entry
  - DLIBZONE definition entry
  - OPTIONS entries
  - UTILITY entries
  - DDDEF entries
  - FMIDSET entries
  - ZONESET entries

- Those that are used to define the status and structure of the target libraries and distribution libraries. These consist of:
  - ASSEM entries

Figure 6. Multiple-CSI structure
Data set entries

- Data element entries
- DLIB entries
- hierarchical file system element entries
- LMOD entries
- MAC entries
- MOD entries
- SRC entries
- SYSMOD entries

Note: The SYSMOD entries also contain information referred to as HOLDDATA.

The following sections describe the entry relationships for the entries that control processing, and entries that define status and structure.

Entries that control processing

The starting point for all SMP/E processing is the SMPCSI DD statement. This DD statement directs SMP/E to the CSI data set containing the GLOBALZONE entry. The next step after obtaining the GLOBALZONE entry depends on which zone you direct SMP/E to process. (For more information on identifying which zone SMP/E is to process, see the SET command chapter in SMP/E Commands.

Processing the global zone

Once the GLOBALZONE entry has been obtained and you direct SMP/E to process the global zone (for instance to receive SYSMODs), the OPTIONS subentry in the GLOBALZONE entry directs SMP/E to the correct OPTIONS entry to use. The OPTIONS entry contains information about the SMP/E processing options to be used. During processing, SMP/E may have to invoke one of the system utilities. Another entry, the UTILITY entry, is used to define to SMP/E information about the utility program to invoke, the parameters to pass to it, and the return code to expect from it. SMP/E finds the UTILITY entry through the OPTIONS entry that names the UTILITY entry. Thus, for SMP/E to use the correct utility program, you must define both the UTILITY entry that describes the utility program and the OPTIONS entry that names that UTILITY entry.

The other processing entries in the global zone are the DDDEF, FMIDSET, and ZONESET entries.

- **DDDEF entries** provide information used by SMP/E to dynamically allocate data sets. These entries are not connected to any other processing entry. They are accessed individually, by name, as SMP/E needs information to dynamically allocate a specific data set. They are not shown in Figure 7 on page 175.
- **FMIDSET entries** define sets of FMIDs. Various other commands, such as APPLY and ACCEPT, can then process SYSMODs by FMIDSET.
- **ZONESET entries** define sets of zones. The REPORT command can then check for SYSMODs in the zones defined in the ZONESET.

Each of these entries (GLOBALZONE, OPTIONS, UTILITY, DDDEF, FMIDSET, and ZONESET) exists in the global zone.

Figure 7 on page 175 illustrates how the various global zone processing entries are related to one another. Subsequent sections of this chapter provide a more detailed explanation of each entry and the data it contains.
A target zone and a distribution zone are processed in very similar ways. The only difference is the name of the controlling entry. Therefore, they are covered together, and the differences are pointed out as appropriate.

When you direct SMP/E to process a target zone (for instance to apply a PTF) or a distribution zone (for instance to accept that PTF), SMP/E accesses the ZONEINDEX subentries in the GLOBALZONE entry. Those subentries list the target zones and distribution zones that you have defined, including the zone type, target or DLIB, and the name of the CSI data set on which they reside.

After SMP/E has determined that the zone specified is valid, it uses the CSI data set name specified to dynamically allocate a DD statement to access the required data set (optionally, SMP/E looks for a DD statement equal to the zone name). SMP/E can now access that DD statement to obtain further processing information for the zone.

The first entry accessed is the TARGETZONE entry (for target zones) or the DLIBZONE entry (for distribution zones). Each of these, in turn, directs SMP/E to the correct OPTIONS entry to use, which in turn directs SMP/E to the correct UTILITY entries. Target and distribution zones also contain DDDEF entries.

- The OPTIONS and UTILITY entries serve the same purpose for the target zone and distribution zone as for the global zone. However, the OPTIONS and UTILITY entries used to process a target zone or distribution zone are defined not in the target or distribution zone, but in the global zone that points to the target or distribution zone.
- TARGETZONE and DLIBZONE entries contain a RELATED subentry, which identifies a related zone. For a target zone, the RELATED subentry identifies the
Data set entries

distribution zone from which this target zone was built. For a distribution zone, the RELATED subentry identifies the target zone that was built from these distribution libraries.

- **DDDEF entries** in the target zone and distribution zone are not connected to any other entries. They provide information used by SMP/E to dynamically allocate data sets.

  [Figure 8 on page 177](#) shows how the various target zone, distribution zone, and global zone processing entries are related. Subsequent sections of this chapter provide a more detailed explanation of each entry and the data it contains. Because neither the FMIDSET entries nor the DDDEF entries are connected to any other distribution zone or target zone entry, they are not shown in this figure.

Entries that define status and structure

Once the processing control information for the specified zone has been determined, SMP/E uses the status and structure entries within the various zones to determine what should be done.

**Processing the global zone**

Processing the global zone is fairly simple, in that only one structure and status entry exists, SYSMOD. **SYSMOD entries** are used to determine whether a SYSMOD has been received already. Various indicators within the SYSMOD entry also indicate whether the SYSMOD has been applied or accepted. The SYSMOD entries, although not directly connected to the PTS **MCS entries**, are implicitly connected, in that SMP/E assumes that there is a one-to-one relationship between global zone SYSMOD entries and PTS MCS entries.

**Processing the target zone**

Processing the target zone is much more complex than processing the global zone, because the operations performed are much more complex and require more entry types to direct SMP/E. The primary purpose of the target zone entries is to enable SMP/E to apply new function and service to the target system libraries; thus, the APPLY command is used to describe the relationship between the various target zone entries.

The starting point for applying a SYSMOD is actually the **global zone SYSMOD entries**. From the global zone SYSMOD entry, SMP/E obtains information about the relationship between this SYSMOD and other SYSMODs. SMP/E then uses other global zone SYSMOD entries and the **target zone SYSMOD entries** to resolve these relationships.

Once the eligible SYSMODs have been determined, the actual MCS statements from the PTS are accessed and lead SMP/E to the other target zone entries:

- **++MAC** and **++MACUPD** statements lead to target zone MAC entries.
- **++SRC** and **++SRCUPD** statements lead to target zone SRC entries.
- **++MOD** and **++ZAP** statements lead to target zone MOD and LMOD entries.
- Data element statements lead to target zone data element entries.
- **++hfs_element** statements lead to target zone hierarchical file system element entries.
If the SYSMOD replaces or modifies a macro (++MAC or ++MACUPD in SYSMOD), SMP/E uses the target zone MAC entry to determine the functional and service level of the macro and to determine whether any assemblies must be redone as a result of the macro update. This is done by checking the GENASM subentries in the target zone MAC entry. The GENASM subentries contain the names of either ASSEM entries or SRC entries in the target zone. In either case, SMP/E accesses the appropriate entry and uses the information stored there to perform the required assemblies.
Data set entries

If the SYSMOD replaces or modifies source (++SRC or ++SRCUPD in SYSMOD), SMP/E uses the target zone SRC entry to determine the functional and service level of the source and the library containing the source code, and then performs the required assembly.

After an assembly has been done (either using data from the ASSEM entry or SRC entry), SMP/E knows that the resulting object deck must be link-edited into the target libraries somewhere. Although there is no direct connection (that is, no subentry value present) between the ASSEM or SRC entries and a MOD entry, there is an implicit relationship. SMP/E assumes that for each ASSEM and SRC entry, there exists a MOD entry with the same name. Thus, after performing the assembly, SMP/E accesses the corresponding MOD entry to determine where to install the object deck. This leads us to the same point as if a MOD were supplied in the SYSMOD.

If the SYSMOD replaces or modifies a module (++MOD or ++ZAP in SYSMOD), or if an assembly was done for a SRC or ASSEM entry, SMP/E uses the target zone MOD entry to determine the functional and service level of the module and the load modules into which the module should be linked. Information about load modules is kept in the LMOD subentries in the MOD entry.

The LMOD subentries within the MOD entry lead SMP/E to the target zone LMOD entries. These represent load modules that exist in the target libraries. LMOD entries contain all the information necessary either to relink the load module or to superzap it.

If the SYSMOD replaces a data element (a data element MCS is in the SYSMOD), SMP/E uses the target zone data element entry to determine the functional and service level of the data element. It then gets the data element installed in the appropriate target library.

If the SYSMOD replaces a hierarchical file system element (a ++hfs_element MCS is in the SYSMOD), SMP/E uses the target zone hierarchical file system element entry to determine the functional and service level of the hierarchical file system element. It then gets the hierarchical file system element installed in the appropriate target library (which is actually in a UNIX file system). If a shell script has been defined for the element, SMP/E passes control to the shell script to allow it to perform any necessary post-installation processing.

After all the updating, assembling, linking, and so on, are done, you arrive back almost at the starting point, the SYSMOD entry. The difference is that this is the target zone SYSMOD entry rather than the global zone SYSMOD entry. The target zone SYSMOD entry contains all the information about what has been done as a result of installing this SYSMOD.

That leaves us with one target zone entry not discussed, the DLIB entry. The DLIB entries are not connected to any other entry. They are used by SMP/E to keep information about libraries that are totally copied during product installation, and are used during APPLY processing to create the appropriate element and LMOD entries for elements coming from the copied DLIB.

Figure 9 on page 179 shows how the various SMP/E status and structure entries are related. Subsequent sections of this chapter provide a more detailed explanation of each entry and the data it contains.
Data set entries

Figure 9. Target Zone: Relationships between Entries that Define Status and Structure

Note: Lines to the left of the figure are implicit connections based on the assumption that entries with equal names will be found.

Processing the distribution zone
Processing the distribution zone is similar to processing the target zone, but more complex than processing the global zone. The primary purpose of the distribution zone entries is to enable SMP/E to accept new function and service to the
Data set entries

distribution libraries; it is also used to remove a SYSMOD from the system. The
ACCEPT command will be used to describe the relationship between the various
distribution zone entries.

The starting point for accepting a SYSMOD is actually the **global zone SYSMOD**
entry. From that entry, SMP/E obtains information about the relationship between
this SYSMOD and other SYSMODs. SMP/E then uses other global zone SYSMOD
entries and the **distribution zone SYSMOD entries** to resolve these relationships.
In addition, SMP/E checks the target zone SYSMOD entries to ensure that the
selected SYSMODs have been applied.

After the eligible SYSMODs have been determined, the various MCS statements
lead SMP/E to the other distribution zone entries:
- ++MAC and ++MACUPD statements lead to distribution zone MAC entries.
- ++SRC and ++SRCUPD statements lead to distribution zone SRC entries.
- ++MOD and ++ZAP statements lead to distribution zone MOD entries.
- Data element statements lead to distribution zone data element entries.
- ++hfs_element statements lead to distribution zone hierarchical file system
element entries.

If the SYSMOD replaces or modifies a macro (++MAC or ++MACUPD in
SYSMOD), SMP/E uses the distribution zone **MAC entry** to determine the
functional and service level of the macro and to determine whether any assemblies
must be redone as a result of the macro update. This is done by checking the
GENASMS subentries in the target zone MAC entry. The names in the list can be
names of either target zone ASSEM or SRC entries. In either case, SMP/E accesses
the appropriate entry and uses the information stored there to perform the
required assemblies.

If the SYSMOD replaces or modifies a source (++SRC or ++SRCUPD in SYSMOD),
SMP/E uses the distribution zone **SRC entry** to determine the functional and
service level of the source and the library containing the source code, and then
performs the required assembly.

After an assembly has been done (with data from either the ASSEM entry or the
SRC entry), SMP/E knows that the resulting object deck may be link-edited into
the distribution libraries somewhere. Although there is no direct connection (that
is, no subentry value present) between the ASSEM or SRC entries and a **MOD
entry**, there is an implicit relationship. SMP/E assumes that for each ASSEM and
SRC entry there exists a MOD entry with the same name. Thus, after performing
the assembly, SMP/E accesses the corresponding MOD entry to determine where
to install the object deck. This leads us to the same point as if a MOD were
supplied in the SYSMOD.

If the SYSMOD replaces or modifies a module (++MOD or ++ZAP in SYSMOD), or
if an assembly was done for a SRC or ASSEM entry, SMP/E uses the distribution
zone **MOD entry** to determine the functional and service level of the module, the
DLIB into which it must be linked, the load modules into which the module
should be linked, and the link-edit attributes that should be used. Information
about load modules is kept in the LMOD subentries in the MOD entry.

The LMOD subentries within the MOD entry lead SMP/E to the distribution zone
**LMOD entries**. These represent load modules that exist in the target libraries.
LMOD entries contain all the information necessary, either to relink the load
module or to update it using IMASPZAP.
If the SYSMOD replaces a data element (a data element MCS is in the SYSMOD), SMP/E uses the distribution zone data element entry to determine the functional and service level of the data element. It then gets the data element installed in the appropriate distribution library.

If the SYSMOD replaces a hierarchical file system element (a ++hfs_element MCS is in the SYSMOD), SMP/E uses the distribution zone hierarchical file system element entry to determine the functional and service level of the hierarchical file system element. It then gets the hierarchical file system element installed in the appropriate distribution library.

After all the updating, assembling, linking, and so on, are done, you arrive back almost at the starting point, the SYSMOD entry. The difference is that this is the distribution zone SYSMOD entry, which contains all the information about what was done as a result of installing this SYSMOD.

Figure 10 on page 182 shows how the various SMP/E status and structure entries are related. Subsequent sections of this chapter provide a more detailed explanation of each entry and the data it contains.
Data set entries

![Diagram of data set entries]

Figure 10. Distribution zone: relationships between entries that define status and structure

**Note:** Lines to the left of the figure are implicit connections based on the assumption that entries with equal names will be found.

The remaining sections of this chapter deal with each of the specific entries in the various SMP/E data sets.
The ASSEM entry contains assembler statements that can be assembled to create an object module. It is created during JCLIN processing when SMP/E encounters an assembler step with inline assembler input. When the module is reassembled using the statements in the ASSEM entry, SMP/E copies those statements into the SMPWRK2 data set, and then assembles the module.

If a macro is invoked in the assembly, the ASSEM entry is pointed to by the GENASM subentry in the MAC entry created for that macro. As a result, when that macro is updated, SMP/E can reassemble the affected module using the statements in the ASSEM entry. For additional information, see the “Processing” section in the JCLIN command chapter in [SMP/E Commands]

Subentries

These are the subentries for the ASSEM entry as they appear in the LIST output:

- **name** is the name of the ASSEM entry. It corresponds to the name of the module that can be reassembled by use of that ASSEM entry.
  The name can contain from 1 to 8 alphanumeric characters.

- **ASSEMBLER INPUT** is the actual assembler statements that were saved for this module during JCLIN processing. These statements are passed to the assembler whenever this module must be reassembled.
  The UCL operands are **++ASMIN** and **++ENDASMIN**.
  - An ASSEM entry must contain at least the **++ASMIN** and **++ENDASMIN** statements, plus the associated assembler statements.
  - The **++ASMIN** and **++ENDASMIN** statements must start in column 1.
  - No other operands can start on the same line as the **++ASMIN** statement.
  - If you specify the **++ASMIN** statement, you must also specify the **++ENDASMIN** statement.

- **LASTUPD** identifies the cause of the last change to this ASSEM entry.
  The UCL operand is **LASTUPD(value)**. This subentry can contain one of the following values:
  - **JCLIN** indicates that the change was made during JCLIN command processing.
  - **UCLIN** indicates that the change was made as a result of UCLIN processing.
  - **sysmod_id** indicates that the change was made during the installation of the indicated SYSMOD.
    The SYSMOD ID must contain 7 alphanumeric characters.

- **LASTUPD TYPE** indicates how the entry was last changed.
  The UCL operand is **LASTUPDTYPE(value)**. This subentry can contain one of the following values:
  - **ADD** The entry was added.
  - **UPD** The entry was updated.
**LIST Examples**

To list all the ASSEM entries in a particular zone, you can use the following commands:

```plaintext
SET BDY(TGT1) /* Set to requested zone. */.
LIST ASSEM /* List all ASSEM entries. */.
```

To list specific ASSEM entries, you can use these commands:

```plaintext
SET BDY(TGT1) /* Set to requested zone. */.
LIST ASSEM(ASSEM01 /* List only these two */ ASSEM02) /* entries. */.
```

The format of the LIST output for each ASSEM entry is the same for both of these commands. The only difference is the number of ASSEM entries listed. Figure 11 is an example of LIST output for ASSEM entries.

---

**Figure 11. ASSEM entry: sample LIST output**

You can use the LIST command to find the MAC entries for macros that are called by the assembler statements in this ASSEM entry. To include the names of these MAC entries in the LIST output, you can use the XREF operand, as shown in these commands:

```plaintext
SET BDY(TGT1) /* Set to requested zone. */.
LIST ASSEM /* List all ASSEM entries */.
XREF /* and macros that use them. */.
```

**Notes:**

1. You can use XREF in either mass mode or select mode.
2. SMP/E obtains the data included for the XREF operand by checking the GENASM subentries in all the MAC entries. Because this data is not contained in the ASSEM entry itself, you cannot use UCLIN to change it in the ASSEM entry.

Figure 12 on page 185 is an example of the LIST output produced when the XREF operand is used.

Figure 12. ASSEM entry: sample LIST output when XREF is specified

UNLOAD Examples

To dump the ASSEM entries in UCL format, you can use the UNLOAD command. To unload all the ASSEM entries in a particular zone, you can use the following commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD ASSEM /* Unload all ASSEM entries. */.
```

To unload specific ASSEM entries, you can use these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD ASSEM(ASSEM01) /* Unload only these two */
               ASSEM(ASSEM02) /* entries. */.
```

The format of the UNLOAD output for each ASSEM entry is the same for both of these commands. The only difference is the number of ASSEM entries listed.

Figure 13 on page 186 is an example of UNLOAD output for ASSEM entries.
ASSEM entry (distribution and target zone)

  LASTUPDTYPE ( UPD )
  +++ASMIN
  ... assembler statements
  ...
  +++ENDASMIN
ENDUCL.
```

Figure 13. ASSEM entry: sample UNLOAD output

**UCLIN Examples**

You can use the ADD, REP, and DEL UCL statements to change subentries in the ASSEM entry. When you use UCLIN to update an ASSEM entry, keep these points in mind:

- After the UCLIN changes are done, the ASSEM entry must contain at least +++ASMIN and +++ENDASMIN statements, plus the associated assembler input. Otherwise, there is not enough information in the entry to assemble the associated module.
- The input following the +++ASMIN statement replaces the existing assembler input in the ASSEM entry.
- If a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.
- When SMP/E processes a DEL statement, it does not compare any assembler input after the +++ASMIN statement with the input that is currently in the ASSEM entry. It just deletes the existing assembler input. This causes an error, because there is now insufficient data in the ASSEM entry.
ASSEM entry (distribution and target zone)

The following examples are provided to help you use the ASSEM entry.

Example 1: Deleting an ASSEM entry
The main use of UCLIN for an ASSEM entry is to delete the entry. Here is an example:

```
SET   BDY(TGT1)   /* Set to target zone. */.
UCLIN /* */.
DEL   ASSEM(ASSEM01) /* Delete the entry. */.
ENDUCL /* */.
```

Example 2: Adding a new ASSEM entry
To create an ASSEM entry, you should run the JCLIN command rather than use UCLIN. (For examples of how JCLIN creates ASSEM entries, see SMP/E Commands. However, you can also use UCLIN to create ASSEM entries. For example, you can use the following commands to create a new ASSEM entry and to update an existing MAC entry to show that the macro is used in the new assembly:

```
SET   BDY(TGT1)   /* Set to target zone. */.
UCLIN /* */.
ADD   ASSEM(ASSEM99) /* New ASSEM entry. */.
++ASMIN /* Assembler data. */.
ASSEM99 CSECT /* */.
MAC99 0,0,1 /* */.
END ASSEM99 /* */.
++ENDASMIN /* End of assembler data. */.
ADD   MAC(MAC99) /* Modify macro entry used */.
GENASM(ASSEM99) /* to indicate use in new */.
++assembly entry. /* */.
ENDUCL /* */.
```
BACKUP Entries (SMPSCDS)

**BACKUP entries (SMPSCDS)**

BACKUP entries are a collection of target zone entries that are copied to the SMPSCDS during APPLY processing before they are updated by inline JCLIN, a ++MOVE MCS, or a ++RENAME MCS, or before they are deleted by an element MCS with the DELETE operand. A BACKUP entry is also created for a MOD entry if a SYSMOD being installed provides a ++MOD statement that either changes the distribution library for the module or adds the module to an existing load module.

- As SMP/E processes the inline JCLIN for a given SYSMOD, it determines which entries will be affected by that JCLIN. Before making the changes, it saves a copy of each of those entries on the SMPSCDS.
- Likewise, as SMP/E processes the ++MOVE, ++RENAME, and element MCSs in a given SYSMOD, it determines which entries will be updated or deleted. Before updating or deleting the entries, it saves a copy of each of those entries on the SMPSCDS.

Besides saving copies of the affected entries, SMP/E also saves a SYSMOD entry on the SMPSCDS to indicate which entries were added by JCLIN, updated by JCLIN or an MCS statement in the SYSMOD, or deleted by an MCS statement in the SYSMOD. Each entry is associated with only one SYSMOD. The entries associated with a SYSMOD are called the BACKUP entries for that SYSMOD.

BACKUP entries consist of:
- A SYSMOD entry indicating what entries were added, deleted, or updated
- ASSEM entries for updated target zone ASSEM entries
- JAR entries for deleted JAR entries
- LMOD entries for updated target zone LMOD entries
- MAC entries for updated or deleted target zone MAC entries
- MOD entries for updated or deleted target zone MOD entries
- SRC entries for updated or deleted target zone SRC entries
- Data element entries for deleted target zone data element entries
- Hierarchical file system entries for deleted target zone hierarchical file system entries
- DLIB entries for updated target zone DLIB entries

SMP/E provides access to the BACKUP entries as a group—for example, through the LIST command—but it does not provide access to the individual entries or subentries.

**Subentries**

The subentries in the BACKUP entries are the same as those in the various entry types that are copied. For more information, see the section in this chapter describing each entry.

**LIST Examples**

To list the BACKUP entries for all the SYSMODs in the SMPSCDS, you can use the following commands:

```plaintext
SET BDY(TGT1) /* Set to requested tgt zone. */.
LIST BACKUP /* List all BACKUP entries. */.
```

To list the BACKUP entries for a specific SYSMOD, you can use these commands:

```plaintext
SET BDY(TGT1) /* Set to requested tgt zone. */.
LIST BACKUP(UZ12345, UZ12346) /* List only BACKUP entries */.
```

```plaintext
/* for these two SYSMODs. */.
```
The format of the LIST output for each group of BACKUP entries is the same for both of these commands. The only difference is the number of SYSMODs for which BACKUP entries are listed.

When you list the BACKUP entries for a SYSMOD, the first entry in the output is a summary entry for the SYSMOD, which indicates the date and time the SYSMOD was applied, as well as which entries were added or updated as a result of applying the SYSMOD. This is followed by a listing of all the existing target zone entries affected by this SYSMOD, before they were updated. Nothing is listed for added entries, because no entry existed before the SYSMOD was installed.

Figure 14 on page 190 is a partial example of LIST output for BACKUP entries. It shows the summary records, but not all the backup copies of the entries modified by the SYSMOD. This is because the format of those copies is the same as the format for the original target zone entries.

UCLIN Examples

You can use the DEL UCL statement to delete BACKUP entries from the SMPSCDS. This can be helpful if you plan to do an APPLY followed by ACCEPT when several target libraries have been created from the same distribution library.

When a SYSMOD is accepted into a distribution zone, the entries associated with the SYSMOD are automatically deleted from the SMPSCDS for the RELATED target zone. However, even if the SYSMOD was also applied to other target zones created from the same distribution zone, SMP/E does not clean up the SMPSCDS data sets for the other target zones.

To delete the entries from these data sets, you can accept the SYSMOD and name these other target zones as the RELATED zone. However, this updates the distribution library each time, which is time-consuming and can use up space in the distribution library data set.

Instead, you can use the DEL command to delete these entries without updating the distribution library. To determine which entries to specify, check the SMPLOG data set to see which ones SMP/E deleted during ACCEPT processing.

Note: You can also use the CLEANUP command to delete BACKUP entries without specifying them individually. For more information on the CLEANUP command, see SMP/E Commands.
Example: Deleting BACKUP entries

Assume BACKUP entries exist on the SCDS for SYSMODs UZ12345 and UZ12346. Those SYSMODs have been accepted, but the BACKUP entries have not been deleted from the SCDS. This can happen when multiple systems are supported off one set of DLIBs, where you accept from only one of the target systems. Here is an example of UCL you could use to delete the BACKUP entries from the SCDS:

```
SET BDY(TGT1) /* Set to TGT1 zone. */.
UCLIN /*.
DEL BACKUP(UZ12345) /* Delete the BACKUP entries. */.
DEL BACKUP(UZ12346) /* Delete the BACKUP entries. */.
ENDUCL /*.
```

Note: You must specify a separate UCL statement for each BACKUP entry to be deleted.

Figure 14. BACKUP entries: sample LIST output
Data element entry (distribution and target zone)

Data element entry (distribution and target zone)
The data element entry describes an element that is not a macro, module, or source (for example, a CLIST or a sample procedure). Data elements may exist in distribution or target libraries. A data element entry is created the first time you install a SYSMOD that contains an MCS for a data element that does not yet have an entry in the CSI data set.

SMP/E records the function and service level of the data element in the entry. Once a data element entry exists, it is updated as subsequent SYSMODs that affect the data element are installed.

Table 2 on page 10 shows the types of entries used for data elements. Some types of elements, such as panels, messages, or text, may have been translated into several languages. In these cases, the entry type contains xxx, which represents the language used for the element. (If an element was not translated, the entry type does not contain any xxx value.) Table 3 on page 13 shows the xxx values and the languages they represent.

Subentries
These are the subentries for the data element entry as they appear in the LIST output:

name
is the name of the data element represented by the entry. It can contain from 1 to 8 alphanumeric characters and $, #, @, or hex C0.

ALIAS
specifies a list of alias names for the element.

The UCL operand is ALIAS(name...).

Each alias name can contain from 1 to 8 alphanumeric characters.

DISTLIB
specifies the ddname of the distribution library for the data element.

The UCL operand is DISTLIB(ddname).

• The ddname can contain from 1 to 8 alphanumeric characters.

• The DISTLIB subentry is required. Without it, SMP/E cannot process any changes for the data element.

FMID
specifies the functional owner of this data element. The functional owner is the last function SYSMOD that replaced this element.

The UCL operand is FMID(sysmod_id).

The SYSMOD ID must contain 7 alphanumeric characters.

LASTUPD
identifies the cause of the last change to this data element entry.

The UCL operand is LASTUPD(value). This subentry can contain one of the following values:

UCLIN
indicates that the change was made as a result of UCLIN processing.

sysmod_id
indicates that the change was made during the installation of the indicated SYSMOD.

Chapter 5. SMP/E data set entries 191
Data element entry (distribution and target zone)

The SYSMOD ID must contain 7 alphanumeric characters.

LASTUPD TYPE
indicates how the entry was last changed.

The UCL operand is \text{LASTUPDTYPE}(value). This subentry may contain one of the following values:
- ADD The entry was added.
- UPD The entry was updated.

RMID
identifies the last SYSMOD that replaced this data element. Any subsequent SYSMOD that modifies this data element must have a defined relationship (such as PRE or SUP) with this SYSMOD.

The UCL operand is \text{RMID}(sysmod\_id).
- The SYSMOD ID must contain 7 alphanumeric characters.
- If RMID is not specified but FMID is, SMP/E sets the RMID value to the specified FMID.

SYSLIB
specifies the ddname of the target library for the data element.

The UCL operand is \text{SYSLIB}(ddname).
- You can specify only one SYSLIB value.
- The ddname can contain from 1 to 8 alphanumeric characters.

LIST Examples
To list all the data element entries of a given type (such as CLIST) in a particular zone, you can use the following commands:

\begin{verbatim}
SET BDY(TGT1)  /* Set to requested zone. */.
LIST CLIST     /* List all CLIST entries. */.
\end{verbatim}

To list specific CLIST entries, you can use these commands:

\begin{verbatim}
SET BDY(TGT1)  /* Set to requested zone. */.
LIST CLIST(CLIST1 CLIST2) /* List only these two entries. */.
\end{verbatim}

The format of the LIST output for each data element entry is the same for both of these commands. The only difference is the number of data element entries listed. Figure 13 is an example of LIST output for data element entries.
By specifying the FORFMID operand, you can reduce the number of data element entries listed. When FORFMID is specified, SMP/E lists a data element entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to list CLIST entries whose FMIDs are defined in FMIDSET TP or else are MYCLST1, you can use these commands:

```
SET BDY(TGT1) /* Set to target zone. */.
LIST CLIST /* List all CLIST entries */
    FORFMID(TP) /* for the TP FMIDSET */
    MYCLST1) /* and FMID MYCLST1. */.
```

You can use the LIST command to find out the names of all SYSMODs that have modified data elements. To include the names of these SYSMODs in the LIST output, you can use the XREF operand, as shown in these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
LIST CLIST /* List all CLIST entries */
    XREF /* and related SYSMODs. */.
```

Notes:
1. You can use XREF in either mass mode or select mode.
2. SMP/E obtains the data included for the XREF operand by checking for entries for this data element in all the SYSMOD entries. Because this data is not contained in the data element entry itself, you cannot use UCLIN to change it in the data element entry.

Figure 16 on page 194 is an example of the LIST output produced when the XREF operand is used.

---

### Data element entry (distribution and target zone)

Figure 16. Data element entry: sample LIST output when XREF is specified

UNLOAD Examples

To dump the data element entries in UCL format, you can use the UNLOAD command. To unload all the CLIST entries in a particular zone, you can use the following commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD CLIST /* Unload all CLIST entries. */.
```

To unload specific CLIST entries, you can use these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD CLIST(CLIST1) /* Unload only these two */.
UNLOAD CLIST(CLIST2) /* entries. */.
```

The format of the UNLOAD output for each data element entry is the same for both of these commands. The only difference is the number of data element entries listed. Figure 17 on page 195 is an example of UNLOAD output for CLIST entries.
Data element entry (distribution and target zone)

By specifying the FORFMID operand, you can reduce the number of data element entries unloaded. When FORFMID is specified, SMP/E unloads a data element entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to unload CLIST entries whose FMIDs are either defined in FMIDSET TP or are MYCLST1, you can use these commands:

```
SET BDY(TGT1) /* Set to target zone. */.
UNLOAD CLIST /* Unload all CLIST entries */
  FORFMID(TP) /* for the TP FMIDSET */
  MYCLST1) /* and FMID MYCLST1. */.
```

UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the data element entry. After the UCLIN changes are made, the data element entry must contain at least the following subentries:
- DISTLIB
- FMID
- RMID

Otherwise, there is not enough information in the entry to process the data element. If any of these subentries are missing, SMP/E does not make the requested UCL updates to the entry, and the entry remains as it was before the UCL command.

Example: Adding a new data element entry

Assume you have installed CLIST3 outside of SMP/E, but now you want to start using SMP/E to track changes to that CLIST. Here is an example of the UCL statements you would use to define entries for that CLIST in the appropriate target and distribution zones:

```
SET BDY(TGT1) /* Set to target zone. */.
SET BDY(DLB1) /* Now do same to DLIB. */.
UCLIN /* */.
ADD CLIST(CLIST3) /* Define new CLIST entry. */
  DISTLIB(AMACLIB) /* Define DLIB. */
  SYSLIB(ISPCLIB) /* System library. */
  FMID(MYCLST1) /* Functional owner. */.
ENDUCL /* */.
ADD CLIST(CLIST3) /* Define new CLIST entry. */
  DISTLIB(AMACLIB) /* Define DLIB. */
```

Figure 17. Data element entry: sample UNLOAD output

UCLIN Examples

Chapter 5. SMP/E data set entries 195
Data element entry (distribution and target zone)

```c
/* no SYSLIB info in DLIB. */
FMID(MYCLST1) /* Functional owner. */
ENDUCL /* */
```
DDDEF entry (distribution, target, and global zone)

The DDDEF entry contains the information SMP/E needs to dynamically allocate a specific data set. With DDDEF entries, you do not have to provide a DD statement for every data set SMP/E may need to process a particular command. When SMP/E determines that it needs a specific data set, it looks for a DD statement that it can use to allocate that data set. If there is no DD statement, SMP/E checks whether the current zone contains a DDDEF entry for that data set. If so, it uses the information in the DDDEF entry to dynamically allocate the data set.

For more information about dynamically allocating data sets, see SMP/E User's Guide

Notes:
1. In a job with multiple SET commands, if you use DDDEF entries that specify SYSOUT for SMP/E output (such as SMPOUT or SMPRPT), SMP/E produces multiple SYSOUT data sets. This can cause undesirable results; for example, the output could appear to be out of sequence from one SET command to the next. Therefore, when you run such a job, you may prefer to use DD statements instead of DDDEF entries for SMP/E output data sets.
2. SMP/E does not strictly enforce rules for which subentries you can specify in DDDEF entries for specific data sets. To prevent possible allocation errors, refer to z/OS MVS JCL User's Guide

Subentries

These are the subentries for the DDDEF entry as they appear in the LIST output:

For more information concerning DDDEF entry syntax, see the UCLIN command chapter in SMP/E Commands

name

is the ddname of the data set to be allocated.

- The name can contain from 1 to 8 alphabetic (A through Z), national (@, #, or $), or numeric (0 through 9) characters. The first character must be alphabetic or national.
- Other than checking for duplicate DDDEF names in a given zone, SMP/E does not check whether the specified name is associated with another data set. For example, SMP/E does not check whether a DDDEF name is the same as a zone name. You must do this checking yourself to avoid undesired results.

BLK(size), CYL, or TRK

specifies the space units to be used in allocating the data set: blocks, cylinders, or tracks.

The UCL operand is BLOCK(size), CYLINDERS, or TRACKS.

- size is the size, in decimal, of each block to be allocated. To specify the number of blocks to be allocated, use SPACE.
- You can specify either the long form or the short form of these operands:
  - BLOCK or BLK
  - CYLINDERS or CYL
  - TRACKS or TRK
- These operands are mutually exclusive with each other and with OLD, MOD, SHR, CONCAT, PATH, and SYSOUT.

CATALOG, DELETE, or KEEP

specifies the final disposition (DISP) of the data set.
DDDEF entry (distribution, target, and global zone)

The UCL operand is **CATALOG, DELETE, or KEEP**.
- These operands are mutually exclusive with each other and with CONCAT and PATH.
- You cannot specify a final disposition for SMPTLIB data sets. SMP/E automatically specifies a final disposition based on the command being processed. For more information, see “SMPTLIB” on page 161.

**CONCAT** identifies one or more DDDEF entries, **existing in the same zone**, that should be concatenated during SMP/E processing.

The UCL operand is **CONCAT(name..)**.
- The DDDEF names can contain from 1 to 8 alphabetic (A through Z), national (@, #, or $), or numeric (0 through 9) characters. The first character must be alphabetic or national.
- There must be a DDDEF entry for each specified name. SMP/E does not check other sources (such as DD statements or GIMDDALC control statements in SMPPARM member GIMDDALC) to get the information needed to allocate the data sets.
- SMP/E allows you to specify up to 123 names. However, the actual number of partitioned data sets that can be concatenated depends on the operating system you are running under. To determine the maximum number of data sets you can concatenate, see [z/OS DFSMS Using Data Sets, SC26-7410](#).
- CONCAT is required for concatenated data sets.
- CONCAT cannot specify any DDDEF entries that contain the CONCAT operand. (You cannot nest concatenated DDDEF entries.)
- CONCAT is mutually exclusive with all other operands.

**Note**: When a DDDEF that specifies a disposition of OLD is allocated as part of a CONCAT, a disposition of SHR is used for the allocation.

**DATACLAS** specifies the name of a data class to be used for allocating a new data set managed by SMS.

The UCL operand is **DATACLAS(name)**.
- The data class name is defined by the storage administrator at your installation. This value can contain from 1 to 8 alphanumeric characters (A through Z and 0 through 9) or national characters (@, #, $) and must start with either an alphabetic or national character.
- You can specify this operand only if SMS manages your storage.
- Specify this operand only when you are allocating a new data set. SMS ignores this parameter if it is specified for an existing data set.
- This operand is mutually exclusive with PATH and CONCAT.

**DATASET** is the name of the data set to be allocated.

The UCL operand is **DATASET(dsname)**.
- You can specify either **DATASET** or **DA**.
- The data set name must conform to standard naming conventions for data sets. Each part of the name must contain from 1 to 8 characters, separated from the other parts by a period (.), with no intervening blanks. The maximum length of the entire name is 44 characters (including the periods).
- The data set name itself cannot contain parentheses.
DDDEF entry (distribution, target, and global zone)

- To define a dummy data set, omit the DATASET operand and specify an initial DISP of NEW.
- DATASET is required if OLD, SHR, or MOD is specified.
- DATASET is mutually exclusive with CONCAT, PATH, and SYSOUT.
- You cannot use DATASET to specify the data set name of an SMPTLIB data set. Instead, you can use the DSPREFIX operand in either the SMPTLIB DDDEF entry or in the OPTIONS entry used to process those data sets.
- SMP/E does not check whether the specified data set name is unique within the zone. For example, SMP/E does not check whether the data set name was also defined in another DDDEF entry in the same zone, or whether the data set name defines the CSI data set containing the zone. You must do this checking yourself to avoid undesired results.

DIR
specifies the number of directory blocks to allocate.

The UCL operand is DIR(nn.nn).
- The number specified can contain from 1 to 4 decimal digits.
- DIR is mutually exclusive with OLD, MOD, SHR, CONCAT, and PATH.

DSNTYPE
specifies the type of partitioned data set to be created.

The UCL operand is DSNTYPE(LIBRARY) or DSNTYPE(PDS).

LIBRARY
specifies that a PDSE (which must be an SMS-managed data set) is to be created.

PDS
specifies that a PDS is to be created.

You can also specify DSNTYPE in either a data class or a member of SYS1.PARMLIB.

Notes:
1. This operand is mutually exclusive with PATH and CONCAT.
2. When SMP/E RECEIVE processing allocates a new SMPTLIB data set, it uses the original DSNTYPE of the corresponding RELFILE data set. If SMP/E cannot determine the original DSNTYPE of the corresponding RELFILE data set, SMP/E uses the DSNTYPE value specified in the SMPTLIB DDDEF entry.

DSPREFIX
specifies the data set prefix to be used to construct the full data set name for SMPTLIB data sets. For more information about names for SMPTLIB data sets, see [SMP/E Commands].

The UCL operand is DSPREFIX(prefix).
- The prefix can contain from 1 to 26 alphanumeric characters.
- The prefix must follow standard conventions for naming data sets.
- Instead of specifying DSPREFIX in the SMPTLIB DDDEF entry, you can specify it in the OPTIONS entry that is in effect when you receive RELFILEs into the SMPTLIB data sets.

If you do not specify a data set prefix in the SMPTLIB DDDEF entry or in the appropriate OPTIONS entry, no prefix is included when SMP/E assigns a name to the SMPTLIB data sets.
- DSPREFIX is mutually exclusive with CONCAT and PATH.
DDDEF entry (distribution, target, and global zone)

**Note:** This subentry exists only in the global zone.

**MGMTCLAS**

specifies the name of a management class to be used for allocating a new data set managed by SMS.

The UCL operand is **MGMTCLAS**(name).

- The management class name is defined by the storage administrator at your installation. This value can contain from 1 to 8 alphanumeric characters (A through Z and 0 through 9) or national characters (@, #, $) and must start with either an alphabetic or national character.
- You can specify this operand only if SMS manages your storage.
- Specify this operand only when you are allocating a new data set. SMS ignores this parameter if it is specified for an existing data set.
- This operand is mutually exclusive with PATH and CONCAT.

**MOD, NEW, OLD, or SHR**

specifies the initial disposition (DISP) of the data set.

The UCL operand is **MOD, NEW, OLD, or SHR**.

- These operands are mutually exclusive with each other and with CONCAT and PATH.

OLD, SHR, and MOD are also mutually exclusive with SYSOUT, PROTECT, BLOCK, CYLINDERS, TRACKS, DIR, and SPACE.

- You cannot specify an initial disposition for SMPTLIB data sets. SMP/E automatically specifies an initial disposition, which is based on the command being processed. For more information, see "SMPTLIB" on page 161.

**PATH**

identifies the name of the path to be allocated in a UNIX file system. The name is not a complete pathname; it is a directory. This value is concatenated with the appropriate element or load module name to create a complete pathname.

The UCL operand is **PATH**(pathname).

- PATH is mutually exclusive with all other DDDEF entry operands.
- The pathname can be from 1 to 255 characters.
- The pathname must begin and end with a slash (/).
- In addition to the required delimiters (/), a pathname must also be enclosed in single apostrophes (’) if any of the following is true:
  - The pathname contains lowercase alphabetic characters.
  - The pathname contains a character that is not uppercase alphabetic, numeric, national ($, #, or @), slash (/), plus (+), hyphen, period, or ampersand (&).
  - The pathname spans more than one line in the UCL control statement.

The apostrophes must be outside the required delimiters, as in "pathname/", not "pathname"/.

The single apostrophes used to enclose a pathname (the delimiters) do not count as part of the 255-character limit.

- Any apostrophes specified as part of a pathname (not the delimiters) must be doubled.
- Double apostrophes count as two characters in the 255-character limit.
- The pathname can include characters X'40' through X'FE'.
DDDEF entry (distribution, target, and global zone)

- Because symbolic substitution is not detected by SMP/E, it is not supported by SMP/E.

PROTECT

specifies that the z/OS SecureWay® Security Server PROTECT option should be used when a new data set is first allocated. If PROTECT is specified and z/OS SecureWay Security Server is installed, the data set allocated by SMP/E will be protected by z/OS SecureWay Security Server.

You can also use PROTECT to indicate that an existing data set is protected by z/OS SecureWay Security Server. In this case, because SMP/E does not allocate the data set, it does not check the PROTECT indicator. However, you can use it to keep a record of which data sets have been protected with z/OS SecureWay Security Server.

The UCL operand is PROTECT.
- PROTECT is mutually exclusive with CONCAT, PATH, OLD, MOD, and SHR.

SPACE

specifies the primary and secondary space allocation for new data sets.

The UCL operand is SPACE(prime,second).
- Each value must contain from 1 to 4 decimal digits, and the two values must be separated by a comma or a blank.
- SPACE is mutually exclusive with CONCAT, PATH, OLD, MOD, and SHR.

STORCLAS

specifies the name of a storage class used for allocating a new data set managed by SMS.

The UCL operand is STORCLAS(name).
- The storage class name is defined by the storage administrator at your installation. This value can contain from 1 to 8 alphanumeric characters (A through Z and 0 through 9) or national characters (@, #, $) and must start with either an alphabetic or national character.
- You can specify this operand only if SMS manages your storage.
- Specify this operand only when you are allocating a new data set. SMS ignores this parameter if it is specified for an existing data set.
- This operand is mutually exclusive with PATH and CONCAT.

SYSOUT

specifies the output class for SYSOUT data sets.

The UCL operand is SYSOUT(value).
- If you specify a class, it must be 1 alphabetic or numeric character (A through Z or 0 through 9).
- If you specify *, the output class depends on references to an OUTPUT JCL statement.
  - If there is an implicit or explicit reference to an OUTPUT JCL statement, the output is written to the same class as the CLASS parameter on the OUTPUT statement.
  - If there is no reference to an OUTPUT JCL statement, the output is written to the same class as the one specified as MSGCLASS on the JOB card.
- SYSOUT is mutually exclusive with BLOCK, CYLINDER, TRACK, CONCAT, PATH, and DATASET.
DDDEF entry (distribution, target, and global zone)

- You cannot specify SYSOUT for SMPTLIB data sets.

UNIT
specifies the UNIT type the data set resides on if it is not cataloged.

The UCL operand is UNIT(type).
- If the data set is not cataloged, you must specify UNIT (unless it is not cataloged because of SMS). If you specify UNIT for a cataloged data set, it overrides the value in the catalog.
- The UNIT value can contain from 1 to 8 characters and should conform to standard UNIT naming conventions.
  SMP/E accepts any nonblank characters specified between the open and close parentheses, up to a maximum length of 8.
- UNIT is mutually exclusive with CONCAT and PATH.

VOLUME
specifies the volume serial number of the volume that the data set resides on if not cataloged.

The UCL operand is VOLUME(serial...).
- If the data set is not cataloged, you must specify VOLUME (unless it is not cataloged because of SMS). If you specify VOLUME for a cataloged data set, it overrides the value in the catalog.
- The volume identifier can contain from 1 to 6 alphanumeric characters.
- For SMPTLIB data sets, you can specify up to five volume serial numbers.
  All the volumes must have the same UNIT type. For other data sets, you can specify only one volume serial number.
- VOLUME is mutually exclusive with CONCAT and PATH.

WAIT=YES or WAIT= NO
indicates whether SMP/E should wait for the data set to be allocated if the volume is not mounted or if the data set is already in use. Not waiting causes allocation to fail for the data set.

The UCL operand is WAITFORDSN.
- You can specify either WAITFORDSN or WAIT.
- WAIT is mutually exclusive with CONCAT and PATH.
- If you do not specify a value, the default is not to wait.
- WAIT is not related to the PROCESS parameter specified on the EXEC statement. PROCESS affects how long a job should wait for a data set before being run. For more information, see Chapter 10, “JCL statements required to invoke SMP/E.”

LIST Examples
To list all the DDDEF entries in a particular zone, you can use the following commands:

```
SET   BDY(TGT1)  /* Set to requested target. */.
LIST   DDDEF    /* List all DDDEF entries. */.
```

To list specific DDDEF entries in a particular zone, you can use these commands:

```
SET   BDY(TGT1)  /* Set to requested target. */.
LIST   DDDEF(SMPTLIB) /* List only these three */
        MACLIB   /* entries. */
        SYSLIB)  /* */
```
### DDDEF entry (distribution, target, and global zone)

The format of the LIST output for each DDDEF entry is the same for both of these commands. The only difference is the number of DDDEF entries listed.

Figure 18 and Figure 19 on page 204 are examples of LIST output for DDDEF entries.

<table>

Figure 18. DDDEF entry: sample LIST output for a target zone
**UNLOAD Examples**

To dump the DDDEF entries in UCL format, you can use the UNLOAD command. To unload all the DDDEF entries in a particular zone, you can use the following commands:

```plaintext
SET BDY(TGT1) /* Set to requested target. */.
UNLOAD DDDEF /* Unload all DDDEF entries. */.
```

To unload specific DDDEF entries in a particular zone, you can use these commands:

```plaintext
SET BDY(TGT1) /* Set to requested target. */.
UNLOAD DDDEF(SMPMTS /* Unload only these three */.
MCLIB /* entries. */.
SYSLIB) /* */.
```

The format of the UNLOAD output for each DDDEF entry is the same for both of these commands. The only difference is the number of DDDEF entries unloaded.

**Note:** You can use the UNLOAD command only for target and distribution zones, not for the global zone.

*Figure 20 on page 205* is an example of UNLOAD output for DDDEF entries.
You can use the ADD, REP, and DEL UCL statements to change subentries in a DDDEF entry. When you use UCLIN to update a DDDEF entry, keep these points in mind:

- If a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.
- When SMP/E dynamically allocates a concatenation list, the order of the concatenation is the same as that specified in the DDDEF entry. Therefore, you cannot use ADD statements to update a DDDEF entry that already contains a concatenation list. SMP/E would not know the correct position for the new data.

For example, suppose you have a DDDEF entry for the SYSLIB data set that concatenates SMPMTS and MACLIB. You cannot use the following commands to add XYZMACS at the end of the list:

```plaintext
UCLIN.
REP DDDEF ( AMACLIB )
  DATASET ( SYS1.AMACLIB )
  VOLUME ( DLIB01 )
  UNIT ( 3380 )
  SHR
REP DDDEF ( BPXLIB1 )
  PATH ( '/path_name1/' )
REP DDDEF ( CMACLIB )
  DATASET ( SYS1.MACLIB )
  SHR
REP DDDEF ( MACLIB )
  DATASET ( SYS1.MACLIB )
  OLD
REP DDDEF ( SMPDATA1 )
  DATASET ( MVSTGT1.SMPDATA1 )
  MOD
REP DDDEF ( SMPDATA2 )
  DATASET ( MVSTGT1.SMPDATA2 )
  MOD
REP DDDEF ( SMPMTS )
  DATASET ( SYS1.SMPMTS )
  OLD
REP DDDEF ( SMPLOG )
  DATASET ( SYS1.SMPLOG )
  MOD
REP DDDEF ( SYSLIB )
  CONCAT ( SMPMTS CMACLIB AMACLIB )
.
ENDUCL.
```

Figure 20. DDDEF entry: sample UNLOAD output

**UCLIN Examples**

You can use the ADD, REP, and DEL UCL statements to change subentries in a DDDEF entry. When you use UCLIN to update a DDDEF entry, keep these points in mind:

- If a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.
- When SMP/E dynamically allocates a concatenation list, the order of the concatenation is the same as that specified in the DDDEF entry. Therefore, you cannot use ADD statements to update a DDDEF entry that already contains a concatenation list. SMP/E would not know the correct position for the new data.

For example, suppose you have a DDDEF entry for the SYSLIB data set that concatenates SMPMTS and MACLIB. You cannot use the following commands to add XYZMACS at the end of the list:
DDDEF entry (distribution, target, and global zone)

```plaintext
SET   BDY(DLIB1)  /* Set to DLIB1 zone. */.
UCLIN /**/
ADD   DDDEF(SYSLIB) /* */
       CONCAT(XYZMACS) /* */
ENDUCL /**/
```

Instead, you can use these commands to replace the entire concatenation list:

```plaintext
SET   BDY(DLIB1)  /* Set to DLIB1 zone. */.
UCLIN /**/
REP   DDDEF(SYSLIB) /* */
       CONCAT(SMPPTS, MACLIB, /* */
               XYZMACS) /* */
ENDUCL /**/
```

The following examples are provided to help you use the DDDEF entry.

**Example 1: Defining global zone DDDEFs for cataloged data sets**
For this example, assume you want to define a DDDEF entry for the SMPPTS and SMPLOG. The data set names are SYS1.SMPPTS and SYS1.GLOBAL.SMPLOG, and both data sets are cataloged on the system that you are running on. Here is an example of how to define the DDDEF entries:

```plaintext
SET   BDY(GLOBAL)  /* Set to global zone. */.
UCLIN /**/
ADD   DDDEF(SMPPTS) /* DDDEF for PTS. */
       DA(SYS1.SMPPTS) /* Data set is cataloged. */
       OLD /* DISP=OLD. */
ADD   DDDEF(SMPLOG) /* DDDEF for LOG. */
       DA(SYS1.SMPLOG) /* Data set is cataloged. */
       MOD /* DISP=MOD. */
ENDUCL /**/
```

**Example 2: Defining DLIB zone DDDEFs for cataloged data sets**
Assume you want SMP/E to dynamically allocate distribution libraries AOS12 and ASAMPLIB during ACCEPT. Assuming these libraries are cataloged on the system you are running SMP/E on, you can use the following commands to define the DDDEF entries:

```plaintext
SET   BDY(DLIB1)  /* Set to DLIB1 zone. */.
UCLIN /**/
ADD   DDDEF(AOS12) /* DLIB dname. */
       DA(SYS1.AOS12) /* Assume cataloged. */
       OLD /* OLD for update. */
ADD   DDDEF(ASAMPLIB) /* DLIB dname. */
       DA(SYS1.ASAMPLIB) /* Assume cataloged. */
       OLD /* OLD for update. */
ENDUCL /**/
```

**Note:** Both data sets have a disposition of OLD. This is because these data sets are used for output when SMP/E calls the system utilities, and you want only one job to update the data sets at a time.

**Example 3: Defining target zone DDDEFs for cataloged data sets**
Assume you want SMP/E to dynamically allocate data sets MODGEN, MACLIB, SMPMTS, and SMPLOG during APPLY. Assuming these data sets are cataloged on the system that you are running SMP/E on, you can use the following commands to define the DDDEF entries:

```plaintext
SET   BDY(TGT1)  /* Set to target zone. */.
UCLIN /**/
ADD   DDDEF(MODGEN ) /* For concatenation. */
       DA(SYS1.MODGEN) /* Data set is cataloged. */
       SHR /* SHR for read. */
ADD   DDDEF(MACLIB ) /* In case updated. */
```
DDDEF entry (distribution, target, and global zone)

```sql
DA(SYS1.MACLIB)  /* Data set is cataloged. */
OLD               /* OLD during update. */
ADD DDDEF(SMPMTS ) /* For update. */
DA(SYS1.SMPMTS)  /* Data set is cataloged. */
OLD               /* OLD for update. */
ADD DDDEF(SMPLIB ) /* For update. */
DA(SYS1.SMPLIB)  /* Data set is cataloged. */
MOD               /* MOD for log. */
ENDUCL            /* */
```

Note: MACLIB and SMPMTS have a disposition of OLD. This is because these data sets are used for output when SMP/E calls the system utilities, and you want only one job to update the data sets at a time.

Example 4: Defining a DDDEF for a noncataloged data set

During APPLY processing, SMP/E may need to refer to some distribution library data sets not cataloged on the system that SMP/E is running on. For example, suppose AMODGEN is a distribution macro library not cataloged on the running system, and you want to use AMODGEN in the SYSLIB concatenation for assemblies. You can use the following commands to define the DDDEF entry:

```sql
SET BDY(TGT1)    /* Set to target zone. */
UCLIN            /* */
ADD DDDEF(AMODGEN ) /* For concatenation. */
DA(SYS1.AMODGEN) /* Data set not cataloged. */
VOLUME(DLIB01)   /* */
UNIT(3330-1)     /* */
SHR              /* SHR for read. */
ENDUCL           /* */
```

Note: This data set has a disposition of SHR. This is because it is not updated during APPLY, but rather is used just for input.

Example 5: Defining a concatenated DDDEF entry

After you have defined DDDEF entries for all the data sets to be included in the SYSLIB concatenation, you can define the DDDEF entry that concatenates the data sets. This entry must specify the concatenation ddname and the order of concatenation. The ddname is the name of the DDDEF entry, and the order of concatenation is the order in which the DDDEF names are specified on the CONCAT operand.

You can use the following commands to define the DDDEF entry:

```sql
SET BDY(TGT1)    /* Set to target zone. */
UCLIN            /* */
ADD DDDEF(SYSLIB) /* ddname for concatenation. */
CONCAT(          /* Concatenation order is */
    SMPMTS       /* SMPMTS first, */
    MACLIB       /* then MACLIB, */
    MODOGEN      /* then MODOGEN, */
    AMODGEN      /* then AMODGEN. */
    )             /* End of list. */
ENDUCL           /* */
```

The SYSLIB concatenation is the same as if the following JCL were used:

```sql
//SYSLIB  DD DSN=SYS1.SMPMTS,DISP=OLD
//       DD DSN=SYS1.MACLIB,DISP=OLD
//       DD DSN=SYS1.MODGEN,DISP=OLD
//       DD DSN=SYS1.AMODGEN,DISP=SHR,
//       UNIT=3330-1,VOL=SER=DLIB01
```
DDDEF entry (distribution, target, and global zone)

Note: SYS1.MACLIB was allocated as DISP=OLD, even though it is not updated during APPLY processing. This is to limit access by any other job while SMP/E is running. If you wanted to use a disposition of SHR when MACLIB is part of the concatenation, you can use the following commands to define an additional DDDEF entry for MACLIB and change the SYSLIB DDDEF entry:

```plaintext
UCLIN
ADD DDDEF(CMACLIB) /* For read access. */
   DA(SYS1.MACLIB) /* Data set is cataloged. */
   SHR /* Change DISP to SHR. */
ADD DDDEF(SYSLIB) /* ddbname for concatenation. */
   CONCAT() /* concatenation order is */
   SMPMTS /* SMPMT first. */
   CMACLIB /* ***** NOTE CHANGE ***** */
   MODGEN /* then MODGEN. */
   AMODGEN /* then AMODGEN. */
   ) /* End of list. */
ENDUCL
```

This corresponds to the following JCL:

```plaintext
//SYSLIB DD DSN=SYS1.SMPMTS,DISP=OLD
// DD DSN=SYS1.CMACLIB,DISP=SHR
// DD DSN=SYS1.MODGEN,DISP=OLD
// DD DSN=SYS1.AMODGEN,DISP=SHR,
// UNIT=3330-1,VOL=SER=DLIB01
```

SYS1.MACLIB is now allocated with DISP=SHR so other jobs can still access it.

Example 6: Defining DDDEFs for temporary data sets

Assume you want SMP/E to dynamically allocate the SMPOUT and SMPWRK1 data sets during ACCEPT. You can use the following commands to define the DDDEF entries:

```plaintext
SET BDY(DLIB1) /* Set to DLIB zone. */
UCLIN /* */
ADD DDDEF(SMPOUT) /* SMPOUT ddbname. */
   SYSOUT(A) /* SYSOUT class. */
ADD DDDEF(SMPWRK1) /* SMPWRK1 ddbname. */
   NEW /* New data set. */
   DELETE /* Delete when finished. */
   TRACKS /* Allocate in tracks. */
   SPACE(25,25) /* prime and secondary space. */
   DIR(25) /* 25 directory blocks. */
   UNIT(SYSDA) /* Allocate on SYSDA. */
ADD DDDEF(SMPWRK2) /* SMPWRK2 ddbname. */
   DATACLAS(FB80CLAS) /* Add DATACLAS name. */
   MGMTCLAS(SMPMCLAS) /* Add MGMTCLAS name. */
   STORCLAS(SMPESCLAS) /* Add STORCLAS name. */
ENDUCL /* */
```

Example 7: Defining a global zone DDDEF for SMPTLIB data sets

Assume you want SMP/E to dynamically allocate the SMPTLIB data sets when it receives SYSMODs packaged in relative files. In addition, you want these data sets to be protected by z/OS SecureWay Security Server. You can use the following commands to define the DDDEF entry:

```plaintext
SET BDY(GLOBAL) /* Set to global zone. */
UCLIN /* */
ADD DDDEF(SMPTLIB) /* SMPTLIB ddbname. */
   DATACLAS(FB80CLAS) /* Add DATACLAS name. */
   DSPREFIX(C87MVSP) /* Data set prefix. */
   MGMTCLAS(SMPMCLAS) /* Add MGMTCLAS name. */
```
**DDDEF entry (distribution, target, and global zone)**

```plaintext
STORCLAS(SMPESCLS) /* Add STORCLAS name. */
PROTECT /* Request SecureWay Security */
    /* Server protection. */
ENDUCL
```

**Note:** No initial or final disposition is specified. This is because when SMP/E dynamically allocates SMPTLIB data sets, it automatically specifies the initial and final disposition based on the command it is processing.

**Example 8: Defining a DLIB zone DDDEF for SMPTLIB data sets**

Assume you want SMP/E to dynamically allocate the SMPTLIB data sets when it accepts SYSMODs packaged in relative files. You can use the following commands to define the DDDEF entry:

```plaintext
SET
    BDY(DLIB1) /* Set to DLIB zone. */
UCLIN /* */
ADD
    DDDEF(SMPTLIB) /* SMPTLIB ddname. */
    VOLUME(DLIB01) /* Volumes used - DLIB01 */
    DLIB02 /* DLIB02 */
    DLIB03 /* DLIB03. */
    UNIT(3380) /* Allocate on 3380. */
ENDUCL /* */
```

**Note:** No initial or final disposition is specified. This is because when SMP/E dynamically allocates SMPTLIB data sets, it automatically specifies the initial and final disposition based on the command it is processing.

**Example 9: Protecting data sets**

Assume you have previously defined your SMPMTS and SMPSTS data sets outside of SMP/E and protected them with z/OS SecureWay Security Server. You now want to have these dynamically allocated, and you also want to keep a record that they are protected by z/OS SecureWay Security Server. You can use the following commands to define the DDDEF entries:

```plaintext
SET
    BDY(TGT1) /* Set to target zone. */
UCLIN /* */
ADD
    DDDEF(SMPMTS) /* SMPMTS ddname. */
    DA(SYS1.SMPMTS) /* Data set is cataloged. */
    OLD /* OLD for update. */
    PROTECT /* Protected by SecureWay Security Server. */
ADD
    DDDEF(SMPSTS) /* SMPSTS ddname. */
    DA(SYS1.SMPSTS) /* Data set is cataloged. */
    OLD /* OLD for update. */
    PROTECT /* Protected by SecureWay Security Server. */
ENDUCL /* */
```

**Example 10: Defining pathnames in a UNIX file system**

Assume a product you plan to add to your system contains load modules and elements that will reside in a UNIX file system. You want to have the pathnames dynamically allocated instead of having DD statements for them in a cataloged procedure. You can use the following commands to define the DDDEF entry for each pathname:

```plaintext
ADD
    DDDEF(BPXLIB1) /* Specify DDDEF name. */
    PATH('/path_name1') /* Define pathname. */
ADD
    DDDEF(BPXLIB2) /* Specify DDDEF name. */
    /* */
ADD
    DDDEF(BPXLIB3) /* Specify DDDEF name. */
    /* */
ADD
    DDDEF(BPXLIB4) /* Specify DDDEF name. */
    /* */
```

**Chapter 5. SMP/E data set entries**

209
DDDEF entry (distribution, target, and global zone)

/* define pathname. */
/* */
ENDUCL
/* */
DLIB entry (distribution and target zone)

The DLIB entry describes a distribution library that was totally copied to a target library. It is created during JCLIN processing when SMP/E encounters a COPY or COPYMOD statement without any SELECT statements. The INDD value on the COPY or COPYMOD statement becomes the name of the DLIB entry, and the OUTDD value on the COPY or COPYMOD statement becomes the SYSLIB value in the DLIB entry. For additional information, see the “Processing” section of the JCLIN command chapter in [SMP/E Commands].

SMP/E uses the DLIB entry to determine where elements and load modules should be applied, as follows:

- **Element entries other than MOD.** If there is no SYSLIB value either in the element entry or on the element MCS, SMP/E looks for a DLIB entry whose name matches the DISTLIB value for the element. SMP/E applies the element to the library indicated by the SYSLIB value in the DLIB entry, and adds that SYSLIB value to the element entry.

- **MOD entries.** For MOD entries, processing is slightly different, because MOD entries do not contain a SYSLIB subentry.
  - For a MOD entry that points to an LMOD entry, SMP/E checks whether the DISTLIB value in the MOD entry matches the name of a DLIB entry. If there is a match, and if the SYSLIB value in the DLIB entry is different from the ones in the LMOD entry, the SYSLIB value in the DLIB entry is used in addition to the LMOD’s SYSLIB values.
  - For a MOD entry that does not point to an LMOD entry, SMP/E checks whether the DISTLIB value in the MOD entry matches the name of a DLIB entry. If there is a match, SMP/E assumes a load module with the same name as the MOD entry should exist in the library specified by the SYSLIB value in the DLIB entry.
    - If there is already an LMOD entry with the same name as the MOD entry, and that LMOD entry does not already contain two SYSLIB values, SMP/E adds the SYSLIB value from the DLIB entry to the LMOD entry.
    - If there is no LMOD entry with the same name as the MOD entry, SMP/E creates one and adds the SYSLIB value from the DLIB entry to the LMOD entry.

Lastly, SMP/E updates the MOD entry by adding an LMOD subentry for the LMOD entry that was updated or created.

**Subentries**

These are the subentries for the DLIB entry as they appear in the LIST output:

- **name**
  - The name of the distribution library represented by the DLIB entry.
  - The name can contain from 1 to 8 alphanumeric characters.

- **LASTUPD**
  - Identifies the cause of the last change to this DLIB entry.
  - The UCL operand is **LASTUPD(value)**. This subentry can contain one of the following values:
    - **JCLIN**
      - Indicates that the change was made during JCLIN command processing.
    - **UCLIN**
      - Indicates that the change was made as a result of UCLIN processing.
DLIB entry (distribution and target zone)

**sysmod_id**
indicates that the change was made during the installation of the indicated SYSMOD.

The SYSMOD ID must contain 7 alphanumeric characters.

**LASTUPD TYPE**
indicates how the entry was last changed.

The UCL operand is **LASTUPDTYPE(value)**. This subentry can contain one of the following values:
- **ADD** The entry has been added.
- **UPD** The entry has been updated.

**SYSTEM LIBRARIES**
identifies the ddnames of the target libraries into which the distribution library should be copied.

The UCL operand is **SYSLIB(ddname...)**.
- A DLIB entry used for modules can contain one or two SYSLIB values.
- A DLIB entry used for macros, source, or data elements should contain only one SYSLIB value.
- The ddnames can contain from 1 to 8 alphanumeric characters.

**LIST Examples**
To list all the DLIB entries in a particular zone, you can use the following commands:

**SET BDY(TGT1) /* Set to requested zone. */.**
**LIST DLIB /* List all DLIB entries. */.**

To list specific DLIB entries, you can use these commands:

**SET BDY(TGT1) /* Set to requested zone. */.**
**LIST DLIB(AMACLIBhổng) /* List only these two */.**
**MACDLB01 */.**

The format of the LIST output for each DLIB entry is the same for both of these commands. The only difference is the number of DLIB entries listed. **Figure 21** is an example of LIST output for DLIB entries.

---

**Figure 21. DLIB entry: sample LIST output**
UNLOAD Examples

To dump the DLIB entries in UCL format, you can use the UNLOAD command. To unload all the DLIB entries in a particular zone, you can use the following commands:

```bash
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD DLIB /* Unload all DLIB entries. */.
```

To unload specific DLIB entries, you can use these commands:

```bash
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD DLIB(AMACLIB /* Unload only these two */
            MACDLB01) /* entries. */.
```

The format of the UNLOAD output for each DLIB entry is the same for both of these commands. The only difference is the number of DLIB entries listed. Figure 22 is an example of UNLOAD output for DLIB entries.

```
UCLIN.
REP DLIB ( AMACLIB )
SYSLIB ( MACLIB )
.
REP DLIB ( MACDLB01 )
SYSLIB ( MACLIB MACTGT01 )
.
REP DLIB ( MODDLB01 )
LASTUPD ( JXY1102 )
LASTUPDTYPE ( ADD )
SYSLIB ( LPALIB MDTGT01 )
.
REP DLIB ( MODDLB02 )
LASTUPD ( JXY1121 )
LASTUPDTYPE ( UPD )
SYSLIB ( LPALIB MDTGT02 )
.
ENDUCL.
```

Figure 22. DLIB entry: sample UNLOAD output

UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the DLIB entry. When you use UCLIN to update a DLIB entry, keep these points in mind:

- After the UCLIN changes are made, the DLIB entry must contain at least a SYSLIB subentry. Otherwise, there is not enough information in the entry to indicate where elements should be installed.
- If a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.

Example: Changing the destination of a copied library

Assume you are doing a system generation and have completed the following steps:

1. Performed stage 1 system generation
2. Allocated new target zone
3. Copied distribution zone to new target zone
4. Ran SMP/E JCLIN command
### DLIB entry (distribution and target zone)

You now want to change the target library into which a module distribution library has been totally copied. Assume that the DLIB was MODDLB01, that it was previously copied to LINKLIB, and that it is now copied to LPALIB. You can do this with the following UCL statements:

```ucl
SET BDY(TGT1) /* Set to target zone. */.
UCLIN /* */.
REP DLIB(MODDLB01) /* Module DLIB. */.
SYSLIB(LPALIB) /* Now copied to LPALIB. */.
/* No longer in LINKLIB. */.
ENDUCL /* */.
```

If the modules should also be copied into LPALIB, the following UCL can be used:

```ucl
SET BDY(TGT1) /* Set to target zone. */.
UCLIN /* */.
ADD DLIB(MODDLB01) /* Module DLIB. */.
SYSLIB(LPALIB) /* Now copied to LPALIB. */.
/* SYSLIB added, not replaced. */.
ENDUCL /* */.
```

In both cases, you must take care of copying the modules from the distribution library. SMP/E does not process elements when it records UCL changes.

Now that the UCL changes are made, when SMP/E installs SYSMODs that update MODDLB01, SMP/E checks the DLIB entry for MODDLB01, determines that the modules are copied to LPALIB, and creates or modifies the LMOD entries (with the same name as the MOD entries) to indicate a copy to LPALIB.

**Note**: This technique works before you actually install any service. If you want to change (not add) another library in the DLIB copy list, you must find all the MOD, MAC, SRC, and LMOD entries with a SYSLIB value matching the old target library, and then change that value using UCLIN. If you do not do this, SMP/E continues to copy entries with the old SYSLIB value to the old library (and also, in some cases, to the new library).
DLIBZONE entry (distribution zone)

The DLIBZONE entry contains information SMP/E uses to process a specific distribution zone and the associated distribution libraries. It is created by UCLIN and must be defined before you can do any other processing for that distribution zone.

Subentries

These are the subentries for the DLIBZONE entry as they appear in the LIST output:

name

is the name of the distribution zone. You assign the name when the zone is created.

The name can contain from one to seven alphanumeric characters (A through Z, 0 through 9) or national characters ($, #, @). The first character must be alphabetic.

ACCJCLIN

indicates that JCLIN is to be saved in the distribution zone whenever a SYSMOD containing inline JCLIN is accepted.

The UCL operand is ACCJCLIN.

• ACCJCLIN should be specified only for zones in which all the products have been installed with SMP/E Release 3, or later.
• To save inline JCLIN for a product at ACCEPT time, you must first accept that product using SMP/E Release 3, or later, and have ACCJCLIN set in the DLIBZONE entry. From then on, you must keep ACCJCLIN set in the DLIBZONE entry. This ensures that any time you accept service for that product, its JCLIN is updated in the distribution zone. For more information, see the section on inline JCLIN in the ACCEPT command chapter in SMP/E Commands.

OPTIONS

is the name of the OPTIONS entry in the global zone that should be used when processing this distribution zone. For more information, see "OPTIONS entry (global zone)" on page 292.

The UCL operand is OPTIONS(name).

• The name can contain from one to eight alphanumeric characters.
• This name can be overridden by using the OPTIONS parameter on the SET command. For more information on the SET command, see SMP/E Commands.
• If no OPTIONS entry name is specified, SMP/E uses a set of default utility values when processing this distribution zone. For more information, see "OPTIONS entry (global zone)" on page 292.

RELATED

is the name of the target zone to which this distribution zone is related. A distribution zone is related to the target zone that was built from these distribution libraries, such as during system generation.

The UCL operand is RELATED(zone).

• The zone name can contain from one to seven alphanumeric characters.
• Although the entry can be defined without this subentry, you must define the subentry before you can install any SYSMODs into the distribution libraries.
DLIBZONE entry (distribution zone)

SREL

lists the system releases to be supported within this distribution zone.

The UCL operand is SREL(srel...).

- The SREL must contain four alphanumeric characters, usually one alphabetic character followed by three numeric characters. These are the SRELs defined by IBM:

<table>
<thead>
<tr>
<th>System</th>
<th>SREL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2</td>
<td>P115</td>
</tr>
<tr>
<td>CICS</td>
<td>C150</td>
</tr>
<tr>
<td>IMS</td>
<td>P115</td>
</tr>
<tr>
<td>MVS</td>
<td>Z038</td>
</tr>
<tr>
<td>NCP</td>
<td>P004</td>
</tr>
</tbody>
</table>

- Although the entry can be defined without this subentry, you must define the subentry before you can install any SYSMODs in the distribution libraries.

Note: Although you can support multiple products with different SREL values from one distribution zone, those products are still subject to all other restrictions related to combining products in one zone. The most common reason for not being able to combine products is common element names. For example, modules or macros with the same name are found in both products, but reside in different libraries.

UPGLEVEL

indicates the highest SMP/E release level that is allowed to make incompatible changes to the distribution zone. Before making an incompatible change to the distribution zone, SMP/E will check the UPGLEVEL value for that zone. If the release level of SMP/E is higher than the zone’s UPGLEVEL value, SMP/E will not make the incompatible change.

The UPGLEVEL value is in the form vr.pp, where vr represents the version and release of SMP/E and pp represents the PTF level of SMP/E.

There is no UCL support for this subentry. When a zone is created by SMP/E using the UCLIN command or the Administration dialog, SMP/E sets the UPGLEVEL subentry value for that zone to the level of SMP/E used to create the zone. The UPGRADE command is used to change the UPGLEVEL subentry value for a zone.

ZDESC

is a user-written description for this zone.

The UCL operand is ZONEDESCRIPTION(text).

- The zone description can be in single-byte characters (such as English alphanumeric characters) or in double-byte characters (such as Kanji).
- The zone description can contain up to 500 bytes of data, including blanks. (For double-byte data, the 500-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters.) Extra blanks are deleted. All data beyond column 72 is ignored, including blanks.
- The zone description cannot be only blanks.
- If parentheses are included in the text, they must be in matched pairs.

LIST Examples

To list the DLIBZONE entry for a particular distribution zone, you can use the following commands:
UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the DLIBZONE entry. When you use UCLIN to update a DLIBZONE entry, remember that if a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.

The following examples are provided to help you use the DLIBZONE entry.

Example 1: Defining a DLIBZONE entry

Assume you are about to add a new function to your system and want to define a separate distribution zone for it named DLIB2. The OPTIONS entry you plan to use is OPTDLIB2, and the SREL for the SYSMOD is Z038. The distribution zone is in data set SMPE.SMPCSI.CSI. After installing the function in the distribution libraries, you plan to do a system generation to build a set of target libraries. The target zone for those libraries is TGT2. The following UCLIN can be used to define the new zone.

```
SET BDY(DLIB) /* Set to requested DLIB */.
LIST DLIBZONE /* List DLIBZONE entry */.
```

**Note:** Even if the OPTIONS entry or TARGETZONE entry has not yet been defined, you can still refer to it in the DLIBZONE entry. However, you must
DLIBZONE entry (distribution zone)

create the entry before you process this distribution zone. For examples of
defining OPTIONS entries, see "OPTIONS entry (global zone)" on page 292.
For examples of defining TARGETZONE entries, see "TARGETZONE entry
(target zone)" on page 346.

Example 2: Formatting a zone description

Assume you enter the following zone description with the first line ending in
column 72 and the second line starting in column 1:

---+----1----+----2---- ... ---5----+----6----+----7----
SET BDY(DLIB1) /* Set to DLIB zone. */.
UCLIN /* UCLIN for DZONE entry */.
ADD DZONE(DLIB1) /* to set up. */.
     ZDESC( THE DLIB1 ZONE) /* THIS IS THE DESCRIPTION FOR
     THIS IS THE DESCRIPTION FOR
     THE DLIB1 ZONE)
     /* End of zone description. */.
ENDUCL /* End DLIB zone update. */.

Because there is no blank between the word ending in column 72 and the next
word starting in column 1, SMP/E runs the two together.

The words in a zone description, even words that end in column 72, must be
separated by blanks. To format the zone description in this example correctly, you
can put a blank at the beginning of the second line:

---+----1----+----2---- ... ---5----+----6----+----7----
SET BDY(DLIB1) /* Set to DLIB zone. */.
UCLIN /* UCLIN for DZONE entry */.
ADD DZONE(DLIB1) /* to set up. */.
     ZDESC( THE DLIB1 ZONE) /* THIS IS THE DESCRIPTION FOR
     THE DLIB1 ZONE)
     /* End of zone description. */.
ENDUCL /* End DLIB zone update. */.

Because there is a blank explicitly coded between the word ending in column 72
and the word starting in column 1, SMP/E does not run the words together.
FEATURE entry (global zone)

The FEATURE entry describes a collection of function SYSMODS called a feature. An SMP/E feature may be associated with an orderable software feature.

Subentries

name is the name of this feature.

DESCRIPTION describes the software feature.

The UCL operand is DESCRIPTION(description).

FMID specifies the FMIDs that make up this software feature. There can be multiple FMID subentries associated with a single feature.

The UCL operand is FMID(fmid,...).

PRODUCT identifies the product with which this feature is associated.

The UCL operand is PRODUCT(prodid, vv, rr, mm).

RECDATE specifies the date on which the feature was received.

There is no UCL support for this subentry.

RECTIME specifies the time at which the feature was received.

There is no UCL support for this subentry.

UCLDATE specifies the date on which the feature was last processed using the UCLIN command.

There is no UCL support for this subentry.

UCLTIME specifies the time at which the feature was last processed using the UCLIN command.

There is no UCL support for this subentry.

REWORK identifies the level of this feature, which was received again for minor changes.

There is no UCL support for this subentry.

LIST Examples

To list all the FEATURE entries in a particular zone, you can use the following commands:

```plaintext
SET BDY(GLOBAL)  /* Set to global zone. */.
LIST FEATURE  /* List all FEATURE entries. */.
```

To list specific FEATURE entries, you can use these commands:

```plaintext
SET BDY(GLOBAL)  /* Set to global zone. */.
LIST FEATURE(OS3250BA)  /* List only these two */
                        FEATURE(OS3250LD)  /* entries. */.
```
FEATURE entry (global zone)

The format of the LIST output for each FEATURE entry is the same for both of these commands. The only difference is the number of FEATURE entries listed. Figure 24 shows an example of LIST output for FEATURE entries. FEATURE entries are listed alphanumerically by name.

By specifying the FORFMID operand, you can reduce the number of FEATURE entries listed. When FORFMID is specified, SMP/E lists a FEATURE entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to list FEATURE entries whose FMIDs either are defined in FMIDSET ZOSSET or are HMP1E00, you can use these commands:

```
SET BDY(GLOBAL) /* Set to global zone. */.
LIST FEATURE /* List all FEATURE entries */.
   FORFMID(ZOSSET /* for the ZOSSET FMIDSET */
   HMP1E00) /* and FMID HMP1E00. */.
```

**UCLIN Examples**

You can use the ADD, REP, and DEL UCL statements to change subentries in the FEATURE entry. When you use UCLIN to update a FEATURE entry, keep in mind that after the UCLIN changes are made, the FEATURE entry must contain at least the DESCRIPTION and PRODUCT subentries.

**Example: Adding a FEATURE entry**

Assume you have a feature, named Sample Feature, for which you wish to create a description and put in an entry named SAMPFEAT. You could set up a FEATURE entry as follows:

```
SET BDY(GLOBAL) /* Set to global zone */.
UCLIN /* Start UCLIN processing */.
   ADD FEATURE(SAMPFEAT) /* Identify the feature: */.
      DESCRIPTION(Sample Feature) /* - Name */.
      PRODUCT(1234-ABC,02.05.00) /* - Owning product */.
      FMID(XYZ1234) /* - FMID */.
   ENDUCL /* End UCLIN processing */.
```
FMIDSET entry (global zone)

The FMIDSET entry defines a group of FMIDs for use in limiting the SYSMODs processed by an SMP/E command. For example, you can specify an FMIDSET on the FORFMID operand of the APPLY command to process only SYSMODs applicable to one of the FMIDs in the FMIDSET.

Subentries

These are the subentries for the FMIDSET entry as they appear in the LIST output:

name

is the name of the FMIDSET.

The name can contain from 1 to 8 alphanumeric characters.

FMID

lists the function SYSMODs (that is, FMIDs) that are to be part of this FMIDSET.

The UCL operand is FMID(sysmod_id...).

The SYSMOD ID must contain 7 alphanumeric characters.

LIST Examples

To list all the FMIDSET entries in a global zone, you can use the following commands:

```
SET BDY(GLOBAL) /* FMIDSET in global only. */.
LIST FMIDSET /* list all FMIDSET entries. */.
```

To list specific FMIDSET entries in a global zone, you can use these commands:

```
SET BDY(GLOBAL) /* FMIDSET in global only. */.
LIST FMIDSET(ALLSET /* List only these two */
              XXSET) /* entries. */.
```

The format of the LIST output for each FMIDSET entry is the same for both of these commands. The only difference is the number of FMIDSET entries listed.

Figure 25 is an example of LIST output for FMIDSET entries.

```
FMIDSET Entries

<table>
<thead>
<tr>
<th>Name</th>
<th>FMID</th>

```

Figure 25. FMIDSET entry: sample LIST output
UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in an FMIDSET entry. When you use UCLIN to update an FMIDSET entry, keep these points in mind:

- After the UCLIN changes are made, the FMIDSET entry must contain at least an FMID subentry. Otherwise there is not enough information in the entry for SMP/E to use the entry.
- If a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.

The following examples are provided to help you use the FMIDSET entry.

Example 1: Defining an FMIDSET entry

Assume you have four function SYSMODs installed, JXX1102, JXX1121, JXX1122, and JXX1123, and that when installing service you would like to be able to install just the PTFs for these products. You could set up an FMIDSET entry as follows:

```
SET BDY(GLOBAL) /* FMIDSETs only in global. */.
UCLIN /* */.
ADD FMIDSET(XXSET) /* Define FMIDSET name. */.
FMID(FXX1102 /* Define function SYSMODs */.
  JXX1121 /* to be part of set. */.
  JXX1122 /* */.
  JXX1123) /* */.
ENDUCL /* */.
```

You can also use the FORFMID operand on the APPLY as follows:

```
SET BDY(TGT1) /* Set for APPLY to TGT1. */.
APPLY FORFMID(XXSET) /* Apply XX PTFs. */.
```

Example 2: Modifying an FMIDSET entry

Once an FMIDSET has been defined, it can be modified as new function SYSMODs are installed or as existing function SYSMODs are replaced. For example, starting with the FMIDSET from the previous example, assume you install a new feature, JXX1124, that deletes JXX1121, and that you want to modify the FMIDSET definition. You can do this as follows:

```
SET BDY(GLOBAL) /* FMIDSETs only in global. */.
UCLIN /* */.
REP FMIDSET(XXSET) /* Define FMIDSET name. */.
FMID(FXX1102 /* Define function SYSMODs */.
  JXX1121 /* JXX1121 left out. */.
  JXX1122 /* */.
  JXX1123 /* */.
  JXX1124) /* JXX1124 added. */.
ENDUCL /* */.
```

You can also do the following:

```
SET BDY(GLOBAL) /* FMIDSETs only in global. */.
UCLIN /* */.
DEL FMIDSET(XXSET) /* Define FMIDSET name. */.
FMID(JXX1121) /* Delete JXX1121 from set. */.
ADD FMIDSET(XXSET) /* Define FMIDSET name. */.
FMID(JXX1124) /* Add new FMID. */.
ENDUCL /* */.
The result in both cases is the same. The choice of which method to use most likely depends on the number of FMIDs defined in the FMIDSET.
GLOBALZONE entry (global zone)

The GLOBALZONE entry contains processing-related information for SMP/E. It is also used by SMP/E as an index to target and distribution zones, either in the same CSI or a different CSI data set. The GLOBALZONE entry is created by UCLIN and must be defined before you can do any other processing for that global zone.

Subentries

These are the subentries for the GLOBALZONE entry as they appear in the LIST output:

FMID
lists the function SYSMODs for which SMP/E is to receive service.

The UCL operand is FMID(sysmod_id...).

The SYSMOD ID must contain seven alphanumeric characters.

OPTIONS
is the name of the OPTIONS entry in the global zone that should be used in processing this global zone. For more information, see "OPTIONS entry (global zone)" on page 292.

The UCL operand is OPTIONS(name).

- The name can contain from one to eight alphanumeric characters.
- This name can be overridden by using the OPTIONS parameter on the SET command. For more information on the SET command, see SMP/E Commands.
- If no OPTIONS entry name is specified, SMP/E uses a set of default utility values when processing the global zone. For more information, see "OPTIONS entry (global zone)" on page 292.

SREL
lists the system releases to be supported in this global zone.

The UCL operand is SREL(srel...).

The SREL must contain four alphanumeric characters, usually one alphabetic character followed by three numerics. These are the SRELs defined by IBM:

<table>
<thead>
<tr>
<th>System</th>
<th>SREL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2</td>
<td>P115</td>
</tr>
<tr>
<td>CICS</td>
<td>C150</td>
</tr>
<tr>
<td>IMS</td>
<td>P115</td>
</tr>
<tr>
<td>MVS</td>
<td>Z038</td>
</tr>
<tr>
<td>NCP</td>
<td>P004</td>
</tr>
</tbody>
</table>

Note: Although you can support multiple products with different SREL values from one global zone, those products are still subject to all other restrictions related to combining products in one zone. The most common reason for not being able to combine products is common element names. For example, modules or macros with the same name are found in both products, but reside in different libraries.

UPGLEVEL
indicates the highest SMP/E release level that is allowed to make incompatible changes to the global zone. Before making an incompatible change to the
GLOBALZONE entry (global zone)

global zone, SMP/E will check the UPGLEVEL value for that zone. If the release level of SMP/E is higher than the zone’s UPGLEVEL value, SMP/E will not make the incompatible change.

The UPGLEVEL value is in the form vr.pp, where vr represents the version and release of SMP/E and pp represents the PTF level of SMP/E.

There is no UCL support for this subentry. When a zone is created by SMP/E using the UCLIN command or the Administration dialog, SMP/E sets the UPGLEVEL subentry value for that zone to the level of SMP/E used to create the zone. The UPGRADE command is used to change the UPGLEVEL subentry value for a zone.

ZDESC

is a user-written description for this zone.

The UCL operand is ZONEDESCRIPTION{text}.

- The zone description can be in single-byte characters (such as English alphanumeric characters) or in double-byte characters (such as Kanji).
- The zone description can contain up to 500 bytes of data, including blanks.
  (For double-byte data, the 500-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters.) Extra blanks are deleted. All data beyond column 72 is ignored, including blanks.
- The zone description cannot be only blanks.
- If parentheses are included in the text, they must be in matched pairs.

ZONEINDEX

identifies all the target zones and distribution zones associated with this global zone. This list is used by SMP/E to determine the data set in which the zone resides and the type of zone.

For ADD and REP statements, the UCL operand is ZONEINDEX{name,dsn,type}...

For DEL statements, the UCL operand is ZONEINDEX{name}...

- ZONEINDEX can also be specified as ZINDEX.

  - name is the name of the zone. The name can contain from one to seven alphanumeric characters (A through Z, 0 through 9) or national characters ($, #, @). The first character must be alphabetic.

  - dsn is the fully qualified name of the data set in which the zone resides.

  - type is the zone type, either TARGET or DLIB.

The ZONEINDEX is only a pointer to a zone. Changes you make to a ZONEINDEX do not affect the associated zone. Therefore, you cannot add, rename, or delete a zone by simply adding, replacing, or deleting its ZONEINDEX. However, these are some other commands you can use:

- Adding a zone: To add a zone, you can use the following commands, depending on the particular situation:
  - UCLIN to add a ZONEINDEX, then UCLIN to define the DZONE or TZONE entry
  - ZONECOPY
  - ZONERENAME
  - ZONEEXPORT, UCLIN for the ZONEINDEX, and ZONEIMPORT

- Renaming a zone: To rename a zone, you must use the following command:
  - ZONERENAME
GLOBALZONE entry (global zone)

- Deleting a zone: To delete a zone, you can use the following commands, depending on the particular situation:
  - ZONEDELETE
  - ZONEEXPORT

For more information about any of these commands, see the chapter on that command.

LIST Examples

To list all the GLOBALZONE entry, you can use the following commands:

```
SET BDY(GLOBAL)  /* Set to global zone. */
LIST GLOBALZONE  /* List GLOBALZONE entry. */
```

Figure 26 is an example of LIST output for a GLOBALZONE entry.

</tbody>
</table>

Figure 26. GLOBALZONE entry: sample LIST output

UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the GLOBALZONE entry. When you use UCLIN to update a GLOBALZONE entry, keep these points in mind:

- After the UCLIN changes are made, the GLOBALZONE entry must contain at least one of these subentries: FMID, OPTIONS, SREL, or ZONEINDEX. Otherwise, there is not enough information in the entry for SMP/E to use the entry.
- If a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.

The following examples are provided to help you use the GLOBALZONE entry.

Example 1: Defining the GLOBALZONE entry

To perform any SMP/E processing, you must first define the GLOBALZONE entry. Given the following assumptions:

- You are supporting functions JXY1102, JXY1121, JXY1122, and JXY1123 from this global zone.
- You are supporting system releases Z038, P115, and R020, and I121.
- You are eventually going to define two target zones, TGT1 and TGT2, to exist on SYS1.TGT.SMPCSI.CSI, and two distribution zones, DLIB1 and DLIB2, to exist on SYS1.DLIB.SMPCSI.CSI.
- The OPTIONS entry used is OPTGBL.
The following UCLIN can be used to define the GLOBALZONE entry:

```
SET  BDY(GLOBAL)  /* Set to global zone. */.
UCLIN /* */.
ADD  GLOBALZONE  /* Define global now. */
   /* Identify SRELs. */
   SREL(2038,P115, /* */
        R020,1115, /* */
        FMID(JXY1102, /* Identify functions. */
            JXY1121, /* */
            JXY1122, /* */
            JXY1123) /* */
   OPTIONS(OPTGBL)  /* OPTIONS entry to be used. */
   ZONEINDEX( /* */
      (TGT1,SYSL.TGT.SMPCS.S)( /* */
        (TGT2,SYSL.TGT.SMPCS.S)( /* */
        (DLIB1,SYSL.DLIB.SMPCS.S,DLIB) /* */
        (DLIB2,SYSL.DLIB.SMPCS.S,DLIB) /* */
      ) /* */
   ) /* */
ENDUCL /* */
```

**Note:** Even though the OPTIONS entry has not been set up yet, you can still refer to it in the GLOBALZONE entry. The same is true for the target zone name. However, the OPTIONS entry must be created before the global zone is processed. For examples of setting up the OPTIONS entries, see "OPTIONS entry (global zone)" on page 292.

**Example 2: Deleting two ZONEINDEX entries**

Assume you decide not to create the TGT1 target zone and the DLIB1 distribution zone defined in the ZONEINDEX of example 1. You should delete the entries for those two zones by using UCL as follows:

```
SET  BDY(GLOBAL)  /* Set to global zone. */.
UCLIN /* */.
DEL  GLOBALZONE  /* Define global now. */
   ZONEINDEX( /* */
      (TGT1) /* Delete TGT1 entry. */
      (DLIB1) /* Delete DLIB1 entry. */
   ) /* */
ENDUCL /* */
```

**Note:** The CSI data set name and the zone type operands are not required for a delete, although the open and close parentheses around the zones are still required.

**Example 3: Formatting a zone description**

Assume you enter the following zone description with the first line ending in column 72 and the second line starting in column 1:

```
----+----1----+----2----  ...  ----5----+----6----+----7--
SET  BDY(GLOBAL)  /* Set to global zone. */.
UCLIN /* UCLIN for GZONE entry */.
ADD  GZONE /* to set up. */.
THE GLOBAL ZONE( /* THIS IS THE DESCRIPTION FOR */
   ZDESC( /* */
      THIS IS THE DESCRIPTION FOR ) /* */
ENDUCL /* End global zone update. */.
```

Because there is no blank between the word ending in column 72 and the next word starting in column 1, SMP/E runs the two together.
GLOBALZONE entry (global zone)

The words in a zone description, even words that end in column 72, must be separated by blanks. To format the zone description in this example correctly, you can put a blank at the beginning of the second line:

```plaintext
----+----1----+----2---- ... ----5----+----6----+----7--
SET   BDY(GLOBAL) /* Set to global zone. */
UCLIN  /* UCLIN for GZONE entry */
ADD    GZONE  /* to set up. */
       ZDESC( THIS IS THE DESCRIPTION FOR
THE GLOBAL ZONE)
       /* End of zone description. */
ENDUCL  /* End global zone update. */
```

Because there is a blank explicitly coded between the word ending in column 72 and the word starting in column 2, SMP/E does not run the words together.

**Example 4: Renaming an SMPCSI data set and updating a ZONEINDEX**

Assume you have a target zone named TGT1 that resides in a data set named SMPE.TEST.TGT1.CSI, and you decide to rename the data set to SYS1.PROD.TGT1.CSI. After renaming the data set, you must use UCLIN to update the ZONEINDEX for the target zone in the global zone, as follows:

```plaintext
SET   BDY(GLOBAL) /* Set to global zone. */
UCLIN  /* UCLIN for GZONE entry. */
DEL   GZONE
       ZINDEX( (TGT1) ) /* Delete old TGT1 zone. */
ADD    GZONE
       ZINDEX( (TGT1, SYS1.PROD.TGT1.CSI, TARGET) )
       /* Supply new TGT1 zone. */
ENDUCL  /* End global zone update. */
```

You cannot use REP to replace a single zone in the ZONEINDEX list. REP will cause the entire list of zones to be replaced. Instead, you must first delete the zone from the ZONEINDEX list, and then add the zone to the list with the new SMPCSI data set name.
Hierarchical file system element entry (distribution and target zone)

The hierarchical file system element entry describes an element that exists in a distribution library or a UNIX file system. A hierarchical file system entry is created the first time you install a SYSMOD containing an MCS for a hierarchical file system element that does not yet have an entry in the CSI data set.

SMP/E records the function and service level of the hierarchical file system element in the entry. Once a hierarchical file system element entry exists, it is updated as subsequent SYSMODs affecting the hierarchical file system element are installed.

Table 4 on page 26 shows the types of entries used for hierarchical file system elements. Some types of elements may be translated into several languages. In these cases, the entry type contains xxx, which represents the language used for the element. If an element was not translated, the entry type does not contain any xxx value. Table 5 on page 27 shows the xxx values and the languages they represent.

Subentries

These are the subentries for the hierarchical file system element entries as they appear in the LIST output:

*name*

is the name of the hierarchical file system element represented by the entry.

The name can contain 1–8 uppercase alphabetic, numeric, or national ($, #, @) characters.

**BINARY or TEXT**

indicates the installation mode to be used when the HFS copy utility is invoked to install the element into a UNIX file system.

The UCL operand is **BINARY** or **TEXT**.

- *Binary* mode means that the element is installed in its entirety as a data stream, with no breaks for logical records.
- *Text* mode means that the element is installed with breakpoints for logical records.
- BINARY and TEXT are mutually exclusive.
- If there is no mode indicator in the hierarchical file system element entry, the HFS copy utility determines how to install the element.

**DISTLIB**

specifies the ddname of the distribution library for the hierarchical file system element.

The UCL operand is **DISTLIB(ddname)**.

- The ddname can contain any uppercase alphabetic, numeric, or national ($, #, @) character, and can be 1–8 characters long.
- The DISTLIB subentry is required. Without it, SMP/E cannot process any changes for the hierarchical file system element.

**FMID**

identifies the functional owner of this hierarchical file system element. The functional owner is the last function SYSMOD that replaced this element.

The UCL operand is **FMID(sysmod_id)**.

The SYSMOD ID must contain 7 uppercase alphabetic, numeric, or national ($, #, @) characters.
Hierarchical file system element entry (distribution and target zone)

LASTUPD
identifies the cause of the last change to this hierarchical file system element entry.
The UCL operand is LASTUPD(value). This subentry can contain one of the following values:

UCLIN
indicates that the change was made as a result of UCLIN processing.

sysmod-id
indicates that the change was made during the installation of the indicated SYSMOD.
The SYSMOD ID must contain 7 uppercase alphabetic, numeric, or national ($, #, @) characters.

LASTUPD TYPE
indicates how the entry was last changed.
The UCL operand is LASTUPDTYPE(value). This subentry can contain one of the following values:
ADD The entry was added.
UPD The entry was updated.

LINK
specifies a list of alternative names by which this hierarchical file system element can be known in a UNIX file system. The full name is produced by concatenating the specified linkname with the UNIX file system directory identified by the SYSLIB subentry.

In LIST output, linknames are always enclosed in single apostrophes. If an apostrophe is part of a linkname, it is always shown as two consecutive apostrophes in LIST output.
The UCL operand is LINK(linkname...).
• The linkname can be from 1 to 1023 characters.
• A linkname can be enclosed in single apostrophes ('). A linkname must be enclosed in single apostrophes if any of the following is true:
  – The linkname contains lowercase alphabetic characters.
  – The linkname contains a character that is not uppercase alphabetic, numeric, national ($, #, or @), slash (/), plus (+), hyphen, period, or ampersand (&).
  – The linkname spans more than one line in the control statement.
The single apostrophes used to enclose a linkname (the delimiters) do not count as part of the 1023-character limit.
• Any apostrophes specified as part of a linkname (not the delimiters) must be doubled.
  Double apostrophes count as two characters in the 1023-character limit.
• The linkname can include characters X'40' through X'FE'.

PARM
specifies a character string that is to be passed to the HFS copy utility as an execution-time parameter. The maximum length of this character string is 300 bytes of nonblank data. If any blanks are specified in the PARM value, they are deleted by SMP/E during processing and do not count toward the 300-byte maximum.
The UCL operand is PARM(character_string).
Hierarchical file system element entry (distribution and target zone)

- PARM is an optional operand.
- The character string can be entered free-form, without regard to blanks (which are compressed out of the string), and can span multiple 80-byte records.
- If parentheses are specified in the PARM value, there must always be a pair (left and right); otherwise, the results are unpredictable.

RMID
identifies the last SYSMOD that replaced this hierarchical file system element. Any subsequent SYSMOD that modifies this hierarchical file system element must have defined a relationship (such as PRE or SUP) with this SYSMOD.

The UCL operand is RMID(sysmod_id).
- The SYSMOD ID must contain 7 uppercase alphabetic, numeric, or national ($) , # , @) characters.
- If RMID is not specified but FMID is, SMP/E sets the RMID value to the specified FMID.

SHSCRIPT
specifies a UNIX shell script to run when this element is copied to (or deleted from) a directory in a UNIX file system.

The UCL operand is SHSCRIPT(scriptname). This subentry optionally contains one or both of the following values, which specify the point in SMP/E processing when the shell script is run:

- PRE The shell script is run before the element is copied to the UNIX file system directory.
- POST The shell script is run after the element is copied to the UNIX file system directory.

POST is the default; the shell script is run after the element is copied to the directory.

SYMLINK
specifies a list of one or more symbolic links, which are file names that can be used as alternate names for referring to this element in a UNIX file system. Each symbolic link name listed here is associated with a path name listed in the SYMPATH entry. See the description of the SYMPATH entry for more information on how the symbolic link names and path names are associated.

The UCL operand is SYMLINK(symlinkname...).
- A hierarchical file system element entry that contains a SYMLINK entry must contain a matching SYMPATH entry. SMP/E will reject any UCLIN command that would violate this condition.
- A symbolic link name can be from one to 1023 characters. Any characters in the range ‘X’40’ through ‘X’FE’ may be specified.
- A symbolic link name can be enclosed in single apostrophes (‘). A symbolic linkname must be enclosed in single apostrophes if any of the following is true:
  - The symbolic linkname contains lowercase alphabetic characters.
  - The symbolic linkname contains a character that is not uppercase alphabetic, numeric, national ($, #, or @), slash (/), plus (+), hyphen, period, or ampersand (&).
  - The symbolic linkname spans more than one line in the control statement. The single apostrophes used to enclose a symbolic linkname (the delimiters) do not count as part of the 1023-character limit.
Hierarchical file system element entry (distribution and target zone)

- Any apostrophes specified as part of a symbolic linkname (not the delimiters) must be doubled. Double apostrophes count as two characters in the 1023-character limit.

**SYMPATH**

specifies a list of one or more pathnames that are associated with symbolic links identified by the SYMLINK operand. The first pathname in the SYMPATH operand is associated with the first symbolic link in the SYMLINK operand, the second pathname with the second symbolic link, and so on. If there are more symbolic links listed than there are pathnames, then the last listed pathname is used for the remaining symbolic links. If more pathnames are specified than symbolic linknames, then the excess pathnames (at the end of the list) are ignored. The UCL operand is **SYMPATH**(sympathname...).

- A hierarchical file system element entry that contains a SYMPATH entry must contain a matching SYMLINK entry. If specified, otherwise it must be omitted.

- A symbolic pathname can be from one to 1023 characters. Any characters in the range X’40’ through X’FE’ may be specified.

- A symbolic pathname can be enclosed in single apostrophes (‘). A symbolic pathname must be enclosed in single apostrophes if any of the following is true:
  - The symbolic pathname contains lowercase alphabetic characters.
  - The symbolic pathname contains a character that is not uppercase alphabetic, numeric, national ($, #, or @), slash (/), plus (+), hyphen, period, or ampersand (&).
  - The symbolic pathname spans more than one line in the control statement.

The single apostrophes used to enclose a symbolic pathname (the delimiters) do not count as part of the 1023-character limit.

- Any apostrophes specified as part of a symbolic pathname (not the delimiters) must be doubled. Double apostrophes count as two characters in the 1023-character limit.

**SYSLIB**

specifies the ddname of the “target library” within a UNIX file system for the hierarchical file system element.

The UCL operand is **SYSLIB**(ddname).

- Only one SYSLIB value can be specified.

- The ddname can contain any uppercase alphabetic, numeric, or national ($, #, @) character, and can be 1 to 8 characters long.

- The SYSLIB subentry is required. Without it, SMP/E cannot process any changes for the hierarchical file system element.

**LIST Examples**

To list all the generic hierarchical file system element entries in a particular zone that support the Spanish language, you can use the following commands:

```
SET  BDY(TGT1) /* Set to requested zone. */.
LIST  HFSESP /* List all generic HFS */
      /* element entries (Spanish)*/.
```

To list specific UNIX1 element entries, you can use these commands:
Hierarchical file system element entry (distribution and target zone)

```
SET BDY(TGT1) /* Set to requested zone. */.
LIST UNIX1(UNXEL1) /* List only these */
  UNXEL2 /* three */
  UNXEL3) /* entries. */.
```

The format of the LIST output for each hierarchical file system element entry is the same for both of these commands. The only difference is the number of hierarchical file system element entries listed. Figure 27 shows an example of LIST output for UNIX1 element entries.

```
NAME UNIX1 ENTRIES

UNXEL1 LASTUPD = UNXFUNC TYPE=ADD LIBRARIES = DISTLIB=APOSIXL1 SYSLIB=UNXTGTL1
  BINARY FMID = UNXFUNC RMID = UNXPTF1 SHSCRIPT = INSTAL01,PRE LINK = 'linkname_1'
  'linkname_2'

UNXEL2 LASTUPD = UNXFUNC TYPE=ADD LIBRARIES = DISTLIB=APOSIXL2 SYSLIB=UNXTGTL2
  TEXT FMID = UNXFUNC RMID = UNXFUNC LINK = 'linkname_3'
  'linkname_4'

UNXEL3 LASTUPD = UNXFUNC TYPE=ADD LIBRARIES = DISTLIB=APOSIXL2 SYSLIB=UNXTGTL2
  TEXT FMID = UNXFUNC RMID = UNXPTF2 LINK = 'linkname_5'
  'linkname_6'
  SHSCRIPT = INSTAL03,PRE,POST
  PARM = This is another sample character string specified as the value of PARM. It is a maximum
  length character string for this subentry. I.e., it is 300 characters long. The string
  has no blanks in it. If you see something that looks like a blank, it's not. The previous
  2 characters are X'41'...
```

Figure 27. Hierarchical file system element entry: sample LIST output

By specifying the FORFMID operand, you can reduce the number of hierarchical file system element entries listed. When FORFMID is specified, SMP/E lists a hierarchical file system element entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to list hierarchical file system element entries whose FMIDs either are defined in FMIDSET HFS or are HFSFUNC, you can use these commands:

```
SET BDY(TGT1) /* Set to target zone. */.
LIST HFS /* List all hierarchical */
  /* file system element */
  /* entries */
  FORFMID(HFS) /* for the HFS FMIDSET */
  HFSFUNC) /* and FMID HFSFUNC. */.
```

You can use the LIST command to find out the names of all SYSMODs that have modified a hierarchical file system element. To include the names of these SYSMODs in the LIST output you can use the XREF operand, as shown in these commands:
Hierarchical file system element entry (distribution and target zone)

```
SET      BDY(TGT1)  /* Set to requested zone. */.
LIST     HFS        /* List all hierarchical */
           /* file system element */
           /* entries */
XREF     /* and related SYSMODs. */.
```

Notes:
1. XREF can be used either in mass mode or in select mode.
2. SMP/E obtains the data included for the XREF operand by checking all the SYSMOD entries for subentries for this hierarchical file system element. Because this data is not contained in the hierarchical file system element entry itself, you cannot use UCLIN to change it in the hierarchical file system element entry.

Figure 28 is an example of the LIST output produced when the XREF operand is used.

```
SET      BDY(TGT1)  /* Set to requested zone. */.
LIST     SHELLSCR  /* List all UNIX shell */
           /* script element entries */.
```

To list the UNIX shell script (SHELLSCR) element entries for a particular zone, you can use the following commands:

```
SET      BDY(TGT1)  /* Set to requested zone. */.
LIST     SHELLSCR  /* List all UNIX shell */
           /* script element entries */.
```

Figure 29 on page 235 shows an example of the LIST output for SHELLSCR element entries.
UNLOAD Examples

To dump the hierarchical file system element entries in UCL format, you can use the UNLOAD command. For example, to unload all the OS21 element entries in a particular zone, you can use the following commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD OS21 /* Unload all OS21 element entries. */.
```

To unload specific OS21 element entries, you can use these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD OS21(OS2EL1) /* Unload only these */
    OS2EL2 /* three */
    OS2EL3 /* entries. */.
```

The format of the UNLOAD output for each OS21 element entry is the same for both of these commands. The only difference is the number of element entries listed. [Figure 30 on page 236](#) is an example of UNLOAD output for OS21 element entries.
By specifying the FORFMID operand, you can reduce the number of OS21 element entries unloaded. When FORFMID is specified, SMP/E unloads an OS21 element entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to unload OS21 element entries whose FMIDs either are defined in FMIDSET OS2 or are OS2FUNC, you can use these commands:

```
SET BDY(TGT1) /* Set to target zone. */.
UNLOAD OS21 /* Unload all OS21 element entries */.
FORFMID(OS21 /* for the OS21 FMIDSET */.
   OS2FUNC) /* and FMID OS2FUNC. */.
```

**UCLIN Examples**

You can use the ADD, REP, and DEL UCL statements to change subentries in the hierarchical file system element entry. After the UCLIN changes are made, the hierarchical file system element entry must contain at least the following subentries:

- DISTLIB
Hierarchical file system element entry (distribution and target zone)

- FMID
- RMID
- SYSLIB

Otherwise, there is not enough information in the entry to process the element. If any of these subentries are missing, SMP/E does not make the requested UCL updates to the entry, and the entry remains as it was before the UCL command.

The following examples are provided to help you use the hierarchical file system element entries.

**Example 1: Adding a new hierarchical file system element entry**

Defining a new hierarchical file system element entry with UCL is very seldom required; generally, hierarchical file system element entries are created from the information specified on the hierarchical file system element MCSs contained in the SYSMODs when the SYSMODs are installed. If, however, you want to use UCL in defining a new hierarchical file system element entry, the following is an example of the minimum information you should provide:

```
SET BDY(TGT1) /* Set to target zone. */.
UCLIN /* */.
ADD HFS(HFS01) /* Define new entry. */
  DISTLIB(AHFSLIB) /* Define DLIB. */
  SYSLIB(HFSLIB) /* target library. */
  FMID(ZUSR001) /* Functional owner (in this example a user function). */
  RMID(ZUSR001) /* Same value as FMID. */
  /* */.
ENDUCL /* */.
SET BDY(DLB1) /* Now do same to DLIB. */.
UCLIN /* */.
ADD HFS(HFS01) /* Define new HFS entry. */
  DISTLIB(AHFSLIB) /* Define DLIB. */
  SYSLIB(HFSLIB) /* target library. */
  FMID(ZUSR001) /* Functional owner (in this example a user function). */
  RMID(ZUSR001) /* Same value as FMID. */
  /* */.
ENDUCL /* */.
```

Note: If the RMID value had not been specified, it would have defaulted to the FMID value.

**Example 2: Defining a linkname for an existing hierarchical file system element**

The following shows how to inform SMP/E of new linkname for an existing hierarchical file system element:

```
SET BDY(TGT1) /* Set to target zone. */.
UCLIN /* */.
ADD HFS(HFS01) /* Existing entry. */
  LINK('..userlk') /* New linkname. */
  /* */.
ADD HFS(HFS02) /* Existing entry. */
  LINK('myname') /* New linkname. */
  /* */.
ENDUCL /* */.
SET BDY(DLB1) /* Now do same thing to appropriate DLIB. */.
UCLIN /* */.
ADD HFS(HFS01) /* Existing entry. */
  LINK('..userlk') /* New linkname. */
  /* */.
```
Hierarchical file system element entry (distribution and target zone)

```
ADD   HFS(HFS02)  /* Existing entry. */
      LINK('myname') /* New linkname. */
ENDUCL /* */
```

Note: UCLIN does not create a linkname in the UNIX file system; that must be done outside of SMP/E using standard utilities. The UCLIN changes ensure that, when the hierarchical file system element is subsequently modified, the hierarchical file system element is updated under both its primary name and its alternative name in the UNIX file system.

Example 3: Adding a hierarchical file system element entry with a PARM subentry

If you want to use UCL in adding a hierarchical file system element entry with a PARM subentry, the following example shows you how this can be done.

```
SET   BDY(TGT1). /* Set to target zone. */
UCLIN . /* */
ADD   HFS(HFSEL3) LASTUPD(HFSFUNC) LASTUPDTYPE(ADD)
      DISTLIB(APOSIXL2) SYSLIB(HFSTGTL2) FMID(HFSFUNC) TEXT
      RMID(HFSPTF2) LINK('linkname_5' 'linkname_6')
      PARM(This_is_another_sample_character_string_specified_as_the_value_of_PARM._It_is_a_maximum__length_character_string_for_this_subentry__I.e._it_is_300_characters_long__The_string__has_no_blanks_in_it__If_you_see_something_that_looks_like_a_blank__it's_not._The_previous_2_characters_are_X'41'...)/* */
ENDUCL . /* */
```
HOLDDATA entry (global zone)

The HOLDDATA entry contains ++HOLD statements that either were received from SMPHOLD (external HOLDDATA) or were within a SYSMOD that was received (internal HOLDDATA). It is a record of the ++HOLD statements and is not used by SMP/E to control exception SYSMOD processing.

The HOLDDATA entry is separate from the SYSMOD entry. However, when SMP/E saves ++HOLD statements to create HOLDDATA entries, it also creates HOLDDATA subentries in the associated global zone SYSMOD entry. (These subentries appear in the LIST output as HOLDERROR, HOLDFIXCAT, HOLDSYSTEM, or HOLDUSER plus the hold reason IDs.) SMP/E uses these HOLDDATA subentries to control exception SYSMOD processing.

LIST Examples

To list all the HOLDDATA entries in a global zone, you can use the following commands:

```
SET BDSY(GLOBAL) /* Set to requested zone. */.
LIST HOLDDATA /* List all HOLDDATA entries. */.
```

To list HOLDDATA entries for a specific type of hold, code one or more of the following operands: HOLDERROR, HOLDSYSTEM, HOLDUSER. Here is an example:

```
SET BDSY(GLOBAL) /* Set to requested zone. */.
LIST HOLDDATA /* List HOLDDATA entries */.
LIST HOLDSYSTEM /* for system holds */.
```

To list specific SYSMOD entries in the global zone along with the associated ++MCSs (HOLDDATA), you can use these commands:

```
SET BDSY(GLOBAL) /* Set to requested zone. */.
LIST SYSMOD(UZ12345) /* List only these two */.
LIST SYSMOD(UZ56789) /* entries */.
LIST HOLDDATA /* plus HOLDDATA for them. */.
```

The output from the LIST requests differs in the amount of information presented. If you list just the HOLDDATA entries, only the HOLDDATA itself is presented, as in Figure 31 on page 240. If you request the HOLDDATA associated with SYSMOD entries, the HOLDDATA is included in the SYSMOD entry, as in Figure 32 on page 241. (For more information about listing HOLDDATA, see the description of the HOLDDATA operand of the LIST command in SMP/E Commands.)

Notes:

1. The ++HOLD statements displayed in the LIST output are exactly as received by SMP/E. They are listed in alphanumeric order by reason ID.
2. If HOLDDATA for a particular SYSMOD has been received but the SYSMOD itself has not yet been received, only the hold information is shown when the SYSMOD entry is listed. For an example, see SYSMOD UZ56789 in Figure 32 on page 241.
3. HOLDDATA entries for system holds show either INT or EXT to indicate the source of the ++HOLD statement. INT means that the ++HOLD statement was contained in the held SYSMOD and can be resolved only with the BYPASS operand on the APPLY or ACCEPT command. EXT means that the ++HOLD statement was obtained from another source, such as SMPHOLD, and can be resolved by either the BYPASS operand or a ++RELEASE statement.
HOLDDATA entry (global zone)

4. You cannot use UCLIN to add, update, or delete HOLDDATA entries or subentries. However, you can use the REJECT command to delete HOLDDATA entries. For more information on the REJECT command, see SMP/E Commands.

**Figure 32.** HOLDDATA listed for SYSMOD entry: sample LIST output when SYSMOD is specified.

---

**Chapter 5. SMP/E data set entries** 241
JAR entry (target and distribution zone)

JAR entry (target and distribution zone)
The JAR entry describes a Java Archive (JAR) file that resides in a UNIX file system and a distribution library. A JAR entry is created the first time a SYSMOD is installed that contains a +++JAR MCS.

Subentries
These are the subentries for the JAR entry as they appear in the LIST output:

name
is the name of the Java ARchive element represented by the JAR entry.
The name can contain 1–8 uppercase alphabetic, numeric, or national ($, #, @) characters.

DISTLIB
specifies the ddname of the distribution library for the JAR element.
The UCL operand is DISTLIB(ddname).
- The ddname can contain any uppercase alphabetic, numeric, or national ($, #, @) character, and can be 1–8 characters long.
- The DISTLIB subentry is required. Without it, SMP/E cannot process any changes for the JAR element.

FMID
identifies the functional owner of this JAR element. The functional owner is the last function SYSMOD that replaced this JAR element.
The UCL operand is FMID(sysmod_id).
The SYSMOD ID must contain 7 uppercase alphabetic, numeric, or national ($, #, @) characters.

JARPARM
specifies a character string that is to be passed to the jar command as an option string when updating the JAR file. The maximum length of this character string is 300 bytes of data.
Any jar command options specified here will be passed to the jar command in addition to the options supplied by SMP/E, which are uvf (u indicates that the JAR file is to be updated, v produces verbose jar command output, and f indicates that the JAR file to be updated is specified on the command line rather than through stdin).
Only those jar command options that require only the option indicator to be specified are supported in the JARPARM entry, such as 0 and M. Options requiring additional input over and above the option indicator are not supported. Examples of unsupported options are the m and -C options. If such options are specified, the jar command will likely fail, since SMP/E does not prohibit their use.

LASTUPD
identifies the cause of the last change to this JAR entry.
The UCL operand is LASTUPD(value). This subentry can contain one of the following values:

UCLIN
indicates that the change was made as a result of UCLIN processing.
JAR entry (target and distribution zone)

sysmod-id
indicates that the change was made during the installation of the indicated
SYSMOD.

The SYSMOD ID must contain 7 uppercase alphabetic, numeric, or national
($, #, @) characters.

LASTUPDTYPE
indicates how the entry was last changed.

The UCL operand is LASTUPDTYPE(value). This subentry can contain one of
the following values:
ADD  The entry was added.
UPD  The entry was updated.

LINK
specifies a list of alternative names by which this JAR element can be known
in the UNIX file system.

In LIST output, linknames are always enclosed in single apostrophes. If an
apostrophe is part of a linkname, it is always shown as two consecutive
apostrophes in LIST output.

The UCL operand is LINK(linkname...).

• The linkname can be from 1 to 1023 characters.
• A linkname can be enclosed in single apostrophes ('). A linkname must be
  enclosed in single apostrophes if any of the following is true:
  – The linkname contains lowercase alphabetic characters.
  – The linkname contains a character that is not uppercase alphabetic,
    numeric, national ($, #, or @), slash (/), plus (+), hyphen, period, or
    ampersand (&).
  – The linkname spans more than one line in the control statement.
  The single apostrophes used to enclose a linkname (the delimiters) do not
do not count as part of the 1023-character limit.
• Any apostrophes specified as part of a linkname (not the delimiters) must be
doubled.
  Double apostrophes count as two characters in the 1023-character limit.
• The linkname can include characters X'40' through X'FE'.

PARM
specifies a character string that is to be passed to the copy utility as an
execution-time parameter. The maximum length of this character string is 300
bytes of nonblank data. If any blanks are specified in the PARM value, they are
deleted by SMP/E during processing and do not count toward the 300-byte
maximum.

The UCL operand is PARM(character_string).

• PARM is an optional operand.
• The character string can be entered free-form, without regard to blanks
  (which are compressed out of the string), and can span multiple 80-byte
  records.
• If parentheses are specified in the PARM value, there must always be a pair
  (left and right); otherwise, the results are unpredictable.

RMID
identifies the last SYSMOD that replaced this JAR element. Any subsequent
JAR entry (target and distribution zone)

SYSMOD that modifies this JAR element must have defined a relationship (such as PRE or SUP) with this SYSMOD.

The UCL operand is **RMID(sysmod_id)**.

- The SYSMOD ID must contain 7 uppercase alphabetic, numeric, or national ($, #, @) characters.
- If RMID is not specified but FMID is, SMP/E sets the RMID value to the specified FMID.

**SHSCRIPT**

specifies a UNIX shell script to run when this JAR element is copied to (or deleted from) a directory in the UNIX file system.

The UCL operand is **SHSCRIPT(scriptname)**. This subentry optionally contains one or both of the following values, which specify the point in SMP/E processing when the shell script is run:

- **PRE** The shell script is run before the JAR element is copied to a UNIX file system directory.
- **POST** The shell script is run after the JAR element is copied to a UNIX file system directory.

**POST** is the default; the shell script is run after the JAR element is copied to the directory.

**SYMLINK**

specifies a list of one or more symbolic links, which are file names that can be used as alternate names for referring to this JAR element in the UNIX file system. Each symbolic link name listed here is associated with a path name listed in the SYMPATH entry. See the description of the SYMPATH entry for more information on how the symbolic link names and path names are associated.

The UCL operand is **SYMLINK(symlinkname...)**.

- A JAR entry that contains a SYMLINK entry must contain a matching SYMPATH entry. SMP/E will reject any UCLIN command that would violate this condition.
- A symbolic linkname can be from one to 1023 characters. Any characters in the range X'40' through X'FE' may be specified.
- A symbolic linkname can be enclosed in single apostrophes ('). A symbolic linkname **must** be enclosed in single apostrophes if any of the following is true:
  - The symbolic linkname contains lowercase alphabetic characters.
  - The symbolic linkname contains a character that is not uppercase alphabetic, numeric, national ($, #, or @), slash (/), plus (+), hyphen, period, or ampersand (&).
  - The symbolic linkname spans more than one line in the control statement.

The single apostrophes used to enclose a symbolic linkname (the delimiters) do not count as part of the 1023-character limit.

- Any apostrophes specified as part of a symbolic linkname (not the delimiters) must be doubled. Double apostrophes count as two characters in the 1023-character limit.

**SYMPATH**

specifies a list of one or more pathnames that are associated with symbolic links identified by the SYMLINK operand. The first pathname in the SYMPATH operand is associated with the first symbolic link in the SYMLINK operand, the second pathname with the second symbolic link, and so on. If
JAR entry (target and distribution zone)

there are more symbolic links listed than there are pathnames, then the last
listed pathname is used for the remaining symbolic links. If more pathnames
are specified than symbolic linknames, then the excess pathnames (at the end
of the list) are ignored. The UCL operand is SYMPATH(sympathname...).

- A JAR entry that contains a SYMPATH entry must contain a matching
  SYMLINK entry. is specified, otherwise it must be omitted.
- A symbolic pathname can be from one to 1023 characters. Any characters in
  the range X'40' through X'FE' may be specified.
- A symbolic pathname can be enclosed in single apostrophes ('). A symbolic
  pathname must be enclosed in single apostrophes if any of the following is
  true:
    - The symbolic pathname contains lowercase alphabetic characters.
    - The symbolic pathname contains a character that is not uppercase
      alphabetic, numeric, national ($, #, or @), slash (/), plus (+), hyphen,
      period, or ampersand (&).
    - The symbolic pathname spans more than one line in the control
      statement.

The single apostrophes used to enclose a symbolic pathname (the delimiters)
do not count as part of the 1023-character limit.
- Any apostrophes specified as part of a symbolic pathname (not the
delimiters) must be doubled. Double apostrophes count as two characters in
the 1023-character limit.

SYSLIB

specifies the ddname of the “target library” within a UNIX file system for the
JAR element.

The UCL operand is SYSLIB(ddname).
- Only one SYSLIB value can be specified.
- The ddname can contain any uppercase alphabetic, numeric, or national ($,
  #, @) character, and can be 1 to 8 characters long.
- The SYSLIB subentry is required. Without it, SMP/E cannot process any
  changes for the JAR element.

UMID

identifies all of the SYSMODs that have updated this JAR file since it was last
replaced. Any subsequent SYSMOD that updates or replaces this JAR file must
have a defined relationship (such as PRE or SUP) with all SYSMODs in the
UMID subentry.

LIST Examples

To list all the JAR entries in a particular zone, you can use the following
commands:

```
SET BDY(TGT1) /* Set to zone. */.
LIST JAR /* List all JAR entries. */.
```

To list specific JAR entries, you can use these commands:

```
SET BDY(TGT1) /* Set to zone. */.
LIST JAR(JAREL1, /* List only these two */.
       JAREL2) /* entries. */.
```

The format of the LIST output for each JAR entry is the same for both of these
commands. The only difference is the number of JAR entries listed.
JAR entry (target and distribution zone)

Figure 33 is an example of LIST output for a JAR entry.

By specifying the FORFMID operand, you can reduce the number of JAR entries listed. When FORFMID is specified, SMP/E lists a JAR entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to list JAR entries whose FMIDs either are defined in FMIDSET JAR or are JARFUNC, you can use these commands:

```
SET BDY(TGT1)  /* Set to target zone. */.
LIST JAR       /* List all JAR entries */.
   FORFMID(JAR  /* for the JAR FMIDSET */.
         JARFUNC) /* and FMID JARFUNC. */.
```

You can use the LIST command to find out the names of all SYSMODs that have modified a JAR element. To include the names of these SYSMODs in the LIST output you can use the XREF operand, as shown in these commands:

```
SET BDY(TGT1)  /* Set to requested zone. */.
LIST JAR       /* List all JAR entries */.
   XREF        /* and related SYSMODs. */.
```

Notes:
1. XREF can be used either in mass mode or in select mode.
2. SMP/E obtains the data included for the XREF operand by checking all the SYSMOD entries for subentries for this JAR element. Because this data is not contained in the JAR entry itself, you cannot use UCLIN to change it in the JAR entry.

Figure 34 on page 247 is an example of the LIST output produced when the XREF operand is used.
UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the JAR entry. After the UCLIN changes are made, the JAR entry must contain at least the following subentries:

- DISTLIB
- FMID
- RMID
- SYSLIB

Otherwise, there is not enough information in the entry to process the element. If any of these subentries are missing, SMP/E does not make the requested UCL updates to the entry, and the entry remains as it was before the UCL command.

The following examples are provided to help you use the JAR entry:

**Example 1**

```plaintext
SET BDY(TGT)               /* Set to target zone */.
UCLIN                       /* Start UCLIN processing */.
   ADD JAR(ABCTTT) JARPARM(OM) /* Add JARPARMs */.
   UCLIN                       /* End UCLIN processing */.
```

**Example 2**

```plaintext
SET BDY(TGT)               /* Set to target zone */.
UCLIN                       /* Start UCLIN processing */.
   REP JAR(ABCTTT) JARPARM(M) /* Replace with new JARPARMs */.
      UMID(OW12345,OW54321) /* and new UMIDs */.
   UCLIN                       /* End UCLIN processing */.
```

**Example 3**

```plaintext
SET BDY(TGT)               /* Set to target zone */.
UCLIN                       /* Start UCLIN processing */.
   DEL JAR(ABCTTT) JARPARM() /* Delete JARPARMs */.
   UCLIN                       /* End UCLIN processing */.
```

In the first example, a string of options is added to the JARPARM subentry in the JAR entry ABCTTT. In the second example, the existing JARPARM subentry value for ABCTTT is replaced with a new value and the UMID subentry list is replaced.
JAR entry (target and distribution zone)

with a new list of values. In the third example, the JARPARM subentry is deleted from the JAR entry for entry name ABCTTT.

UNLOAD Examples

To dump all the JAR entries in UCL format, you can use the UNLOAD command:

```
SET BDY(TGT1) /* Set to zone. */.
UNLOAD JAR /* Unload all JAR entries. */.
```

To dump specific JAR entries, you can use these commands:

```
SET BDY(TGT1) /* Set to zone. */.
UNLOAD JAR(JAREL1, /* Unload only these two */
JAREL2) /* entries. */.
```

The format of the UNLOAD output for each JAR entry is the same for both of these commands. The only difference is the number of JAR entries unloaded.

Figure 35 is an example of the output created by the UNLOAD command for a JAR entry:

```
UCLIN .
REP   JAR      ( ABCTTT  )
      LASTUPD ( HABC100  )
      LASTUPDATE ( ADD  )
      DISTLIB ( AABCBIN  )
      SYSLIB ( SABCBIN  )
      FMID ( HABC100  )
      RMID ( HABC100  )
      UMIN ( OW12345 OW54321 OW34567 )
      SHSCRIPT ( ABCSCRIPT,PRE,POST )
      PARM ( PATHMODE(0,6,4,4) )
      JARPARM ( "M" )
      SYMLINK ( '../.../usr/lib/TicTacToe.jar' )
      SYMPATH ( '../.../usr/lpp/ttt/bin/TicTacToe.jar' )
      LINK ( '../TicTacToe.jar' )
ENDUCL.
```

Figure 35. Example UNLOAD output for JAR entry

By specifying the FORFMID operand, you can reduce the number of JAR element entries unloaded. When FORFMID is specified, SMP/E unloads an JAR element entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to unload JAR element entries whose FMIDs either are defined in FMIDSET JAR or are JARFUNC, you can use these commands:

```
SET BDY(TGT1) /* Set to target zone. */.
UNLOAD JAR /* Unload all JAR element entries */
FORFMID(JAR /* for the JAR FMIDSET */
JARFUNC) /* and FMID JARFUNC. */.
```
LMOD entry (distribution and target zone)

The LMOD entry contains all the information needed to replace or update a given load module. This includes information such as whether the load module is link-edited or copied during the system generation process, any link-edit statements required to relink the load module, the link-edit attributes of the load module, and the libraries in which it resides. An LMOD entry is generally created by one of the following methods:

- **Installing a SYMOM that adds the load module.** LMOD entries can be created when a SYMOM is installed. SMP/E builds an LMOD entry if it encounters a ++MOD statement for a load module that does not yet have an LMOD entry and if the distribution library for the module was totally copied during system generation. For more information about copied load modules, see “DLIB entry (distribution and target zone)” on page 211 and SMP/E Commands.

- **Processing JCLIN.** LMOD entries can be created during JCLIN processing when SMP/E scans the copy and link-edit steps. At the same time, SMP/E builds MOD entries for modules that are linked or copied to the load module. For more information, see “MOD entry (distribution and target zone)” on page 275 and the “Processing” section of the JCLIN command chapter in SMP/E Commands.

**Subentries**

These are the subentries for the LMOD entry as they appear in the LIST output:

*name*

is the name of the load module described by the LMOD entry.

The name can contain from 1 to 8 alphanumeric characters.

**CALLLIBS**

specifies one or more DDDEF entries, existing in the same zone, that compose the SYSLIB allocation to be used when the load module is link-edited.

The UCL operand is CALLLIBS(name...).

- The DDDEF names can contain from 1 to 8 alphabetic (A through Z), national (@, #, or $), or numeric (0 through 9) characters. The first character must be alphabetic or national.
- SMP/E does not enforce any limit on the number of names that can be specified in a CALLLIBS subentry list. However, DFSMS/MVS® sets its own limits on how many data sets can be concatenated. The actual limit depends on the kind of data sets to be concatenated (partitioned data sets or PDSEs) and the total number of extents for partitioned data sets. Refer to DFSMS Using Data Sets, SC26-7410 for information on calculating this limitation.
- The order in which the libraries are specified is important because it indicates the order in which the SYSLIB concatenation is built.

**COPY**

is a special SMP/E indicator meaning that the load module was copied during system generation, and that there is a one-to-one correspondence between the distribution library module (the MOD entry) and the target system load module (the LMOD entry). This information is used during APPLY processing to determine whether the LEPARM values from a ++MOD statement are applicable to the load module. It is also used during delete and compress processing to determine whether a load module can be deleted before the new modules are installed.

The UCL operand is COPY.
**LMOD entry (distribution and target zone)**

**LASTUPD**
identifies the cause of the last change to this LMOD entry.

**Note:** If a given UCLIN command specifies only cross-zone subentries, this field is not changed.

The UCL operand is **LASTUPD(value)**. This subentry can contain one of the following values:

**JCLIN**
indicates that the change was made during JCLIN command processing.

**UCLIN**
indicates that the change was made as a result of UCLIN processing.

**sysmod_id**
indicates that the change was made during the installation of the indicated SYSMOD. The SYSMOD did one of the following:
- Contained inline JCLIN that affected the LMOD entry.
- Renamed the load module using the ++RENAME statement.
- Moved the load module to a new target system library using the ++MOVE statement.

A SYSMOD that does not do any of the previously listed actions will not cause an update to the LASTUPD subentry. For example, a SYSMOD that supplies one or more modules (++MOD) that cause the load module to be link edited does not necessarily cause the LMOD entry’s LASTUPD subentry to be updated. The LASTUPD subentry only indicates when the LMOD entry was updated, not when the module content of a load module is updated.

The SYSMOD ID must contain 7 alphanumeric characters.

**LASTUPD TYPE**
indicates how the entry was last changed.

**Note:** If a given UCLIN command specifies only cross-zone subentries, this field is not changed.

The UCL operand is **LASTUPDTYPE(value)**. This subentry can contain one of the following values:

**ADD** The entry was added.

**DEL** A subentry in the entry was deleted.

**MOV** The load module was moved.

**REN** The load module was renamed.

**UPD** The entry was updated.

**LKED ATTRIBUTES**
identifies the link-edit attributes that must be used when this load module is link-edited. **SMP/E supports the following link-edit attributes.** For more information, see [z/OS MVS Program Management: User's Guide and Reference](SA22-7643).

**AC=1** specifies that the AC=1 parameter (which is the authorization code) is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **AC=1**.
LMOD entry (distribution and target zone)

ALIASES
specifies that the ALIASES parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is ALIASES(ALL).

ALIGN2
specifies that the ALIGN2 parameter (alignment on a 2KB boundary) is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is ALIGN2 or ALN2.

AMODE=24
specifies that the AMODE=24 parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is AMODE=24 or AMOD=24.

AMODE=31
specifies that the AMODE=31 parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is AMODE=31 or AMOD=31.

AMODE=64
specifies that the AMODE=64 parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is AMODE=64 or AMOD=64.

AMODE=ANY
specifies that the AMODE=ANY parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is AMODE=ANY or AMOD=ANY.

AMODE=MIN
specifies that the AMODE=MIN parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is AMODE=MIN or AMOD=MIN.

CALL indicates that the CALL parameter has been specified for a load module in a JCLIN link-edit step.

Note: If the load module being link-edited contains a CALLLIBS subentry list, SMP/E uses NCAL for the link to the SMPLTS library, and ignores the CALL subentry in the LMOD entry.

For more information about link-edit parameters, see the discussion of “Link-edit utility” under the PARM subentry of [UTILITY entry](global zone) Also see the APPLY command chapter in [SMP/E Commands](global zone).

The UCL operand is CALL.

CASE
specifies that the CASE parameter, which controls case sensitivity and folding, is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is CASE(UPPER|MIXED).

- CASE(UPPER) and CASE(MIXED) are mutually exclusive.
LMOD entry (distribution and target zone)

**COMPAT**
specifies that the COMPAT parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is `COMPAT=LKED | PM1 | PM2 | PM3 | PM4`.

**DC**
specifies that the DC parameter, which is the downward compatible attribute, is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is `DC`.

**DYNAM**
specifies that the DYNAM parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is `DYNAM(DLL)`.

**FETCHOPT**
specifies that the FETCHOPT parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is `FETCHOPT(PACK | NOPACK, PRIME | NOPRIME)`.

**FILL**
specifies that the FILL parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is `FILL(nn)`, where `nn` is the 2-character representation of a single hex byte (00 - FF).

**HOBSET**
specifies that the HOBSET parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is `HOBSET`.

**MAXBLK**
specifies that the MAXBLK parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is `MAXBLK(nnnnn)`, where `nnnnn` is a number between 256 and 32760.

**NE**
specifies that the NE parameter, which is the noneditable attribute, is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is `NE`.

**NOCALL**
specifies that the NCAL parameter is to be passed to the link-edit utility when the load module is link-edited.

**Note:** If the load module being link-edited contains a CALLLIBS subentry list, SMP/E uses CALL for the link to the actual target library, and ignores the NOCALL subentry in the LMOD entry.

For more information about link-edit parameters, see the discussion of “Link-edit utility” under the PARM subentry of **UTILITY entry (global zone)**. Also see the APPLY command chapter in **SMP/E Commands**.

The UCL operand is `NOCALL` or `NCAL`. 
### LMOD entry (distribution and target zone)

**OL** specifies that the OL parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **OL**.

**OVLY** specifies that the OVLY parameter, which specifies that the load module is in overlay structure, is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **OVLY**.

**REFR** specifies that the REFR parameter, which is the refreshable attribute, is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **REFR**.

**RENT** specifies that the RENT parameter, which indicates that the load module is re-entrant, is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **RENT**.

**REUS** specifies that the REUS parameter, which indicates that the load module is reusable, is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **REUS**.

**REUS(NONE)** specifies that the REUS(NONE) parameter, which indicates that the load module cannot be reused, is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **REUS(NONE)**.

**RMODE=24** specifies that the RMODE=24 parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **RMODE=24** or **RMOD=24**.

**RMODE=ANY** specifies that the RMODE=ANY parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **RMODE=ANY** or **RMOD=ANY**.

**RMODE=SPLIT** specifies that the RMODE=SPLIT parameter is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **RMODE=SPLIT** or **RMOD=SPLIT**.

**SCTR** specifies that the SCTR parameter, which indicates that the load module can be scatter-loaded, is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is **SCTR**.

**STD** is a special SMP/E indication that the load module should be link-edited with none of the previously listed attributes.
LMOD entry (distribution and target zone)

STD appears in LIST and UNLOAD output in these cases:
- STD was specified on a UCL statement for this entry.
- No link-edit attributes were specified for this entry. SMP/E uses the standard system link-edit parameters.
- The LMOD entry was created by a JCLIN copy step.

If this attribute is specified when a load module is to be link-edited and no UTILITY entry is being used, SMP/E passes the default link-edit parameters to the link-edit utility. For more information about link-edit parameters, see the APPLY command chapter in [SMP/E Commands]

The UCL operand is STD.

UPCASE
specifies that the UPCODE parameter, which indicates how the Binder should process symbol names, is to be passed to the link-edit utility when the load module is link-edited.

The UCL operand is UPCODE(YES | NO).
- UPCODE(YES) and UPCODE(NO) are mutually exclusive.

LKED CONTROL
contains all the link-edit control cards necessary to relink-edit this load module.

Note: Relink-editing a load module is triggered by a replacement for one of the modules within that load module. SMP/E performs only CSECT replaces when relink-editing the load module; it does not completely rebuild the load module from the distribution libraries. Therefore, it is not necessary to save all the link-edit control statements in the LMOD entry; for example, the INCLUDE statements are not saved.

The UCL operands are ++LMODIN and ++ENDLMODIN.
- The ++LMODIN and ++ENDLMODIN statements must start in column 1.
- No other operands can start on the same line as the ++LMODIN statement.
- The ++ENDLMODIN statement must be specified if the ++LMODIN statement is specified.
- The link-edit control statements must follow SMP/E’s coding conventions. For more information, see the “General JCLIN Coding Conventions” section of the JCLIN command chapter in [SMP/E Commands]
- Comment statements are ignored and are not saved in the LMOD entry. (Any link-edit control statement with an asterisk in column 1 is considered a comment statement.)

MODDEL
specifies the modules that were once part of this load module but have been deleted. If the modules are reinstalled, they are linked back into this load module.

The UCL operand is MODDEL(module...).

The module names can contain from 1 to 8 alphanumeric characters.

RETURN CODE
specifies the maximum acceptable return code from the link edit utility for this specific load module. If the return code from the link edit utility is higher than this value, SMP/E normally assumes the link edit operation failed.
LMOD entry (distribution and target zone)

The UCL operand is RC(rc), where the rc value can be any decimal number from 0 to 16.

SIDE DECK LIBRARY

specifies the library to contain the definition side deck.

The definition side deck may be created as a member of a partitioned data set (PDS or PDSE), or as a file within a directory in a UNIX file system. The definition side deck is created by the link edit utility when the DYNAM(DLL) binder option is specified for DLL load modules that export symbols. If a load module does not export symbols, or if the DYNAM(DLL) option is not specified, the definition side deck is not created. The member or file name of the definition side deck is the same as the load module name. In addition, the definition side deck will have the same aliases as those specified for the load module.

The UCL operand is SIDEDECKLIB(ddname), where ddname is the ddname of the library where the load module’s definition side deck will reside.

Notes:
1. This subentry name appears in the LIST output as SIDE DECK LIB.
2. When this subentry value is SMPDUMMY, the SIDE DECK LIBRARY will be allocated as a DUMMY data set, and the definition side deck will not be created by the link edit utility.

SYSTEM LIBRARIES

specifies the target system libraries in which this load module resides.

The UCL operand is SYSLIB(ddname...).
- There can be up to two SYSLIB values in an LMOD entry.
- The ddnames can contain from 1 to 8 alphanumeric characters.

Note: This subentry name appears in the LIST output as SYSTEM LIBRARY.

UTILITY INPUT

specifies one or more files to be included when this load module is link-edited. The ddname of the library where the file resides is also indicated.

The UCL operand is UTIN(name,ddname...), where name is a data set member name or relative UNIX filename, and ddname is the ddname of the library where the file resides.
- The name can be from 1 to 1023 characters in length.
- The name can include any nonblank characters X’41’ through X’FE’.
- The name cannot begin or end with a slash (/) because any UNIX filename specification must be relative to the directory associated with the ddname.
- A name can be enclosed in single quotation marks (‘). A name value must be enclosed in single quotation marks if any of the following are true:
  - The name contains a character that is not uppercase alphabetic, numeric, national ($,#, or @), slash (/), plus (+), hyphen (-), period (.) or ampersand (&).
  - The name spans more than one line in the UCLIN statement.

The single quotation marks used to enclose a name (the delimiters) do not count as part of the 1023-character limit.
- Any quotation marks specified as part of a name (not the delimiters) must be doubled. Double quotation marks count as two characters in the 1023 character limit.
LMOD entry (distribution and target zone)

- If the name value spans lines, it must extend through column 72 of the first line and begin in column 1 of the subsequent line.

The combination of name and ddbname determines the uniqueness of a subentry in the UTILITY INPUT subentry list. Only one subentry value for a given name and ddbname combination is saved in the UTILITY INPUT subentry list.

XZMOD

specifies one or more modules that were added to the load module by the LINK MODULE command. The name of the zone supplying each module is also indicated.

The UCL operand is XZMOD((module,zone)....)

- The zone name specified for an XZMOD subentry cannot match the name of the set-to zone.
- The XZMOD subentry is added to an LMOD entry automatically during LINK MODULE command processing. However, it is almost never removed automatically, except during JCLIN processing. For more information, see the "Cross-Zone Relationships" section of the JCLIN command chapter in [SMP/E Commands]
- An LMOD entry can contain XZMOD and XZMODP subentries without any other subentries. Such an LMOD entry represents a stub load module, which is retained after a load module with cross-zone relationships is deleted. If the deleted load module is later reinstated, SMP/E uses the information in the stub load module to issue messages reminding the user to use the LINK MODULE command to restore those previous cross-zone relationships, if they are still appropriate.
- If UCLIN is used to update an existing LMOD entry and only cross-zone subentries (XZMOD and XZMODP) are changed, SMP/E does not update the LASTUPD and LASTUPDTYPE subentries.

XZMODP

indicates that the load module contains one or more modules from another zone and that XZMOD subentries exist in this LMOD entry.

The UCL operand is XZMODP.

- You never need to specify the XZMODP subentry on a UCL statement. SMP/E automatically determines the setting of XZMODP, according to whether the LMOD entry contains XZMOD subentries.
- You cannot add the XZMODP subentry to an LMOD entry that does not contain XZMOD subentries.
- You cannot delete the XZMODP subentry from an LMOD entry containing XZMOD subentries.
- An LMOD entry can contain XZMOD and XZMODP subentries without any other subentries.
- If UCLIN is used to update an existing LMOD entry and only cross-zone subentries are changed (XZMOD and XZMODP), SMP/E does not update the LASTUPD and LASTUPDTYPE subentries.

LIST Examples

To list all the LMOD entries in a particular zone, you can use the following commands:

```
SET  BDY(TGT1)  /* Set to requested zone. */.
LIST  LMOD  /* List all LMOD entries. */.
```

To list specific LMOD entries, you can use these commands:
LMOD entry (distribution and target zone)

```plaintext
SET BDY(TGT1) /* Set to requested zone. */
LIST LMOD(LMOD01 /* List only these two */
   LMOD02) /* entries. */
```

The format of the LIST output for each LMOD entry is the same for both of these commands. The only difference is the number of LMOD entries listed. Figure 36 is an example of LIST output for LMOD entries.

---

**Figure 36. LMOD entry: sample LIST output (Part 2 of 2)**

You can use the LIST command to find out the names of all the distribution library modules that are link-edited into this load module. To include the names of these modules in the LIST output you can use the XREF operand, as shown in these commands:

```
SET  BDY(TGT1)  /* Set to requested zone. */.
LIST  LMOD  /* List all LMOD entries */.
XREF  /* and MODs in them. */.
```

**Notes:**

1. XREF can be used either in mass mode or in select mode.
2. SMP/E obtains the data included for the XREF operand by checking the LMOD subentries in all the MOD entries. Because this data is not contained in the LMOD entry itself, you cannot use UCLIN to change it in the LMOD entry.

Figure 37 on page 259 is an example of the LIST output produced when the XREF operand is used.

*Figure 37. LMOD entry: sample LIST output when XREF is specified (Part 2 of 2)*

**UNLOAD Examples**

To dump the LMOD entries in UCL format, you can use the UNLOAD command.

To unload all the LMOD entries in a particular zone, you can use the following commands:

```plaintext
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD LMOD /* Unload all LMOD entries. */.
```

To unload specific LMOD entries, you can use these commands:

```plaintext
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD LMOD(LMOD01) /* Unload only these two */.
UNLOAD LMOD(LMOD02) /* entries. */.
```

The format of the UNLOAD output for each LMOD entry is the same for both of these commands. The only difference is the number of LMOD entries listed. Figure 38 on page 261 is an example of UNLOAD output for LMOD entries.

UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the LMOD entry. When you use UCLIN to update an LMOD entry, keep these points in mind:

- After the UCLIN changes are made, the LMOD entry must contain at least a SYSLIB subentry. Otherwise, there is not enough information in the entry to indicate where the load module should be installed.
- The input following the ++LMODIN statement replaces all existing link-edit control cards in the LMOD entry. This is different from JCLIN processing, where all control cards are replaced except CHANGE and REPLACE, which are merged with the existing CHANGE and REPLACE control cards.
- If a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.
- When SMP/E processes a DEL statement, it does not compare any control cards after the ++LMODIN statement with the control cards that are currently in the LMOD entry. It deletes all the existing control cards.

The following examples are provided to help you use the LMOD entry.

Example 1: Adding a new LMOD entry

The correct method of adding a new LMOD entry is through JCLIN, so that in addition to the LMOD entry being created, SMP/E also ensures that all related MOD entries are updated. If, however, you want to define a new load module entry using UCL, the following is an example of the minimum information you should provide.

```
SET BDY(TGT1) /* Set to target zone. */
UCLIN /* */
ADD LMOD(LMOD01) /* Define new LMOD entry. */
SYSLIB(LPALIB) /* System library 1. */
PPLIB01) /* System library 2. */
RENT REUS AC=1 /* All link attributes. */
++LMODIN /* All link-edit stmts. */
INCLUDE AOS12(MOD01)
```

Figure 38. LMOD entry: sample UNLOAD output (Part 3 of 3)
LMOD entry (distribution and target zone)

```
INCLUDE A0S12(MOD02)
ENTRY MOD01
ALIAS LMOD01A1
NAME LMOD01(R)
++ENDLMO

REP   MOD(MOD01) /* Now fix MOD entries. */
      DISTLIB(A0S12) /* MOD DLIB. */
      FMID(FXY1102) /* Functional owner. */
      LMOD(LMOD01) /* Connect to LMOD. */
      /* */
REP   MOD(MOD02) /* Now fix MOD entries. */
      DISTLIB(A0S12) /* MOD DLIB. */
      FMID(FXY1102) /* Functional owner. */
      LMOD(LMOD01) /* Connect to LMOD. */
      /* */
ENDUCL /* */
```

**Note:** In this example, the entire set of control cards needed to link the load module was specified. MOD entries for modules within the load module were also updated.

**Example 2: Changing the link-edit attributes of an LMOD**

As in the previous example, the correct way to change any part of a LMOD entry is through the use of JCLIN. However, at times, assuming a knowledge of SMP/E and UCL processing, you may decide to use UCL to do it. For this example, assume you have a load module, LMOD99, with link-edit attributes of RENT REUS, and that you have made changes so that it is no longer reentrant but is now authorized and will fill uninitialized areas. This change can be made as follows:

```
SET   BDY(TGT1)   /* Set to target zone. */
UCLIN /* */
DEL   LMOD(LMOD99) /* Existing LMOD entry. */
      RENT. /* Delete RENT attribute. */
ADD   LMOD(LMOD99) /* Existing LMOD entry. */
      AC=1 FILL(00) /* Add authorization, */
      /* and fill uninitialized */
      /* areas to hex byte 00. */
ENDUCL /* */
```

**Example 3: Deleting a MODDEL subentry**

Suppose load module LMOD03 for product A included module MOD01 from product B, and both products are installed in zone ZOSZN. Product B deleted MOD01 without replacing it, and as a result, SMP/E created a MODDEL subentry for MOD01 in the LMOD entry for LMOD03. You have decided to reintroduce your own version of MOD01, but do not want it relinked into LMOD03. To prevent this relinking, delete the MODDEL subentry from the LMOD entry, as shown below:

```
SET   BDY(ZOSZN)   /* Set to zone. */
UCLIN /* Start UCLIN processing. */
DEL   LMOD(LMOD03) /* Identify LMOD entry. */
      MODDEL(MOD01) /* Delete MODDEL subentry. */
ENDUCL /* */
```

**Example 4: Completing cross-zone updates**

If SMP/E could not complete cross-zone updates for APPLY or RESTORE processing, you may need to use UCLIN to make the remaining changes. (SMP/E issues messages and reports to tell you what cross-zone work you may need to finish.) Here are some examples of using UCLIN to change XZMOD subentries in
LMOD entry (distribution and target zone)

LMOD entries. Make sure you check the messages and reports to determine whether any additional changes are needed for cross-zone subentries in MOD entries or TARGETZONE entries.

- **Adding XZM0D subentries:** This example adds module IGCXXX from zone ZXXX and module IGCABC from zone ZABC to the IENU0C01 LMOD entry. If this LMOD entry previously had no XZM0D subentries, SMP/E automatically sets XZMODP to indicate that the LMOD entry now contains XZM0D subentries.

```
SET BDY(ZOSZN) /* Set to z/OS zone */.
UCLIN /* start UCLIN processing */.
ADD LMOD(IEANU01) /* identify LMOD entry */
   XZMOD((IGCXXX,ZXXX), /* add module from ZXXX zone */
         (IGCABC,ZABC)) /* add module from ZABC zone */.
ENDUCL /* end UCLIN processing */.
```

- **Replacing XZM0D subentries:** This example replaces all the XZM0D subentries in LMOD entry CICSDIAG with a single subentry for module ISPLINK from zone ZOSZN. If this LMOD entry previously had no XZM0D subentries, SMP/E automatically sets XZMODP to indicate that the LMOD entry now contains XZM0D subentries.

```
SET BDY(CICS1) /* set to CICS zone */.
UCLIN /* start UCLIN processing */.
REP LMOD(CICSDIAG) /* identify LMOD entry */
   XZMOD((ISPLINK,ZOSZN)) /* replace list with one value */.
ENDUCL /* end UCLIN processing */.
```

- **Deleting XZM0D subentries:** This example shows how to delete a single XZM0D subentry or all XZM0D subentries.
  - For LMOD entry IMSDIAG1, one XZM0D subentry is deleted. If no XZM0D values are left, SMP/E turns the XZM0DP indicator off to indicate that the LMOD entry no longer has XZM0D subentries.
  - For LMOD entry IMSDIAG2, all XZM0D subentries are deleted. SMP/E turns the XZM0DP indicator off to indicate that the LMOD entry no longer contains XZM0D subentries.

```
SET BDY(IMS1) /* set to IMS zone */.
UCLIN /* start UCLIN processing */.
DEL LMOD(IMSDIAG1) /* identify LMOD entry */
   XZMOD((ISPLINK,ZOSZN)) /* delete ISPLINK reference */.
DEL LMOD(IMSDIAG2) /* identify LMOD entry */
   XZMOD() /* delete entire list */.
ENDUCL /* end UCLIN processing */.
```

**Example 5: Adding a CALLLIBS subentry list to an LMOD entry**
You can use either the ADD or the REP statement to add a CALLLIBS subentry list to an LMOD entry, depending on whether the CALLLIBS already exists or not. The order in which the libraries are specified is important because it indicates the order in which the SYSLIB concatenation is built. This is shown in the examples that follow.

- **Adding a CALLLIBS subentry:** This example adds a CALLLIBS subentry list containing PLIBASE and APPLIB to LMOD entry LMOD04.

```
SET BDY(ZOSZN) /* set to z/OS zone */.
UCLIN /* start UCLIN processing */.
ADD LMOD(LMOD04) /* identify LMOD entry */
   CALLLIBS(PLIBASE,APPLIB) /* add CALLLIBS subentry */.
ENDUCL /* end UCLIN processing */.
```

- **Adding to an existing CALLLIBS subentry:** Suppose LMOD entry LMOD05 has a CALLLIBS subentry list containing PLIBASE and APPLIB, and CSSLIB is to be added to this list. The entire CALLLIBS subentry must be replaced as shown below:
**LMOD entry (distribution and target zone)**

```plaintext
SET BDY(ZOSZN)    /* set to z/OS zone */.
UCLIN           /* start UCLIN processing */.
REP LMOD(LMOD05)
    CALLLIBS(PLIBASE,APPLIB,
    CSSLIB)   /* replace entire CALLLIBS */.
ENDUCL.        /* end UCLIN processing */.
```

**Example 6: Deleting link-edit control statements**

Suppose you have installed a SYSMOD that was packaged incorrectly and added unwanted link-edit control statements to the LMOD entry for an existing load module. As a result, you now need to delete those statements from the LMOD entry. Here is an example of the UCLIN statements you can use to make this change:

```plaintext
SET BDY(ZOSZN)    /* set to z/OS zone */.
UCLIN           /* start UCLIN processing */.
DEL LMOD(LMODx2) /* delete LMOD entry */.
++LMODIN        /* delete all link-edit */.
++ENDLMODIN     /* control statements. */.
ENDUCL.        /* end UCLIN processing */.
```

Using the REP command instead of the DEL command gives you the same result. There is no need to specify the control statements to be deleted. In fact, you cannot selectively delete link-edit control statements from an LMOD entry—you can only delete them all.

**Example 7: Adding a UTIN and SIDEDECKLIB subentry to an LMOD**

In this example, a utility input subentry list, containing DSOMCMPI from library SDSOMSD and DSOMCMP2 from library SDSOMSD, is added to the LMOD entry for load module LMOD1. In addition, a side deck library subentry of SGOSSD is added to the LMOD entry for load module LMOD5.

```plaintext
SET BDY(TGT)    /* set to target zone. */.
UCLIN          /* start UCLIN processing. */.
ADD LMOD(LMOD1) /* identify LMOD entry. */.
    UTIN((DSOMCMPI,SDSOMSD)) /* add utility input... */.
    UTIN((DSOMCMP2,SDSOMSD)) /* ...subentry list. */.
ADD LMOD(LMOD5) /* identify LMOD entry. */.
    SIDEDECKLIB(SGOSSD) /* add side deck library. */.
ENDUCL.    /* end UCLIN processing. */.
```

**Example 8: Deleting a UTIN subentry from an LMOD**

In this example, DSOMCMPI1 is deleted from the utility input subentry for LMOD entry LMOD2, and the entire utility input subentry list is removed from LMOD entry LMOD3.

```plaintext
SET BDY(TGT)    /* set to target zone. */.
UCLIN          /* start UCLIN processing. */.
DEL LMOD(LMOD2) /* identify LMOD entry. */.
    UTIN((DSOMCMPI,SDSOMSD)) /* remove DSOMCMPI from */.
DEL LMOD(LMOD3) /* utility input subentry. */.
    UTIN()               /* delete all utility input. */.
ENDUCL.    /* end UCLIN processing. */.
```
MAC entry (distribution and target zone)

The MAC entry describes a macro that exists in the distribution or target macro libraries. A MAC entry is generally created by one of the following methods:

- **Installing a SYSMOD that contains the macro.** MAC entries are created the first time you install a SYSMOD containing a ++MAC statement for a macro that does not yet have a MAC entry.

- **Processing JCLIN.** MAC entries can be built during JCLIN processing when SMP/E scans the assembler statements for inline assemblies to determine which macros are used in that assembly. The name of the assembly is kept in the MAC entry, so when the macro is updated, SMP/E can reassemble the required modules.

MAC entries can also be built when SMP/E scans copy steps and finds a SELECT statement that specifies TYPE=MAC.

For additional information, see the “Processing” section of the JCLIN command chapter in [SMP/E Commands](#).

SMP/E records the function and service level of each macro in the MAC entry, as well as information about how that macro affects the structure of the distribution or target libraries and modules.

Once a MAC entry exists for a macro, it is updated as subsequent SYSMODs are installed.

**Subentries**

These are the subentries for the MAC entry as they appear in the LIST output:

- **name**
  
  is the name of the macro represented by the MAC entry.
  
  The name can contain from 1 to 8 alphanumeric characters and $, #, @, or hex C0.

- **DISTLIB**
  
  is the ddname of the macro distribution library.
  
  The UCL operand is `DISTLIB(ddname)`.
  
  - The ddname can contain from 1 to 8 alphanumeric characters.
  
  - The DISTLIB subentry is not required when the MAC entry is first defined. For example, during JCLIN processing SMP/E builds MAC entries without a DISTLIB value. However, SMP/E can add a DISTLIB value later when it processes the ++MAC statement. A DISTLIB value is needed at some time to process any changes for the macro.

- **FMID**
  
  identifies the functional owner of this macro. The functional owner is the last function SYSMOD that replaced this macro.
  
  The UCL operand is `FMID(sysmod_id)`.
  
  The SYSMOD ID must contain 7 alphanumeric characters.

- **GENASM**
  
  identifies those assemblies that have to be done during APPLY each time this macro is modified. These assemblies must exist as either ASSEM or SRC entries in the target zone.
  
  The UCL operand is `GENASM(name...)`. 
MAC entry (distribution and target zone)

The names can contain from 1 to 8 alphanumeric characters.

**LASTUPD**
identifies the cause of the last change to this MAC entry.

The UCL operand is **LASTUPD(value)**. This subentry can contain one of the following values:

**JCLIN**
indicates that the change was made during JCLIN command processing.

**UCLIN**
indicates that the change was made as a result of UCLIN processing.

**sysmod-id**
indicates that the change was made during the installation of the indicated SYSMOD.

The SYSMOD ID must contain 7 alphanumeric characters.

**LASTUPD TYPE**
indicates how the entry was last changed.

The UCL operand is **LASTUPDTYPE(value)**. This subentry can contain one of the following values:

**ADD** The entry was added.

**MOV** The entry was moved.

**UPD** The entry was updated.

**MALIAS**
identifies any alias names for this macro.

The UCL operand is **MALIAS(name...)**.

The alias names can contain from 1 to 8 alphanumeric characters.

**RMID**
identifies the last SYSMOD that replaced this macro. Any subsequent SYSMOD that modifies this macro must have a defined relationship (such as PRE or SUP) with this SYSMOD.

The UCL operand is **RMID(sysmod_id)**.

• The SYSMOD ID must contain 7 alphanumeric characters.

• If RMID is not specified, but **FMI**D is, SMP/E sets the RMID value to the specified FMID.

**SYSLIB**
is the ddname of the target system macro library.

The UCL operand is **SYSLIB(ddname)**.

• Only one SYSLIB value may be specified.

• The ddname can contain from 1 to 8 alphanumeric characters.

**UMID**
identifies all those SYSMODs that have updated this macro since it was last replaced. Any subsequent SYSMOD that modifies this macro must have a defined relationship (such as PRE or SUP) with all these SYSMODs.

The UCL operand is **UMID(sysmod_id...)**.

The SYSMOD ID must contain 7 alphanumeric characters.
MAC entry (distribution and target zone)

LIST Examples

To list all the MAC entries in a particular zone, you can use the following commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
LIST MAC /* List all MAC entries. */.
```

To list specific MAC entries, you can use these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
LIST MAC(MAC01) /* List only these two entries. */
         MAC02  /* */.
```

The format of the LIST output for each MAC entry is the same for both of these commands. The only difference is the number of MAC entries listed. Figure 39 shows an example of LIST output for MAC entries.

![Figure 39. MAC entry: sample LIST output](image)

By specifying the FORFMID operand, you can reduce the number of MAC entries listed. When FORFMID is specified, SMP/E lists a MAC entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to list MAC entries whose FMIDs either are defined in FMIDSET TP or are JXY1102, you can use these commands:

```
SET BDY(TGT1) /* Set to target zone. */.
LIST MAC /* List all macro entries */
         FORFMID (TP /* for the TP FMIDSET */
                   JXY1102) /* and FMID JXY1102. */.
```

You can use the LIST command to find out the names of all SYSMODs that have modified a macro. To include the names of these SYSMODs in the LIST output, you can use the XREF operand, as shown in these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
LIST MAC /* List all macro entries */
         XREF /* and related SYSMODs. */.
```

Notes:

1. XREF can be used either in mass mode or in select mode.
MAC entry (distribution and target zone)

2. SMP/E obtains the data included for the XREF operand by checking for MAC and MACUPD entries for this macro in all the SYSMOD entries. Because this data is not contained in the MAC entry itself, you cannot use UCLIN to change it in the MAC entry.

Figure 40 is an example of the LIST output produced when the XREF operand is used.

Figure 40. MAC entry: sample LIST output when XREF is specified

**UNLOAD Examples**

To dump the MAC entries in UCL format, you can use the UNLOAD command.

To unload all the MAC entries in a particular zone, you can use the following commands:

```
SET BDY(TGT1)    /* Set to requested zone. */
UNLOAD MAC       /* Unload all MAC entries. */
```

To unload specific MAC entries, you can use these commands:

```
SET BDY(TGT1)    /* Set to requested zone. */
UNLOAD MAC(MAC01) /* Unload only these two */
             MAC02)       /* entries. */
```

The format of the UNLOAD output for each MAC entry is the same for both of these commands. The only difference is the number of MAC entries listed.

Figure 41 on page 271 is an example of UNLOAD output for MAC entries.
By specifying the FORFMID operand, you can reduce the number of MAC entries unloaded. When FORFMID is specified, SMP/E unloads a MAC entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to unload MAC entries whose FMIDs either are defined in FMIDSET TP or are JXY1102, you can use these commands:

```sh
SET BDY(TGT1) /* Set to target zone. */.
UNLOAD MAC /* Unload all macro entries */
  FORFMID(TP /* for the TP FMIDSET */
    JXY1102) /* and FMID JXY1102. */.
```

### UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the MAC entry. After the UCLIN changes are made, the MAC entry must contain at least the following subentries:
- FMID
- RMID

Otherwise, there is not enough information in the entry to process the macro. If any of these subentries are missing, SMP/E does not make the requested UCL updates to the entry, and the entry remains as it was before the UCL command.

The following examples are provided to help you use the MAC entry.

### Example 1: Adding a new MAC entry

Defining a new macro entry with UCL is very seldom required; generally, MAC entries are created from the information specified on the ++MAC statements contained in the SYSMODs when SYSMODs are installed. If, however, you want to use UCL in defining a new macro entry, the following is an example of the minimum information you should provide:

```sh
SET BDY(TGT1) /* Set to target zone. */.
UCLIN /* */.
ADD MAC(MAC01) /* Define new macro entry. */
  DISTLIB(AMACLIB) /* Define DLIB. */
  SYSLIB(MACLIB) /* system library */.
```

---

Chapter 5. SMP/E data set entries 271
MAC entry (distribution and target zone)

```plaintext
FMID(ZUSR001) /* Functional owner (in this example a user function). */
ENDUCL /* */
SET BDY(DLB1). /* Now do same to DLIB. */
UCLIN /* */
ADD MAC(MAC01) /* Define new macro entry. */
DISTLIB(AMACLIB) /* Define DLIB. */
FMID(ZUSR001) /* Functional owner (in this example a user function). */
ENDUCL /* */
```

**Example 2: Defining an alias for an existing macro**

The following defines the method of adding an alias to an existing macro:

```plaintext
SET BDY(TGT1)  /* Set to target zone. */
UCLIN /* */
ADD MAC(MAC01) /* Existing macro entry. */
MALIAS(MAC01AL1) /* New alias name. */
ENDUCL /* */
```

```plaintext
SET BDY(DLB1)  /* Now do same thing to appropriate DLIB. */
UCLIN /* */
ADD MAC(MAC01) /* Existing macro entry. */
MALIAS(MAC01AL1) /* New alias name. */
ENDUCL /* */
```

**Note:** This UCL does not create an alias entry in the target or distribution libraries; that must be done outside of SMP/E using standard utilities. This ensures that, when the macro is subsequently modified, both the major entry and the alias entry are updated.
MCS entry (SMPPTS)

The MCS entry is a copy of a SYSMOD exactly as it was received from the SMPPTFIN data set. The MCS entry is in the SMPPTS data set, which is used as a warehouse for SYSMODs. When SMP/E receives a SYSMOD, it stores the SYSMOD as a separate member in the SMPPTS. The member name matches the SYSMOD ID, and each member is an MCS entry. SMP/E also creates a SYSMOD entry in the global zone to describe the SYSMOD that was received. Thus, the MCS entry and the global zone SYSMOD entry are closely related.

When SMP/E accepts or applies SYSMODs, it gets them from the MCS entries in the SMPPTS. An MCS entry is generally kept in the SMPPTS until the associated SYSMOD is accepted; then the entry is deleted.

- You may want SMP/E to save the MCS entries after ACCEPT processing, for example, if you plan to do a system generation. To do this, specify NOPURGE in the OPTIONS entry that is in effect during ACCEPT processing.
- Likewise, you may want to save the MCS entries after RESTORE processing. To do this, specify NOREJECT in the OPTIONS entry that is in effect during RESTORE processing.

Subentries

The MCS entry contains no SMP/E data and appears to the system as a member of a normal partitioned data set.

LIST Examples

To list all the MCS entries in the SMPPTS, you can use the following commands:

```plaintext
SET BDY(GLOBAL) /* Set to global. */.
LIST MCS /* List all MCS entries. */.
```

To list specific MCS entries, you can use these commands:

```plaintext
SET BDY(GLOBAL) /* Set to global. */.
LIST MCS(UZ12345, UZ12346) /* List only these two entries. */.
```

The format of the LIST output for each MCS entry is the same for both of these commands. The only difference is the number of MCS entries listed.

Figure 42 on page 274 is an example of LIST output for MCS entries.
As the example for UZ12346 shows, SMP/E includes inline JCLIN when listing the MCS entries.

You can use various SYSMOD-related LIST operands to limit which MCS entries are listed. For more information, see “SYSMOD entry (distribution and target zone)” on page 322 and “SYSMOD entry (global zone)” on page 336.

In addition to the LIST command, you can use standard system utility programs (such as IEBGENER, IEBPITPC, IEHLIST, and so on) or products such as ISPF to display these entries or information about the data set.

**UCLIN Examples**

You cannot use UCLIN to add, update, or delete MCS entries. However, you can use the REJECT command to delete MCS entries. For more information on the REJECT command, see  

**Do not use** system utility programs to update MCS entries. The global zone SYSMOD entry is coordinated with the MCS entry. Any changes to the MCS entry made outside of SMP/E may get these entries out of synchronization and can result in unpredictable results when the associated SYSMOD is processed.
MOD entry (distribution and target zone)

The MOD entry describes a particular module, its function and service level, and how it relates to a load module in the target library. A MOD entry is generally created by one of the following methods:

- **Installing a SYSMOD that contains the module.** MOD entries are created the first time you install a SYSMOD that contains a ++MOD statement for a module that does not yet have a MOD entry. If the module comes from a copied distribution library, SMP/E also builds an LMOD entry with the same name. For additional information about copied libraries and the creation of LMOD entries, see “DLIB entry (distribution and target zone)” on page 211 and [SMP/E Commands](#).

A MOD entry can also be created when you install a SYSMOD that causes the assembled source to be linked to the distribution library. This can happen when a SYSMOD contains both a ++MOD and a ++SRC statement for the same module, or when the DISTMOD operand is specified on the ++SRC statement.

- **Processing JCLIN.** MOD entries can be built during JCLIN processing when SMP/E scans the link-edit and copy steps. A MOD entry built during JCLIN processing is always associated with an LMOD entry. Thus, when the module is changed, SMP/E can determine which load modules are affected. For additional information, see the “Processing” section of the JCLIN command chapter in [SMP/E Commands](#).

**Subentries**

These are the subentries for the MOD entry as they appear in the LIST output:

- **name**
  - is the name of the module represented by the MOD entry.
  - The name can contain from 1 to 8 alphanumeric characters and $, #, @, or hex C0.

**ASSEMBLE**
- indicates that the source for this module must always be assembled, even if the object module is supplied in the SYSMOD.
- The UCL operand is **ASSEMBLE**.

**CSECT**
- specifies the CSECTs present in this module.
- The UCL operand is **CSECT(name...)**.
  - The CSECT subentry is not required. However, if CSECT is missing, SMP/E assumes that the module contains only one CSECT, whose name matches the module name.
  - A CSECT name can contain from 1 to 8 characters.
  - The name can contain any characters except the following:
    - Comma ,
    - Left parenthesis (,
    - Right parenthesis )
    - Blank
  - Comments are not allowed within a CSECT name. For example, the following is not allowed:
    - CSECT ( /* this is a csect name */ CSECT01)
    - The comment is interpreted as part of the CSECT name, instead of a comment.
MOD entry (distribution and target zone)

- The list of CSECT names must include all of the CSECTs in the module, even if one of the CSECTs matches the module name.
- Once a ++MOD with the CSECT operand is processed, SMP/E saves the CSECT information in the MOD entry. From then on, SMP/E uses that saved information if it is not supplied on subsequent SYSMODs.
- If a module is changed from multiple CSECTs to a single CSECT that matches the module name, the CSECT operand must be specified with one name in order to get SMP/E to store that information in the MOD entry.

DALIAS
specifies the alias name for the module, where the alias exists only in the distribution library.

The UCL operand is `DALIAS(name)`.
The DALIAS name can contain from 1 to 8 alphanumeric characters.

DISTLIB
is the ddname of the module distribution library.

The UCL operand is `DISTLIB(ddname)`.
The ddname can contain from 1 to 8 alphanumeric characters.

FMID
identifies the functional owner of this module. The functional owner is the last function SYSMOD that replaced this module.

The UCL operand is `FMID(sysmod_id)`.
- The SYSMOD ID must contain 7 alphanumeric characters.
- Some MOD entries, specifically those associated with a system generation assembly, may have no functional owner. The DISTLIB for these modules is SYSPUNCH. They may have either no FMID, or one of the following values:
  - If the module has no functional owner but was assembled during system generation, *SYSGEN appears as the FMID.
  - If the module has no functional owner and was not assembled during system generation, ?????? appears as the FMID.

LASTUPD
identifies the cause of the last change to this MOD entry.

Note: If a given UCLIN command specifies only cross-zone subentries, this field is not changed.

The UCL operand is `LASTUPD(value)`. This subentry can contain one of the following values:

JCLIN
indicates that the change was made during JCLIN command processing.

UCLIN
indicates that the change was made as a result of UCLIN processing.

sysmod-id
indicates that the change was made during installation of the specified SYSMOD. The SYSMOD did one of the following:
- Contained inline JCLIN that affected the module
- Changed the distribution library for the module through the DISTLIB operand on the ++MOD statement
MOD entry (distribution and target zone)

- Added the module to an existing load module through the LMOD operand on the ++MOD statement

The SYSMOD ID must contain 7 alphanumeric characters.

LASTUPD TYPE
indicates how the entry was last changed.

Note: If a given UCLIN command specifies only cross-zone subentries, this field is not changed.

The UCL operand is LASTUPDTYPE(value). This subentry can contain one of the following values:
ADD The entry was added.
DEL A subentry in the entry was deleted.
MOV The module was moved.
UPD The entry was updated.

LKED ATTRIBUTES
identifies the link-edit attributes that must be used when this module is link-edited. SMP/E supports the following link-edit attributes. For more information, see z/OS MVS Program Management: User's Guide and Reference, SA22-7643.

AC=1 specifies that the AC=1 parameter, which is the authorization code, is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is AC=1.

ALIGN2 specifies that the ALIGN2 parameter (alignment on a 2KB boundary) is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is ALIGN2 or ALN2.

AMODE=24 specifies that the AMODE=24 parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is AMODE=24 or AMOD=24.

AMODE=31 specifies that the AMODE=31 parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is AMODE=31 or AMOD=31.

AMODE=64 specifies that the AMODE=64 parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is AMODE=64 or AMOD=64.

AMODE=ANY specifies that the AMODE=ANY parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is AMODE=ANY or AMOD=ANY.

AMODE=MIN specifies that the AMODE=MIN parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is AMODE=MIN or AMOD=MIN.
MOD entry (distribution and target zone)

COMPAT
specifies that the COMPAT parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is COMPAT=LKED | PM1 | PM2 | PM3 | PM4.

DC
specifies that the DC parameter, which is the downward compatible attribute, is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is DC.

FETCHOPT
specifies that the FETCHOPT parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is FETCHOPT(PACK | NOPACK, PRIME | NOPRIME).

FILL
specifies that the FILL parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is FILL(nn), where nn is the 2-character representation of a single hex byte (00 - FF).

HOBSET
specifies that the HOBSET parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is HOBSET.

MAXBLK
specifies that the MAXBLK parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is MAXBLK(nnnnn), where nnnnn is a number between 256 and 32760.

NE
specifies that the NE parameter, which is the noneditable attribute, is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is NE.

NOCALL
specifies that the NCAL parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is NOCALL or NCAL.

OL
specifies that the OL parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is OL.

OVLY
specifies that the OVLY parameter, which specifies that the module is in overlay structure, is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is OVLY.

REFR
specifies that the REFR parameter, which is the refreshable attribute, is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is REFR.
MOD entry (distribution and target zone)

RENT
specifies that the RENT parameter, which indicates that the module is reentrant, is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is RENT.

REUS
specifies that the REUS parameter, which indicates that the module is reusable, is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is REUS.

REUS(NONE)
specifies that the REUS(NONE) parameter, which indicates that the module cannot be reused, is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is REUS(NONE).

RMODE=24
specifies that the RMODE=24 parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is RMODE=24 or RMOD=24.

RMODE=ANY
specifies that the RMODE=ANY parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is RMODE=ANY or RMOD=ANY.

RMODE=SPLIT
specifies that the RMODE=SPLIT parameter is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is RMODE=SPLIT or RMOD=SPLIT.

SCTR
specifies that the SCTR parameter, which indicates that the module can be scatter-loaded, is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is SCTR.

STD
is a special SMP/E indication that the module should be link-edited with none of the previously listed attributes.

When this indicator is present and a link-edit is to be done, SMP/E will pass the link-edit utility only those parameters specified in the appropriate link-edit UTILITY entry.

The UCL operand is STD.

UPCASE
specifies that the UPCASE parameter, which indicates how the Binder should process symbol names, is to be passed to the link-edit utility when the module is link-edited.

The UCL operand is UPCASE(YES|NO).
• UPCASE(YES) and UPCASE(NO) are mutually exclusive.
MOD entry (distribution and target zone)

LMOD
specifies the names of the load modules into which this module was copied or
link-edited on the target system.

The UCL operand is LMOD(name...).

- The load module names can contain from 1 to 8 alphanumeric characters.
- If there are no LMOD names in a MOD entry, SMP/E assumes that the
module was not selected when the SYSMOD containing the module was
initially installed. Therefore, during APPLY processing, SMP/E will not link
or copy the module into any target library.

RMID
identifies the last SYSMOD that replaced this module. Any subsequent
SYSMOD that modifies this module must have a defined relationship (such as
PRE or SUP) with this SYSMOD.

The UCL operand is RMID(sysmod_id).

- The SYSMOD ID must contain 7 alphanumeric characters.
- If RMID is not specified, but FMID is, SMP/E sets the RMID subentry to
the FMID value.
- RMID is not required for a module assembled during system generation.
The DISTLIB for these modules is SYSPUNCH.

RMIDASM
specifies that the last replacement (RMID) to the module was done by a
SYSMOD that caused an assembly of the module as a result of a source or
macro modification.

The UCL operand is RMIDASM.

TALIAS
specifies one or more alias names for the module, where the alias exists in the
distribution library and, for copied modules, also in the target library.

The UCL operand is TALIAS(name...).

The alias names can contain from 1 to 8 alphanumeric characters.

UMID
identifies all those SYSMODs that have updated this module since it was last
replaced. Any subsequent SYSMOD that modifies this module must have a
defined relation (such as PRE or SUP) with all these SYSMODs.

The UCL operand is UMID(sysmod_id...).

The SYSMOD ID must contain 7 alphanumeric characters.

XZLMOD
specifies one or more load modules in other zones into which this module was
added by the LINK MODULE command. The name of the zone supplying
each module is also indicated.

The UCL operand is XZLMOD(load module,zone...).

- The zone name specified for an XZLMOD subentry cannot match the name
of the set-to zone.
- An entry can contain XZLMOD and XZLMDP subentries without any
other subentries.
- If UCLIN is used to update an existing MOD entry and only cross-zone
subentries are changed (XZLMOD and XZLMDP), SMP/E does not update
the LASTUPD and LASTUPDTYPE subentries.
MOD entry (distribution and target zone)

- The XZLMOD subentry is added to a MOD entry automatically during LINK MODULE command processing. However, it is never automatically removed.

**XZLMODP**
indicates that this module has been linked into one or more load modules controlled by a different target zone, and that XZLMOD subentries exist in this MOD entry.

The UCL operand is **XZLMODP**.
- It is never necessary to specify the XZLMODP subentry on a UCL statement. SMP/E automatically determines the setting of XZLMODP, according to whether the MOD entry contains XZLMOD subentries.
- You cannot add the XZLMODP subentry to a MOD entry that does not contain XZLMOD subentries.
- You cannot delete the XZLMODP subentry from a MOD entry containing XZLMOD subentries.
- An entry can contain XZLMOD and XZLMODP subentries without any other subentries.
- If UCLIN is used to update an existing MOD entry and only cross-zone subentries are changed (XZLMOD and XZLMODP), SMP/E does not update the LASTUPD and LASTUPDTYPE subentries.

**LIST Examples**

To list all the MOD entries in a particular zone, you can use the following commands:

```plaintext
SET BDY(TGT1) /* Set to requested zone. */.
LIST MOD /* List all MOD entries. */.
```

To list specific MOD entries, you can use these commands:

```plaintext
SET BDY(TGT1) /* Set to requested zone. */.
LIST MOD(MOD01) /* List only these two */
MOD(MOD02) /* entries. */.
```

The format of the LIST output for each MOD entry is the same for both of these commands. The only difference is the number of MOD entries listed. The following examples show LIST output for MOD entries. [Figure 43 on page 282] does not have cross-zone subentries. [Figure 44 on page 283] does.

Figure 43. MOD entry: sample LIST output (no cross-zone subentries)
MOD entry (distribution and target zone)

By specifying the FORFMID operand, you can reduce the number of MOD entries listed. When FORFMID is specified, SMP/E lists a MOD entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to list MOD entries whose FMIDs are either defined in FMIDSET TP or are JXY1102, you can use these commands:

```
SET BDY(TGT1) /* Set to target zone. */.
LIST MOD /* List all MOD entries */
FORFMID(TP) /* for the TP FMIDSET */
  JXY1102 /* and FMID JXY1102. */
```

You can also use the LIST command to find out the names of all SYSMODs that have updated a module. To include the names of these SYSMODs in the LIST output, you can use the XREF operand, as shown in these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
LIST MOD /* List all module entries */
  XREF /* and related SYSMODs. */
```

Notes:
1. XREF can be used either in mass mode or in select mode.
2. SMP/E obtains the data included for the XREF operand by checking all the SYSMOD entries to find which SYSMODs contained ++MOD or ++ZAP

UNLOAD Examples

To dump the MOD entries in UCL format, you can use the UNLOAD command.

To unload all the MOD entries in a particular zone, you can use the following commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD MOD /* Unload all MOD entries. */.
```

To unload specific MOD entries, you can use these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD MOD(MOD01, MOD02) /* Unload only these two entries. */.
```

The format of the UNLOAD output for each MOD entry is the same for both of these commands. The only difference is the number of MOD entries unloaded. The following examples show UNLOAD output for MOD entries. Figure 46 does not have cross-zone subentries. Figure 47 on page 287 does.

ENDUCL.

Figure 46. MOD entry: sample UNLOAD output (no cross-zone subentries) (Part 2 of 2)
By specifying the FORFMID operand, you can reduce the number of MOD entries unloaded. When FORFMID is specified, SMP/E unloads a MOD entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to unload MOD entries whose FMIDs are either defined in FMIDSET TP or are JXY1102, you can use these commands:

```
SET BDY(TGT1) /* Set to target zone. */.
UNLOAD MOD /* Unload all MOD entries */.
FORFMID(TP) /* for the TP FMIDSET */.
       JXY1102 /* and FMID JXY1102. */.
```

**UCLIN Examples**

You can use the ADD, REP, and DEL UCL statements to change subentries in the MOD entry. After the UCLIN changes are done, the MOD entry must contain at least the following subentries:

- DISTLIB

---

**Figure 47. MOD entry: sample UNLOAD output (cross-zone subentries)**

- FMID
- RMID

Otherwise, there is not enough information in the entry to process the module. If any of the required subentries are missing, SMP/E does not make the requested UCL updates to the entry, and the entry remains as it was before the UCL command.

The following examples are provided to help you use the MOD entry.

Example 1: Adding a new MOD entry
To create a MOD entry, you should use one of the following methods rather than UCLIN:

- JCLIN, if a new module is being added to a new load module. For examples of how JCLIN creates MOD entries, see [SMP/E Commands](#).
- The LMOD operand on the ++MOD statement, if a new module is being added to an existing load module and no changes are needed in the link-edit control statements other than the INCLUDE for the new module. For an example of how to do this, see "++MOD MCS" on page 76.

You could make the same changes with the UCLIN command. However, you should make sure the changes are correct and complete. For example, assume you want to define two new modules, MOD99A and MOD99B. These are linked together to form load module LMOD99AB, which has an entry point of MOD99A and exists in LINKLIB. The FMID of both new modules is ZUSR001, a user-created function. You could use these commands to create the MOD and LMOD entries:

```plaintext
SET  BDY(TGT1) /* Set to target zone. */
UCLIN /* */
ADD  MOD(MOD99A) /* Define new module entry. */
     DISTLIB(USRDLIB1) /* Define DLIB. */
     LMOD(LMOD99AB) /* Load module. */
     FMID(ZUSR001) /* Functional owner. */
ADD  MOD(MOD99B) /* Define new module entry. */
     DISTLIB(USRDLIB1) /* Define DLIB. */
     LMOD(LMOD99AB) /* Load module. */
     FMID(ZUSR001) /* Functional owner. */
ADD  LMOD(LMOD99AB) /* Now define LMOD. */
     SYSLIB(LINKLIB) /* */
     RENT REUS /* Attributes. */
++LMODIN /* Link statements. */
ENTRY MOD99A
++ENDLMODIN /* */
/* */
ENDUCL /* */
```

Example 2: Forcing assembly of a module
Assume you have a macro that is used by a source, and you want to make sure the source is always assembled when the macro is changed. You can do this by setting the ASSEMBLE indicator as follows:

```plaintext
SET  BDY(DLIB1) /* Set to DLIB zone. */
UCLIN /* */
ADD  MOD(SRC01) /* MOD entry for source. */
     ASSEMBLE /* Always assemble it. */
     /* */
ENDUCL /* */
```
MOD entry (distribution and target zone)

Example 3: Completing cross-zone updates

If SMP/E could not complete cross-zone updates for APPLY or RESTORE processing, you may need to use UCLIN to make the remaining changes. (SMP/E issues messages and reports to tell you what cross-zone work you may need to finish.) Here are some examples of using UCLIN to change XZLMOD subentries in MOD entries. Make sure to check the messages and reports to determine whether any additional changes are needed for cross-zone subentries in LMOD entries or TARGETZONE entries.

- **Adding XZLMOD subentries**: This example adds LMOD IEANUC01 to the IGCXXX MOD entry in zone IMS1. If this MOD entry previously had no XZLMOD subentries, SMP/E automatically sets XZLMODP to indicate that the MOD entry now contains XZLMOD subentries.

```plaintext
SET BDY(IMS1) /* set to IMS zone */.
UCLIN /* start UCLIN processing */.
ADD MOD(IGCXXX) /* identify MOD entry */
   XZLMOD((IEANUC01,ZOSZNA)) /* add load module from zone ZOSZNA */.
ENDUCL /* end UCLIN processing */.
```

- **Replacing XZLMOD subentries**: This example replaces all the XZLMOD subentries in MOD entry ISPLINK with two XZLMOD subentries. If this MOD entry previously had no XZLMOD subentries, SMP/E automatically sets XZLMODP to indicate that the MOD entry now contains XZLMOD subentries.

```plaintext
SET BDY(ZOSZNA) /* set to first zone. */.
UCLIN /* start UCLIN processing */.
REP MOD(ISPLINK) /* identify MOD entry */
   XZLMOD((CICSDIAG,CICS1) /* replace list with two values */
      (IMSDIAG1,IMS1)) /* */.
ENDUCL /* end UCLIN processing */.
```

- **Deleting XZLMOD subentries**: This example deletes an XZLMOD subentry from the ISPLINK subentry. If this causes the XZLMOD subentry list to become empty, SMP/E automatically turns XZLMODP off to indicate that the MOD entry no longer contains XZLMOD subentries.

```plaintext
SET BDY(ZOSZNB) /* set to second zone. */.
UCLIN /* start UCLIN processing */.
DEL MOD(ISPLINK) /* identify MOD entry */
   XZLMOD((IMSDIAG2,IMS1)) /* delete IMSDIAG2 reference */.
ENDUCL /* end UCLIN processing */.
```
MTSMAC entry (SMPMTS)

The MTSMAC entry is a copy of a macro that resides only in a distribution library but is needed temporarily during APPLY processing. The MTSMAC entry is in the SMPMTS data set, which serves as a target macro library for such macros.

When SMP/E applies the SYSMODs that affect these macros, it calls utility programs to store the macros on the SMPMTS. This way, the most current service level of each macro is available for use in assemblies. After SMP/E has accepted all the SYSMODs that affect these macros, it deletes the associated MTSMAC entries from the SMPMTS.

Note: If you specify SAVEMTS in the OPTIONS entry that is in effect during ACCEPT processing, SMP/E will not delete MTSMAC entries from the SMPMTS after the SYSMODs that affect those macros have been successfully accepted.

Subentries
The MTSMAC entry contains no SMP/E data and appears to the system as a member of a normal macro library.

LIST Examples
You cannot use SMP/E to list the MTSMAC entries. However, you can use standard system utility programs (such as IEBGENER, IEBPTPCH, and IEHLIST) or products such as ISPF to display these entries or information about the data set.

UCLIN Examples
You can use the DEL UCL statement to delete an MTSMAC entry from the SMPMTS. This can be helpful if you plan to do an APPLY followed by ACCEPT when several target libraries have been created from the same distribution library.

When a SYSMOD is accepted into a distribution zone, the entries associated with it are automatically deleted from the SMPMTS for the RELATED target zone. However, even if the SYSMOD was also applied to other target zones created from the same distribution zone, SMP/E does not clean up the SMPMTS data sets for the other target zones.

To delete the entries from these data sets, you can accept the SYSMOD and name these other target zones as the RELATED zone. However, this would update the distribution library each time; this is time-consuming and could use up space in the distribution library data set.

Instead, you can use the DEL command to delete these entries without updating the distribution library. To determine which entries to specify, check the SMPLOG data set to see which ones SMP/E deleted during ACCEPT processing.

Note: You can also use the CLEANUP command to delete MTSMAC entries without specifying them individually. For more information on the CLEANUP command, see [SMP/E Commands](#).

Example: Deleting an MTSMAC entry
Assume that you have two target zones, TGT1 and TGT2, generated off the same distribution zone, DLB1. During ACCEPT processing of a SYSMOD, SMP/E has deleted MTSMAC MAC01 and MAC02 from the SMPMTS data set associated with target zone TGT2. After performing the ACCEPT, you want to delete the same
macro from the SMPMTS associated with target zone TGT1. Assume either that you have a cataloged procedure for TGT1 with the correct SMPMTS specified, or that you have set up the correct DDDEF entries. The following UCLIN can be used to delete the MTSMAC entry:

```
SET  BDY(TGT1) /* Set to TGT zone. */.
UCLIN /* */.
DEL  MTSMAC(MAC01) /* Delete the macro. */.
DEL  MTSMAC(MAC02) /* Delete the macro. */.
ENDUCL /* */.
```

**Note:** One UCL statement is required for each MTSMAC entry to be deleted.

You can make the same changes by use of system utilities. However, the SMPLOG will not reflect the processing done.
OPTIONS entry (global zone)

OPTIONS entry (global zone)
The OPTIONS entry defines processing options that are to be used for an SMP/E command or set of commands. Although OPTIONS entries exist only in the global zone, they are also used to process commands for target and distribution zones. There are two ways you can specify the OPTIONS entry that should be in effect when you are processing a zone:

- In the GLOBALZONE, TARGETZONE, and DLIBZONE entries. The OPTIONS entry specified here is the default OPTIONS entry for that zone.
- On the SET command. The name specified on the SET command overrides the default OPTIONS name.

When SMP/E processes a command, it checks these sources to determine which OPTIONS entry should be in effect for that command. If SMP/E cannot find a reference to an OPTIONS entry, it will use defaults for some of the subentries. The following section describes these defaults, as well as the other values you can specify for each subentry.

Subentries
These are the subentries for the OPTIONS entry as they appear in the LIST output:

name

- is the name of the OPTIONS entry.
  - The name can contain from 1 to 8 alphanumeric characters.

AMS

- is the name of the UTILITY entry that SMP/E is to use to obtain information when calling the access method services (AMS) utility.
  - The UCL operand is AMS(name).
    - The name can contain from 1 to 8 alphanumeric characters.
    - If no entry name is specified, SMP/E uses a default UTILITY entry. For details, see Table 6 on page 350

ASM

- is the name of the UTILITY entry that SMP/E is to use to obtain information when calling the assembler utility.
  - The UCL operand is ASM(name).
    - The name can contain from 1 to 8 alphanumeric characters.
    - If no entry name is specified, SMP/E uses a default UTILITY entry. For details, see Table 6 on page 350

CHANGEFILE

specifies whether library change file records should be generated and written to the SMPDATA1 and SMPDATA2 data sets during APPLY and RESTORE command processing.

- The UCL operand is CHANGEFILE(YES | NO), where:
  - YES
    - indicates that library change file records should be generated during APPLY or RESTORE processing.
  - NO
    - indicates that library change file records should not be generated during APPLY or RESTORE processing. This is the default for APPLY and RESTORE processing.
OPTIONS entry (global zone)

COMP

is the name of the UTILTY entry that SMP/E is to use to obtain information when calling the utility program to compress data sets.

The UCL operand is COMP(name).

- The name can contain from 1 to 8 alphanumeric characters.
- If no entry name is specified, SMP/E uses a default UTILTY entry. For details, see Table 6 on page 350.

COMPACT

specifies whether inline element data within SYSMODs in the SMPPTS data set should be compacted. The element data is normally compacted during the GZONEMERGE and RECEIVE commands.

The UCL operand is COMPACT(YES|NO), where:

YES

indicates inline element data within SYSMODs in the SMPPTS should be compacted to reduce the space requirements of the SMPPTS during the GZONEMERGE and RECEIVE commands. The element data is expanded as needed during ACCEPT and APPLY command processing. YES is the default.

NO

indicates inline element data within SYSMODs in the SMPPTS should not be compacted during the GZONEMERGE and RECEIVE commands. The element data will reside in the SMPPTS data set in its original form.

COPY

is the name of the UTILTY entry that SMP/E is to use to obtain information when calling the copy utility.

The UCL operand is COPY(name).

- The name can contain from 1 to 8 alphanumeric characters.
- If no entry name is specified, SMP/E uses a default UTILTY entry. For details, see Table 6 on page 350.

DSPREFIX

specifies the data set prefix to be used to construct the full data set name when SMPTLIB data sets are being allocated for RELFILEs. For more information about names for SMPTLIB data sets, see SMP/E Commands.

The UCL operand is DSPREFIX(prefix).

- The prefix can contain from 1 to 26 alphanumeric characters.
- The prefix must follow standard naming conventions for data sets.
- If a DDDEF entry is in effect for the SMPTLIB data sets, the DSPREFIX value in that DDDEF entry overrides the DSPREFIX value specified in the OPTIONS entry in effect.
- If no DSPREFIX value is specified in either the OPTIONS entry or the DDDEF entry, no high-level qualifier is assigned to the SMPTLIB data sets.
- If the DSPREFIX value is the same as the RFDSNPFX value for the RELFILE data sets that are being processed, the SMPTLIB data sets cannot be allocated in either of these cases:
  - The RELFILE data sets are on DASD.
  - The RELFILE data sets are on tape and are cataloged.

DSSPACE

specifies the primary and secondary space allocation (in tracks) and the number of directory blocks to be allocated for each SMPTLIB data set. After
OPTIONS entry (global zone)

the data set is loaded, unused space is freed. For more information about SMPTLIB data sets, see [SMP/E Commands](#).

The UCL operand is **DSSPACE**(prime, secondary, directory).
- Each value can contain from 1 to 4 numeric characters.
- If a DDDEF entry is in effect for the SMPTLIB data sets, the SPACE and DIR values in that DDDEF entry override the DSSPACE values specified in the OPTIONS entry in effect.
- These values should be specified in the appropriate OPTIONS or DDDEF entries before you receive a relative file. Otherwise, SMP/E cannot allocate any new SMPTLIB data sets.

**EXRTYDD**

specifies the list of ddnames that are not eligible for retry processing after an x37 abend. EXRTYDD is used with RETRYDDN in order to exclude a subset of libraries from retry processing.

The UCL operand is **EXRTYDD**(ddname...).
- The ddnames can contain from 1 to 8 alphanumeric characters.
- If a ddname is specified in both the EXRTYDD list and the RETRYDDN list, the ddname is excluded from retry processing.
- If no ddnames are specified for RETRYDDN, no retry processing will be done for any libraries. The ddnames specified on EXRTYDD are ignored.
- If **ALL** is specified on EXRTYDD, it is treated as just another ddname; it does not exclude all ddnames from retry processing. To exclude all libraries from retry processing, do **one** of the following instead:
  - Specify **RETRY(NO)** on the SMP/E command being processed.
  - Do not specify a RETRYDDN list in the OPTIONS entry that is in effect for the SMP/E command being processed.
  - Do not have an OPTIONS entry in effect for the SMP/E command being processed.

**FIXCAT**

specifies the list of fix categories. During APPLY, ACCEPT, and REPORT MISSINGFIX processing, this subentry, or the FIXCAT operand on the command, identifies the fix categories of interest and is used to determine which FIXCAT HOLDDATA entries will affect command processing.

The UCL operand is **FIXCAT**(category...).
- A Fix Category value is case sensitive, can be 1- to 64-characters in length, can contain any nonblank character in the range X’41’ - X’FE’ except single quotation mark (‘), comma (,), left parenthesis (()), and right parenthesis ()), and can be specified in two ways:
  - Explicitly, by fully specifying a particular fix category value. For example, IBM.Device.ziIP. In this case, all HOLDDATA associated with this Fix Category is applicable to command processing.
  - Implicitly, by partially specifying a fix category value using any number of asterisks (*) as global characters and percent signs (%) as placeholders.
- A single asterisk indicates that zero or more characters can occupy that position. Here are some examples:
  - **IBM.Device**
    - In this example, all HOLDDATA associated with a fix category that begins with the character string IBM.Device is applicable.
In this example, all HOLDDATA associated with a fix category that ends with the character string z/OS is applicable.

In this example, all HOLDDATA associated with a fix category that begins with the character string IBM and ends with the character string z/OS is applicable.

- A single percent sign indicates that any one single character can occupy that position. For example, IBM.Device.20%4 indicates that HOLDDATA associated with any of the following fix categories is applicable: IBM.Device.2084, IBM.Device.2094, and IBM.Device.20t4. HOLDDATA associated with a fix category of IBM.Device.20914, however, is not applicable.

The following examples are all acceptable fix categories:

IBM.Device.z1IP
*  
IBM.Function*
IBM.Device.20%4.*
*.HealthChecker

HFSCOPY
is the name of the UTILITY entry that SMP/E is to use to obtain information when calling the HFS copy utility.

This is the utility used to install hierarchical file system elements and must meet the same program-to-program interface as BPXCOPY.

The UCL operand is HFSCOPY(name).

- The name can contain from 1 to 8 uppercase alphanumeric characters.
- If no HFSCOPY subentry is specified in the OPTIONS entry, SMP/E uses a default UTILITY entry. For details, see Table 6 on page 350

IOSUP
is the name of the UTILITY entry that SMP/E is to use to obtain information when calling the IEHIOSUP utility program to process maintenance for an OS/VS1 system.

The UCL operand is IOSUP(name).

- The name can contain from 1 to 8 alphanumeric characters.

LKED
is the name of the UTILITY entry that SMP/E is to use to obtain information when calling the link-edit utility.

The UCL operand is LKED(name).

- The name can contain from 1 to 8 alphanumeric characters.
- If no entry name is specified, SMP/E uses a default UTILITY entry. For details, see Table 6 on page 350

MSGWIDTH
specifies whether the message output (SMPOUT only) should be formatted in 80 or 120 character widths.

The UCL operand is MSGWIDTH(value). The subentry can contain one of the following values:

80 indicates that the message text should be formatted to an 80 character width.
OPTIONS entry (global zone)

120 indicates that the message text should be formatted to a 120 character width. This is the default.

MSGFILTER
specifies whether messages issued to SMOUT during APPLY, ACCEPT, and RESTORE processing should be filtered to contain only the following:
• Messages with a severity of Warning or higher.
• Messages with a severity of Informational that add clarity or additional information to a previously issued higher severity message.
• Messages GIM20501I and GIM20502I.
The UCL operand is MSGFILTER(YES | NO), where:
YES indicates that the number of messages issued to SMOUT should be in a filtered format for APPLY, ACCEPT, and RESTORE processing.
NO indicates that the number of messages issued to SMOUT should be in an unfiltered format for APPLY, ACCEPT, and RESTORE processing. This is the default.

NOPURGE
indicates that after SMP/E accepts SYSMODs, it should not delete the associated global zone SYSMOD entries, HOLDDATA entries, SMPPTS MCS entries, or SMPTLIB data sets.
The UCL operand is NOPURGE.
• The default is for NOPURGE not to be specified. In this case, SMP/E deletes the entries after the SYSMOD has been successfully accepted. (This is true only if the SYSMOD has been applied and BYPASS(APPLYCHECK) was not specified on the ACCEPT command.)
• Although this operand can be specified in any OPTIONS entry, it is effective only when the OPTIONS entry is used during ACCEPT processing.

NOREJECT
specifies that the global zone SYSMOD entry and the associated MCS entry should not be deleted after the SYSMOD is restored.
The UCL operand is NOREJECT.
• The default is for NOREJECT not to be specified. In this case, SMP/E deletes the entries after the SYSMOD has been successfully restored.
• Although this operand can be specified in any OPTIONS entry, it is effective only when the OPTIONS entry is used during RESTORE processing.

ORDERRET
Indicates the retention period, in days, that ORDER entries are kept in the global zone before being deleted. During RECEIVE ORDER processing, an ORDER entry will be deleted from the global zone if either of the following conditions occurs:
• The ORDER entry has a status of DOWNLOADED, and the difference between the current date and the ORDER entry’s DOWNLDATE subentry value is greater than the OPTIONS entry ORDER RETENTION subentry value.
• The ORDER entry has a status of ERROR or PENDING and the difference between the current date and the ORDER entry’s ORDERDATE subentry value is greater than the OPTIONS entry ORDER RETENTION subentry value.
When an ORDER entry is deleted from the global zone, SMP/E also deletes the order package stored in the SMPNTS.
OPTIONS entry (global zone)

The UCL operand is ORDERRET(mmnn).
- The value can contain from 1 to 4 numeric characters from 0 to 9999.
- If no value is specified, the default is 180 days.

PAGELEN
specifies the page length for the SMPLIST, SMHRPT, SMPOUT, and SMPRPT data sets.

The UCL operand is PAGELEN(mmnn).
- The value can contain from 1 to 4 numeric characters.
- If no value is specified, the default is 60.

PEMAX
specifies the maximum number of subentries that can be present in any CSI entry. Most often, the largest entry is a SYSMOD entry.

The UCL operand is PEMAX(mmnn).
- The value can contain from 1 to 4 numeric characters, with a value range of 1 to 9999.
- If no value is specified, the default is 32767. Therefore, if you want a value higher than 9999, you must use the default.

RECEXZGRP
specifies a list of zones or zonesets to be excluded during APPLYCHECK and ACCEPTCHECK processing during the SYSMOD selection phase of RECEIVE processing.

The UCL operand is RECEXZGRP(value...).
- Each value is a zone or zoneset name. Each name can contain from 1 to 8 alphanumeric characters.
- The zone or zonesets can contain both target and distribution zones.

Note: The value specified cannot be GLOBAL nor ALLZONES.
- If a zone is specified in both the RECEXZGRP list and the RECZGRP list, the zone is excluded from processing.
- If no zones are specified for RECZGRP, the zones specified on RECEXZGRP are ignored.

RECZGRP
specifies a list of zones and zonesets eligible for APPLYCHECK and ACCEPTCHECK processing during the SYSMOD selection phase of RECEIVE processing. Any SYSMOD that has been applied or accepted into any of the zones specified by this list will not be received by the RECEIVE command, unless the SYSMOD is specified on the SELECT operand of the RECEIVE command or the list is overridden by the BYPASS(ACCEPTCHECK) or BYPASS(APPLYCHECK) operands, or a new list is specified by the ZONEGROUP operand.

The UCL operand is RECZGRP(value...).
- Each value is a zone or zoneset name. Each name can contain from 1 to 8 alphanumeric characters.
- The zone or zonesets can contain both target and distribution zones.

Note: The value specified cannot be GLOBAL.
- ALLZONES can be specified to indicate that all zones defined by a ZONEINDEX subentry in the GLOBALZONE entry are eligible. When ALLZONES is specified, all other values specified are ignored.
OPTIONS entry (global zone)

- If no zones or zonesets are specified, no APPLYCHECK or ACCEPTCHECK processing is performed unless the ZONEGROUP operand is specified on the RECEIVE command.

RETRY
is the name of the UTILITY entry that SMP/E is to use to obtain information when calling the utility program to compress a data set after an x37 abend.

The UCL operand is RETRY(name).
- The name can contain from 1 to 8 alphanumeric characters.
- If no entry name is specified, SMP/E uses a default UTILITY entry. For details, see Table 6 on page 350

RETRYDDN
specifies the list of ddnames eligible for retry processing after an x37 abend.

The UCL operand is RETRYDDN(ddname...).
- The ddnames can contain from 1 to 8 alphanumeric characters.
- ALL can be specified to indicate that all ddnames are eligible.
- If no ddnames are specified, no retry processing will be done, even if RETRY was specified on the command being processed.
- Retry processing is attempted for partitioned data sets (PDSs) and partitioned data sets extended (PDSEs) that experience an x37 abend, indicating that they have run out of space.
- For pointers on how to set up the desired retry processing, see SMP/E User’s Guide

SAVEMTS
indicates that MTSMAC entries should not be deleted from the SMPMTS after the SYSMODs that affect those macros have been successfully accepted.

The UCL operand is SAVEMTS.
- If SAVEMTS is not specified, SMP/E deletes the entries after all the SYSMODs that affect the macros have been successfully accepted. (This is true only if the SYSMOD has been applied and BYPASS(APPLYCHECK) was not specified on the ACCEPT command.)
- Although this operand can be specified in any OPTIONS entry, it is effective only when the OPTIONS entry is used during ACCEPT processing.

SAVESTS
indicates that STSSRC entries should not be deleted from the SMPSTS after the SYSMODs that affect the source have been successfully accepted.

The UCL operand is SAVESTS.
- If SAVESTS is not specified, SMP/E deletes the entries after all the SYSMODs that affect the source have been successfully accepted. (This is true only if the SYSMOD has been applied and BYPASS(APPLYCHECK) was not specified on the ACCEPT command.)
- Although this operand can be specified in any OPTIONS entry, it is effective only when the OPTIONS entry is used during ACCEPT processing.

SUPPHOLD
specifies a list of HOLD reason ids for which the HOLDDATA card image should not be displayed on either the Unresolved HOLD Reason Report or Bypassed HOLD Reason Report.

The UCL operand is SUPPHOLD(value...), where:
OPTIONS entry (global zone)

value is a HOLD reason id, which is from 1 to 7 alphanumeric characters, #, @, and $. The first character cannot start with 0-9.

UPDATE
is the name of the UTILITY entry that SMP/E is to use to obtain information when calling the update utility.

The UCL operand is UPDATE(name).

• The name can contain from 1 to 8 alphanumeric characters.
• If no entry name is specified, SMP/E uses a default UTILITY entry. For details, see Table 6 on page 350.

ZAP
specifies the name of the UTILITY entry that SMP/E is to use to obtain information when calling the superzap utility.

The UCL operand is ZAP(name).

• The name can contain from 1 to 8 alphanumeric characters.
• If no entry name is specified, SMP/E uses a default UTILITY entry with NAME(IMASPZAP), RC(4), PRINT(SYSPRINT), and PARM().

LIST Examples

To list all the OPTIONS entries in a global zone, you can use the following commands:

```
SET BDY(GLOBAL) /* Set to requested zone. */.
LIST OPTIONS /* List all OPTIONS entries. */.
```

To list specific OPTIONS entries in a global zone, you can use these commands:

```
SET BDY(GLOBAL) /* Set to requested zone. */.
LIST OPTIONS(OPT1, /* List only these three */
             TGT1, /* entries. */
             DLIB1) /* */.
```

The format of the LIST output for each OPTIONS entry is the same for both of these commands. The only difference is the number of OPTIONS entries listed.

Figure 48 on page 300 is an example of LIST output for OPTIONS entries.
OPTIONS entry (global zone)

```
UCLIN
Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in an OPTIONS entry. When you use UCLIN to update an OPTIONS entry, remember that if a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.

The following examples are provided to help you use the OPTIONS entry.

Example 1: Connecting an OPTIONS entry to UTILITY entries
Assume that you have set up three UTILITY entries: IEUASM, IEWL, and MYX37. For examples of setting up these entries, see "UTILITY entry (global zone)" on page 350. Now you wish to define an OPTIONS entry, OPT1, that will be used during APPLY processing. The following UCL can be used to set up that entry:

```
SET BDY(GLOBAL) /* Set to global zone. */
UCLIN /* */
ADD OPTIONS(OPT1) /* New OPTIONS entry. */
   ASM(IEUASM) /* Connect to assembler data. */
   LKED(IEWL) /* Connect to link data. */
   RETRY(MYX37) /* Connect to retry. */
ENDUCL /* */
```

Figure 48. OPTIONS entry: sample LIST output

UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in an OPTIONS entry. When you use UCLIN to update an OPTIONS entry, remember that if a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.

The following examples are provided to help you use the OPTIONS entry.

Example 1: Connecting an OPTIONS entry to UTILITY entries
Assume that you have set up three UTILITY entries: IEUASM, IEWL, and MYX37. For examples of setting up these entries, see "UTILITY entry (global zone)" on page 350. Now you wish to define an OPTIONS entry, OPT1, that will be used during APPLY processing. The following UCL can be used to set up that entry:

```
SET BDY(GLOBAL) /* Set to global zone. */
UCLIN /* */
ADD OPTIONS(OPT1) /* New OPTIONS entry. */
   ASM(IEUASM) /* Connect to assembler data. */
   LKED(IEWL) /* Connect to link data. */
   RETRY(MYX37) /* Connect to retry. */
ENDUCL /* */
```

Figure 48. OPTIONS entry: sample LIST output
OPTIONS entry (global zone)

To use the OPTIONS entry, you need either to define it as the default OPTIONS entry for the desired GLOBALZONE, DLIBZONE, or TARGETZONE entry, or to specify it on the OPTIONS operand of the SET command for the zone you want to process with these values.

Example 2: Changing the SMPOUT page length
Assume that you wish to modify the OPTIONS entry created in “Example 1: Connecting an OPTIONS entry to UTILITY entries” on page 300 to indicate that your printer now prints 120 lines per page. The following UCL will do this:

```c
SET  BDY(GLOBAL)  /* Set to global zone. */.
UCLIN */
ADD OPTIONS(OPT1) */ Add because page length is not there yet. */
    PAGELEN(120) /* Change page length. */*
ENDUCL */
```

Example 3: Preparing to receive RELFILEs
To receive a new function packaged in RELFILE format, you have to define the amount of space to allocate the SMPTLIB data sets and, optionally, the prefix to be used in building the data set names. Assume that the program directory indicates that 300 tracks of primary space should be used, 50 tracks of secondary space, and 25 directory blocks, and that you want the data set names to start with SMP.RELFILE.M9801. The following UCL can be used to add this information to the OPTIONS entry created in “Example 1: Connecting an OPTIONS entry to UTILITY entries” on page 300.

```c
SET  BDY(GLOBAL)  /* Set to global zone. */.
UCLIN */
ADD OPTIONS(OPT1) /* Add because data is not there yet. */
    DSSPACE(300,50,25) /* Space allocation. */
    DSPREFIX(SMP.RELFILE.M9801) /* Prefix. */
ENDUCL */
```

Example 4: Identifying libraries for retry processing
During processing of commands that update product libraries (such as ACCEPT, APPLY, RESTORE, and LINK), utilities called by SMP/E may issue x37 abends when the libraries they are updating run out of space. SMP/E can attempt to recover from such out-of-space errors if RETRY(YES) was specified on the command being processed and if a RETRYDDN list is available in the OPTIONS entry that is in effect.

Assume that you want SMP/E to attempt this retry processing for all libraries except LINKLIB, MIGLIB, and NUCLEUS. The following UCL can be used to specify the desired ddnames in the OPTIONS entry created in “Example 1: Connecting an OPTIONS entry to UTILITY entries” on page 300.

```c
SET  BDY(GLOBAL)  /* Set to global zone. */.
UCLIN */
ADD OPTIONS(OPT1) /* Add because data is not there yet. */
    RETRYDDN(ALL) /* Retry all ddnames */
    EXRTYDDN(LINKLIB,MIGLIB,NUCLEUS) /* except these. */
ENDUCL */
```
ORDER entry (global zone)

ORDER entry (global zone)
The ORDER entry describes a HOLDDATA or PTF order initiated with the RECEIVE ORDER command. When SMP/E sends an order request to the IBM Automated Delivery Request server and the server accepts the order, SMP/E creates an ORDER entry in the global zone. The ORDER entry is used to record information about the order so that SMP/E can query the server for status of orders that have not been completed. Once the processing for an order has been completed by the server, SMP/E can download the HOLDDATA or PTF package for the order and store the package files in the SMPNTS directory.

Subentries
These are the subentries for the ORDER entry as they appear in the LIST output:

name
is the name of the ORDER entry.
The name can contain from 1 to 8 alphanumeric characters.

CONTENT
the HOLDDATA or PTF content for this order. The value can be one of the following:

ALL
indicates a request for all available PTFs.

APARS
indicates a request for PTFs that resolve the APARS specified in the APARS subentry.

CRITICAL
indicates a request for all available PTFs that resolve a critical problem. A critical problem is a high impact pervasive (HIPER) or a PTF in error (PE).

HOLDDATA
indicates a request for HOLDDATA only. A HOLDDATA package contains the last 2-years worth of Enhanced HOLDDATA for the entire z/OS software platform. See http://service.software.ibm.com/holdata/390holddata.html for further information on Enhanced HOLDDATA.

PTFS
indicates a request for the PTFs indicated in the PTFS subentry.

sourceid
indicates a request for all the recommended PTFs identified with the indicated Recommended Service Update SOURCEID (RSUyymm), and PTFs that resolve a critical problem (HIPER or PE). Recommended service includes PTFs through the indicated RSU level, which is the most current RSU level at the time the order is created.

STATUS
indicates the status of the HOLDDATA or PTF order. Status values can be any one of the following:

PENDING
the order request has been submitted to the server but the order’s package has not yet been downloaded.

DOWNLOADED
the order package has been downloaded and stored in the SMPNTS directory.
ERROR
the server reported an uncorrectable error with the processing of this order.

APARS
identifies the APARS for which resolving PTFs were requested.

PTFS
identifies the specific PTFs that were requested.

ORDERDATE
indicates the date on which the order request was sent to the server.

ORDERTIME
indicates the time at which the order request was sent to the server.

DOWNLDATE
indicates the date on which the order’s package was downloaded and stored in the SMPNTS directory.

DOWNLTIME
indicates the time at which the order’s package was downloaded and stored in the SMPNTS directory.

ORDERID
the order identifier assigned by the IBM Automated Delivery Request server when the order request was sent. The value is used to correlate ORDER entries in the global zone with orders being processed by the server.

USERID
the userid that submitted the SMP/E job which created the ORDER entry.

PKGID
indicates the subdirectory name within the SMPNTS directory that contains the package associated with the order.

ZONES
indicates the target zones used to represent the software inventory associated with this order.

ORDERSERVER
contains the <ORDERSERVER> tags used to identify the IBM Automated Delivery Request server scheduled to fulfill the order request. This information is obtained from the ORDERSERVER data set specified in the RECEIVE ORDER command when the ORDER entry was created.

This subentry exists only when the order has a STATUS of PENDING. This subentry is deleted once the order package has been downloaded.

LIST Examples
To list all the ORDER entries in a global zone, you can use the following commands:

```plaintext
SET BDY(GLOBAL) /* Set to requested zone. */
LIST ORDER /* List all ORDER entries. */
```

To list specific ORDER entries in a global zone, you can use these commands:

```plaintext
SET BDY(GLOBAL) /* Set to requested zone. */
LIST ORDER(ORD00034, /* List only these three */
          ORD00035, /* entries. */
          ORD00036) /* */
```

The format of the LIST output for each ORDER entry is the same for both of these commands. The only difference is the number of ORDER entries listed.
ORDER entry (global zone)

Figure 49 is an example of LIST output for ORDER entries. In this example, processing for ORDER entries ORD00034 and ORD00035 is completed and the packages have been downloaded. The order described by ORDER entry ORD00036 is in the PENDING state and the package has not yet been downloaded.

Figure 49. ORDER entry: sample LIST output

Note: An alternative url for the IBM Automated Delivery Request server is https://eccgw02.rochester.ibm.com/services/projects/ecc/ws/.

UCLIN Examples

You can use the DEL UCL statement to delete an ORDER entry as shown in the following example. UCLIN does not support either adding entries or updating subentries for an ORDER entry.

Example: Deleting an ORDER entry

The following UCL can be used to delete an ORDER entry:

```
SET BDY(GLOBAL)  /* Set to global zone */.
UCLIN            /* Start UCLIN processing */.
DEL ORDER(ORD00035) /* Delete ORDER entry */.
ENDUCL           /* End UCLIN processing */.
```
PRODUCT entry (global zone)

ORDER entries may reside only in the GLOBALZONE.
PRODUCT entry (global zone)

The PRODUCT entry describes a software product. A product is known to SMP/E by the combination of its prodid and the vv.rr.mm values. PRODUCT entries reside only in the global zone.

Subentries

prodid
specifies the product identifier for the product described in the PRODUCT entry. For IBM products, it is recommended that the prodid be the IBM program product number (for example, “5647-A01”).

vv.rr.mm
specifies the version, release and modification level for the product described in the PRODUCT entry.

DESCRIPTION
 describes the product.

The UCL operand is DESCRIPTION(description).

SREL
 specifies the system or subsystem releases on which the PRODUCT can be installed. There can be multiple SREL subentries associated with a PRODUCT.

The UCL operand is SREL(srel,...).

PRODSUP
 specifies the PRODUCTS that are superseded by this PRODUCT. Multiple PRODSUP subentries can be associated with a PRODUCT. The combination of prodid and vv.rr.mm determines the uniqueness of a subentry in the PRODSUP subentry list. Only one subentry value for a given prodid and vv.rr.mm combination is saved in the PRODSUP subentry list.

The UCL operand is PRODSUP((prodid,vv.rr.mm),...).

URL
 specifies the URL that can be accessed to obtain additional information about the product.

The UCL operand is URL(product_url).

VENDOR
 specifies the name of the vendor supplying the product.

The UCL operand is VENDOR(vendor_name).

RECDATE
 specifies the date on which the PRODUCT was received.

There is no UCL support for this subentry.

RECTIME
 specifies the time at which the PRODUCT was received.

There is no UCL support for this subentry.

UCLDATE
 specifies the date on which the PRODUCT was last processed using the UCLIN command.

There is no UCL support for this subentry.
PRODUCT entry (global zone)

**UCLTIME**

specifies the time at which the PRODUCT was last processed using the UCLIN command.

There is no UCL support for this subentry.

**REWORK**

identifies the level of this PRODUCT, which was received again for minor changes.

There is no UCL support for this subentry.

**LIST Examples**

To list all the PRODUCT entries in a particular zone, you can use the following commands:

```
SET BDY(GLOBAL) /* Set to global zone. */.
LIST PRODUCT /* List all PRODUCT entries. */.
```

To list specific PRODUCT entries, you can use these commands:

```
SET BDY(GLOBAL) /* Set to global zone. */.
LIST PRODUCT(5647-A01) /* List all PRODUCT entries */
/* with prodid of 5647-A01 */.
LIST PRODUCT((5645-001,01.03.00)) /* List PRODUCT entry */
/* with prodid of 5645-001 */
/* and VRM of 01.03.00 */.
LIST PRODUCT(5668-949,(5645-001,1.2.0)) /* List all PRODUCT entries */
/* with prodid of 5668-949, */
/* plus PRODUCT entry with */
/* prodid of 5645-001 */
/* and VRM of 01.02.00 */.
```

The format of the LIST output for each PRODUCT entry is the same for all of these commands. The only difference is the number of PRODUCT entries listed. Figure 5.0 shows an example of LIST output for PRODUCT entries. PRODUCT entries are listed alphanumerically by prodid. PRODUCT entries with the same prodid value are further sorted by vv.rr.mm.

---

**Notes:**

1. The entry name value for the PRODUCT entries formatted to the left of the subentry names is the prodid value.
PRODUCT entry (global zone)

2. If the URL value extends past column 120, it is continued on the next line.
3. The display for each PRODSUP subentry occupies two columns. The first column is the prodid and the second column is the vrr.mm. Four subentries can fit on a row.

UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the PRODUCT entry. When you use UCLIN to update a PRODUCT entry, keep in mind that after the UCLIN changes are made, the PRODUCT entry must contain at least the DESCRIPTION and SREL subentries.

Example: Adding a PRODUCT entry

Assume you have a product, SAMPLE V1R2, for which you wish to create a description and put in an entry named “1234-567,1.2.0”. You could set up a PRODUCT entry as follows:

```
SET BDY(GLOBAL) /* Set to global zone */.
UCLIN /* Start UCLIN processing */.
ADD PRODUCT(1234-567,1.2.0) /* Identify the product */.
  DESCRIPTION(SAMPLE) /* - Name */.
  VENDOR(IBM) /* - Vendor */.
  PRODSUP((1234-456,01.04.00)) /* - Product sups */.
  SREL(Z038) /* - SREL */.
  URL(http://www.ibm.com/) /* URL */.
ENDUCL /* End UCLIN processing */.
```
PROGRAM entry (distribution and target zone)

The PROGRAM entry describes a program element (a pre-built load module or a program object). Program elements may exist in distribution or target libraries. A PROGRAM entry is created the first time you install a SYSMOD that contains a ++PROGRAM MCS for a program element that does not yet have a PROGRAM entry.

SMP/E records the function and service level of the program element in the entry. Once a PROGRAM entry exists, it is updated as subsequent SYSMODs that affect the program element are installed.

Subentries

These are the subentries for the PROGRAM entry as they appear in the LIST output:

name

is the name of the program element represented by the entry. It can contain from 1 to 8 alphanumeric characters and $, #, @, or hex C0.

ALIAS

specifies a list of alias names for the element.

The UCL operand is ALIAS(name...).

Each alias name can contain from 1 to 8 alphanumeric characters.

DISTLIB

specifies the ddname of the distribution library for the program element.

The UCL operand is DISTLIB(ddname).

• The ddname can contain from 1 to 8 alphanumeric characters.

• The DISTLIB subentry is required. Without it, SMP/E cannot process any changes for the program element.

FMID

specifies the functional owner of this program element. The functional owner is the last function SYSMOD that replaced this element.

The UCL operand is FMID(sysmod_id).

The SYSMOD ID must contain 7 alphanumeric characters.

LASTUPD

identifies the cause of the last change to this PROGRAM entry.

The UCL operand is LASTUPD(value). This subentry can contain one of the following values:

UCLIN

indicates that the change was made as a result of UCLIN processing.

sysmod_id

indicates that the change was made during the installation of the indicated SYSMOD.

The SYSMOD ID must contain 7 alphanumeric characters.

LASTUPD TYPE

indicates how the entry was last changed.

The UCL operand is LASTUPDTYPE(value). This subentry may contain one of the following values:
PROGRAM entry (distribution and target zone)

ADD  The entry was added.
UPD  The entry was updated.

RMID
identifies the last SYSMOD that replaced this program element. Any subsequent SYSMOD that modifies this program element must have a defined relationship (such as PRE or SUP) with this SYSMOD.
The UCL operand is RMID(sysmod_id).
• The SYSMOD ID must contain 7 alphanumeric characters.
• If RMID is not specified but FMID is, SMP/E sets the RMID value to the specified FMID.

SYSLIB
specifies the ddname of the target library for the program element.
The UCL operand is SYSLIB(ddname).
• You can specify only one SYSLIB value.
• The ddname can contain from 1 to 8 alphanumeric characters.

LIST Examples
To list all the PROGRAM entries in a particular zone, you can use the following commands:
SET BDY(TGT1)  /* Set to requested zone. */.
LIST PROGRAM  /* List all PROGRAM entries. */.

To list specific PROGRAM entries, you can use these commands:
SET BDY(TGT1)  /* Set to requested zone. */.
LIST PROGRAM(PGM1 PGM2)  /* List only these two entries. */.

The format of the LIST output for each PROGRAM entry is the same for both of these commands. The only difference is the number of PROGRAM entries listed. Figure 51 is an example of LIST output for PROGRAM entries.

By specifying the FORFMID operand, you can reduce the number of PROGRAM entries listed. When FORFMID is specified, SMP/E lists a PROGRAM entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to list PROGRAM entries whose FMIDs are defined in FMIDSET ABC or else are MYPROG1, you can use these commands:
PROGRAM entry (distribution and target zone)

SET BDY(TGT1) /* Set to target zone. */.
LIST PROGRAM /* List all PROGRAM entries */
FORFMID(ABC /* for the ABC FMIDSET */
MYPROG1) /* and FMID MYPROG1. */.

You can use the LIST command to find out the names of all SYSMODs that have modified program elements. To include the names of these SYSMODs in the LIST output, you can use the XREF operand, as shown in these commands:

SET BDY(TGT1) /* Set to requested zone. */.
LIST PROGRAM /* List all PROGRAM entries */
XREF /* and related SYSMODs. */.

Notes:
1. You can use XREF in either mass mode or select mode.
2. SMP/E obtains the data included for the XREF operand by checking for entries for this program element in all the SYSMOD entries. Because this data is not contained in the PROGRAM entry itself, you cannot use UCLIN to change it in the PROGRAM entry.

Figure 52 is an example of the LIST output produced when the XREF operand is used.

UNLOAD Examples

To dump the PROGRAM entries in UCL format, you can use the UNLOAD command. To unload all the PROGRAM entries in a particular zone, you can use the following commands:

SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD PROGRAM /* Unload all PROGRAM entries. */.

To unload specific PROGRAM entries, you can use these commands:

SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD PROGRAM(PGM1) /* Unload only these two */
PGM2 /* entries. */.

The format of the UNLOAD output for each PROGRAM entry is the same for both of these commands. The only difference is the number of PROGRAM entries listed.
PROGRAM entry (distribution and target zone)

Figure 53 is an example of UNLOAD output for PROGRAM entries.

```
UCLIN.
REP PROGRAM ( PGM1 )
  LASTUPD ( MYPROG1 )
  LASTUPDTYPE ( ADD )
  DISTLIB ( ADSTLIB )
  SYSLIB ( SPGMLIB )
  FMID ( MYPROG1 )
  RMID ( MYPROG1 )
REP PROGRAM ( PGM2 )
  LASTUPD ( PGMTF1 )
  LASTUPDTYPE ( ADD )
  DISTLIB ( ADSTLIB )
  SYSLIB ( SPGMLIB )
  FMID ( MYPROG1 )
  RMID ( PGMTF1 )
ENDUCL.
```

By specifying the FORFMID operand, you can reduce the number of PROGRAM entries unloaded. When FORFMID is specified, SMP/E unloads a PROGRAM entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to unload PROGRAM entries whose FMIDs are either defined in FMIDSET ABC or are MYPROG1, you can use these commands:

```
SET BDY(TGT1) /* Set to target zone. */.
UNLOAD PROGRAM /* Unload all PROGRAM entries */
  FORFMID(ABC /* for the ABC FMIDSET */
              MYPROG1) /* and FMID MYPROG1. */.
```

UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the PROGRAM entry. After the UCLIN changes are made, the PROGRAM entry must contain at least the following subentries:

- DISTLIB
- FMID
- RMID

Otherwise, there is not enough information in the entry to process the program element. If any of these subentries are missing, SMP/E does not make the requested UCL updates to the entry, and the entry remains as it was before the UCL command.

Example: Adding a new PROGRAM entry

Assume you have installed PGM3 outside of SMP/E, but now you want to start using SMP/E to track changes to that program element. Here is an example of the UCL statements you would use to define entries for that program element in the appropriate target and distribution zones:

```
SET BDY(TGT1) /* Set to target zone. */.
UCLIN /* */.
ADD PROGRAM(PGM3) /* Define new PROGRAM entry.*/
  DISTLIB(ADSTLIB) /* Define DLIB. */
  SYSLIB(SPGMLIB) /* System library. */
  FMID(MYPROG1) /* Functional owner. */.
ENDUCL /* */.
```
PROGRAM entry (distribution and target zone)

<table>

</tr>
<tr>
<td></td>
<td>FMID(MYPROG1) /* Functional owner */</td>
</tr>
<tr>
<td>ENDUCL</td>
<td>/*</td>
</tr>
</tbody>
</table>
SRC entry (distribution and target zone)

The SRC entry describes source that exists in the distribution or target libraries. (SMP/E assumes that for each SRC entry in a particular zone there exists a MOD entry with the same name.) There are two ways a SRC entry can be created:

- **Installing a SYSMOD that contains the source.** SRC entries are created the first time you install a SYSMOD that contains a ++SRC statement for source that does not yet have a SRC entry.
- **Processing JCLIN.** SRC entries can be built during JCLIN processing when SMP/E scans the assembler step and determines that the assembler input is a member of a partitioned data set.

SRC entries can also be built when SMP/E scans copy steps and finds a SELECT statement that specifies TYPE=SRC.

SMP/E records the function and service level of the source in the SRC entry, as well as information about how that source affects the structure of the distribution or target libraries and modules. Once a SRC entry exists for source, it is updated as subsequent SYSMODs that affect the source are installed.

**Subentries**

These are the subentries for the SRC entry as they appear in the LIST output:

- **name**
  - is the name of the source represented by the SRC entry.
  - The name can contain from 1 to 8 alphanumeric characters and $, #, @, or hex C0.

- **DISTLIB**
  - specifies the ddname of the distribution library for the source.
  - The UCL operand is DISTLIB(ddname).
  - The ddname can contain from 1 to 8 alphanumeric characters.

- **FMID**
  - identifies the functional owner of this source. The functional owner is the last function SYSMOD that replaced this module.
  - The UCL operand is FMID(sysmod_id).
  - The SYSMOD ID must contain 7 alphanumeric characters.

- **LASTUPD**
  - identifies the cause of the last change to this SRC entry.
  - The UCL operand is LASTUPD(value). This subentry can contain one of the following values:
    - **JCLIN**
      - indicates that the change was made during JCLIN command processing.
    - **UCLIN**
      - indicates that the change was made as a result of UCLIN processing.
    - **sysmod_id**
      - indicates that the change was made during the installation of the indicated SYSMOD.
      - The SYSMOD ID must contain 7 alphanumeric characters.
LASTUPD TYPE
indicates how the entry was last changed.

The UCL operand is \texttt{LASTUPD(value)}. This subentry can contain one of the following values:
\begin{itemize}
  \item \texttt{ADD} \quad The entry was added.
  \item \texttt{MOV} \quad The entry was moved.
  \item \texttt{UPD} \quad The entry was updated.
\end{itemize}

RMID
identifies the last SYMMOD that replaced this source. Any subsequent SYMMOD that modifies this module must have a defined relationship (such as PRE or SUP) with this SYMMOD.

The UCL operand is \texttt{RMID(sysmod_id)}.
\begin{itemize}
  \item The SYMMOD ID must contain 7 alphanumeric characters.
  \item If \texttt{RMID} is not specified, but \texttt{FMID} is, SMP/E sets the RMID value to the specified FMID.
\end{itemize}

SYSLIB
specifies the ddname of the target library for the source.

The UCL operand is \texttt{SYSLIB(ddname)}.
\begin{itemize}
  \item Only one SYSLIB value can be specified.
  \item The ddname can contain from 1 to 8 alphanumeric characters.
\end{itemize}

UMID
identifies all the SYMMODs that have updated this source since it was last replaced. Any subsequent SYMMOD that modifies this module must have a defined relationship (such as PRE or SUP) with all these SYMMODs.

The UCL operand is \texttt{UMID(sysmod_id...)}.

The SYMMOD ID must contain 7 alphanumeric characters.

\section*{LIST Examples}
To list all the SRC entries in a particular zone, you could use the following commands:
\begin{verbatim}
SET BDY(TGT1) /* Set to requested zone. */.
LIST SRC    /* List all SRC entries. */.
\end{verbatim}

To list specific SRC entries, you could use these commands:
\begin{verbatim}
SET BDY(TGT1) /* Set to requested zone. */.
LIST SRC(SRC01) /* List only these two */
  SRC02)      /* entries. */.
\end{verbatim}

The format of the LIST output for each SRC entry is the same for both of these commands. The only difference is the number of SRC entries listed. Figure 54 is an example of LIST output for SRC entries.
By specifying the FORFMID operand, you can reduce the number of SRC entries listed. When FORFMID is specified, SMP/E lists a SRC entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to list SRC entries whose FMIDs either are defined in FMIDSET TP or are JXY1102, you could use these commands:

```
SET BDY(TGT1) /* Set to target zone. */.
LIST SRC /* List all source entries */
  FORFMID(TP) /* for the TP FMIDSET */ JXY1102 /* and FMID JXY1102. */.
```

You can also use the LIST command to find out the name of every SYSMOD that has modified source. To include the names of these SYSMODs in the LIST output, you can use the XREF operand, as shown in these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
LIST SRC /* List all source entries */
  XREF /* and related SYSMODs. */.
```

Notes:
1. XREF can be used either in mass mode or in select mode.
2. SMP/E obtains the data included for the XREF operand by checking for SRC and SRCUPD entries for this module in all the SYSMOD entries. Because this data is not contained in the SRC entry itself, you cannot use UCLIN to change it in the SRC entry.

Figure 54. SRC entry: sample LIST output

Figure 55 on page 317 is an example of the LIST output produced when the XREF operand is used.
**UNLOAD Examples**

To dump the SRC entries in UCL format, you can use the UNLOAD command. To unload all the SRC entries in a particular zone, you could use the following commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD SRC /* Unload all SRC entries. */.
```

To unload specific SRC entries, you could use these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD SRC(SRC01) /* Unload only these two */.
   SRC02) /* entries. */.
```

The format of the UNLOAD output for each SRC entry is the same for both of these commands. The only difference is the number of SRC entries listed. Figure 56 is an example of UNLOAD output for SRC entries.
### SRC entry (distribution and target zone)

```plaintext
UCLIN.
REP SRC ( SRC01 )
  LASTUPD ( JXY1102 )
  LASTUPDTYPE ( ADD )
  DISTLIB ( ASRCLIB )
  SYSLIB ( SRCLIB )
  FMID ( JXY1102 )
  RMID ( JXY1102 )
REP SRC ( SRC02 )
  LASTUPD ( JXY1121 )
  LASTUPDTYPE ( UPD )
  DISTLIB ( ASRCLIB )
  SYSLIB ( SRCLIB )
  FMID ( JXY1121 )
  RMID ( UZ00010 )
  UMID ( UZ00014 UZ00015 )
ENDUCL.
```

*Figure 56. SRC entry: sample UNLOAD output*

By specifying the FORFMID operand, you can reduce the number of SRC entries unloaded. When FORFMID is specified, SMP/E unloads a SRC entry only if its FMID matches one of the FMIDs specified on the FORFMID operand. For example, to unload SRC entries whose FMIDs either are defined in FMIDSET TP or are JXY1102, you could use these commands:

```plaintext
SET BDY(TGT1) /* Set to target zone. */.
UNLOAD SRC /* Unload all source entries*/
  FORFMID(TP /* for the TP FMIDSET */
     JXY1102) /* and FMID JXY1102. */.
```

### UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the SRC entry. After the UCLIN changes are done, the SRC entry must contain at least the following subentries:

- DISTLIB
- FMID
- RMID

Otherwise, there is not enough information in the entry to process the macro. If any of these subentries are missing, SMP/E does not make the requested UCL updates to the entry, and the entry remains as it was before the UCL command.

The following examples are provided to help you use the SRC entry.

### Example 1: Adding a new SRC entry

Assume that you have a user application installed and want to support it with SMP/E. To do this, you must record the modules in the target and distribution zones. You should identify the MOD and LMOD entries for your application by running the JCLIN function, using the appropriate link and copy steps as input. The source elements in your application will have to be entered through UCLIN. Assume that the FMID you wish to assign the product is ZUSR001 and that no service level is to be recorded. The following UCL statements should be used for each such source:

```plaintext
SET BDY(TGT1) /* Set to target zone. */.
UCLIN /* */.
ADD SRC(SRC01) /* Define new source entry. */
  DISTLIB(ASRCLIB) /* Define DLIB. */
```

---

*318 SMP/E V3R5.0 for z/OS V1R11.0 Reference*
SRC entry (distribution and target zone)

```c
SYSLIB(SRCLIB)  /* system library
               (never the SMPSTS or STS). */
FMID(ZUSR001)   /* Functional owner (in this
               example a user function). */
ENDUCL
SET BDY(DLIB1)  /* Now do same to DLIB. */
UCLIN
ADD SRC(SRC01)  /* Define new source entry. */
DISTLIB(ASRCLIB) /* Define DLIB, */
SYSLIB(SRCLIB)  /* system library
               (never the SMPSTS or STS). */
FMID(ZUSR001)   /* Functional owner (in this
               example a user function). */
ENDUCL
```

Example 2: Recording the application of a corrective fix

Assume that you have installed a corrective fix, AZ12345, to source SRC01, outside of SMP/E, and that now you want to record that fix after it has been installed. (This is not necessary if the fix was initially installed with SMP/E.) Three updates must be made:

1. Record that the fix, AZ12345, is in the system.
2. Record that the fix is on the source.
3. Record that the source has been reassembled and installed.

The following UCL can be used to record these changes:

```c
SET BDY(TGT1)  /* Set to target zone. */
UCLIN
ADD SYSMOD(AZ12345)  /* Add SYSMOD entry. */
APAR  /* Corrective fix. */
APPDATE(07100)  /* Date applied. */
APPTIME(08:00:00)  /* Time applied. */
FMID(FXY1102)  /* Functional owner. */
SRCUPD(SRC01)  /* Updated SRC01. */
ASSEM(SRC01)  /* Assembled it too. */
REP SRC(SRC01)  /* Update SRC01 to */
UMID(AZ12345)  /* add update ID of APAR. */
REP MOD(SRC01)  /* Update MOD entry */
RMID(AZ12345)  /* with new replacement ID. */
RMIDASM  /* Was assembled. */
ENDUCL
SET BDY(DLIB1)  /* Set to DLIB zone. */
UCLIN
ADD SYSMOD(AZ12345)  /* Add SYSMOD entry. */
APAR  /* Corrective fix. */
RECDATE(07100)  /* Date received. */
RECTIME(08:00:00)  /* Time received. */
INSDATE(07100)  /* Date accepted. */
INSTIME(09:00:00)  /* Time accepted. */
FMID(FXY1102)  /* Functional owner. */
SRCUPD(SRC01)  /* Updated SRC01. */
ASSEM(SRC01)  /* Assembled it too. */
REP SRC(SRC01)  /* Update SRC01 to */
UMID(AZ12345)  /* add update ID of APAR. */
REP MOD(SRC01)  /* Update MOD entry */
RMID(AZ12345)  /* with new replacement ID. */
RMIDASM  /* Was assembled. */
ENDUCL
```
STSSRC entry (SMPSTS)

STSSRC entry (SMPSTS)

The STSSRC entry is a copy of source that resides only in a distribution library but is needed temporarily during APPLY processing. The STSSRC entry is in the SMPSTS data set, which serves as a target source library for such modules.

When SMP/E applies the SYSMODs that affect these source, it calls utility programs to store the modules on the SMPSTS. This way, the most current service level of each module is available for use in assemblies. After SMP/E has accepted all the SYSMODs that affect these source modules, it deletes the associated STSSRC entries from the SMPSTS.

**Note:** If you specify SAVESTS in the ORDER entry that is in effect during ACCEPT processing, SMP/E will not delete STSSRC entries from the SMPSTS after the SYSMODs that affect those source have been successfully accepted.

Subentries

The STSSRC entry contains no SMP/E data and appears to the system as a member of a normal source library.

LIST Examples

You cannot use SMP/E to list the STSSRC entries. However, you can use standard system utility programs (such as IEBGENER, IEBPTPCH, and IEHLIST) or products such as ISPF to display these entries or information about the data set.

UCLIN Examples

You can use the DEL UCL statement to delete an STSSRC entry from the SMPSTS. This can be helpful if you plan to do an APPLY followed by ACCEPT when several target libraries have been created from the same distribution library.

When a SYSMOD is accepted into a distribution zone, the entries associated with it are automatically deleted from the SMPSTS for the related target zone. However, even if the SYSMOD was also applied to other target zones created from the same distribution zone, SMP/E does not clean up the SMPSTS data sets for the other target zones.

To delete the entries from these data sets, you could accept the SYSMOD and name these other target zones as the related zone. However, this would update the distribution library each time; this is time-consuming and could use up space in the distribution library data set.

Instead, you can use the DEL command to delete these entries without updating the distribution library. To determine which entries to specify, check the SMPLOG data set to see which ones SMP/E deleted during ACCEPT processing.

**Note:** You can also use the CLEANUP command to delete STSSRC entries without specifying them individually. For more information, see the CLEANUP command in [SMP/E Commands](#)

**Example: Deleting an STSSRC entry**

Assume that you have two target zones, TGT1 and TGT2, generated off the same distribution zone, DLB1. During ACCEPT processing of a SYSMOD, SMP/E has deleted STSSRC SRC01 and SRC02 from the SMPSTS data set associated with target zone TGT2. After performing the ACCEPT, you want to delete the same
source from the SMPSTS associated with target zone TGT1. Assume either that you have a cataloged procedure for TGT1 with the correct SMPSTS specified, or that you have set up the correct DDDEF entries. You can use the following UCLIN to delete the STSSRC entry:

```c
SET   BDY(TGT1)    /* Set to TGT1 zone. */
UCLIN /* */
DEL   STSSRC(SRC01)  /* Delete the source. */
DEL   STSSRC(SRC02)  /* Delete the source. */
ENDUCL /* */
```

**Note:** One UCL statement is required for each STSSRC entry to be deleted.

You can make the same changes by using system utilities; however, the SMPLOG will not reflect the processing done.
SYSMOD entry (distribution and target zone)

The SYSMOD entry in a distribution zone or a target zone describes a SYSMOD that has been installed in the corresponding distribution library or target library. This SYSMOD entry contains the same information as the global zone SYSMOD entry, except that it has information from only one ++VER statement, the one to install the SYSMOD.

When SMP/E installs a SYSMOD, it uses SYSMOD entries in the distribution or target zone to do the following:

- Determine the functional level of the system. SMP/E checks which function SYSMODs have been installed, and then uses that information to determine which service SYSMODs may be applicable.
- Determine the service level of the system. SMP/E checks which service SYSMODs have been installed.
- Make sure the requisites are satisfied for each SYSMOD to be installed. SMP/E checks whether a SYSMOD entry exists in the distribution or target zone for each requisite.

Subentries

These are the subentries for the SYSMOD entry as they appear in the LIST output:

sysmod_id
is the SYSMOD identification.

The SYSMOD ID must contain 7 alphanumeric characters.

ACCEPT
indicates that the SYSMOD has been successfully accepted.

The UCL operand is ACCEPT, ACPT, or ACC.

Note: This subentry exists only in the distribution zone. It is required in distribution zone SYSMOD entries.

APAR
indicates that this SYSMOD is an APAR, which provides a corrective fix to a problem.

The UCL operand is APAR.

APAR, FUNCTION, PTF, and USERMOD are mutually exclusive. If none of these operands is specified, PTF is the default.

APPLY
indicates that the SYSMOD has been successfully applied.

The UCL operand is APPLY, APPL, or APP.

Note: This subentry exists only in the target zone. It is required in target zone SYSMOD entries.

ASSEM
lists the assemblies done during the installation of this SYSMOD.

The UCL operand is ASSEM(name...).

The name can contain from 1 to 8 alphanumeric characters.
**SYSMOD entry (distribution and target zone)**

**BYPASS**
indicates that the BYPASS operand was specified when this SYSMOD was installed.

The UCL operand is **BYPASS**.

**CIFREQ**
lists the conditional requisites that must be installed when this function SYSMOD is installed.

**Note:** The data specified is used by SMP/E only when present in a function SYSMOD.

The UCL operand is **CIFREQ**(causer,req...).

- **causer** is the SYSMOD that specified this function SYSMOD on the FMID operand of an ++IF statement. **req** is the SYSMOD specified on the REQ operand as the conditional requisite associated with this function SYSMOD.
- The **causer** and **req** fields must contain 7 alphanumeric characters each.
- The CIFREQ operand is mutually exclusive with all other UCL operands. It will not cause LASTUPD and LASTUPDTYPE to be updated.

**DELBY**
specifies the SYSMOD that deleted this SYSMOD.

The UCL operand is **DELBY**(sysmod_id).

- The SYSMOD ID must contain 7 alphanumeric characters.
- This subentry is valid only for function SYSMODs.
- The DELBY operand is mutually exclusive with all other UCL operands.

**DELETE**
lists the SYSMODs deleted by this SYSMOD.

The UCL operand is **DELETE**(sysmod_id...).

The SYSMOD ID must contain 7 alphanumeric characters.

**DELLMOD**
indicates that the SYSMOD contained a ++DELETE statement.

The UCL operand is **DELLMOD**.

**DESCRIPTION**
specifies the descriptive name to be associated with this SYSMOD.

The UCL operand is **DESCRIPTION**(description).

**DLMOD**
lists the load modules deleted by ++DELETE statements contained in this SYSMOD.

The UCL operand is **DLMOD**(name...).

**element**
lists the data element replacements contained in the SYSMOD.

The UCL operand is **element**(name...).

- The name can contain from 1 to 8 alphanumeric characters.
- In place of **element**, specify one of the replacement values shown in Table 2 on page 10.
- Some types of elements, such as panels, messages, or text, may have been translated into several languages. In these cases, the **element** operand contains *xxx*, which represents the language used for the element. (If an
SYSMOD entry (distribution and target zone)

   element was not translated, the element operand does not contain any xxx value.) Table 3 on page 13 shows the xxx values and the languages they represent.

ELEMMOV
   indicates that the SYSMOD contained a ++MOVE statement.
   The UCL operand is ELEMMOV.

EMOVE
   lists the elements and load modules that were moved by ++MOVE statements contained in this SYSMOD.
   The UCL operand is EMOVE(name...).

ERROR
   indicates that an error has occurred during the processing of this SYSMOD.
   The UCL operand is ERROR.
   • This operand can also be specified as ERR.
   • If the RESTORE subentry is set, the RESDATE operand must be specified, and the RESTIME and ERROR operands should be specified (SMP/E will automatically set it otherwise).

FEATURE
   lists the names of the software features that contain this SYSMOD. The identified software features correspond to FEATURE entries in the global zone.
   The UCL operand is FEATURE(name...).

FESN
   identifies the field engineering (FE) service number.
   The UCL operand is FESN(string).
   The string must contain 7 alphanumeric characters.

FMID
   identifies the function SYSMOD to which this SYSMOD is applicable.
   The UCL operand is FMID(sysmod_id).
   The SYSMOD ID must contain 7 alphanumeric characters.

FUNCTION
   indicates that this SYSMOD is a function, which introduces a new function into the system.
   The UCL operand is FUNCTION.
   APAR, FUNCTION, PTF, and USERMOD are mutually exclusive. If none of these operands is specified, PTF is the default.

hfs_element
   lists the hierarchical file system element replacements in the SYSMOD.
   The UCL operand is hfs-element(name...).
   The name can contain 1 to 8 uppercase alphabetic, numeric, or national ($, #, @) characters.

IFREQ
   lists the conditional requisites that were installed with this SYSMOD.
   The UCL operand is IFREQ(sysmod_id...).
SYSDOM entry (distribution and target zone)

INSTALLDATE
specifies the date on which this SYSDOM was installed.

The UCL operand is INSTALLDATE(yyddd).
- This operand can also be specified as INSDATE. For a distribution zone
  SYSDOM entry, it can be specified as ACCDATE. For a target zone SYSDOM
  entry, it can be specified as APPDATE.
- The yyddd must contain 5 numeric characters. SMP/E does not check
  whether the specified numbers are valid.
- For the distribution zone SYSDOM entry, INSTALLDATE is the date the
  SYSDOM was accepted. For the target zone SYSDOM entry, INSTALLDATE
  is the date the SYSDOM was applied.

INSTALLTIME
specifies the time at which this SYSDOM was installed.

The UCL operand is INSTALLTIME(hh:mm:ss).
- This operand can also be specified as INSTIME. For a distribution zone
  SYSDOM entry, it can be specified as ACCTIME. For a target zone SYSDOM
  entry, it can be specified as APPTIME.
- The hh, mm, and ss must contain 2 numeric characters each. The ”:” must be
  coded as specified. SMP/E does not check whether the specified numbers
  are valid.
- For a distribution zone SYSDOM entry, INSTALLTIME is the time the
  SYSDOM was accepted. For a target zone SYSDOM entry, INSTALLTIME is
  the time the SYSDOM was applied.

JAR
lists the JAR file replacements (++JAR) supplied by the SYSDOM.

The UCL operand is JAR.

JARUPD
lists the JAR file updates (++JARUPD) supplied by the SYSDOM.

The UCL operand is JARUPD.

JCLIN
indicates that the SYSDOM contained inline JCLIN.

The UCL operand is JCLIN.

LASTSUP
specifies the most recent SYSDOM that superseded this SYSDOM. All previous
superseding SYSDOMs are saved in the SUPBY subentry list.

The UCL operand is LASTSUP(sysmod_id).

The SYSDOM ID must contain 7 alphanumeric characters.

LASTUPD
identifies the cause of the last change to this entry.

The UCL operand is LASTUPD(UCLIN), indicating that the change was made
as a result of UCLIN processing.

LASTUPDTYPE
identifies the last type of update made to this entry.

The UCL operand is LASTUPDTYPE(value). This subentry can contain one of
the following values:
ADD  The entry was added.
SYSMOD entry (distribution and target zone)

**UPD**  The entry was updated.

**MAC**  lists the macro replacements (++MAC statements) in the SYSMOD.

- The UCL operand is **MAC**(name...).
- The name can contain from 1 to 8 alphanumeric characters.

**MACUPD**  lists the macro updates (++MACUPD statements) in the SYSMOD.

- The UCL operand is **MACUPD**(name...).
- The name can contain from 1 to 8 alphanumeric characters.

**MOD**  lists the module replacements (++MOD statements) in the SYSMOD.

- The UCL operand is **MOD**(name...).
- The name can contain from 1 to 8 alphanumeric characters.

**NPRE**  lists negative prerequisite SYSMODs (that is, SYSMODs that must not be present in the system at the same time as this SYSMOD).

- The UCL operand is **NPRE**(sysmod_id...).
  - The SYSMOD ID must contain 7 alphanumeric characters.
  - This subentry is valid only for function SYSMODs.

**PRE**  lists the prerequisite SYSMODs (that is, SYSMODs that must be present before this SYSMOD can be installed).

- The UCL operand is **PRE**(sysmod_id...).
- The SYSMOD ID must contain 7 alphanumeric characters.

**PROGRAM**  lists the program element replacements (++PROGRAM statements) in the SYSMOD.

- The UCL operand is **PROGRAM**(name...).
- The name can contain from 1 to 8 alphanumeric characters.

**PTF**  indicates that this SYSMOD is a PTF, which provides preventive service fixes.

- The UCL operand is **PTF**.

  APAR, FUNCTION, PTF, and USERMOD are mutually exclusive. If none of these operands is specified, **PTF** is the default.

**RECDATE**  specifies the date on which this SYSMOD was received.

- The UCL operand is **RECDATE**(yyddd).
- The yyddd must contain 5 numeric characters. SMP/E does not check whether the specified numbers are valid.

**RECTIME**  specifies the time at which this SYSMOD was received.

- The UCL operand is **RECTIME**(hh:mm:ss).
SYSMOD entry (distribution and target zone)

The hh, mm, and ss must contain 2 numeric characters each. The ":" must be coded as specified. SMP/E does not check whether the specified numbers are valid.

REGEN
indicates how the SYSMOD was installed in the target libraries.
- In a DLIB zone SYSMOD entry, REGEN is not important. It is automatically set for all SYSMODs when they are accepted.
- In a target zone SYSMOD entry, if REGEN is set, it indicates that SYSGEN was used to install the SYSMOD in the target libraries. (The REGEN indicator was carried over when the distribution zone was copied into the target zone. This is generally done as part of SYSGEN.)
  If REGEN is not set, it indicates that the APPLY command was used to install the SYSMOD in the target libraries.

The UCL operand is REGEN or RGN.

RENLMOD
indicates that the SYSMOD contained a ++RENAME statement.

The UCL operand is RENLMOD.

REQ
lists requisite SYSMODs (that is, SYSMODs that must be installed concurrent with this SYSMOD).

The UCL operand is REQ(sysmod_id...).

The SYSMOD ID must contain 7 alphanumeric characters.

RESDATE
specifies the date on which this SYSMOD was restored.

The UCL operand is RESDATE(yyddd).
- This subentry exists only in the target zone.
- The yyddd must contain 5 numeric characters. SMP/E does not check whether the specified numbers are valid.
- If a SYSMOD is marked “RESTORE”, the RESDATE operand must be specified, and the RESTIME and ERROR operands should be specified (SMP/E will automatically set it otherwise).

RESTIME
specifies the time that this SYSMOD was restored.

The UCL operand is RESTIME(hh:mm:ss).
- This subentry exists only in the target zone.
- The hh, mm, and ss must contain 2 numeric characters each. The ":" must be coded as specified. SMP/E does not check whether the specified numbers are valid.
- If a SYSMOD is marked “RESTORE”, the RESDATE operand must be specified, and the RESTIME and ERROR operands should be specified (SMP/E will automatically set it otherwise).

RESTORE
indicates that a RESTORE attempt has been made for this SYSMOD. The RESTORE was not successful; otherwise, the SYSMOD entry would have been deleted.

The UCL operand is RESTORE.
- This subentry exists only in the target zone.
SYSMOD entry (distribution and target zone)

- This operand can also be specified as REST or RES.
- If a SYSMOD is marked “RESTORE”, the RESDATE operand must be specified, and the RESTIME and ERROR operands should be specified (SMP/E will automatically set it otherwise).

**REWORK**
identifies the level of the SYSMOD, which was received again for minor changes.
The UCL operand is REWORK(level).
- Up to 8 numeric characters can be specified.
- For SYSMODs supplied by IBM, the REWORK level is yyyyddd, where yyyy is the year the SYSMOD was reworked and ddd is the Julian date.
- SMP/E does not check whether this data is valid.

**RLMOD**
indicates the load modules renamed by ++RENAME statements in this SYSMOD.
The UCL operand is RLMOD(name...).

**SOURCEID**
lists the character strings assigned to this SYSMOD during RECEIVE. These values might have been specified by the user on the RECEIVE command, included inline on the ++ASSIGN statement, or assigned by SMP/E when processing the contents of an order.
The UCL operand is SOURCEID(source_id...).
- The source ID can be from 1 to 64 characters in length and contain any nonblank character (X’41’ through X’FE’) except single quotation mark (‘), asterisk (*), percent (%), comma (,), left parenthesis (()), and right parenthesis ()),
- A source ID value cannot span lines.
- A source ID value is case sensitive.

**SRC**
lists the source replacements (++SRC statements) in the SYSMOD.
The UCL operand is SRC(name...).
The name can contain from 1 to 8 alphanumeric characters.

**SRCUPD**
lists the source updates (++SRCUPD statements) in the SYSMOD.
The UCL operand is SRCUPD(name...).
The name can contain from 1 to 8 alphanumeric characters.

**SUPBY**
lists the SYSMODs that superseded this SYSMOD. For functions, this includes SYSMODs that both deleted and superseded this SYSMOD.

**Notes:**
1. The most recent SYSMOD to supersede this SYSMOD is not included in the SUPBY list. It is saved in the LASTSUP field.
2. The SUPBY field may appear as “SUPBY(IN SYSMD)”. For example, this is the case if the superseding SYSMODs were installed separately instead of on the same APPLY or ACCEPT command.

The UCL operand is SUPBY(sysmod_id...).
SYSMOD entry (distribution and target zone)

- This operand can also be specified as SUP.
- The SYSMOD ID must contain 7 alphanumeric characters.

SUPING
lists the SYSMODs superseded by this SYSMOD.
The UCL operand is SUPING(sysmod_id...).
The SYSMOD ID must contain 7 alphanumeric characters.

SZAP
lists the module superzaps (++ZAP statements) in the SYSMOD.
The UCL operand is SZAP(name...).
The name can contain from 1 to 8 alphanumeric characters.

UCLDATE
specifies the date on which this SYSMOD was last modified through UCLIN.
The UCL operand is UCLDATE(yyddd).
The yyddd must contain 5 numeric characters. SMP/E does not check whether the specified numbers are valid.

UCLTIME
specifies the time that this SYSMOD was last modified through UCLIN.
The UCL operand is UCLTIME(hh:mm:ss).
The hh, mm, and ss must contain 2 numeric characters each. The “:” must be coded as specified. SMP/E does not check whether the specified numbers are valid.

USERMOD
indicates that this SYSMOD is a USERMOD, which puts a user modification in the system.
The UCL operand is USERMOD.
APAR, FUNCTION, PTF, and USERMOD are mutually exclusive. If none of these operands is specified, PTF is the default.

VERNUM
specifies the relative number of the ++VER statement used when this SYSMOD was installed.
The UCL operand is VERNUM(mnn).
- mnn can contain from 1 to 3 numeric characters.
- When updating an existing entry, you should not specify VERNUM. This causes SMP/E to assume the same VERNUM value as in the current entry.
- If you do not specify VERNUM when adding a new entry, SMP/E assumes a VERNUM value of 1.
- The VERNUM values are kept in each entry built from information from the ++VER statements. (For example, subentries such as PRE and REQ have unique VERNUM values.) If all entries do not have the same VERNUM, an error will result.

VERSION
lists the function SYSMODs that are versioned by this SYSMOD. Versioning indicates that, if there are any elements in common between the SYSMODs listed and this SYSMOD, this SYSMOD’s elements are at a higher functional level, and are thus the ones that should be installed.
SYSMOD entry (distribution and target zone)

The UCL operand is **VERSION(sysmod_id...)**.
The SYSMOD ID must contain 7 alphanumeric characters.

**XZAP**
lists the module superzaps in the SYSMOD (++ZAP statements) that contain an EXPAND statement (indicating that the module should be expanded before it is updated).

The UCL operand is **XZAP(name...)**.
The name can contain from 1 to 8 alphanumeric characters.

**LIST Examples**
To list all the SYSMOD entries in a particular zone, you could use the following commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
LIST SYSMOD /* List all SYSMOD entries. */.
```

To list specific SYSMOD entries, you could use these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
LIST SYSMOD(UZ00001 /* List only these two */
             UZ00002) /* entries. */.
```

The format of the LIST output for each SYSMOD entry is the same for both of these commands. The only difference is the number of SYSMOD entries listed. [Figure 57 on page 331](#) and [Figure 58 on page 332](#) are examples of LIST output for SYSMOD entries.

```

*Figure 58. SYSMOD entry: sample LIST output for a target zone*
SYSMOD entry (distribution and target zone)

By specifying various operands, you can reduce the number of SYSMOD entries listed. If you specify any of these operands on the LIST command, SMP/E automatically assumes that SYSMOD entries are to be processed, regardless of whether the SYSMOD operand was also specified. If you specify more than one of these operands on the same LIST command, only the SYSMODs that meet all the specified conditions are processed. For more information about these operands, see [SMP/E Commands](#).

You can also use the LIST command to find any other SYSMODs that specify this SYSMOD in their DEL, PRE, REQ, NPRE, SUP, or VERSION lists. To include the names of these SYSMODs in the LIST output, you can use the XREF operand, as shown in these commands:

```plaintext
SET BDY(DLIB1) /* Set to requested zone. */.
LIST SYSMOD /* List all SYSMOD entries */
XREF /* and SYSMOD that hit them. */.
```

**Note**: XREF can be used either in mass mode or in select mode.

[Figure 59](#) is an example of the LIST output produced when the XREF operand is used.

![SYSMOD entry: sample LIST output when XREF is specified](#)

**Note**: Some of the xxxBY subentries listed in this example are not actually valid for the type of SYSMOD shown (that is, PTF). For example, a SYSMOD does not specify VERSION, NPRE, or DELETE for a PTF SYSMOD. Those subentries are included here only to show the format of the output.

### UNLOAD Examples

To dump the SYSMOD entries in UCL format, you can use the UNLOAD command. To unload all the SYSMOD entries in a particular zone, you could use the following commands:

```plaintext
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD SYSMOD /* Unload all SYSMOD entries. */.
```
To unload specific SYSMOD entries, you could use these commands:

```
SET BDY(TGT1) /* Set to requested zone. */.
UNLOAD SYSMOD(UZ00001 /* Unload only these two */ UZ00002) /* entries. */.
```

The format of the UNLOAD output for each SYSMOD entry is the same for both of these commands. The only difference is the number of SYSMOD entries listed. Figure 60 is an example of UNLOAD output for one SYSMOD.

```
UCLIN.
REP      SYSMOD      ( HZY2102 )

      .
ENDUCL.
```

Figure 60. SYSMOD entry: sample UNLOAD output

By specifying various operands, you can reduce the number of SYSMOD entries unloaded. If you specify any of these operands on the UNLOAD command, SMP/E automatically assumes that SYSMOD entries are to be processed. If you specify more than one of these operands on the same UNLOAD command, only those SYSMODs that meet all the specified conditions are processed. For more information about these operands, see "SMP/E Commands".

**UCLIN Examples**

You can use the ADD, REP, and DEL UCL statements to change subentries in the SYSMOD entry. Generally, after UCLIN changes are done, the SYSMOD entry must contain at least these subentries, unless the entire entry has been deleted:

- ACCEPT or APPLY
- APAR, FUNCTION, PTF, or USERMOD
- INSTALLDATE
- RECDATE
- FMID

Otherwise, there is not enough information in the entry to process the SYSMOD. If any of the required subentries are missing, SMP/E does not make the requested UCL updates to the entry, and the entry remains as it was before the UCL command.
SYSMOD entry (distribution and target zone)

Note: The entry for a deleted SYSMOD can contain just the DELBY subentry. The entry for a superseded SYSMOD can contain just the SUPBY subentry. The entry for a SYSMOD that is both deleted and superseded can contain just the DELBY and SUPBY subentries.

The following examples are provided to help you use the SYSMOD entry.

Example 1: Creating a SYSMOD entry
Assume that you have installed an APAR fix outside of SMP/E and now wish to get that fix recorded in the distribution zone. The APAR number was AZ12345, and was an update to a source SRC01. The following UCL should be used:

```
SET  BDY(DLIB1)  /* Set to DLIB zone. */.
UCLIN */.
ADD  SYSMOD(AZ12345)  /* Specify SYSMOD. */
    SRCUPD(SRC01)  /* Changed this source. */
    RECDATE(06100) /* Received on this date. */
    INSDATE(06100) /* Accepted same day. */
    ASSEM(SRC01)  /* Assembled source. */
    FMID(FZY2102) /* Functional owner. */
    */.
ADD  SRC(SRC01)  /* Now update source entry */
    UMID(AZ12345) /* with update ID. */
    */.
REP  MOD(SRC01)  /* Now update MOD */
    RMID(AZ12345) /* with new replacement ID */
    RMIDASM /* from assembly. */
    */.
ENDUCL */.
```

Example 2: Removing the ERROR indicator
Assume that during an APPLY you encountered an error that caused a PTF to be marked as in error. After looking at the output you determine that the PTF actually installed correctly, and rather than reinstall the PTF you decide to make the appropriate changes to make the PTF look installed. The following UCL can be used:

```
SET  BDY(TGT1)  /* Set to target zone. */.
UCLIN */.
DEL  SYSMOD(UZ12345) /* Specify SYSMOD. */
    RESTORE /* Delete restore. */
    RESDATE() /* Delete restore date. */
    RESTIME() /* Delete restore time. */
    */.
ADD  SYSMOD(UZ12345) /* Specify SYSMOD. */
    APPLY /* Add apply info. */
    INSDATE(06100) /* */
    INSTIME(08:00:00) /* */
    */.
ENDUCL */.
```

Note: This method is very prone to errors. The preceding example gets the SYSMOD marked as having been applied; however, you have not made all the changes necessary to get the rest of the target zone entries coordinated. Those changes include updating the RMID and UMID fields of all the elements affected by the PTF, storing superseded SYSMOD entries, and updating the global zone SYSMOD entry.

If you are not extremely familiar with SMP/E internals and how to complete the update process, the recommended method is to reapply the PTF.
SYSMOD entry (global zone)

SYSMOD entry (global zone)

The global zone SYSMOD entry describes a SYSMOD that exists as an MCS entry in the SMPPTS. It contains information that SMP/E obtained when it received that SYSMOD. Because SMP/E processing is designed to keep the global zone SYSMOD entry and the MCS entry synchronized, you should use only SMP/E commands to update these entries. If you use system utilities to update the MCS entries, you will get unpredictable results when processing the corresponding SYSMOD. For more information about MCS entries, see “MCS entry (SMPPTS)” on page 273.

When SMP/E processes SYSMODs, it uses the global zone SYSMOD entry to determine which SYSMODs are applicable or whether the SYSMODs you selected are applicable. In addition, after a SYSMOD has been successfully applied or accepted, SMP/E records in the SYSMOD entry the names of the zones to which the SYSMOD was applied or accepted.

**Note:** Although this information is saved in the global zone SYSMOD entry, it is used only for reporting purposes. SMP/E does not use it during APPLY, ACCEPT, or RESTORE processing to determine the status of a SYSMOD. Instead, SMP/E uses SYSMOD entries in the target and distribution zones to determine whether a SYSMOD has been applied or accepted.

A SYSMOD entry is generally kept in the global zone until the associated SYSMOD is accepted; then the entry is deleted. You may want SMP/E to save the global zone SYSMOD entries after ACCEPT processing (for example, if you plan to do a system generation). To do this, specify NOPURGE in the ORDER entry that is in effect during ACCEPT processing. Likewise, you may want to save the global zone SYSMOD entries after RESTORE processing. To do this, specify NOREJECT in the ORDER entry that is in effect during RESTORE processing.

**Subentries**

These are the subentries for the global zone SYSMOD entry as they appear in the LIST output. Only a few of these subentries can be changed with UCLIN. The description of each entry indicates whether UCLIN may be used and, if so, what the correct syntax is.

sysmod_id
- is the SYSMOD identification.
- The SYSMOD ID must contain 7 alphanumeric characters.

**ACCEPT ZONE**
- lists the distribution zones into which the SYSMOD has been successfully accepted.
- The UCL operand is **ACCID**(zone...).
- The name can contain from 1 to 7 alphanumeric characters.

**APAR**
- indicates that this SYSMOD is an APAR, which provides a corrective fix to a problem.
- There is no UCL support for this subentry in the global zone.

**APPLY ZONE**
- lists the target zones to which the SYSMOD has been successfully applied.
- The UCL operand is **APPID**(zone...).
SYMSMOD entry (global zone)

The name can contain from 1 to 7 alphanumeric characters.

DELLMOD
indicates that the SYMSMOD contained a ++DELETE statement.
The UCL operand is DELLMOD.

DELETE
lists the SYMSMODs deleted by this SYMSMOD.
There is no UCL support for this subentry in the global zone.

DESCRIPTION
specifies the descriptive name to be associated with this SYMSMOD.
The UCL operand is DESCRIPTION(description).

DLMOD
lists the load modules deleted by ++DELETE statements contained in this SYMSMOD.
The UCL operand is DLMOD(name...).

element
lists the data element replacements in the SYMSMOD.
There is no UCL support for this subentry in the global zone.

In place of element, you will see one of the values shown in Table 2 on page 10.
Some types of elements, such as panels, messages, or text, may have been translated into several languages. In these cases, the element operand contains xxx, which represents the language used for the element. (If an element was not translated, the element operand does not contain any xxx value.) Table 3 on page 13 shows the xxx values and the languages they represent.

ELEMMOV
indicates that the SYMSMOD contained a ++MOVE statement.
The UCL operand is ELEMMOV.

EMOVE
lists the elements and load modules that were moved by ++MOVE statements contained in this SYMSMOD.

ERROR
indicates that an error occurred when this SYMSMOD was received.
There is no UCL support for this subentry in the global zone.

FEATURE
lists the names of the software features that contain this SYMSMOD. The identified software features correspond to FEATURE entries in the global zone.
The UCL operand is FEATURE(name,...).

FESN
identifies the field engineering (FE) service number.
There is no UCL support for this subentry in the global zone.

FMID
identifies the function SYMSMOD to which this SYMSMOD is applicable.
There is no UCL support for this subentry in the global zone.
SYSMOD entry (global zone)

FUNCTION
indicates that this SYSMOD is a function, which introduces a new function into the system.

There is no UCL support for this subentry in the global zone.

**hfs_element**
lists the hierarchical file system element replacements (++hfs_element statements) in the SYSMOD.

There is no UCL support for this subentry in the global zone.

HOLDERROR
lists the error hold reason IDs in effect for this SYSMOD.

The actual ++HOLD statement associated with each reason ID (HOLDDATA) is not in the SYSMOD entry. However, if the LIST command specified HOLDDATA and SYSMOD, the listing of the SYSMOD entry includes the HOLDDATA. For more information, see information about listing HOLDDATA with the LIST command in [SMP/E Commands](#).

There is no UCL support for this subentry in the global zone.

HOLDFIXCAT
lists the fix category hold reason IDs in effect for this SYSMOD.

There is no UCL support for this subentry in the global zone.

HOLDSYSTEM
lists the system hold reason IDs in effect for this SYSMOD.

The actual ++HOLD statement associated with each reason ID (HOLDDATA) is not in the SYSMOD entry. However, if the LIST command specified HOLDDATA and SYSMOD, the listing of the SYSMOD entry includes the HOLDDATA. For more information, see information about listing HOLDDATA with the LIST command in [SMP/E Commands](#).

HOLDSYSTEM subentries show either INT or EXT to indicate the source of the ++HOLD statement.

- **INT** means that the ++HOLD statement was contained in the held SYSMOD. The held SYSMOD can be installed only if the BYPASS operand is specified on the APPLY or ACCEPT command.
- **EXT** means that the ++HOLD statement was obtained from another source, such as SMPHOLD. The held SYSMOD can be installed only if the BYPASS operand is specified on the APPLY or ACCEPT command or if the hold is removed by a ++RELEASE statement.

There is no UCL support for this subentry in the global zone.

HOLDUSER
lists the user hold reason IDs in effect for this SYSMOD.

The actual ++HOLD statement associated with each reason ID (HOLDDATA) is not in the SYSMOD entry. However, if the LIST command specified HOLDDATA and SYSMOD, the listing of the SYSMOD entry includes the HOLDDATA. For more information, see information about listing HOLDDATA with the LIST command in [SMP/E Commands](#).

There is no UCL support for this subentry in the global zone.

JAR
lists the JAR file replacements (++JAR) supplied by the SYSMOD.

There is no UCL support for this subentry in the global zone.
SYSMOD entry (global zone)

JARUPD
lists the JAR file updates (++JARUPD) supplied by the SYSMOD.
There is no UCL support for this subentry in the global zone.

JCLIN
indicates that the SYSMOD contained inline JCLIN.
There is no UCL support for this subentry in the global zone.

MAC
lists the macro replacements (++MAC statements) in the SYSMOD.
There is no UCL support for this subentry in the global zone.

MACUPD
lists the macro updates (++MACUPD statements) in the SYSMOD.
There is no UCL support for this subentry in the global zone.

MOD
lists the module replacements (++MOD statements) in the SYSMOD.
There is no UCL support for this subentry in the global zone.

NPRE
lists negative prerequisite SYSMODs (that is, SYSMODs that must not be present in the system at the same time as this SYSMOD).
There is no UCL support for this subentry in the global zone.

PRE
lists prerequisite SYSMODs (that is, SYSMODs that must be present before this SYSMOD can be installed).
There is no UCL support for this subentry in the global zone.

PROGRAM
lists the program element replacements (++PROGRAM statements) in the SYSMOD.
There is no UCL support for this subentry in the global zone.

PTF
indicates that this SYSMOD is a PTF, which provides preventive service fixes.
There is no UCL support for this subentry in the global zone.

RECDATE
specifies the date on which this SYSMOD was received.
There is no UCL support for this subentry in the global zone.

RECTIME
specifies the time at which this SYSMOD was received.
There is no UCL support for this subentry in the global zone.

RENLMOD
indicates that the SYSMOD contained a ++RENAME statement.
The UCL operand is RENLMOD.

REQ
lists requisite SYSMODs (that is, SYSMODs that must be installed concurrent with this SYSMOD).
There is no UCL support for this subentry in the global zone.
**SYSMOD entry (global zone)**

**REWORK**
identifies the level of the SYSMOD, which was received again for minor changes.

For SYSMODs supplied by IBM, the REWORK level is \textit{yyyydd}, where \textit{yyyy} is the year the SYSMOD was reworked and \textit{dd} is the Julian date.

There is no UCL support for this subentry in the global zone.

**RLMOD**
indicates the load modules renamed by \texttt{++RENAME} statements in this SYSMOD.

The UCL operand is \texttt{RLMOD(name...)}.

**SOURCEID**
lists the character strings assigned to this SYSMOD during RECEIVE. These values might have been specified by the user on the RECEIVE command, included inline on the \texttt{++ASSIGN} statement, or assigned by SMP/E when processing the contents of an order.

The UCL operand is \texttt{SOURCEID(source_id...)}.

- The source ID can be from 1 to 64 characters in length and contain any nonblank character (X'41' through X'FE') except single quotation mark ('), asterisk (*), percent (%), left parenthesis (()), and right parenthesis ()).
- A source ID value cannot span lines.
- A source ID value is case sensitive.

**SRC**
lists the source replacements (\texttt{++SRC} statements) in the SYSMOD.

There is no UCL support for this subentry in the global zone.

**SRCUPD**
lists the source updates (\texttt{++SRCUPD} statements) in the SYSMOD.

There is no UCL support for this subentry in the global zone.

**SREL**
is the system or subsystem release specified on the indicated \texttt{++VER} MCS in the SYSMOD; for example, SREL VER(001) = Z038. This SREL value matches an SREL value defined in the GLOBALZONE entry that was used when receiving the SYSMOD. These are the systems and subsystems defined by IBM, with their SRELS:

<table>
<thead>
<tr>
<th>System</th>
<th>SREL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2</td>
<td>P115</td>
</tr>
<tr>
<td>CICS</td>
<td>C150</td>
</tr>
<tr>
<td>IMS</td>
<td>P115</td>
</tr>
<tr>
<td>MVS</td>
<td>Z038</td>
</tr>
<tr>
<td>NCP</td>
<td>P004</td>
</tr>
</tbody>
</table>

There is no UCL support for this subentry in the global zone.

**SUPING**
lists the SYSMODs superseded by this SYSMOD.

There is no UCL support for this subentry in the global zone.

**SZAP**
lists the module superzaps (\texttt{++ZAP} statements) in the SYSMOD.

There is no UCL support for this subentry in the global zone.
SYSMOD entry (global zone)

TLIBPREFIX
is the high-level data set name qualifier of the SMPTLIB data sets used to receive this SYSMOD, which was packaged in RELFILEs. This is the DSPREFIX value that was used during RECEIVE processing.

The UCL operand is TLIBPREFIX(prefix).
- The prefix can contain from 1 to 26 alphanumeric characters.
- The prefix must follow standard naming conventions for data sets.

Note: If the TLIBPREFIX subentry is deleted from the entry for a SYSMOD packaged in RELFILE format, the SYSMOD cannot be applied or accepted until the TLIBPREFIX subentry is re-created with the current prefix for the SMPTLIB data sets.

USERMOD
indicates that this SYSMOD is a USERMOD, which puts a user modification into the system.

There is no UCL support for this subentry in the global zone.

VERSION
lists the function SYSMODs that are versioned by this SYSMOD. Versioning indicates that, if there are any elements in common between the SYSMODs listed and this SYSMOD, this SYSMOD's elements are at a higher functional level, and are therefore the ones that should be installed.

There is no UCL support for this subentry in the global zone.

XZAP
lists the module superzaps (++ZAP statements) in the SYSMOD that contain an EXPAND statement (indicating that the module should be expanded before it is updated).

There is no UCL support for this subentry in the global zone.

LIST Examples
To list all the SYSMOD entries in a global zone, you can use the following commands:

```bash
SET BDY(GLOBAL) /* Set to requested zone. */.
LIST SYSMOD /* List all SYSMOD entries. */.
```

To list specific SYSMOD entries in a global zone, you can use these commands:

```bash
SET BDY(GLOBAL) /* Set to requested zone. */.
LIST SYSMOD(UZ00001) /* List only these two */
   UZ00002) /* entries. */.
```

To list specific SYSMOD entries in the global zone along with the associated HOLDDATA, you can use these commands:

```bash
SET BDY(GLOBAL) /* Set to requested zone. */.
LIST SYSMOD(UZ12345) /* List only these two */
   UZ56789) /* entries */
   HOLDDATA /* plus HOLDDATA for them. */.
```

The format of the LIST output for each SYSMOD entry is the same for all of these commands. The only differences are the number of SYSMOD entries listed and the amount of information presented for each entry (HOLDDATA causes additional information to be listed).
**SYSMOD entry (global zone)**

Figure 61, Figure 62 on page 343, and Figure 63 on page 344 are examples of LIST output for SYSMOD entries.

**Note:** If HOLDDATA for a particular SYSMOD has been received but the SYSMOD itself has not yet been received, only the hold information for the SYSMOD is listed. For an example, see SYSMOD UZ56789 in Figure 63 on page 344.

Figure 63. SYSMOD entry: sample LIST output when HOLDDATA is specified

**UCLIN Examples**

You can use the ADD, REP, and DEL UCL statements to change subentries in a
SYSMOD entry. When you use UCLIN to update a SYSMOD entry, remember that
if a DEL statement deletes all the existing subentries in the entry, SMP/E deletes
the entire entry.

The following examples are provided to help you use the SYSMOD entry.

**Example 1: Changing the SOURCEID of a SYSMOD**

Assume that you received a SYSMOD and assigned it a SOURCEID value of
DATALINK, and that you now wish to change the SOURCEID value to PUT0701
so that the SYSMOD will be installed with that service level. The following UCL
can be used to change the SOURCEID value:

```
SET BDY(GLOBAL) /* Set to global zone. */.
UCLIN /* */.
REP SYSMOD(UZ00001) /* Specify SYSMOD. */
     SOURCEID(PUT0701) /* Change SOURCEID value. */
     /* */.
ENDUCL /* */.
```
Example 2: Indicating that a SYSMOD was applied

Assume that you have received some service, accepted it with the
BYPASS(APPLYCHECK) operand, and then performed a system generation. That
service is now actually in the target libraries, and you would like that recorded in
the global zone SYSMOD entry. Assume that the name of your target zone is
TGT1. The following UCL can be used:

```
SET BDY(GLOBAL) /* Set to global zone. */.
UCLIN /* */.
ADD SYSMOD(UZ00001) /* Specify SYSMOD. */
   APPID(TGT1) /* Applied to this zone. */
ENDUCL /* */.
```

Note: One UCL statement is required for each SYSMOD.
TARGETZONE entry (target zone)

The TARGETZONE entry contains information SMP/E uses to process a specific target zone and the associated target libraries. It is created by UCLIN and must be defined before you can do any other processing for that target zone.

Subentries
These are the subentries for the TARGETZONE entry as they appear in the LIST output:

name
is the name of the target zone. You assign the name when the zone is created.

The name can contain from one to seven alphanumeric characters (A–Z, 0–9) or national characters ($, #, @). The first character must be alphabetic.

OPTIONS
is the name of the OPTIONS entry in the global zone that should be used in processing this target zone. For more information, see "OPTIONS entry (global zone)" on page 292.

The UCL operand is OPTIONS(name).

- The name can contain from one to eight alphanumeric characters.
- This name can be overridden by using the OPTIONS parameter on the SET command. For more information, see SMP/E Commands.
- If no OPTIONS entry name is specified, SMP/E uses a set of default utility values when processing this target zone. For more information, see "OPTIONS entry (global zone)" on page 292.

RELATED
is the name of the distribution zone to which this target zone is related. A target zone is related to the distribution zone used to build the target libraries, such as during system generation.

The UCL operand is RELATED(zone).

- The zone name can contain from one to seven alphanumeric characters.
- Although the entry can be defined without this subentry, you must define the subentry before you can install any SYSMODs in the target libraries.

SREL
lists the system releases to be supported in this target zone.

The UCL operand is SREL(srel...).

- The SREL must contain four alphanumeric characters, usually one alphabetic character followed by three numeric characters. These are the SRELs defined by IBM:

<table>
<thead>
<tr>
<th>System</th>
<th>SREL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2</td>
<td>P115</td>
</tr>
<tr>
<td>CICS</td>
<td>C150</td>
</tr>
<tr>
<td>IMS</td>
<td>P115</td>
</tr>
<tr>
<td>MVS</td>
<td>Z038</td>
</tr>
<tr>
<td>NCP</td>
<td>P004</td>
</tr>
</tbody>
</table>

- Although the entry can be defined without this subentry, you must define the subentry before you can install any SYSMODs in the target libraries.

Note: Although you can support multiple products with different SREL values from one target zone, those products are still subject to all other
TARGETZONE entry (target zone)

restrictions related to combining products in one zone. The most common reason for not being able to combine products is common element names. For example, modules or macros with the same name are found in both products, but reside in different libraries.

TIEDTO
specifies other target zones that either:
• Supplied modules for load modules controlled by this target zone
• Control load modules that have been link-edited with modules supplied by this target zone

The UCL operand is TIEDTO(zone...).

Note: TIEDTO subentries are added automatically during LINK MODULE command processing. However, they are never automatically deleted.

UPGLEVEL
indicates the highest SMP/E release level that is allowed to make incompatible changes to the target zone. Before making an incompatible change to the target zone, SMP/E will check the UPGLEVEL value for that zone. If the release level of SMP/E is higher than the zone’s UPGLEVEL value, SMP/E will not make the incompatible change.

The UPGLEVEL value is in the form vr.pp, where vr represents the version and release of SMP/E and pp represents the PTF level of SMP/E.

There is no UCL support for this subentry. When a zone is created by SMP/E using the UCLIN command or the Administration dialog, SMP/E sets the UPGLEVEL subentry value for that zone to the level of SMP/E used to create the zone. The UPGRADE command is used to change the UPGLEVEL subentry value for a zone.

XZLINK
specifies whether APPLY and RESTORE processing in another zone should automatically update load modules in this zone when cross-zone modules previously added to those load modules by the LINK MODULE command are changed.

The UCL operand is XZLINK(value).
• This subentry can contain one of the following values:

DEFERRED
Cross-zone load modules controlled by this zone should not be automatically updated when modules previously included in them by the LINK MODULE command are updated or deleted.

To make sure that the modules are synchronized with the cross-zone load modules and that the cross-zone information in SMP/E entries is correct, some combination of the following commands must be run later (depending on how the module changes affect the load modules):
– LINK MODULE command, to include modules in the affected load modules
– Link-edit (outside of SMP/E), to delete modules from the affected load modules
– UCLIN command, to update cross-zone subentries as necessary

AUTOMATIC
Cross-zone load modules controlled by this zone should be
TARGETZONE entry (target zone)

automatically updated when modules previously included in them by the LINK MODULE command are updated or deleted.

- If XZLINK is not specified, SMP/E uses the default value of DEFERRED.
- XZLINK does not affect processing of the LINK command.
- The XZLINK(DEFERRED) value is listed only when the TARGETZONE entry contains TIEDTO records.

ZDESC

is a user-written description for this zone.

The UCL operand is ZONEDESCRIPTION(text).

- The zone description can be in single-byte characters (such as English alphanumeric characters) or in double-byte characters (such as Kanji).
- The zone description can contain up to 500 bytes of data, including blanks. (For double-byte data, the 500-byte maximum includes all shift-in and shift-out characters, as well as the double-byte characters.) Extra blanks are deleted. All data beyond column 72 is ignored, including blanks.
- The zone description cannot be only blanks.
- If parentheses are included in the text, they must be in matched pairs.

LIST Examples

To list the TARGETZONE entry for a particular target zone, you can use the following commands:

```
SET BDY(TGT1) /* Set to requested target. */.
LIST TARGETZONE /* List TARGETZONE entry. */.
```

Figure 64 is an example of LIST output for a TARGETZONE entry.

```
TGT1 TZONE ENTRY

NAME

TGT1 TZONE = TGT1
ZDESC = ZONE DESCRIPTION FOR TGT1 ZONE
RELATED = DLIB1
SREL = P115 R020 Z038
OPTIONS = OPITGT1
XZLINK = AUTOMATIC
TIEDTO = CICS1 IMS1
```

Figure 64. TARGETZONE entry: sample LIST output

UCLIN Examples

You can use the ADD, REP, and DEL UCL statements to change subentries in the TARGETZONE entry. When you use UCLIN to update a TARGETZONE entry, remember that if a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.

The following examples are provided to help you use the TARGETZONE entry.

Example 1: Defining a TARGETZONE entry

Assume that you are about to build a new set of target libraries and thus wish to define a new target zone named TGT2. The distribution zone that you have done
TARGETZONE entry (target zone)

the system generation from is DLIB1, the OPTIONS entry that will be set up will be called OPTTGT2, and the target zone will contain MVS (Z038) and two additional programs, each with its own SREL value (P010 and R020). The target zone will exist in data set SMPE.SMFCI.CSI. Use the following UCLIN to define the new zone.

```
SET BDY(GLOBAL) /* Set to global zone. */
UCLIN /* UCLIN for GZONE entry */
ADD GZONE /* to set up */
   ZONEINDEX( /* index for new zone. */
      (TGT2,SMPE.SMPCI.CSI,TARGET) /* */
    ) /* */
   /* */
   /* */
ENDUCL /* */
```

Note: Even though the OPTIONS entry has not been set up yet, you can still refer to it in the TARGETZONE entry. Prior to processing this target zone the OPTIONS entry must be created. For examples of setting up the OPTIONS entries, see [OPTIONS entry (global zone)] on page 292.

Example 2: Formatting a zone description

Assume that you enter the following zone description with the first line ending in column 72 and the second line starting in column 1:

```
---+++---1---+++---2--- ... ---5+++---6+++---7---
SET BDY(TGT1) /* Set to tgt zone. */
UCLIN /* UCLIN for TZONE entry */
ADD TZONE(TGT1) /* to set up. */
   ZDESC( THIS IS THE DESCRIPTION FOR
   THE TGT1 ZONE)
ENDUCL /* End of zone description. */
```

Because there is no blank between the word ending in column 72 and the next word starting in column 1, SMP/E will run the two together.

Words in a zone description, even words that end in column 72, must be separated by a blank. To format the zone description in this example correctly, you can put a blank at the beginning of the second line:

```
---+++---1---+++---2--- ... ---5+++---6+++---7---
SET BDY(TGT1) /* Set to tgt zone. */
UCLIN /* UCLIN for TZONE entry */
ADD TZONE(TGT1) /* to set up. */
   ZDESC( THIS IS THE DESCRIPTION FOR
   THE TGT1 ZONE)
ENDUCL /* End of zone description. */
```

Because there is a blank explicitly coded between the word ending in column 72 and the word starting in column 1, SMP/E will not run the words together.
The UTILITY entry contains information that SMP/E uses when invoking a particular system utility program, such as the load module name of the program and the parameters that should be passed. This information is used only if the UTILITY entry is named in the OPTIONS entry that is in effect. For example, to have SMP/E use certain parameters when it calls a specific link-edit utility, you must do the following:

1. Define a UTILITY entry that names the program and specifies the parameters.
2. Define an OPTIONS entry that specifies that UTILITY entry as the one to use for the link-edit utility.
3. Put that OPTIONS entry into effect, either by specifying it on the SET command or by defining it as the default OPTIONS entry for the zone to be processed.

If the OPTIONS entry does not point to a UTILITY entry for a particular system utility, SMP/E uses default values for that utility. Table 6 lists the default values for the various types of utility programs.

### Table 6. Default values for UTILITY entries

</tr>
</tbody>
</table>
If a UTILITY entry defines some, but not all, of these subentries, SMP/E uses the default values for the subentries not specified. For more information about OPTIONS entries, see "OPTIONS entry (global zone)" on page 292.

The names of the utilities SMP/E may call include all of SMP/E’s default utility program names (BPXCOPY, ASMA90, IEBCOPY, IEBUPDTE, IEWBLINK, IEWL, and IMAISPZAP) and any utility program name specified in an active UTILITY entry. Because SMP/E runs authorized, all the utility programs called by SMP/E must reside in an authorized library. Also, if a particular utility program is to be restricted, the z/OS Security Server must be used to control its execution.

Subentries

These are the subentries for the UTILITY entry as they appear in the LIST output:

name  
is the name of the UTILITY entry.

The name can contain from 1 to 8 alphanumeric characters.

LIST  
indicates whether member names should be listed when SMP/E invokes a copy utility to perform compress processing, retry processing, or element installation.

The UCL operand is LIST(YES | NO).
  • YES indicates that member names should be listed during copy processing.
    This is the default.
  • NO indicates that the list of member names should be suppressed during copy processing.
  • The LIST value (including the default value) is ignored when the UTILITY entry is not for a copy utility.

NAME  
is the name of the load module for the utility program that SMP/E is to call. Table 6 on page 350 lists the default names used by SMP/E if the OPTIONS entry in effect does not point to a UTILITY entry for a specific system utility.

The UCL operand is NAME(prog).

The name can contain from 1 to 8 alphanumeric characters. The first character must be alphabetic.
UTILITY entry (global zone)

PARM

specifies the parameters to be passed to the utility program. SMP/E may add other parameters to this list. Table 6 on page 350 lists the default parameters used by SMP/E if the OPTIONS entry in effect does not point to a UTILITY entry for a specific system utility.

The UCL operand is PARM(string).

• If you specify PARM, you must specify all the parameters to be passed. You cannot specify a single value to add or change just one parameter.

• The parameter string is usually a hexadecimal character string with a length of up to 100 characters. This 100-character limit can be exceeded for a binder link-edit step using the OPTION option. For a more detailed explanation, see the GENERATE command chapter in SMP/E Commands. No validity checking is done on the string. If any blanks are specified between the parentheses, they will be deleted by SMP/E during processing.

• If the string contains parentheses, they must be in matched pairs. SMP/E assumes it has reached the end of the specified string when it encounters a closing parenthesis for the opening parenthesis. For example, the following is valid because there are matching parentheses within the string:

  PARM(LIST, LET, SIZE=(1526K, 80K), NCAL)

Parentheses within quotation marks are still considered parentheses. The next example is not valid because there are unmatched parentheses. SMP/E would continue scanning after the last parenthesis looking for another “)”.

  PARM(PRINT(A), SPECIALCHAR(‘)‘)

Likewise, the following example is not valid. SMP/E would stop at the “)”) after SPECIALCHAR and give a syntax error on the closing quotation mark.

  PARM(PRINT(A), SPECIALCHAR(’)‘)

• Assembler utility: If no PARM subentry is specified for an assembler utility, SMP/E passes the default PARM values shown for assembler utilities in Table 6 on page 350.

  If you change the PARM subentry, either include DECK in the parameters chosen or ensure that the assembler program produces an object deck.

• HFS copy utility: If the UTILITY entry for the HFS copy utility specifies a PARM value, those parameters are passed to the utility in addition to any parameters saved in the hierarchical file system element entry.

• Link-edit utility: SMP/E constructs the string of link-edit parameters to be passed to the link-edit utility in the following steps:
  1. If a PARM subentry is specified for a link-edit utility, SMP/E starts the string with the parameters specified in the PARM subentry. Otherwise, SMP/E starts the string with the default parameters LET, LIST, NCAL, and XREF.
  2. If SMP/E finds any link edit parameters in the LMOD entry for the load module being link-edited, SMP/E adds those parameters to the string.
  3. If the load module being link-edited contains a CALLLIBS subentry list, then:
     - SMP/E adds CALL for the link to the actual target library
     - SMP/E adds NCAL for the link to the SMPLTS library
     Any parameter added by this step will override any CALL or NCAL parameters added in previous steps, whether they were explicitly specified or assumed by default.
  4. Finally, if SMP/E determines that the binder is available on the system and SMP/E is processing CSECT deletes, SMP/E adds the STORENX
UTILITY entry (global zone)

link-edit parameter to the parameter list. (If you use the linkage-editor instead of the binder, STORENX will cause "INVALID" to appear in the "invocation parameters list" output of the linkage-editor. This has no effect on processing.)

The consolidated parameter list is passed to the link-edit utility.

LET, LIST, and sometimes either CALL or NCAL are ordinarily required for maintenance of IBM operating systems. If you change the PARM subentry, be sure to include LET, LIST, and any other required parameters in the parameters chosen. For more information, see the APPLY command chapter in [SMP/E Commands].

Note: Before using the GENERATE command to create JCL that will update files in a UNIX file system, you may want to add UID(0) to the PARM value so that the JCL created by GENERATE will include UID(0) in the execution parameter string for the link-edit utility. Specify UID(0) if all the following are true:

1. Your UID is not 0 but you are authorized to the BPX.SUPERUSER facility class profile. The UID(0) option, in this case, causes the binder to set an effective UID of 0 for its execution.
2. The binder invoked by the generated JCL is at the proper level to understand the UID option.
3. UID 0 authority is needed for the binder's execution in the JCL created by the GENERATE command in order to update files in a UNIX file system.

If you do specify UID(0) for GENERATE, you must remove it after GENERATE has run, so that it is not used for other SMP/E commands (such as APPLY, which handles setting the effective UID itself prior to invoking the binder).

- Update utility: The PARM subentry for an update utility must not specify MOD or NEW.

PRINT

specifies the ddname that is to contain output from the utility (for example, SYSPRINT). [Table on page 350] lists the default ddnames used by SMP/E if the OPTIONS entry in effect does not point to a UTILITY entry for a specific system utility.

The UCL operand is PRINT(ddname).

The value specified can contain from 1 to 8 alphanumeric characters. The first character must be alphabetic.

Notes:

1. The ddname specified for PRINT can affect whether you receive print output from this utility. For example, if you specify a DDDEF for a DUMMY data set or a DDDEF for a data set that is sent to a SYSOUT class that suppresses output, you do not receive print output from this utility.
2. If SYSTSPRT is specified as the PRINT value for the HFS copy utility, it is ignored and the default of SYSPRINT is used instead.
3. To exploit utility multi-tasking in SMP/E, ensure that the ddname that is to contain the link edit utility output is defined with a DDDEF entry that identifies a SYSOUT class. SMP/E's default ddname for utility output is SYSPRINT, but can be changed using the PRINT subentry of the LKED UTILITY entry. When multi-tasking, SMP/E will invoke multiple instances of the link edit utility at the same time, thus decreasing the total time...
UTILITY entry (global zone)

required to complete an ACCEPT, APPLY, LINK LMODS, or RESTORE command. Multi-tasking of link edits can occur when there are different target libraries, and there are no dependencies on previous or subsequent link edits. If you do not define the print ddname using a DDDEF entry, if the DDDEF identifies something other than a SYSOUT class, or if you override the SYSPRINT DDDEF with a ddname in your JCL, then SMP/E will not multi-task link edit utility operations.

RC

specifies the maximum acceptable return code from this utility. If the return code is higher than this value, SMP/E normally assumes that the requested processing failed. However, the RETURN CODE value in the LMOD entry overrides (for that load module) the value in the UTILITY entry. Also, the success of a link-edit in the SMPLTS library is based on the following:

• Link-edits into the SMPLTS with a return code of 8 or less are considered successful regardless of the threshold return code specified in the UTILITY entry.
• Link-edits into the SMPLTS with a return code of greater than 8 are considered successful or failures based on the threshold (normal processing). If the SMPLTS link-edit return code is less than or equal to the threshold return code, it is considered successful. If the SMPLTS link-edit return code is greater than the threshold return code, it is considered a failure.

Table 6 on page 350 lists the default return codes used by SMP/E if the OPTIONS entry in effect does not point to a UTILITY entry for a specific system utility.

The UCL operand is RC(rc).
• The value can be from 0 to 16.
• The installation information for a product (such as the product program directory) may state the utility return codes you should expect during SMP/E processing. For example, it may state the expected link-edit return codes for its load modules during SMP/E processing. The expected return code may be 4 or 8, because post-SMP/E link-edit work is required (for example, the load modules may require interface routines or compiler library routines). Such return codes allow the SYSMODs to be installed, but they also require you to check the actual link-edit return code in the GIM23903I or GIM23903W messages in order to determine the actual success of utility processing.

Before using the default SMP/E return codes (especially for link-edit processing), check the installation information for the products you plan to install and determine the appropriate maximum acceptable return codes for utility processing. You may find that you need to set up more than one UTILITY entry for a particular utility program in order to accommodate different maximum return codes for various products. (As a result, you may need additional OPTIONS entries to point to the appropriate UTILITY entries.)

LIST Examples

To list all the UTILITY entries in a global zone, you can

SET       BDY(GLOBAL)  /* Set to requested zone. */.
LIST       UTILITY      /* List all UTILITY entries. */.

To list specific UTILITY entries in a global zone, you can use these commands:
The format of the LIST output for each UTILITY entry is the same for both of these commands. The only difference is the number of UTILITY entries listed.

Figure 65 shows an example of LIST output for UTILITY entries.

Figure 65. UTILITY entry: sample LIST output

**UCLIN Examples**

You can use the ADD, REP, and DEL UCL statements to change subentries in a UTILITY entry. When you use UCLIN to update a UTILITY entry, keep these points in mind:

- After the UCLIN changes are done, the UTILITY entry must contain at least one of the following subentries:
  - NAME
  - PARM
  - PRINT
  - RC

  Otherwise, there is not enough information in the entry for SMP/E to use the entry.

- If a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.

The following examples are provided to help you use the UTILITY entry.

**Example 1: Changing the DD statement for SYSPRINT output**

Assume that you wish to direct all the SYSPRINT output for assemblies to the MYSYSPRT DD statement rather than to the SYSPRINT DD statement. To do this you need to build a UTILITY entry for the assembler and then specify that UTILITY entry in the OPTIONS entry that will be in effect. Assume that the UTILITY entry to be defined is named IEUASM, and that the OPTIONS entry to be used is MYOPT1. The following UCL will accomplish your objectives:
UTILITY entry (global zone)

```assembly
REP OPTIONS(MYOPT1) /* Connect to OPTIONS. */
ASM(IEWL) /* Use IEUASM for ASM. */
/* in SMP/E defaults. */
ENDUCL /* */
```

**Note:** Remember, if you specify a DDDEF for a DUMMY data set or a DDDEF for a data set that is sent to a SYSOUT class that suppresses output, you do not receive SYSPRINT output from this utility.

**Example 2: Defining link-edit utility parameters**

Assume that you wish to always pass the `SIZE=(1526K,80K)` parameter to the link-edit utility. To do this you need to build a UTILITY entry for the link-edit utility and then specify that UTILITY entry in the OPTIONS entry that will be in effect. Assume that the UTILITY entry to be defined is named IEWL, and that the OPTIONS entry to be used is MYOPT1. The following UCL will accomplish your objectives:

```assembly
SET BDY(GLOBAL) /* Set to global zone. */
UCLIN /* */
ADD UTILITY(IEWL) /* Link-edit utility. */
PARAM(LET, /* PARM values. */
SIZE=(1526K,80K), /* */
NCAL) /* */
/* Other values remain as in SMP/E defaults. */
REP OPTIONS(MYOPT1) /* Connect to OPTIONS. */
LKED(IEWL) /* Use IEWL for LKED. */
/* */
ENDUCL /* */
```

**Example 3: Defining a user utility program**

Assume that you wish SMP/E to call a user routine, USERRCVR, rather than IEBCOPY, in order to recover from X37 abends. In addition to the program name change, the program must also receive parameter `TYPE=FAST`. You want to indicate that the output should go to X37PRINT rather than SYSPRINT, and that a return code of 4 or less is acceptable. You also want to suppress the listing of member names during retry processing done by your program. To do this you need to build a UTILITY entry for the program, and then specify the UTILITY entry in the OPTIONS entry that will be in effect. Assume that the UTILITY entry to be defined is named MYX37, and that the OPTIONS entry to be used is MYOPT1. The following UCL will accomplish your objectives:

```assembly
SET BDY(GLOBAL) /* Set to global zone. */
UCLIN /* */
ADD UTILITY(MYX37) /* Retry/recovery program. */
NAME(USERRCVR) /* Program name. */
PARAM(TYPE=FAST) /* PARM value. */
PRINT(X37PRINT) /* SYSPRINT ddname. */
RC(4) /* Highest acceptable return code. */
LIST(NO) /* No list of member names. */
/* */
REP OPTIONS(MYOPT1) /* Connect to OPTIONS. */
RETRY(MYX37) /* Use MYX37 for RETRY. */
/* */
ENDUCL /* */
```
ZONESET entry (global zone)

The ZONESET entry defines a group of zones to be used to limit the SYMMDs processed by an SMP/E command. For example, you can specify a ZONESET on the ZONESET operand of the REPORT command. This defines which zones SMP/E should check for installed SYMMDs that specify conditional requisites that might be needed for functions in other zones in the ZONESET. A ZONESET may also define a group of zones to be checked or ignored by the REJECT command.

Subentries

These are the subentries for the ZONESET entry as they appear in the LIST output:

name

is the name of the ZONESET. The name can contain from 1 to 8 alphanumeric characters.

To avoid confusion and undesired results, you may want to avoid giving a ZONESET the same name as any of the target or distribution zones defined to the global zone that will contain the ZONESET entry. This is because, on some SMP/E command operands, you can specify zones and ZONESETS. When ZONESETS and zones have the same name, you might not get the results you wanted.

For example, suppose you have a ZONESET named Z001 and a zone named Z001. If you specify Z001 on an SMP/E command operand, SMP/E assumes that you want to use the zones defined in ZONESET Z001 (which might or might not include zone Z001), and not the individual zone Z001.

XZREQCHK

indicates whether this ZONESET should be used when establishing the default zone group for the APPLY, ACCEPT, and RESTORE commands.

The UCL operand is XZREQCHK(YES|NO).

- YES indicates that the ZONESET should be used when establishing the default zone group.
- NO indicates that the ZONESET should not be used when establishing the default zone group. NO is the default.
- The XZREQCHK value (including the default value) is ignored when the XZGROUP operand is specified on the APPLY, ACCEPT, or RESTORE command.

ZONE

lists the target or distribution zones that are to be part of this ZONESET.

The UCL operand is ZONE(zone...).

- Each value can contain from 1 to 7 alphanumeric characters.
- A ZONESET can contain both target and distribution zones.
- All the zones in a ZONESET must be defined in the same global zone as the ZONESET entry.
- The zones cannot be defined in global zones that are in different SMPCSI data sets. For an example of defining a ZONESET in order to report on zones controlled by different global zones, see the REPORT CROSSZONE command in \[SMP/E Commands\]

LIST Examples

To list all the ZONESET entries in a global zone, you can use the following commands:
ZONESET entry (global zone)

```
SET   BDY(GLOBAL)      /* Set to global zone. */.
LIST  ZONESET          /* List all ZONESET entries. */.
```

To list specific ZONESET entries in a global zone, you can use these commands:

```
SET   BDY(GLOBAL)      /* Set to global zone. */.
LIST  ZONESET(ZST2)    /* List only these */
       ZST4            /* entries. */.
```

The format of the LIST output for each ZONESET entry is the same for both of these commands. The only difference is the number of ZONESET entries listed.

Figure 66 shows an example of LIST output for ZONESET entries.

```
PAGE nnnn - NOW SET TO zzzzzz ZONE nnnnnnnn DATE mm/dd/yy TIME hh:mm:ss SMP/E 35.nn SMPLIST OUTPUT
GLOBAL ZONESET ENTRIES

ZST2 ZONE = ZONE21 ZONE22 ZONE23
ZST4 ZONE = ZONE41 ZONE42 ZONE43
```

**Figure 66. ZONESET entry: sample LIST output**

**UCLIN Examples**

You can use the ADD, REP, and DEL UCL statements to change subentries in a ZONESET entry. When you use UCLIN to update a ZONESET entry, keep these points in mind:

- After the UCLIN changes are done, the ZONESET entry must contain at least a ZONE subentry. Otherwise, the entry contains so little information that SMP/E cannot use it.
- If a DEL statement deletes all the existing subentries in the entry, SMP/E deletes the entire entry.

**Example: Defining a ZONESET entry**

Assume that you have a system with four target zones: BP11, PROD11, BP999, and PROD999. BP11 and BP999 define two different base control programs. PROD11 and PROD999 are two versions of the same product that must be synchronized with each other and with their base control programs (PROD11 with BP11 and PROD999 with BP999). To keep service for these products at the same level, you can group BP11, PROD11, and PROD999 in one ZONESET (S111) and BP999, PROD999, and PROD11 in a second ZONESET (S999). The following UCL will define the ZONESET entries:

```
SET   BDY(GLOBAL)      /* Set to global zone. */.
UCLIN /* */.
ADD   ZONESET(S111)    /* ZONESET S111. */.
       ZONE(BP111,  /* Include these target */
       PROD111,   /* zones. */
       PROD999)  /* */.
       /* */.
ADD   ZONESET(S999)    /* ZONESET S999. */.
       ZONE(BP999,  /* Include these target */
       PROD999,   /* zones. */
       PROD111)  /* */.
       /* */.
ENDUCL /* */.
```
Chapter 6. SMP/E CSI application programming interface

This chapter documents intended Programming Interfaces that allow the customer to write programs to obtain the services of IBM SMP/E for z/OS, V3R5.

This chapter describes the SMP/E CSI application program interface (GIMAPI), which provides access to data stored and used by SMP/E. This data is stored in a VSAM data set called the CSI (Consolidated Software Inventory). The purpose of GIMAPI is to provide you with read-only access to data maintained by SMP/E in the CSI.

Note: GIMAPI can not be called from within an SMP/E user exit routine.

Overview of GIMAPI

GIMAPI is a program (load module) provided with IBM SMP/E for z/OS, V3R5 that can be called by a user-written application program to query the contents of the CSI.

GIMAPI uses data structures both to receive the query parameters from the caller and to return the query output to the caller. To request a query, you must set up the data structure containing the appropriate query parameters and call GIMAPI.

The general form of the GIMAPI call is:

where *apicmd* specifies the API command that GIMAPI is to process (either QUERY, FREE or VERSION). See "QUERY command," "FREE command" on page 393 and "VERSION command" on page 394 for descriptions of these commands and a detailed description of how the remaining parameters *parmptr*, *outptr*, *language*, *rc*, *cc*, and *msgbuff*) are used on those commands.

QUERY command

Use the QUERY command to retrieve data from a zone or set of zones within a CSI. You specify the details of your query by setting parameters on the call to the QUERY command. These parameters determine what data is returned from the query. The data is returned to the calling program in a set of data structures.

QUERY command parameters

Here is an example of a call to the QUERY command:

```gimapi('QUERY ',parmptr,outptr,'language',rc,cc,msgbuff)```
program that contains a data structure whose elements are the
parameters for the QUERY command. A generic data structures
definition can be found in “Data structures for QUERY command”
on page 390.

**outptr**
A pointer variable that is to be set by GIMAPI with the address of
an area of storage owned by GIMAPI that contains the output from
the QUERY command. For the QUERY command, the output is a
set of linked lists that both contains and describes the requested
data. See section “QUERY command output” on page 387 for more
details on the QUERY command output.

**language**
A 3-byte character string specifying the language that QUERY
command is to use when issuing messages. The valid values are:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENU</td>
<td>US English</td>
</tr>
<tr>
<td>JPN</td>
<td>Japanese</td>
</tr>
</tbody>
</table>

Note: Specifying language as three blanks is also valid and is
equivalent to specifying “ENU”.

**rc**
A storage area owned by the calling program representing a 4-byte
numeric variable. The value of the variable is set by GIMAPI to the
return code of the QUERY command processing. The return code
represents the severity of the condition raised by the GIMAPI
processing. These codes may be returned:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Indicates the function terminated successfully. The cc value is also set to zero (0) when the return code is 0.</td>
</tr>
<tr>
<td>4</td>
<td>Indicates a warning condition was detected during execution of GIMAPI. The cc value given indicates the specific warning condition. When a warning occurs, the GIMAPI command continues processing. Appropriate warning messages are written to the message buffer.</td>
</tr>
<tr>
<td>8</td>
<td>Indicates an error condition was detected during execution of GIMAPI. The cc value given indicates the specific error condition. When an error occurs, the GIMAPI command terminates after storing the error condition in the message buffer. Other GIMAPI commands may be invoked from the calling program.</td>
</tr>
<tr>
<td>12</td>
<td>Indicates a severe error condition was detected during execution of GIMAPI. The cc value given indicates the specific error condition. When a severe error occurs, GIMAPI terminates after storing the severe condition in the message buffer. The calling program should not make any more calls to GIMAPI.</td>
</tr>
<tr>
<td>16</td>
<td>Indicates a terminating error condition was detected during execution of GIMAPI. The cc value given indicates the specific error condition. When a terminating error occurs, GIMAPI terminates after storing the condition in the message buffer. The calling program should not make any more calls to GIMAPI.</td>
</tr>
</tbody>
</table>

**cc**
A storage area owned by the calling program representing a 4-byte
numeric variable. The value of the variable is set by GIMAPI to the
condition code of the GIMAPI processing. The condition code, also
known as a reason code, indicates the specific situation that
Building the QUERY parameters data structure

The QUERY command parameter list must include a pointer to a data structure (paramptr) that defines the query to be processed. This data structure, in turn, contains pointers to character strings that specify from where data is to be retrieved (that is, which CSI, zones, and entry types) and, optionally, a list of subentries and a filter, which allow you to specify conditions that will be used to determine which entries are retrieved.

The following parameters are part of the structure pointed to by the paramptr parameter of the QUERY command. All the parameters are required except the subentry and filter parameters.

csi
Input is accepted in mixed case. A character string that specifies the name of the global CSI to be searched by the QUERY command. The DDNAME used when allocating the data set is SMPCSI.

Input is accepted in mixed case. It is folded to upper case when the command is processed.

csilenc
A decimal number specifying the size of the character string containing the csi parameter. This value cannot be greater than 44.

A zero (0) value indicates that the calling program has already allocated a global CSI data set as the SMPCSI DDNAME. That allocation is used and the csi parameter is ignored.

zone
A character string that specifies the zones from which data is to be retrieved. You may enter one or more specific zone names separated by commas or blanks, or any of these values:

GLOBAL Use the global zone
ALLTZONES Use all target zones
ALLDZONES Use all DLIB zones

The msgbuff is a pointer variable that is set by GIMAPI to the head of a linked list of messages issued by the QUERY command processing. The elements of the list are ITEM_LIST structures. See section “Data structures for QUERY command” on page 390 for a description of that structure.
Use all zones defined in the GLOBAL zone index

Except for the asterisk (*), these values can be used together and with specific zone names, provided that all values are separated by commas or blanks. The asterisk (*) must be used alone.

For example, these specifications are valid:

- GLOBAL, ALLTZONES
- ALLTZONES, ALLDZONES
- ALLTZONES, MYIDLIB, MY2DLIB
- ALLTZONES MYIDLIB, MY2DLIB

whereas this is not valid:

- GLOBAL, *, ALLTZONES

A zone can be specified only once in the zone parameter. A specific DLIB zone name along with the ALLDZONES keyword or a specific target zone name along with the ALLTZONES keyword does not cause a message to be issued. However, processing for the duplicated zone names will be done only once.

Spaces can be used freely between values and commas.

Input is accepted in mixed case. It is folded to upper case when the command is processed.

The specific zone name can be a ZONESET name. The command will first check whether the name is a ZONESET. If not, it will check the ZONEINDEX.

**zonelen**

A decimal number specifying the size of the character string containing the zone parameter.

**entry**

A character string that indicates the entry types from the specified zones to be searched. You can specify one or more entries, separated by commas or blanks, or you can specify an asterisk (*) to indicate that all entries are to be searched. If an asterisk is used, no other values may be specified.

An entry can be specified only once in the entry parameter.

Spaces can be used freely between entry names and commas.

Input is accepted in mixed case. It is folded to upper case when the command is processed.

The entry types specified must be valid CSI entry types. Refer to "Valid entry types" on page 365 for a list of the valid types.

**entrylen**

A decimal number specifying the size of the character string containing the entry parameter.

**subentry**

Each CSI entry has a set of subentries associated with it. The subentry parameter is a pointer to a character string used to indicate the subentries for which data is retrieved. Several subentries can be specified separated by commas or blanks, or you can specify an asterisk (*) to indicate that all subentries are to be searched. If an asterisk is used, no other values may be specified.

A subentry can be specified only once in the subentry parameter.

Spaces can be used freely between subentry names and commas.

Input is accepted in mixed case. It is folded to upper case when the command is processed.
Note: The entry parameter allows multiple entries to be specified. It may be that a subentry to be returned does not apply to all the specified entries. In this case, the subentry is simply ignored for a particular entry to which it does not apply.

Refer to "Valid subentry types" on page 366 for more details.

subentrylen A decimal number specifying the size of the character string containing the subentry parameter.

filter A character string that specifies the set of conditions with which to limit the set of entries being retrieved. A condition is in the form 
subentry operator 'value'

For example, FMID = 'HP10230' or INSTALLDATE >= '07203'.

Input is accepted in mixed case. The subentry types are folded to upper case when the command is processed. The fixed values are not changed.

Filter is an optional parameter. When no filtering is desired, set the length field (filterlen) to zero (0).

Refer to ["Filter parameter syntax"] for a detailed description of the syntax of the filter parameter.

filterlen A decimal number specifying the size of the character string containing the filter parameter.

Filter parameter syntax

The filter parameter is used to limit the entries returned for a particular query. You specify a filter by listing a set of conditions. These conditions specify a comparison between two values; a subentry value in the CSI is compared with a fixed value specified in the condition.

Multiple filter conditions may be specified using the operators, & (logical AND) and | (logical OR). Parentheses may be used to group search conditions to ensure a desired evaluation sequence for the filter. The parentheses, when used, may be preceded by one or more blanks and also may be followed by one or more blanks.

When a subentry name represents a list of values, such as PRE, which is a list of all the prerequisite SYM OdS, each value in the list from the CSI is compared to the fixed value. If any match, the condition is evaluated as true.

These subentry types may be specified in the filter parameter only with the = or != operators and a null value (for example, ASMIN="" or LEPARM!=""): 
- ASMIN
- HFSPARM
- HOLDDATA
- LECNTL
- LEPARM
- LMODALIAS
- LMODSYMMLINK
- ORDERSERVER
- UTILPARAM
- ZDESC
The fixed value must be enclosed within single quotation marks. Any set of characters may be used in the fixed value. If the fixed value is shorter than the subentry value, GIMAPI left-justifies the fixed value and pads it with blanks before doing the comparison.

Any apostrophes specified as part of a DESCRIPTION, VENDOR, or URL subentry (excluding delimiters) must be doubled. Double apostrophes count as two characters in the filter length.

Blanks may be freely used to separate the subentry, operator, and fixed value.

The values of some subentry types are lists of composite values. An example of this is the CIFREQ parameter whose value is *causer, requisite*. The fixed value for conditions containing these types of subentries must match the format of the output provided by the QUERY command. For example:

\[
\text{CIFREQ} = 'PTF0001,PTF0002'
\]

Refer to "Valid subentry types" on page 366 for the format of each composite subentry type.

A null value for a subentry is specified by using two single quotation marks with no blanks between them (""). This can be used to find all entries whose value is not blank, for example, \text{PATH} = "".

The operators that can be used to compare a subentry value to a fixed value, or to join a set of conditions together, are:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Equal to</td>
</tr>
<tr>
<td>!=</td>
<td>Not equal to</td>
</tr>
<tr>
<td>&lt;</td>
<td>Less than</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Less than or equal to</td>
</tr>
<tr>
<td>&gt;</td>
<td>Greater than</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Greater than or equal to</td>
</tr>
<tr>
<td>!</td>
<td>Logical OR, at least one of two conditions are true</td>
</tr>
<tr>
<td>&amp;</td>
<td>Logical AND, both conditions must be true</td>
</tr>
</tbody>
</table>

Subentry names that may appear to the left of operators are the subentries defined in "Valid subentry types" on page 366. Potential values for each subentry can be found in Chapter 5, "SMP/E Data Set Entries". When a subentry is an indicator, such as PROTECT for the DDDEF entry, its value is either YES or NO.

A requested subentry may not have a value for a particular entry. This value is considered null. This may occur for one of the following reasons:

\- The subentry has not been set for the entry.
\- The subentry does not apply to that entry.

An example of the latter case is a request for the SYSLIB subentry with the SYSMOD entry type. SYSMOD entries do not contain SYSLIB subentries, causing a request for such a value to always return a null value.

When the not equal sign is used with some value within a filter, for example \text{SYSLIB} = 'MACLIB', the case where no data is found for the subentry is considered...
a match, because “MACLIB” does not equal a null value. Therefore, if this filter is
used when requesting the SYSMOD entry type, all the SYSMODs in the selected
zones are returned. To exclude entries having no value, write the filter as
(SYSLIB!=’MACLIB’ & SYSLIB!=’’).

The >, >=, < and <= operators can be used only with the subentry types that have
date, time, or return code values, which are:
• HOLDDATE
• INSTALLDATE
• INSTALLTIME
• RC
• RECDATE
• RECTIME
• RESDATE
• RESTIME
• UCLDATE
• UCLTIME

The >, >=, < and <= operators have no meaning when applied to a subentry that
has a null value. GIMAPI will always resolve such comparisons to “false”.

A date fixed value must use the format ‘yyddd’. It must be five numeric
characters. For example, specify ‘01365’ to represent “December 31, 2001”.

A time fixed value must use the format ‘hh:mm:ss’, where hh is a two-digit decimal
number in the range 00 through 23, and mm and ss are both two-digit decimal
numbers in the range 00 through 59. (That is, in 24-hour clock format.)

The filter parameter is made up of a combination of these parts:
• Subentry name
• Operator
• Fixed value
• Conjunction (& or |)
• Left parenthesis
• Right parenthesis

The following list indicates for each part, what other part or parts can follow it.
Any other sequence of parts is considered a syntax error.

Filter part Can be followed by
Subentry Operator
Operator Fixed value
Fixed value Conjunction, Right parenthesis, End of filter
Conjunction Subentry Left parenthesis
Left parenthesis Subentry, Left parenthesis
Right parenthesis Conjunction, Right parenthesis, End of filter

Valid entry types
Table 7 on page 366 lists the values that are valid as entry parameters and the
zones to which they are applicable.

</tbody>
</table>

Notes:
1. The data element entry type has many possible values. Refer to "Data Element Entry (Distribution and Target Zone)" in Chapter 5 for the complete list. Any one of these values can be supplied as part of the entry parameter.

2. ELEMENT is a pseudo-entry value indicating that JAR, MOD, MAC, PROGRAM, SRC, and all data element and hierarchical file system element entries are returned.

3. The hierarchical file system element entry type has many possible values. Refer to "Hierarchical File System Element Entry (Distribution and Target Zone)" in Chapter 5 for the complete list. Any one of these values can be supplied as part of the entry parameter.

When you specify an entry that is not applicable to a particular zone, the result is simply that no data is returned. This is not an error condition.

Valid subentry types

For each entry type there is a set of valid subentry types that may be specified as part of the subentry and filter parameters. The following sections contain a table for each entry. Each table lists the valid subentries for that entry. The subentry types
GIMAPI

generally correspond to the types used for UCLIN processing. However, some additional types are used for GIMAPI processing (for example, the SMODTYPE subentry of the SYSMOD entry type). This specifies what type the SYSMOD is and is used instead of having a separate subentry for each SYSMOD type.

Notes:
1. ENAME and zone name are automatically returned for each instance of an entry as part of the ENTRY structure so they do not have to be requested on the subentry parameter. ENAME can be used on the filter parameter.
   For a PRODUCT entry, ENAME has no meaning and is always blank. PRODID and VRM values are automatically returned instead of ENAME for PRODUCT entries. PRODID and VRM can be used on the filter parameter.
2. A maximum length of (*) indicates that a linked list of that subentry is returned to the caller. Details of the return structures passed back to the caller can be found in “Data structures for QUERY command” on page 390.

<td>DSNTYPE</td>
<td>7</td>
<td>Specifies the type of partitioned data set to be created. - LIBRARY - PDS</td>
</tr>
<tr>
<td>DSPREFIX</td>
<td>26</td>
<td>Specifies the data set prefix to be used to construct the full data set name for SMPTLIB data sets. GLOBAL zone only.</td>
</tr>
<tr>
<td>ENAME</td>
<td>8</td>
<td>Name of the entry.</td>
</tr>
<tr>
<td>INITDISP</td>
<td>3</td>
<td>Specifies the initial disposition of the data set. - MOD - NEW - OLD - SHR</td>
</tr>
<tr>
<td>MGMTCLAS</td>
<td>8</td>
<td>Specifies the name of the management class to be used for allocating a new data set managed under SMS.</td>
</tr>
<tr>
<td>PATH</td>
<td>255</td>
<td>Identifies the name of the path to be allocated in a UNIX file system.</td>
</tr>
<tr>
<td>PROTECT</td>
<td>3</td>
<td>Indicates whether RACF® PROTECT option should be used when a new data set is allocated. (YES or NO).</td>
</tr>
<tr>
<td>SPACE</td>
<td>9</td>
<td>Specifies the primary and secondary space allocation in the format mmmn,mnnn.</td>
</tr>
<tr>
<td>STORCLAS</td>
<td>8</td>
<td>Specifies the name of a storage class used for allocating a new data set managed by SMS.</td>
</tr>
<tr>
<td>SYSOUT</td>
<td>1</td>
<td>Specifies the output class for SYSOUT data sets.</td>
</tr>
<tr>
<td>UNIT</td>
<td>8</td>
<td>Specifies the UNIT type the data set resides on if it is not cataloged.</td>
</tr>
<tr>
<td>UNITS</td>
<td>12</td>
<td>Specifies the space units to be used in allocating the data set. - BLK(size) - CYL - TRK</td>
</tr>
<tr>
<td>VOLUME</td>
<td>*</td>
<td>A linked list containing volume serial numbers of the device the data set resides on if it is not cataloged. Each volume serial number may be up to 6 bytes in length.</td>
</tr>
<tr>
<td>WAITFORDSN</td>
<td>3</td>
<td>Indicates whether SMP/E should wait for the data set to be allocated if the volume is not mounted or if the data set is already in use. (YES or NO).</td>
</tr>
</tbody>
</table>

<th>Description</th>
</tr>
</thead>
</table>
| INSTMODE      | 6                        | Indicates the installation mode to be used when the HFS copy utility is invoked to install the element into a UNIX system. It can be one of the following:  
• BINARY  
• TEXT |
| LASTUPD       | 7                        | Cause of last change to this hierarchical file system element entry. |
| LASTUPDTYPE   | 3                        | Indicates how the entry was last changed. |
| LINK          | *                       | A linked list containing the alternate names by which this element can be known in a UNIX file system. Each alternate name may be up to 1023 bytes in length. |
| RMID          | 7                        | Identifies the last SYSMOD that replaced this hierarchical file system element. |
| SHSCRIPT      | 17                       | Specifies a shell script, along with the point in processing in which SMP/E passes control to the shell script. The format is `script_name.PRE,POST`, where PRE and POST are optional. |
| SYMLINK       | *                       | A linked list containing the names of symbolic links associated with a hierarchical file system element. Each symbolic link may be up to 1023 bytes in length. |
| SYMPATH       | *                       | A linked list containing the path values for symbolic links associated with a hierarchical file system element. Each path value may be up to 1023 bytes in length. |
| SYSLIB        | 8                        | Specifies the ddname of the target library within a UNIX file system for the element. |

### HOLDDATA

### Table 17. Valid subentries for the HOLDDATA entry

<table>
<thead>
<tr>
<th>Subentry name</th>
<th>Maximum length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENAME</td>
<td>7</td>
<td>Name of the entry. This is the name of the held SYSMOD.</td>
</tr>
<tr>
<td>HOLDCLASS</td>
<td>7</td>
<td>A 1- to 7-character string indicating an alternative reason to release an exception SYSMOD for processing.</td>
</tr>
<tr>
<td>HOLDDATA</td>
<td>*</td>
<td>A linked list containing records that contain the entire HOLDDATA entry. Each record may be up to 80 bytes in length.</td>
</tr>
<tr>
<td>HOLDDATE</td>
<td>5</td>
<td>Specifies the date that the ++HOLD statement was generated.</td>
</tr>
<tr>
<td>HOLDFIXCAT</td>
<td>*</td>
<td>A linked list that contains Fix Category values. Each value can be up to 64 characters in length.</td>
</tr>
<tr>
<td>HOLDFMID</td>
<td>7</td>
<td>Specifies the FMID to which the held SYSMOD is applicable.</td>
</tr>
<tr>
<td>HOLDREASON</td>
<td>7</td>
<td>A 1- to 7-character string used to help you identify the reason why the SYSMOD has been put into exception SYSMOD status.</td>
</tr>
<tr>
<td>HOLDRESOLVER</td>
<td>7</td>
<td>Specifies the SYSMOD that resolves the exception condition, if known.</td>
</tr>
<tr>
<td>HOLDTYPE</td>
<td>9</td>
<td>Specifies the hold category into which the SYSMOD has been put. ERROR, FIXCAT, SYSTEM, or USER are the only valid values.</td>
</tr>
</tbody>
</table>

Refer to the "++HOLD MCS" section for specific details for each of the subentries listed in the HOLDDATA entry.

<tr>
<td>ENAME</td>
<td>8</td>
<td>Name of the entry.</td>
</tr>
<tr>
<td>FMID</td>
<td>7</td>
<td>Specifies the functional owner of the JAR element.</td>
</tr>
<tr>
<td>HFSPARM</td>
<td>300</td>
<td>Specifies a character string that is to be passed to the hierarchical file system copy utility as an execution-time parameter.</td>
</tr>
<tr>
<td>JARPARM</td>
<td>300</td>
<td>Specifies a character string that is to be passed to the jar command when updating the JAR file.</td>
</tr>
<tr>
<td>LASTUPD</td>
<td>7</td>
<td>Cause of last change to this JAR element entry.</td>
</tr>
<tr>
<td>LASTUPDTYPE</td>
<td>3</td>
<td>Indicates how the entry was last changed.</td>
</tr>
<tr>
<td>LINK</td>
<td>*</td>
<td>A linked list containing alternate names by which this element can be known in a UNIX file system. Each alternate name may be up to 1023 bytes in length.</td>
</tr>
<tr>
<td>RMID</td>
<td>7</td>
<td>Identifies the last SYSMOD that replaced this JAR element.</td>
</tr>
<tr>
<td>SHSCRIPT</td>
<td>17</td>
<td>Specifies a shell script, along with the point in processing in which SMP/E passes control to the shell script. The format is script_name,PRE,POST where PRE and POST are optional.</td>
</tr>
<tr>
<td>SYMLINK</td>
<td>*</td>
<td>A linked list containing the names of symbolic links associated with this element. Each symbolic link may be up to 1023 bytes in length.</td>
</tr>
<tr>
<td>SYMPATH</td>
<td>*</td>
<td>A linked list containing the path values for symbolic links associated with this element. Each path value may be up to 1023 bytes in length.</td>
</tr>
<tr>
<td>SYSLIB</td>
<td>*</td>
<td>Specifies the ddname of the target library within a UNIX file system for the element.</td>
</tr>
<tr>
<td>UMID</td>
<td>*</td>
<td>A linked list containing 7-byte names of all SYSMODs that have updated this JAR file since it was last replaced.</td>
</tr>
</tbody>
</table>

### LMOD

Table 19. Valid subentries for the LMOD entry

<table>
<thead>
<tr>
<th>Subentry name</th>
<th>Maximum length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALLLIBS</td>
<td>*</td>
<td>A linked list containing the names of the DDDEF entries, existing in the same zone, that compose the SYSLIB allocation to be used when the load module is link-edited. Each entry name may be up to 8 bytes in length.</td>
</tr>
<tr>
<td>COPIED</td>
<td>3</td>
<td>A special SMP/E indicator meaning that the load module was copied during system generation, and that there is a one-to-one correspondence between the distribution library module (the MOD entry) and the target system load module (the LMOD entry) (YES or NO).</td>
</tr>
<tr>
<td>ENAME</td>
<td>8</td>
<td>Name of the entry.</td>
</tr>
<tr>
<td>LASTUPD</td>
<td>7</td>
<td>Cause of last change to this LMOD entry.</td>
</tr>
<tr>
<td>LASTUPDTYPE</td>
<td>3</td>
<td>Indicates how the entry was last changed.</td>
</tr>
<tr>
<td>LEPARM</td>
<td>*</td>
<td>A character string containing the link-edit attributes that must be used when this load module is link-edited. This is not a linked list.</td>
</tr>
</tbody>
</table>
Table 19. Valid subentries for the LMOD entry (continued)

<table>
<thead>
<tr>
<th>Subentry name</th>
<th>Maximum length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LECNTL</td>
<td>*</td>
<td>A linked list containing records of link-edit control cards necessary to relink-edit this load module. Each record may be up to 80 bytes in length.</td>
</tr>
<tr>
<td>LMODALIAS</td>
<td>*</td>
<td>A linked list containing the names of the aliases associated with this LMOD. Each alias name may be up to 1023 bytes in length.</td>
</tr>
<tr>
<td>LMODSYMRELINK</td>
<td>*</td>
<td>A linked list containing the names of symbolic links associated with a load module. The values are the values specified on ALIAS (SYMLINK,&lt;symlink_value&gt;) link-edit control statements. Each symbolic link may be up to 1023 bytes in length.</td>
</tr>
<tr>
<td>MODDEL</td>
<td>*</td>
<td>A linked list containing the names of modules that were once part of this load module, but have been deleted. Each module name may be up to 8 bytes in length.</td>
</tr>
<tr>
<td>RC</td>
<td>2</td>
<td>Highest acceptable link edit return code for this load module.</td>
</tr>
<tr>
<td>SIDEDECKLIB</td>
<td>8</td>
<td>Specifies the ddname of the library where the load module’s definition side deck resides.</td>
</tr>
<tr>
<td>SYSLIB</td>
<td>*</td>
<td>A linked list containing the ddnames of the target system libraries in which this load module resides. Each ddname may be up to 8 bytes in length.</td>
</tr>
<tr>
<td>UTIN</td>
<td>*</td>
<td>A linked list containing utility input (UTIN) subentries, each of which contains the filename of the input to be included during a link-edit operation, and the library ddname where the file resides. The format is filename.ddname. Each UTIN subentry may be up to 1032 bytes in length. (The filename may be up to 1023 characters in length. The ddname may be up to 8 characters in length. And then there is the delimiting comma.) Note: It should be noted that a comma is a valid character within the filename value. The comma is also the delimiter separating the filename from the ddname. Therefore, the utility input data should be scanned from the last byte to the first byte in order to accurately find the comma that separates the ddname from the filename.</td>
</tr>
<tr>
<td>XZMOD</td>
<td>*</td>
<td>A linked list containing the XZMOD subentries containing the names of the modules that were added to the load module by the LINK MODULE command. The name of the zone supplying each module is also indicated. The format is module.zone. Each XZMOD subentry may be up to 16 bytes in length.</td>
</tr>
<tr>
<td>XZMODP</td>
<td>3</td>
<td>Indicates whether the load module contains one or more modules from another zone and that XZMOD subentries exist in this LMOD entry. (YES or NO).</td>
</tr>
</tbody>
</table>

MAC

Table 20. Valid subentries for the MAC entry

<table>
<thead>
<tr>
<th>Subentry name</th>
<th>Maximum length (decimal)</th>

</table>

**ORDER**

**Table 23. Valid subentries for the ORDER entry**

<table>
<thead>
<tr>
<th>Subentry name</th>
<th>Maximum length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>APARS</td>
<td>*</td>
<td>A linked list containing 7-byte names of all the APARs for which resolving PTFs are to be in the order.</td>
</tr>
<tr>
<td>CONTENT</td>
<td>8</td>
<td>Indicates the content selected for the order. The value may be ALL, APARS, CRITICAL, HOLDDATA, PTFs, or a Recommended Service Update SOURCEID value (RSUyyym).</td>
</tr>
<tr>
<td>DOWNLDATE</td>
<td>5</td>
<td>Indicates the date (yyddd) on which the order was downloaded and stored in the SMPNTS directory.</td>
</tr>
<tr>
<td>DOWNLTIME</td>
<td>8</td>
<td>Indicates the time (hh:mm:ss) at which the order was downloaded and stored in the SMPNTS directory.</td>
</tr>
<tr>
<td>ENAME</td>
<td>8</td>
<td>Name of the entry.</td>
</tr>
</tbody>
</table>
### Table 23. Valid subentries for the ORDER entry (continued)

<table>
<thead>
<tr>
<th>Subentry name</th>
<th>Maximum length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORDERDATE</td>
<td>5</td>
<td>Indicates the date (yyddd) on which the order request was made to the server.</td>
</tr>
<tr>
<td>ORDERID</td>
<td>10</td>
<td>Specifies the order identifier assigned by the server when the order was created. This value is used to correlate ORDER entries in the global zone with orders processed by the server.</td>
</tr>
<tr>
<td>ORDERSERVER</td>
<td>*</td>
<td>A linked list containing the <code>&lt;ORDERSERVER&gt;</code> tags used to identify the server used to fulfill the order request.</td>
</tr>
<tr>
<td>ORDERTIME</td>
<td>8</td>
<td>Indicates the time (hh:mm:ss) at which the order request was made to the IBM Automated Delivery Request server.</td>
</tr>
<tr>
<td>PKGID</td>
<td>50</td>
<td>Specifies the order package id value used to create a package subdirectory within the SMPNTS directory to contain the order’s package files.</td>
</tr>
<tr>
<td>PTFs</td>
<td>*</td>
<td>A linked list containing 7-byte names of all the PTF SYSMODs to be in the order.</td>
</tr>
<tr>
<td>STATUS</td>
<td>10</td>
<td>Specifies the current status of the ORDER entry. Possible values are PENDING, DOWNLOADED, and ERROR.</td>
</tr>
<tr>
<td>USERID</td>
<td>8</td>
<td>Specifies the userid associated with the address space where SMP/E was executing when the ORDER entry was created.</td>
</tr>
<tr>
<td>ZONES</td>
<td>*</td>
<td>A linked list containing 8-byte names of all the target zones used to define the scope of the software inventory associated with this order.</td>
</tr>
</tbody>
</table>

### Table 24. Valid subentries for the PRODUCT entry

<table>
<thead>
<tr>
<th>Subentry name</th>
<th>Maximum length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESCRIPTION</td>
<td>64</td>
<td>Specifies the name of this product.</td>
</tr>
<tr>
<td>PRODID</td>
<td>8</td>
<td>Product identifier</td>
</tr>
<tr>
<td>PRODSUP</td>
<td>*</td>
<td>A linked list containing the <code>prodid,vv.rr.mm</code> values for the products superseded by this product.</td>
</tr>
<tr>
<td>RECDATA</td>
<td>5</td>
<td>Specifies the date on which this product was received.</td>
</tr>
<tr>
<td>RECTIME</td>
<td>8</td>
<td>Specifies the time at which the ++PRODUCT MCS was received.</td>
</tr>
<tr>
<td>REWORK</td>
<td>8</td>
<td>Specifies the level of this PRODUCT, which was received again for minor changes.</td>
</tr>
<tr>
<td>SREL</td>
<td>*</td>
<td>A linked list containing 4-byte names of the system or subsystem releases on which the PRODUCT can be installed.</td>
</tr>
<tr>
<td>UCLDATE</td>
<td>5</td>
<td>Specifies the date on which this PRODUCT entry was last modified through UCLIN.</td>
</tr>
<tr>
<td>UCLTIME</td>
<td>8</td>
<td>Specifies the time at which this PRODUCT entry was last modified through UCLIN.</td>
</tr>
<tr>
<td>URL</td>
<td>256</td>
<td>Specifies a uniform resource locator (URL) that can be accessed to obtain additional information about this product.</td>
</tr>
<tr>
<td>VENDOR</td>
<td>64</td>
<td>Specifies the name of the vendor supplying the product.</td>
</tr>
<tr>
<td>VRM</td>
<td>8</td>
<td>Specifies the version, release, and modification level <code>(vv.rr.mm)</code> of this product.</td>
</tr>
</tbody>
</table>
Note: For a PRODUCT entry, the ENAME value is always blank, because the PRODID and VRM subentries, taken together, make up the “entry name” normally provided by ENAME. For each PRODUCT entry satisfying the QUERY request, the PRODID and VRM subentries are returned instead of ENAME.

**PROGRAM**

<tr>
<td>SREL²</td>
<td>*</td>
<td>A linked list containing the names of the system or subsystem releases on which the SYSMOD can be installed. Each name may be up to four bytes in length.</td>
</tr>
<tr>
<td>SUPING²</td>
<td>*</td>
<td>A linked list containing the 7-byte names of SYSMODs superseded by this SYSMOD.</td>
</tr>
</tbody>
</table>
### Table 27. Valid subentries for the SYSMOD entry (GLOBAL zone) (continued)

<table>
<thead>
<tr>
<th>Subentry name</th>
<th>Maximum length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SZAP</td>
<td>*</td>
<td>A linked list containing the names of module superzaps (++ZAP statements) in the SYSMOD. Each name may be up to 8 bytes in length.</td>
</tr>
<tr>
<td>TLIBPREFIX</td>
<td>26</td>
<td>Specifies the high-level data set name qualifier of the SMPTLIB data sets used to receive the SYSMOD, which was packaged in RELFILES.</td>
</tr>
<tr>
<td>VERSION2</td>
<td>*</td>
<td>A linked list containing 7-byte names of function SYSMODs that are versioned by this SYSMOD.</td>
</tr>
</tbody>
</table>

### Notes:

1. For the data element subentry, the data is returned to the caller in separate linked lists for each unique data element type requested.
2. When PRE, NPRE, REQ, DELETE, SUPING, VERSION, FMID, or SREL subentries are requested, a subentry structure of type ‘VER’ is returned, along with the necessary associated VER pseudo-subentries. See "VER" on page 392 for more details.
3. For the hierarchical file system element subentry the data is returned to the caller in separate linked lists for each unique hierarchical file system element type requested.
4. For SYSMODs that are only superseded, a value of "UNKNOWN" is returned for the SMODTYPE subentry.

### Table 28. Valid subentries for the SYSMOD entry (DLIB and target zones)

<table>
<thead>
<tr>
<th>Subentry name</th>
<th>Maximum length (decimal)</th>

</tr>
<tr>
<td>XZAP</td>
<td>*</td>
<td>A linked list containing the names of module superzaps the SYSMOD (++ZAP statements) that contain an EXPAND statement (indicating that the module should be expanded before it is updated). Each name may be up to 8 bytes in length.</td>
</tr>
</tbody>
</table>

Notes:
1. For the data element subentry, the data is returned to the caller in separate linked lists for each unique data element type requested.
2. When PRE, NPRE, REQ, DELETE, SUPING, or VERSION subentries are requested, a subentry structure of type 'VER' is returned for each unique version statement, along with its associated pseudo-subentries. See “VER” on page 392 for more details.
3. For the hierarchical file system element subentry the data is returned to the caller in separate linked lists for each unique hierarchical file system element type requested.
4. For SYSMODs that are only superseded, a value of "UNKNOWN" is returned for the SMODTYPE subentry.

TARGETZONE

QUERY command processing

GIMAPI checks to see if the SMPCSI DDNAME is already allocated. If it is, GIMAPI notes the data set name. GIMAPI then determines if the caller expects GIMAPI to allocate the global CSI data set. The caller indicates this by setting the csilen parameter to zero. The data set name previously noted is used so a shared enqueue can be done. The enqueue is to protect GIMAPI processing from updates by any other SMP/E processing that might be going on at the same time.
If the csilen parameter is not zero, GIMAPI verifies that the csi parameter provided is a valid CSI data set name.

If the SMPCSI DDNAME has already been allocated, the data set name of the allocation must be the same as the CSI parameter value. If they match, GIMAPI treats it as if the calling program already did the allocation. The data set is not allocated again (and is not deallocated at the end of the command).

If the CSI data set must be allocated, GIMAPI dynamically allocates the data set with DISP=SHR.

GIMAPI continues by validating the rest of the required QUERY parameters that it has received. Syntax checking is done for each QUERY parameter received. If GIMAPI encounters an error, it stops syntax checking for that parameter list and moves on to begin syntax checking for the next QUERY parameter. If any errors are found, the QUERY command terminates after syntax checking is done. The command continues if warnings are the highest severity found.

GIMAPI enforces these syntax rules:
- When multiple values are specified on the zone, entry or subentry parameters, they must be appropriately separated by commas or spaces.
- When an asterisk (*) is used on the zone, entry or subentry parameters, no other values can be specified.
- Entry types entered on the entry parameter must be a valid CSI entry type.
- A specific value can be specified only once on the zone, entry or subentry parameters.
- A condition using the >, >=, < or <= operator with a subentry type that is not a date or time field is not allowed.
- There are a set of subentry types that are not allowed to be used in conditions on the filter parameter. See section "Filter parameter syntax" on page 363 for the list.

A null value for a subentry may be specified by using two single quotation marks with no other characters or blanks between them (" "). A null value may be used with the "not equal" ( = ) operator to find all entries that have some value — for example, PATH!=" ".
- A date fixed value must use the format 'yyddd'. GIMAPI checks the characters entered to make sure they are all numeric.
- A time fixed value must use the format 'hh:mm:ss', where hh is a two-digit decimal number in the range 00 through 23, and mm and ss are both two-digit decimal numbers in the range 00 through 59. (That is, in 24-hour clock format.)
- A null value can be used with date and time fields with the = and != operators to check if the values have been set or not.
- A closing quotation mark " " must be found by the end of the filter parameter.
- All parentheses must be closed before the filter parameter string ends.
- When any other syntax errors are found in the filter parameter, GIMAPI issues a general syntax error message specifying the character position with the error.

Once the syntax is checked and zones other than the GLOBAL zone are specified, specific zone names are checked to see if they are ZONESETs. If so, the ZONESET name is removed from the list of zones passed by the caller and replaced with the zone names from the ZONESET. An attempt is then made to read the ZONEINDEX for each of the zones to be processed to see if any other CSI data
sets need to be dynamically allocated. If one of the zones specified is not a ZONESET and cannot be found in the ZONEINDEX, the QUERY command terminates.

If any of the target zones or DLIB zones are contained in separate CSI data sets than the global CSI, those data sets must be allocated. The command first determines if they are already allocated by the calling routine. If so, that allocation is used and the data sets are not deallocated later. If not, the data sets are allocated with DISP=SHR. In either case, a shared enqueue is done.

The command now attempts to process the query. The requested entries are read from the CSI and compared with the filter. If there is a match, the requested subentries and their values are attached to the output storage. This is a set of data structures linked together, with storage being allocated for each structure used.

Once all entries are processed, any CSI data sets that were dynamically allocated are dequeued and deallocated.

**Note:** Any successful allocations and enqueues are undone, even if errors are found. The data sets are always freed when the program ends.

If the query requested from the calling program did not result in any data being returned, the command output parameter is set to zero.

**QUERY command output**

The CSI data is made up of entries, which can be thought of as record types, and subentries, which can be considered the fields within those records. Each entry has a set of subentries. Those subentry values may be a single value, such as FMID subentry of the MOD entry. Other subentries are made up of a list of values, such as the LMOD subentry of the MOD entry, which lists all the LMODs that contain the MOD. Refer to Chapter 5, “SMP/E Data Set Entries” for a complete description of the CSI entry types and their associated subentries.

The data returned from the query follows this principle in that it is organized by entries and subentries.

What is returned from the QUERY command is a pointer to storage containing the output data. The storage is a set of linked lists that describe the output as well as contain the values.

The pointer returned points to the head of a linked list of records describing each of the entry types returned from the query. The entry type structures (ENTRY_LIST) contain a 12-character name of the entry type (padded with blanks) and a pointer to a link list of entry structures (ENTRY) representing the instances of that entry type. It also contains a pointer to the next entry type record.

The entry record points to a linked list of subentry type structures (SUBENTRY) and to the next instance of that entry type. It also contains a string with the name of the entry and a string with the name of the zone where the entry was found.

**Note:** If no subentries are requested on the subentry parameter, the entry name and zone name are still returned with the entry structure, with no subentry structures attached.
The subentry type structure contains a 12-character name of the subentry type and a pointer to the value structure (ITEM_LIST), as well as a pointer to the next subentry type.

The value structure contains the length of the value, a pointer to the character string value and a pointer to the next value structure, for subentries that have lists of values.

Refer to "Data structures for QUERY command" on page 390 for details on the structures defined. "Example of QUERY command" contains pictures of what the output looks like in storage.

Some subentries are lists of values, while others are single values. There are some subentries that are composite values as well as being lists. For example, the ZONEINDEX subentry of the GLOBALZONE entry contains the zone name, the CSI data set containing the zone name, and the zone type. Subentries such as these are returned with their parts combined into one string separated by commas, as shown here:

TARG1,UID,TARG1.CSI,TARGET

The order of the parts for subentries whose values have multiple parts follow the description of that subentry in Chapter 5, "SMP/E Data Set Entries".

Other subentries are indicator variables. This means they do not have a value, but the fact that they do (or do not) exist in the CSI indicates something. The PROTECT subentry of the DDDEF entry is an example of this. These types of subentries will have values in the QUERY output. If the subentry exists, the value is set to ‘YES’, if it does not, the value is set to ‘NO ’.

If an asterisk is used in either the entry or subentry parameters, QUERY will create a complete list, internally, of the specified type (entries, subentries, or both). If all entries and subentries are requested, then a list for each type is generated. Each list will be processed as if the user had entered it from the command. The following output will result:

<table>
<thead>
<tr>
<th>ENTRY/SUBENTRY contents</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>• ENTRY set to *</td>
<td>All valid subentries are returned for all instances of all valid entry types that fulfill the filter restrictions.</td>
</tr>
<tr>
<td>• SUBENTRY set to *</td>
<td></td>
</tr>
<tr>
<td>• ENTRY set to specific entry types</td>
<td>All valid subentries are returned all instances of each of the specified entry types that fulfill the filter restrictions.</td>
</tr>
<tr>
<td>• SUBENTRY set to *</td>
<td></td>
</tr>
<tr>
<td>• ENTRY set to *</td>
<td>The specific subentries are returned for all instances of all entry types that fulfill the filter restrictions.</td>
</tr>
<tr>
<td>• SUBENTRY set to specific subentries</td>
<td></td>
</tr>
</tbody>
</table>

**Example of QUERY command**

Suppose you want to write an application that will perform the following query:

Find all PTF and USERMOD type SYSMODs having an FMID of HMP1E00 that were received after December 1, 2008 and that were applied with BYPASS(anything). Return the SYSMOD name, the zone, the MODs that are replaced by the SYSMOD, and the installation date.
The storage containing the input parameters may be represented like this:

```
| QPARAM | CSI            | "USERID.GLOBAL.CSI" |
|        | ZONE           | "ALLTZONES"          |
|        | ENTRY          | "SYSMOD"             |
|        | SUBENTRY       | "MOD, INSTALLDATE"   |
|        | 17             |
|        | 9              |
|        | 6              |
|        | 16             |
|        | 101            |
```

Note: The SYMOD name and zone are automatically returned without your asking for them.

QPARM is a variable containing a pointer to a QUERY_PARMS data structure. The elements of the data structure point to strings in storage containing the values of the parameters.

Your program would then execute this call:

```
GIMAPI('QUERY',QPARM,QRESULT,'ENU',RC,CC,MSGBUFF)
```

The result of the query is two SYMODS, SMOD019 and SMOD022. SMOD019 is in target zone TARG1 with two MODs, MOD01 and MOD02 and was installed on December 6, 2008. SMOD022 is in target zone MYTARG and has no MODs. It was installed on December 14, 2008.

Figure 67 on page 390 provides a picture of what the output storage looks like. See section "Data structures for QUERY command" on page 390 for a description of the data structures used in the picture.
There are no values for the MOD subentry for SYSMOD SMOD022. Therefore, no SUBENTRY structure is added to the output for that subentry type.

Data structures for QUERY command

The data structures shown in this section are defined in a language-independent format. See "Programming in C" on page 396, "Programming in PL/I" on page 398, and "Programming in assembler" on page 400 to see the syntax of the data structures for those languages. Headers or macros with the language-specific
structure definitions are provided in members named GIMHC370 (for C/370™), GIMMPLI (for PL/I), and GIMMASM (for assembler) in libraries with these DDDEFs:

<table>
<thead>
<tr>
<th>DDDEF</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MACLIB</td>
<td>Target library</td>
</tr>
<tr>
<td>AMACLIB</td>
<td>Distribution library</td>
</tr>
</tbody>
</table>

**Note:** The pointer and numeric values found in the tables in this section are 4-byte fields.

**QUERY_PARMS**

Table 33 lists the elements of the data structure used as input to the QUERY command. Only a brief description of each parameter is given here. See “QUERY command” on page 359 for a more complete description.

<table>
<thead>
<tr>
<th>Element</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>csi</td>
<td>Pointer</td>
<td>Global CSI data set name to be searched by the query.</td>
</tr>

<td>type</td>
<td>Character(12)</td>
<td>Text representation of the type of subentry pointed to by the subentry structure.</td>
</tr>
</tbody>
</table>

VER

The VER structure is used when SYSMOD entry information is requested from the GLOBAL, target, or distribution zone. More specifically, this structure is used to return information that is typically associated with a ++VER statement. Refer to the "Valid subentry types" on page 366 for valid subentry and pseudo-subentry specification for the SYSMOD entry.

For each request for data associated with any of the information that is contained in a ++VER statement, a VER pseudo-subentry structure is returned.

The type value in the subentry structure is set to the 12-character string ‘VER’ and the subentrydata pointer points to a VER pseudo-subentry structure.

For each VER pseudo-subentry returned, a linked list of subentry structures are returned.

Each subentry structure returned will be associated with one of the types of data related to a ++VER statement. In other words, the ‘type’ field in the subentry structure will contain one of these text strings: SREL, FMID, PRE, NPRE, REQ, DELETE, SUP, or VERSION.

Each subentry structure returned will point to an item_list structure containing the actual VER-related data.
### Table 37. VER pseudo-subentry structure (GLOBAL, target, and DLIB zone)

<table>
<thead>
<tr>
<th>Element</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>next</td>
<td>Pointer</td>
<td>Pointer to the next VER pseudo-subentry structure. This value is zero (0) for the last item in the list.</td>
</tr>
<tr>
<td>verdata</td>
<td>Pointer</td>
<td>Pointer to a linked list of subentry structures. This value is zero (0) if there is no data associated with the VER.</td>
</tr>
<tr>
<td>vernum</td>
<td>Character(3)</td>
<td>Contains the relative number of the ++VER statement when the SYSMOD was installed.</td>
</tr>
</tbody>
</table>

### ITEM_LIST

This structure is used by many of the entry structures to hold an element in a list of subentry values attached to the entry. For example, it may contain a list of SYSMOD values, SRELs, or ALIAS names.

### Table 38. Item list structure

<td>Numeric</td>
<td>Number of characters in the item string.</td>
</tr>
<tr>
<td>data</td>
<td>Pointer</td>
<td>Pointer to the data associated with this item.</td>
</tr>
</tbody>
</table>

### FREE command

The FREE command frees all the storage allocated by GIMAPI for query output, message buffer, and any other data that is saved between different calls to GIMAPI. The FREE command will free storage allocated by any previous queries that has not already been freed. It is suggested that the FREE command be run after each query, but this is not required. It is good practice to use the FREE command prior to terminating the calling program.
FREE command parameters

Here is an example of a call to the FREE command:

```
GIMAPI('FREE ',0,0,'ENU',rc,cc,msgbuff)
```

**FREE** is a keyword that specifies that GIMAPI is to process a free request. Note that it is necessary to pad the string containing the FREE command with blanks to bring it to a length of eight characters.

**0,0** The `parmptr` and `outptr` parameters must both be set to zero (0) on the FREE command.

**ENU** The `language` parameter must be specified as either ENU, JPN, or three blanks. The FREE command does not return any messages, so it does not matter which of these choices is specified.

**rc** A storage area owned by the calling program representing a 4-byte numeric variable. This variable will contain the return code for the FREE command. GIMAPI will always set this variable to zero (0) after processing the FREE command.

**cc** A storage area owned by the calling program representing a 4-byte numeric variable. This variable will contain the condition code for the FREE command. GIMAPI will always set this variable to zero (0) after processing the FREE command.

**msgbuff** A pointer variable. No messages are issued by the FREE command, but this pointer variable must be passed to GIMAPI.

The `parmptr`, `outptr`, `language`, `rc`, `cc`, and `msgbuff` parameters must all be specified on the GIMAPI call, even though none of these parameters are used by the FREE command.

FREE command processing

The FREE command frees any storage obtained by GIMAPI on previous QUERY requests made by this caller.

VERSION command

The VERSION command is used to query the version of GIMAPI module being accessed by the calling program.

The version is returned as 8 bytes worth of data representing the current version of SMP/E in the format `vvrrmmpp`, where:

- **vv** version
- **rr** release
- **mm** modification level
- **pp** PTF

The version of IBM SMP/E for z/OS, V3R5 is displayed as 35.00. This translates to an 8 byte value of "03050000".

VERSION command parameters

Here is an example of a call to the VERSION command:
GIMAPI

GIMAPI(‘VERSION’,0,verout,’ENU’,rc,cc,msgbuff)

No input parameters are defined for this command. A parameter passed to GIMAPI for this command would be ignored.

The output is a pointer to an API_VERSION structure containing the version of the current running GIMAPI module. Refer to

**VERSION command processing**

GIMAPI allocates the storage for an API_VERSION structure. If the storage cannot be allocated, existing message GIM30700E is issued and the module terminates.

If allocation was successful, GIMAPI sets the elements of the structure with the values of the current version, release, modification and PTF level then returns to the calling program.

For example, the level of IBM SMP/E for z/OS, V3R5 is 35.00. As the result of a call to GIMAPI with the VERSION command, the elements of the API_VERSION structure are set as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiver</td>
<td>Character(2)</td>
<td>A 2-digit character string representing the version of the API. Leading zeros are included.</td>
</tr>
<tr>
<td>apirel</td>
<td>Character(2)</td>
<td>A 2-digit character string representing the release of the API. Leading zeros are included.</td>
</tr>
<tr>
<td>apimod</td>
<td>Character(2)</td>
<td>A 2-digit character string representing the modification of the API. Leading zeros are included.</td>
</tr>
<tr>
<td>apiptf</td>
<td>Character(2)</td>
<td>A 2-digit character string representing the PTF associated with the API. Leading zeros are included.</td>
</tr>
</tbody>
</table>

The version can be accessed by the user as the complete string, "03050000" or as the previously listed individual parts.

The calling program needs to issue the FREE command at some point after calling the VERSION command.

**VERSION command output**

The data structure shown in this section are defined in a language independent format. See "Programming in C" on page 396, "Programming in PL/I" on page 398, and "Programming in assembler" on page 400 to see the syntax of the data structures for those languages. Headers or macros with the language-specific structure definitions are provided in members named GIMHC370 (for C/370), GIMMPLI (for PL/I), and GIMMASM (for assembler) in libraries with these DDDEFs:

<table>
<thead>
<tr>
<th>MACLIB</th>
<th>Target Library</th>

</tr>
</tbody>
</table>
For GIMAPI to be invoked from a C/370 program, GIMAPI must first be loaded into storage. The calling program must identify the parameter linkage as standard OS linkage and must declare the routine. Figure 69 shows the statements to load and unload the module, the #pragma statement that identifies the linkage, the function declaration, and the calling syntax.

```c
typedef void APIPGM();
typedef void CFUNC();
#pragma linkage(APIPGM,OS)
...
APIPGM * gimapi;
gimapi = (APIPGM *) fetch("GIMAPI");
...
(*gimapi) (apicmd,&parmptr,&outptr,language,&rc,&cc,&msgbuff);
...
release((CFUNC*) gimapi)
```

**Figure 69. C syntax of GIMAPI invocation**

The FETCH must be done once, then GIMAPI can be invoked any number of times before it is released. The release function requires a pointer to a C function as its parameter. APIPGM becomes an OS program. The typedef of CFUNC is used to cast the `gimapi` parameter so the program compiles correctly.

- **apicmd** The `apicmd` parameter is a string of length 8 that contains the name of the command to be passed to GIMAPI.
- **&parmptr** A `parmptr` pointer variable is set to the address of the query parameter structure. The address of the pointer variable is passed to GIMAPI.
- **&outptr** The `outptr` variable is a pointer variable that will be set to the address of the beginning of storage containing the output of the command processing. The address of `outptr` is passed to GIMAPI.
- **language** A character string of length 3 to indicate the language to use for messaging by GIMAPI. Valid values are ENU and JPN.
- **&rc** Address of a variable defined as `long` to be set to the command’s return code by GIMAPI.
- **&cc** Address of a variable defined as `long` to be set to the command’s condition code by GIMAPI.
- **&msgbuff** The msgbuff variable is a pointer variable that is set to the head of a linked list of messages that could be created by GIMAPI processing. The elements to the link list are `ITEM_LIST` structures. The address of the pointer variable is passed to GIMAPI.

**Data structures in C**

Many of the structures contain character string data. The strings are not null terminated.
A header file will be provided in the MACLIB library. The member name for C/370 is GIMHC370.

**QUERY_PARMS**

typedef _Packed struct QUERY_PARMS
{
    char *csi;
    long csilen;
    char *zone;
    long zonelen;
    char *entrytype;
    long entrylen;
    char *subentrytype;
    long subentrylen;
    char *filter;
    long filterlen;
} QUERY_PARMS, *P_QUERY_PARMS;

**API_VERSION**

typedef _Packed struct API_Version
{
    char apiver[2];
    char apirel[2];
    char apimod[2];
    char apiptf[2];
} API_VERSION, *P_API_VERSION;

**ENTRY**

typedef _Packed struct CSI_ENTRY
{
    _Packed struct CSI_ENTRY *next;
    _Packed struct SUBENTRY *subentries;
    char entryname[8];
    char zonename[7];
} CSI_ENTRY, *P_CSI_ENTRY;

**ENTRY_LIST**

typedef _Packed struct ENTRY_LIST
{
    _Packed struct ENTRY_LIST *next;
    _Packed struct CSI_ENTRY *entries;
    char type[12];
} ENTRY_LIST, *P_ENTRY_LIST;

**ITEM_LIST**

typedef _Packed struct ITEM_LIST
{
    _Packed struct ITEM_LIST *next;
    long datalen;
    char *data;
} ITEM_LIST, *P_ITEM_LIST;

**SUBENTRY**

typedef _Packed struct SUBENTRY
{
    _Packed struct SUBENTRY *next;
    void *subentrydata;
    char type[12];
} SUBENTRY, *P_SUBENTRY;

**Note:** Given that C requires pointers to indicate the data type they will point to, a void pointer must be used here since more than one structure may be attached, the ITEM_LIST or the VER structure.
**GIMAPI**

```c
typedef _Packed struct VER
{
    _Packed struct VER      *next;
    _Packed struct SUBENTRY *verdata;
    char          vernum[3];
} VER,  *P_VER;
```

### Programming in PL/I

Before the GIMAPI program can be invoked from a PL/I program, it must be declared. This identifies the variable as a callable routine and indicates to PL/I that standard OS linkage is used to pass parameters. The program must be loaded into storage before it can be invoked. The declaration, linkage, load and call syntax are shown in [Figure 70](#).

```pli
DECLARE GIMAPI(CHAR(8), PTR, PTR, CHAR(3), FIXED, FIXED, PTR)
ENTRY OPTIONS(ASSEMBLER INTER);

FETCH GIMAPI;
CALL GIMAPI(APICMD,PARMPTR,OUTPTR,LANGUAGE,RC,CC,MSGBUFF);

RELEASE GIMAPI;
```

*Figure 70. PL/I syntax of GIMAPI invocation*

The FETCH must be done once, then GIMAPI can be invoked any number of times before it is released.

**APICMD**
A variable defined as CHAR(8) that contains the string representing the command GIMAPI is to process.

**PARMPTR**
A command parameter structure (QUERY_PARMS) that contains the parameters of the command being processed is declared in the calling program. PARMPTR is a pointer variable that contains the address of that structure. The variable is passed to GIMAPI.

**OUTPTR**
A pointer variable that will be set to the address of the beginning of storage containing the output of the command processing.

**LANGUAGE**
3-character national language identifier to use for messages. Valid values are ENU and JPN.

**RC**
A return code variable declared as FIXED BIN(31). The value of the variable is set to the return code of GIMAPI call by GIMAPI program.

**CCP**
A condition code variable declared as FIXED BIN(31). The value of the variable is set to the condition code of GIMAPI call by GIMAPI program.

**MSGBUFF**
The MSGBUFF variable is a pointer variable that is set to the head of a linked list of messages that could be created by GIMAPI processing. The elements to the link list are ITEM_LIST structures.

### Data structures in PL/I

This section shows the data structures defined in "Data structures for QUERY command" on page 390 as they would appear in PL/I. The calling program must declare all the structures it is going to use before calling GIMAPI.

---

398  SMP/E V3R5.0 for z/OS V1R11.0 Reference
The data structures defined for the entries are BASED variables. This means no storage is allocated for the variables, but they are used to reference data allocated by the GIMAPI command. The calling program must declare pointer variables to reference the storage.

A macro file for PL/I is provided in member GIMMPLI of the MACLIB library.

**QUERY_PARMS**

```
DECLARE
  1 QUERY_PARMS UNALIGNED,
     2 CSI POINTER,
     2 CSILEN FIXED BIN(31),
     2 ZONE POINTER,
     2 ZONELEN FIXED BIN(31),
     2 ENTRYTYPE POINTER,
     2 ENTRYLEN FIXED BIN(31),
     2 SUBENTRYTYPE POINTER,
     2 SUBENTRYLEN FIXED BIN(31),
     2 FILTER POINTER,
     2 FILTERLEN FIXED BIN(31);
```

**API_VERSION**

```
DECLARE
  1 API_VERSION UNALIGNED,
     2 APIVER CHAR(2),
     2 APIREL CHAR(2),
     2 APIMOD CHAR(2),
     2 APIPTF CHAR(2);
```

**ENTRY**

```
DECLARE
  1 CSI_ENTRY BASED UNALIGNED,
     2 NEXT POINTER,
     2 SUBENTRIES POINTER,
     2 ENTRYNAME CHAR(8),
     2 ZONENAME CHAR(7);
```

**ENTRY_LIST**

```
DECLARE
  1 ENTRY_LIST BASED UNALIGNED,
     2 NEXT POINTER,
     2 ENTRIES POINTER,
     2 TYPE CHAR(12);
```

**ITEM_LIST**

```
DECLARE
  1 ITEM_LIST BASED UNALIGNED,
     2 NEXT POINTER,
     2 DATALEN FIXED BIN(31),
     2 DATA POINTER;
```

**SUBENTRY**

```
DECLARE
  1 SUBENTRY BASED UNALIGNED,
     2 NEXT POINTER,
     2 SUBENTRYDATA POINTER,
     2 TYPE CHAR(12);
```
Programming in assembler

Before the GIMAPI program can be invoked from an assembler program, the load module must be brought into virtual storage using the LOAD macro. It can then be invoked using the CALL macro passing the required parameters. An example of the declares, LOAD, CALL and FREE syntax are shown in Figure 71.

```
LA 2,APIPGM
LOAD EPLOC=(2),LOADPT=PGMADR
L 15,PGMADR
CALL (15),(QUERYCMD,QUERY_PARMS@,CMDOUT,APILANG,RC,CC,MSG@)
L 15,PGMADR
CALL (15),(FREECMD,0,CMDOUT,APILANG,RC,CC,MSG@)

APIPGM DC CL8'GIMAPI '
QUERYCMD DC CL8'QUERY '
FREECMD DC CL8'FREE '
APILANG DC CL3'ENU'
DS 0F
QUERY_PARMS@ DC AL4(QUERY_PARMS)
PGMADR DC AL4(0)
CMDOUT DC AL4(0)
MSG@ DC AL4(0)
RC DS F'0'
CC DS F'0'
```

**Figure 71. Assembler syntax of GIMAPI invocation**

- **QUERYCMD**: A variable defined as CHAR(8) that contains the string representing the QUERY command GIMAPI is to process.

- **FREECMD**: A variable defined as CHAR(8) that contains the string representing the FREE command GIMAPI is to process.

- **QUERY_PARMS@**: A command parameter structure (QUERY_PARMS) that contains the parameters of the command being processed is declared in the calling program. QUERY_PARMS@ is a pointer variable that contains the address of that structure. The variable is passed to GIMAPI.

- **CMDOUT**: A pointer variable that will be set to the address of the beginning of storage containing the output of the command processing.

- **APILANGE**: 3-character national language identifier to use for messages. Valid values are ENU and JPN.

- **RC**: A return code variable declared as a fullword. The value of the variable is set to the return code of GIMAPI call by GIMAPI program.
CC A condition code variable declared as a fullword. The value of the variable is set to the condition code of GIMAPI call by GIMAPI program.

MSG@ The MSG@ variable is an address variable that is set to the head of a linked list of messages that could be created by GIMAPI processing. The elements to the link list are ITEM_LIST structures.

Data structures in assembler

This section shows the data structures defined in "Data structures for QUERY command" on page 390 as they would appear in assembler. The calling program must declare all the structures it is going to use before calling GIMAPI.

The data structures defined for the entries are DSECTS. This means no storage is allocated for the variables, but they are used to reference data allocated by the GIMAPI command. The calling program must declare address variables to reference the storage.

A macro file for assembler code is provided in member GIMMASM of the MACLIB library.

Additional programming considerations

GIMAPI is installed in SYS1.LINKLIB and SYS1.MGLIB with the GIMSM module. Because GIMAPI resides in LINKLIB, which is considered an authorized library, GIMAPI is available to both authorized and unauthorized callers.

The GIMAPI load module cannot be reused. A new copy must be brought into virtual storage for each use. Each task must load its own copy of GIMAPI. However, a single task can load GIMAPI once and then call GIMAPI several times before deleting GIMAPI.

GIMAPI runs in AMODE 31. It will obtain storage from either above or below the 16MB line, based on the AMODE of the caller upon entry to GIMAPI.

GIMAPI will not provide an ESTAE environment. If an ESTAE environment is required, the calling program must establish it before invoking GIMAPI.

Callers of GIMAPI should not link-edit a copy of the load module into the application program. GIMAPI should be called as an external routine.

The caller of GIMAPI must first load the GIMAPI load module into virtual storage using the appropriate syntax for the language in which the application is written. For example, an assembler application may use the LOAD or LINK macros. Once the GIMAPI module is loaded into virtual storage, it can be called by the application.

The caller of GIMAPI must adhere to standard linkage conventions. For more information regarding standard linkage conventions, refer to "z/OS MVS Programming: Assembler Services Guide" and the appropriate documentation for the language you are using for your application.

GIMAPI can only be invoked from a user-written program. GIMAPI cannot be invoked from JCL.

GIMAPI exposes certain control blocks to the user. These are the data structures defined in section "Data structures for QUERY command" on page 390. A macro
data set is provided for you to include the definition of the control blocks in your program. The DDDEF of the macro library is MACLIB for the target library and AMACLIB for the distribution library. Refer to “Programming in C” on page 396, “Programming in PL/I” on page 398, and “Programming in assembler” on page 400 for the member names used for each language.

Sample programs that use GIMAPI

This section contains three sample programs that use GIMAPI. Each program does the same basic function, where differences are mostly due to the syntax of the languages involved.

Note: In addition to the programs documented here, SYS1.SAMPLIB provides other sample programs that use GIMAPI, such as GIMCRSAM and GIMPRSAM.

Each program follows these steps:
1. The query described in “Example of QUERY command” on page 388 is set up to be invoked. The global CSI data set used is ‘SMP.VSAM.CSI’.
2. GIMAPI is called with the QUERY command to retrieve the data.
3. If the query is successful, it calls a generic result print function that prints the data retrieved from any query.
4. Once these are done, the storage is freed by calling GIMAPI with the FREE command.

The following is an example of the output of the sample programs:

Entry Type: SYMSMOD
----------------------------------------
ENAME   : SMOD19
ZONE    : TARG1
INSTALLDATE : 07340
MOD     : MOD01
        : MOD02
----------------------------------------
ENAME   : SMOD22
ZONE    : MYTARG
INSTALLDATE : 07340

Sample C/370 program

This sample program can be found in the SAMPLIB library as member name GIMCSAMP.

```c
#include <stdio.h>
#include <stdlib.h>
#include <DD:SYSLIB(GIMHC370)>
/* Contains API structure definitions */

#define FREE "FREE"

Chapter 7. Writing UNIX shell scripts

This chapter documents intended Programming Interfaces that allow the customer to write programs to obtain the services of IBM SMP/E for z/OS, V3R5.

To simplify the post-install work for z/OS UNIX Services application programs, some UNIX applications include shell scripts. These scripts perform additional processing when SMP/E installs elements into a UNIX file system. A product packager normally includes any necessary shell scripts with the product.

For example, if the hierarchical file system element is a TAR or PAX file, you can provide a shell script that performs the necessary steps to restore the file. As with other products, you use SMP/E to copy the element (a TAR or PAX file) to a directory in a UNIX file system. However, you rely on the element’s shell script to actually explode the file into its component subdirectories and files.

SMP/E provides IBM and vendor product packagers with a generic interface for writing UNIX shell scripts. This chapter describes the interface and includes suggestions for designing a shell script for SMP/E processing.

You define the shell script to SMP/E through a hierarchical file system MCS statement, as described in “Hierarchical file system element MCS” on page 26.

Once defined, the shell script receives control whenever SMP/E installs or deletes the element.

Designing a shell script for SMP/E processing

To process a file in a UNIX file system, a shell script must be able to cope with both of the actions that SMP/E can potentially perform on the file: copy and delete. That is, SMP/E can copy the file to a directory in a UNIX file system (as a new file or a replacement for an existing file) and, later, SMP/E can delete the file from a UNIX file system directory. A shell script must be able to detect either of these conditions (copy or delete) and respond accordingly.

Assume, for example, that as part of deleting or replacing a product on your system, you delete a function that was shipped in the product’s tar file. SMP/E deletes only the original tar file from the directory in a UNIX file system. It is the responsibility of the shell script to clean up (delete) the tar file’s exploded component subdirectories and files.

Fortunately, SMP/E provides shell scripts with the necessary input. This input comes in the form of environment variables that SMP/E sets, as follows:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMP_Directory</td>
<td>Directory in a UNIX file system that contains the file to be processed by your shell script. This directory should be considered the working directory for the shell script, and the shell script should not update any directories or files which do not reside within the working directory.</td>
</tr>
</tbody>
</table>
### SMP_File
Name of the file to be processed by your shell script. This is the hierarchical file system element processed by SMP/E.

### SMP_Action
Action that SMP/E is performing on the file. This value can be either of the following:
- **COPY**: SMP/E is copying the file into a UNIX file system directory.
- **DELETE**: SMP/E is deleting the file from a UNIX file system directory.

### SMP_Phase
Point in processing in which SMP/E calls the shell script. This value can be either of the following:
- **PRE**: SMP/E is calling the shell script before performing the action indicated by the SMP_Action variable.
- **POST**: SMP/E is calling the shell script after performing the action indicated by the SMP_Action variable.

SMP_Phase is always set to PRE when SMP_Action is DELETE to ensure that SMP/E calls the shell script before deleting its corresponding element.

### LC_ALL
The default value for all of the UNIX locale environment variables. This value is always set to IBM-1047.

IBM-1047 defines the United States English character set. By specifying a specific locale, all shell scripts invoked by SMP/E receive the same environment, regardless of the locale being used on any particular driving system.

### PATH
The Java runtime directory concatenated with the base PATH value (/bin:). The Java runtime directory is obtained from either the SMPJHOME DD statement or the SMPJHOME DDDEF entry. The Java runtime directory is required only if the UNIX shell script invokes Java commands.

For example, if the SMPJHOME DD is allocated to "/usr/lpp/java/j1.4", the PATH environment variable value will be set to "/usr/lpp/java/j1.4/bin:/bin:".

If neither the SMPJHOME DD statement nor the SMPJHOME DDDEF entry is specified, SMP/E will not set the PATH environment variable.

This input allows you to design a shell script that can respond to SMP/E’s actions, as described in the sections that follow.
UNIX shell scripts

Designing for copy actions
For a copy action, SMP/E sets the SMP_Action variable to COPY (as well as setting the other environmental variables) and passes control to the shell script.

The shell script should not assume a first-time environment for the file. For example, if APPLY REDO is in effect, previous copy processing for a file might have already completed successfully. Therefore the shell script should begin by performing some kind of clean-up processing before taking any copy-related actions.

Designing for delete actions
For a delete action, SMP/E sets the SMP_Action variable to DELETE (as well as setting the other environmental variables) and passes control to the shell script.

The shell script should not assume that the file has previously been installed. For example, if during an APPLY, a file is being installed for the first time, and is also being deleted by a subsequent SYSMOD, SMP/E might invoke the shell script to delete the file before it has actually been copied to a UNIX file system. Therefore, the shell script should determine whether the file exists before taking any delete-related actions.

Designing for diagnosis
Code your shell script to write status information to the STDOUT and STDERR files during the course of its processing. Doing so will aid users in verifying the successful completion of shell script processing, and, if necessary, diagnosing problems when failures occur.

SMP/E copies this information from the STDOUT and STDERR files to the print data set specified in the active HFSCOPY UTILITY entry where it can be viewed by the user. By default, SYSPRINT is the print data set.

It is recommended that shell scripts provide sufficient information about the completion of any functions they use, and especially about any detected error conditions.

Returning control to SMP/E
When your shell script completes processing, it must return control to SMP/E. Your shell script returns control to SMP/E through the exit shell command, specifying an appropriate exit status (for example, exit 0 or exit –1). SMP/E uses your shell script’s exit status value to determine whether the shell script completed successfully.

SMP/E recognizes the following exit statuses from shell scripts:

<table>
<thead>
<tr>
<th>Exit status</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Shell script has completed successfully.</td>
</tr>
<tr>
<td>Any other value</td>
<td>Shell script processing has failed.</td>
</tr>
</tbody>
</table>

Example shell script
In the following example, the shell script is designed to process a UNIX tar file. The shell script is written so that it:
1. Explores the tar file in response to a COPY action by SMP/E
2. Deletes all files from the directory in response to a DELETE action by SMP/E.
# This script will either explode a tar file or delete all files in 
# the directory. The script uses the following environment variables 
# for input:
# 
# SMP_Directory - directory in which the tar file resides
# SMP_File     - name of the tar file
# SMP_Phase    - indicates whether the shell script is being called
#                before or after SMP/E has processed the file
# SMP_Action   - the action that SMP/E is performing: COPY or DELETE
#
#echo "Starting script processing..."
status=0       # initialize script status
#
# Verify that the required input was received by the shell script.
if test ! "$SMP_Directory"
then
  echo "** No SMP_Directory parameter specified."
  status=-1
elif test ! "$SMP_File"
then
  echo "** No SMP_File parameter specified."
  status=-1
elif test ! "$SMP_Phase"
then
  echo "** No SMP_Phase parameter specified."
  status=-1
elif test ! "$SMP_Action"
then
  echo "** No SMP_Action parameter specified."
  status=-1
fi
#
# If a parameter error was detected, then exit now.
if test $status -ne 0               # If status is not 0, an error was detected
then
  echo " Ensure the input environment variables for this script have been provided."
  echo " If SMP/E was not used to invoke the script, correct the caller to specify "
  echo " the input environment variables. If SMP/E invoked this script, contact "
  echo " the IBM support center."
  echo "Parameter error. Exiting script with status $status"
  exit $status
fi
#
# If the script is being invoked after the tar file has been copied 
# to the directory (SMP/E phase is post-copy), and the desired action 
# is COPY, explode the tar file.
if test $SMP_Phase = POST
then
  if test $SMP_Action = COPY
  then
    cd $SMP_Directory               # Set the working directory for pax
    echo "Expanding all components of "$SMP_Directory"$SMP_File using the pax command"
    pax -rvf $SMP_Directory$SMP_File # Expand the tar file
    status=$?                      # Get the status of the pax command
    if test $status -ne 0          # If pax failed, indicate so to the user
    then
      echo "** pax command failure: pax ended with status $status"
    else
      echo "pax command completed successfully."
    fi
    ls -l $SMP_Directory           # List the contents of the directory
  fi
fi
#
# If the action is DELETE, delete all component files.
if test $SMP_Action = DELETE then
echo "Deleting the following from $SMP_Directory using the rm command:"  
ls -l $SMP_Directory # List the contents of the directory  

cd $SMP_Directory  # Set the working directory for rm  
rm * # Delete the directory and all files  
status=$? # Get the status of the delete  
if test $status -ne 0 # If rm failed, indicate so to the user then  
  echo "* rm command failure: rm ended with status $status"  
else  
  echo "rm command completed successfully."  
fi  
if test $status = 0 # If rm was OK, then... then  
  mkdir $SMP_Directory # ...recreate the directory, albeit empty  
  status=$? # Get the status of the mkdir  
  if test $status -ne 0 # If mkdir failed, indicate so to the user then  
    echo "** mkdir command failure: mkdir ended with status $status"  
  fi  
fi  
fi  
else  
  echo "Exiting script with status $status"  
fi  
exit $status
UNIX shell scripts
Chapter 8. Library change file records

This chapter documents intended Programming Interfaces that allow the customer to write programs to obtain the services of IBM SMP/E for z/OS, V3R5.

This chapter documents the various record types that are produced and written to the SMPDATA1 and SMPDATA2 data sets as a result of APPLY or RESTORE processing. You can use these records to propagate the libraries and members modified by SMP/E APPLY and RESTORE processing to other systems that require the same changes.

Note: The CHANGEFILE subentry in the OPTIONS entry must be set to **YES** to instruct SMP/E to create these records.

SMP/E provides macros containing the mappings of these records:
- GIMMALLC for assembler
- GIMMCLC for C
- GIMMPLC for PL/I.

Library change file record structure

The following sections provide samples of the various library change file records that are written to the SMPDATA1 and SMPDATA2 data sets as a result of APPLY or RESTORE processing.

**Notes:**
1. SMP/E COMPRESS processing does not create any library change records.
2. The library change file records are of varying lengths.
3. All character data in all library change records are in uppercase, except for the following, which contain mixed-case character data:
   - Aliases in Alias Record Type 0 records
   - Link names in Alias Record Type 0 records
   - Symbolic link names in Alias Record Type 1 records
   - Path names in Element Record Type 1 records
   - Path names in Library Record Type 1 records

   See [“A0 - Alias record type 0” on page 420](#) and [“L1 - Library record type 1” on page 429](#) for details.
4. The scale lines shown in the examples do not appear in the actual SMPDATA1 and SMPDATA2 data sets.
5. In [Figure 72 on page 421](#), the binary zeros after the alias name are not shown in the example.
6. In [Figure 73 on page 423](#), the binary zeros after the symbolic link name are not shown in the example.

Library change file record types

The following are the valid record types produced by the library change interface:

<table>
<thead>
<tr>
<th>Record type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A0</td>
<td>Alias Record Type 0</td>
</tr>
<tr>
<td>A1</td>
<td>Alias Record Type 1</td>
</tr>
<tr>
<td>C0</td>
<td>Continuation Record Type 0</td>
</tr>
</tbody>
</table>
Library change file records

E0  Element Record Type 0
E1  Element Record Type 1
H0  Header Record Type 0
L0  Library Record Type 0
L1  Library Record Type 1
L2  Library Record Type 2
P0  SYSMOD Status Record Type 0
S0  SMP/E Environment Record Type 0
T0  Trailer Record Type 0

A0 - Alias record type 0

An Alias Record Type 0 (A0) is created for each alias for an element or LMOD processed during APPLY or restore processing. For hierarchical file system elements, the linkname is indicated in the record.

Multiple A0 records may be produced for the same element or LMOD, because more than one alias can exist for the same element or LMOD.

The purpose of the A0 record is to identify the aliases associated with the changed elements or LMODs associated with this execution of the APPLY or RESTORE command.

The format and contents of this record type are shown in Table 40.

<table>
<thead>
<tr>
<th>Field name</th>
<th>Position (decimal)</th>
<th>Length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Record type</td>
<td>1</td>
<td>2</td>
<td>The characters ‘A0’.</td>
</tr>
<tr>
<td>Name</td>
<td>3</td>
<td>8</td>
<td>The name of an SMP/E element or LMOD processed during APPLY or RESTORE processing. The data is left-justified and padded with blanks.</td>
</tr>
</tbody>
</table>
| Type          | 11                 | 12               | The type of SMP/E element or LMOD processed during APPLY or RESTORE processing. The valid element types for an Alias Record Type 0 are:  
- Data elements
- Hierarchical file system elements
- JAR
- MAC
- LMOD
- PROGRAM
- SIDEDECK
  The data is left-justified and padded with blanks. |
| Action        | 23                 | 8                | The type of action SMP/E took against this alias of this element or LMOD during APPLY or RESTORE processing. Valid values are ADDREP and DELETE. This data is left-justified and padded with blanks. |
Table 40. Alias record type 0 (continued)

<table>
<thead>
<tr>
<th>Field name</th>
<th>Position (decimal)</th>
<th>Length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DD name</td>
<td>31</td>
<td>8</td>
<td>The ddname associated with the target library associated with the named element or LMOD in this A0 record. For action type DELETE, this field indicates the target library ddname from which the alias has been deleted. For action type ADDR EP , this field indicates the target library ddname into which the alias has been added or replaced. An A0 record is created for every unique library that has an alias change. Elements with multiple SYSLIBs will have the appropriate A0 records created for each unique SYSLIB changed. Therefore, it is possible to have the same element have the same change in alias structure in multiple SYSLIBs. The data is left-justified and padded with blanks. This field contains the ddname of the associated target library regardless of whether the allocation was done by a DD statement or DDDEF.</td>
</tr>
<tr>
<td>Alias</td>
<td>39</td>
<td>1023</td>
<td>This is an alias name associated with this SMP/E element or LMOD. If the element is a hierarchical file system element, then the linkname is placed in this field. The data is mixed-case characters and is left-justified and padded with binary zeros.</td>
</tr>
</tbody>
</table>

For LMODs that have an associated side deck, there is one A0 record created for each unique alias associated with the LMOD (indicated by LMOD in the element type field of the A0 record) and one A0 record created for each unique alias associated with the LMOD’s side deck (indicated by SIDEDECK in the element type field of the A0 record). Both the A0 record with element type LMOD and the A0 record with element type SIDEDECK contain the same name (the LMOD’s name) in the Name field of the A0 record.

For example, suppose that SMP/E adds load module LMODA, which has two aliases, LMA and LMDA. Load module LMODA has a side deck. Figure 72 shows the A0 records created for LMODA:

```
   1  2  3  4  5  6  7  8
   -----0-----0-----0-----0-----0-----0-----0-----0-----0-----0-----0-----0-----0-----0
A0LMODA LMOD ADDR EP LINKLIB LMA
A0LMODA LMOD ADDR EP LINKLIB LMDA
A0LMODA SIDEDECK ADDR EP SidelIB LMA
A0LMODA SIDEDECK ADDR EP SidelIB LMDA
```

Figure 72. Example of alias record type 0 records

**A1 - Alias record type 1**

An Alias Record Type 1 (A1) is created for each symbolic link associated with a hierarchical file system element and for each symbolic link associated with a load module within a UNIX file system that is processed during APPLY or RESTORE processing. For hierarchical file system elements, the symbolic link names are
Library change file records

placed in the records. For load modules, values from the
ALIAS (SYMLINK,synmlink) control statements are placed in the records.

Multiple A1 records may be produced for the same hierarchical file system element
or load module, because more than one symbolic link can exist for the same
hierarchical file system element or load module.

The purpose of the A1 record is to identify the symbolic links associated with the
changed hierarchical file system elements and the symbolic links associated with
load modules processed with this execution of the APPLY or RESTORE command.

The format and contents of this record type are shown in Table 41.

Table 41. Alias record type 1

<table>
<thead>
<tr>
<th>Field name</th>
<th>Position (decimal)</th>
<th>Length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Record type</td>
<td>1</td>
<td>2</td>
<td>The characters 'A1'.</td>
</tr>
<tr>
<td>Name</td>
<td>3</td>
<td>8</td>
<td>The name of an SMP/E hierarchical file system element or load module processed during APPLY or RESTORE processing. The data is left-justified and padded with blanks.</td>
</tr>
</tbody>
</table>
| Type        | 11                 | 12               | The type of SMP/E hierarchical file system element or LMOD processed during APPLY or RESTORE processing. The valid values are:
• a hierarchical file system element type
• JAR
• LMOD
The data is left-justified and padded with blanks. |
| Action      | 23                 | 8                | The type of action SMP/E took against this symbolic link during APPLY or RESTORE processing. Valid values are ADDREP and DELETE. The data is left-justified and padded with blanks. |
| DD name     | 31                 | 8                | The ddname associated with the target library for the named hierarchical file system element or load module in this A1 record. The data is left-justified and padded with blanks. For action type DELETE, this field indicates the target library ddname from which the symbolic link has been deleted. For action type ADDREP, this field indicates the target library ddname into which the symbolic link has been added or replaced. An A1 record is created for all libraries modified within a UNIX file system by having a hierarchical file system element replaced or deleted or by having a load module replaced or deleted. This field contains the ddname of the associated target library regardless of whether the allocation was done by a DD statement or DDDEF. |
| Symbolic link | 39              | 1023             | This is a symbolic link associated with this SMP/E hierarchical file system element or LMOD. The data is mixed-case characters and is left-justified and padded with binary zeros. |
Library change file records

For example, suppose that load module LMODA, which has two symbolic links, LMA and LMDA, is added to the BPXUSER library. Figure 73 shows the A1 records created for LMODA:

![Figure 73. Example of alias record type 1](image)

**C0 - Continuation record type 0**

One Continuation Record Type 0 (C0) is created for each delta produced by the results of APPLY or RESTORE processing when spill processing has occurred. The purpose of the C0 record is to uniquely identify the continuation of a set of library change records.

The format and contents of this record type are shown in Table 42.

</tbody>
</table>
Library change file records

For example, suppose that a delta is produced for target zone TZONEA on January 16, 2008 at 9:57:22 AM. During this execution of SMP/E, two SYSMODs were applied in error, one SYSMOD was left incomplete, 123 SYSMODs were applied successfully, seven SYSMODs were deleted, and three SYSMODs were superseded. Figure 74 shows the C0 records created that for delta:

![C0TZONEA 200801609572200000200000100123000007000003]

**Figure 74. Example of continuation record type 0**

**E0 - Element record type 0**

An Element Record Type 0 (E0) is created for each element or LMOD that changed in a target library during APPLY or RESTORE processing. The term changed in this context refers to an element or LMOD that been deleted or replaced in a target library as a result of SMP/E processing. See “Valid action types” on page 435 for more information.

The purpose of the E0 record is to identify the changed elements or LMODs in the associated target libraries identified by the L0 and L1 records.

The format and contents of this record type are shown in Table 43.

<table>
<thead>
<tr>
<th>Field name</th>
<th>Position (decimal)</th>
<th>Length (decimal)</th>
<th>Description</th>

</tr>
</tbody>
</table>
### Library change file records

Table 43. Element record type 0 (continued)

<table>
<thead>
<tr>
<th>Field name</th>
<th>Position (decimal)</th>
<th>Length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DD name</td>
<td>31</td>
<td>8</td>
<td>The ddname associated with the target library associated with the named element or LMOD in this E0 record. The data is left-justified and padded with blanks. For cross-zone elements, this field indicates the SMP/E generated ddname associated with the SYSLIB for this element. The associated L0 record also contains the related true name for the SYSLIB in the cross-zone. For action type DELETE, this field indicates the target library ddname from which the element has been deleted. For action type ADDREP, this field indicates the target library ddname into which the element has been added or replaced. An E0 record is created for every unique library that has an element change. Elements with multiple SYSLIBs will have the appropriate E0 records created for each unique SYSLIB changed. Therefore, it is possible to have the same element have the same change take place in multiple SYSLIBs. This field contains the ddname of the associated target library regardless of whether the allocation was done by a DD statement or DDDEF.</td>
</tr>
</tbody>
</table>

For LMODs that have an associated side deck, there is one E0 record created for each LMOD (indicated by LMOD in the element type field of the E0 record) and one E0 record created for the LMOD’s side deck (indicated by SIDEDECK in the element type field of the E0 record). Both the E0 record with element type LMOD and the E0 record with element type SIDEDECK contain the same name (the LMOD’s name) in the name field of the E0 record.

For example, suppose that SMP/E adds load module LMODA, which has a SIDEDECK. **Figure 75** shows the E0 records created for LMODA:

![Figure 75. Example of element record type 0](image)

**E1 - Element record type 1**

One Element Record Type 1 (E1) is created for each element having a UNIX shell script that changed in a target library during APPLY or RESTORE processing. The term changed in this context refers to an element that has been deleted or replaced in a target library as a result of SMP/E processing. See "Valid action types" on page 435 for more information.

The purpose of the E1 record is to identify the changed elements in the associated target libraries identified by the L0 and L1 records.

The format and contents of this record type are shown in Table 44 on page 426.
## Library change file records

**Table 44. Element record type 1**

<table>
<thead>
<tr>
<th>Field name</th>
<th>Position (decimal)</th>
<th>Length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Record type</td>
<td>1</td>
<td>2</td>
<td>The characters ‘E1’.</td>
</tr>
<tr>
<td>Name</td>
<td>3</td>
<td>8</td>
<td>The name of an SMP/E element processed during APPLY or RESTORE processing. The data is left-justified and padded with blanks.</td>
</tr>
<tr>
<td>Type</td>
<td>11</td>
<td>12</td>
<td>The type of hierarchical file system element processed by the APPLY or RESTORE command. The data is left-justified and padded with blanks.</td>
</tr>
<tr>
<td>Action</td>
<td>23</td>
<td>8</td>
<td>The type of action SMP/E took against this element during APPLY or RESTORE processing. Valid values are ADDREP and DELETE. This data is left-justified and padded with blanks.</td>
</tr>
<tr>
<td>DD name</td>
<td>31</td>
<td>8</td>
<td>The ddname associated with the target library associated with the named element in this E1 record. The data is left-justified and padded with blanks.</td>
</tr>
</tbody>
</table>

For cross-zone elements, this field indicates the SMP/E generated ddname associated with the SYSLIB for this element. The associated L1 record also contains the related true name for the SYSLIB in the cross-zone.

For action type DELETE, this field indicates the target library ddname from which the element has been deleted.

For action type ADDREP, this field indicates the target library ddname into which the element has been added or replaced.

An E1 record is created for every unique library that has an element change. Elements with multiple SYSLIBs will have the appropriate E1 records created for each unique SYSLIB changed. Therefore, it is possible to have the same element have the same change take place in multiple SYSLIBs.

It is also possible to have multiple E1 records for the same element in the same SYSLIB if the element is both deleted and replaced. Normally, only the net effect would be represented in the E1 record. However, when a shell script is run, two records are produced because the shell script is run for each action.

This field contains the ddname of the associated target library regardless of whether the allocation was done by a DD statement or DDDEF.

<table>
<thead>
<tr>
<th>Phase</th>
<th>39</th>
<th>8</th>
<th>The phase of processing when the shell script was invoked to complete the installation of the identified element. Valid values are:</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRE</td>
<td>Shell script was invoked before the action was performed.</td>

<tr>
<td>POST</td>
<td>Shell script was invoked after the action was performed.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PRE,POST</td>
<td>Shell script was invoked both before and after the action was performed.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The data is left-justified and padded with blanks.
Library change file records

For example, suppose that an HFS element named XMPHFS was added to target zone TZONEB using a shell script named MYSHELL in directory /usr/lpp/abc/ and that shell script MYSHELL was invoked after XMPHFS was installed. Figure 76 shows the E1 records created for LMODA:

Figure 76. Example of element record type 1

H0 - Header record type 0

One Header Record Type 0 (H0) is created for each delta produced by the results of APPLY or RESTORE processing. The purpose of the H0 record is to uniquely identify the start of a set of library change records.

The format and contents of this record type are shown in Table 45:

Table 45. Header record type 0

<table>

</tbody>
</table>

For example, suppose that a delta is produced for target zone TZONEA on January 16 of 2008 at 9:57:22 AM. During this execution of SMP/E, two SYSMODs were applied in error, one SYSMOD was left incomplete, 123 SYSMODs were applied successfully, seven SYSMODs were deleted, and three SYSMODs were superseded. Figure 77 shows the H0 records created for that delta:

```
H0TZONEA 20080160957200000200000100012300000700003
```

Figure 77. Example of header record type 0

L0 - Library record type 0

One Library Record Type 0 (L0) is created for each target library changed during APPLY or RESTORE processing that is not associated with a pathname. A Library Record Type 1 (L1) is created for pathnames.

The purpose of the L0 record is to identify the target libraries (excluding pathnames) that were changed by this execution of APPLY or RESTORE.

SYSLIB concatenations used during the APPLY or RESTORE do not produce any L0 records.

The format and contents of this record type are shown in Table 46.

Table 46. Library record type 0

<table>
<thead>
<tr>

</tbody>
</table>

For example, Figure 79 shows the L1 record generated for a pathname of ‘/hfs_path_name/’, which is an HFS library with the ddname of HFSLIB1.

```
+----+----+----+----+----+----+----+----+
| 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  |
| L1HFSLIB1 | HFS/hfs_path_name/ |
```

Figure 79. Example of library record type 1

L2 - Library record type 2

A Library Record Type 2 (L2) is created for each physical data set associated with a directory in a UNIX file system that was changed during APPLY or RESTORE processing. The purpose of the L2 record is to identify the physical data set in which a particular directory is located, how the data set is related to the directory, and the ddname that was used to allocate the directory.

The format and contents of this record type are shown in Table 48.

Table 48. Library record type 2

<table>
<thead>
<tr>
<th>Field name</th>
<th>Position (decimal)</th>
<th>Length (decimal)</th>

Table 48. Library record type 2 (continued)

<table>
<thead>
<tr>
<th>Field name</th>
<th>Position (decimal)</th>
<th>Length (decimal)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DD name</td>
<td>3</td>
<td>8</td>
<td>The SMP/E ddname associated with this Library Type 2 record. The data is left-justified and padded with blanks. This field contains the ddname that was used to allocate the directory in a UNIX file system that was updated. This value can be used to correlate the Library Type 2 records with the Library Type 1 records that describe the directory.</td>
</tr>
<tr>
<td>Relationship</td>
<td>11</td>
<td>8</td>
<td>This field describes the relationship between the updated directory and the physical data set identified in the record. Valid relationships are: PATHHFS: The HFS data set specified in this record contains the directory that contains a file updated by SMP/E. SYMHFS: The HFS data set specified in this record contains the directory that contains a symbolic link associated with a file updated by SMP/E. Library Type 2 records with a type of SYMHFS are created only when the SYMHFS data set names are different than the PATHHFS data set name. In addition, records only for unique SYMHFS data set names are produced. For example, if a file updated by SMP/E has two symbolic link values, and those symbolic link values reside in two directories that reside in the same physical data set, then only one Library Type 2 record with a type of SYMHFS is produced to describe this data set. In addition, if the data set that contains the symbolic links is the same physical data set that contains the file updated by SMP/E, then no Library Type 2 records with a type of SYMHFS are produced; a single record with a type of PATHHFS describes the physical data set that contains the file and its symbolic links. The data is left-justified and padded with blanks.</td>
</tr>
<tr>
<td>Physical data set name</td>
<td>19</td>
<td>44</td>
<td>data set name of the physical data set that was updated when SMP/E updated a file in a UNIX file system. The data is left-justified and padded with blanks.</td>
</tr>
</tbody>
</table>

For example, suppose the following PTF is selected for APPLY processing and that the SBKSBIN library is allocated to directory /service/usr/lpp/booksrv/cgi-bin/IBM/ in a UNIX file system.

++PTF(UW12345).
++VER(2038) FMID(HY2900).
++HFS(BKSMMAIN) SYSLIB(SBKSBIN) DISTLIB(ABKSBIN)
   PARM(PATHMODE(7,5,5))
   LINK('..bksmain')
   SYMLINK('.../..../..../bin/bksmain')
   SYMPATH('.../usr/lpp/booksrv/cgi-bin/bksmain').

The resulting APPLY processing replaces the BKSMMAIN file in the /service/usr/lpp/booksrv/cgi-bin/IBM/ directory with the copy of the HFS element supplied in the PTF. Also, when the file’s symbolic link value specified on the MCS is concatenated with the file’s directory, the symbolic link value resolves to /service/bin/bksmain. This file is the symbolic link and resides in the
Library change file records

/service/bin/ directory. In this example, the directory containing the symbolic link is in a different physical data set than the directory that contains the file BKSMAIN.

At the end of APPLY processing, SMP/E produces L1 and L2 records to summarize the updates performed. Figure 80 shows the L1 record that describes the directory that contains the file, as well as the L2 records that describe the data sets that contain the file and its symbolic links.

| Status     | 10                 | 8               | The status of the SYSMOD. The following text may appear in this field. Where the text is less than 8 characters, it is left justified and padded with blanks. • APPLIED • DELETED • ERROR • INCMPNL • RESTORED • SUPD

Note: The superseded SYSMODs are included to aid in analyzing when a set of deltas is ready for distribution. When a SYSMOD in ERROR status is noted as superseded in a subsequent delta, its error status may be considered resolved.

The status in this library change record is consistent with the status of the SYSMOD as reported in the SYSMOD STATUS REPORT.

Note: SYSMODs identified in the SYSMOD STATUS REPORT with the following status are not included in the library change records, because they failed during SYSMOD selection processing.
• EXCLUDED • HELD • NOGO • NOGO(E) • NOGO(H)

</tr>
</tbody>
</table>

The SYSMOD Status (P0) records follow the E0 record in the set of library change records for the command. [Figure 81] shows examples of P0 records written for APPLY processing.

![Figure 81. Example of SYSMOD status records](image)

Additionally, fields are added to the header and trailer records to represent the count of SYSMODs represented in the P0 records with each status.

This information tells you whether any errors are contained in the current delta. However, just because a delta is error free, it does not mean that it can be distributed without resolving errors in previous deltas. You must perform the task of error resolution among deltas prior to distribution in order to ensure an error free package. Refer to “Usage recommendations” on page 436 for usage information.

S0 - SMP/E environment record type 0

One SMP/E Environment Record Type 0 (S0) is created for each delta produced by the results of APPLY or RESTORE processing.

The purpose of the S0 record is to identify the SMP/E environment from which this set of library change records was derived.

The format and contents of this record type are shown in Table 50.

Table 50. SMP/E environment record type 0

</tr>
</tbody>
</table>

For example, Figure 83 shows a T0 record for a target zone named MYTZN. The delta processing for this zone ended on January 16, 2008 at 10:12:34 AM. During this execution of SMP/E, one SYSMOD was applied in error, four SYSMODs were left incomplete, ten SYSMODs were applied successfully, one SYSMOD was deleted, and two SYSMODs were superseded.

For example, Figure 83 shows a T0 record for a target zone named MYTZN. The delta processing for this zone ended on January 16, 2008 at 10:12:34 AM. During this execution of SMP/E, one SYSMOD was applied in error, four SYSMODs were left incomplete, ten SYSMODs were applied successfully, one SYSMOD was deleted, and two SYSMODs were superseded.

Valid action types

**Action**    **Meaning**

**ADDREP**

The ADDREP action indicates either that a new element or LMOD was added to a target library during APPLY or RESTORE processing, or that an existing element or LMOD was replaced in a target library during APPLY or RESTORE processing.

This includes elements added or replaced by way of:
Library change file records

- Data element MCS
- Hierarchical file system element MCS
- Link-edits or copies of load modules:
  - ++MOD MCS (add or replace)
- ++MAC MCS
- ++JAR MCS
- ++JARUPD MCS
- ++MACUPD MCS
- ++MOVE MCS for MACs, SRC, and LMODs
- ++PROGRAM MCS
- ++RENAME MCS for load modules
- ++SRC MCS
- ++SRCUPD MCS
- ++MACUPD MCS

This also includes aliases added or replaced by way of:
- Data element MCS with ALIAS operand
- Hierarchical file system element MCS with LINK operand
- Link-edits or copies of load modules:
  - ++MOD MCS with TALIAS operand
  - LMODs defined in JCLIN
- ++JAR or ++JARUPD MCS with LINK operand
- ++MAC MCS with MALIAS operand
- ++MACUPD MCS with MALIAS operand
- ++MOVE MCS for MACs and LMODs
- ++PROGRAM MCS with ALIAS operand
- ++RENAME MCS for load modules

DELETE
The DELETE action indicates that an element or LMOD was deleted from a target library during APPLY processing.

This includes elements and their aliases deleted by way of:
- DELETE operand on data element MCS
- DELETE operand on hierarchical file system element MCS
- DELETE operand on ++JAR MCS
- DELETE operand on ++MAC MCS
- DELETE operand on ++PROGRAM MCS
- DELETE operand on ++SRC MCS
- DELETE operand on ++VER MCS
- ++DELETE MCS for load modules

This also includes aliases deleted by way of:
- ALIAS operand on ++DELETE MCS for load modules

Usage recommendations

Users cannot simply look at the records created by the library change interface and move the identified parts. As is the case whenever SMP/E is executed, each processed SYSMOD has a specific completion status when the particular APPLY or RESTORE completes. Therefore, the results of each APPLY or RESTORE must be looked at collectively. Until a set of SYSMODs has been successfully processed, you cannot distribute the library change records associated with those SYSMODs.

Therefore, you must first get a successful APPLY CHECK or RESTORE CHECK before attempting to use the records produced by library change processing for a specified target zone. Since there are no records produced during CHECK processing, there are no records to be lost until delta processing is activated.
Library change file records

Once activated, delta processing produces records for an execution of APPLY or RESTORE. Since all SYSMODs may not successfully complete in one run, the records from each run against the same set of SYSMODs must be kept.

Once a successful APPLY or RESTORE is obtained, the net result of the processing must be analyzed by elements, LMODs, or both to determine the appropriate action to take to distribute the elements and LMODs.

Alternatively, once a successful APPLY or RESTORE is obtained, the net result of the libraries updated can be analyzed to determine the appropriate action to take to distribute the libraries affected by the APPLY/RESTORE activity.
Chapter 9. SMP/E exit routines

This chapter describes intended Programming Interfaces that allow the customer to write programs to obtain the services of IBM SMP/E for z/OS, V3R5.

This chapter describes how to write exit routines that:
- Process statements in SMPPTFIN at RECEIVE time
- Control retry processing when data sets run out of space during ACCEPT, APPLY, GZONEMERGE, LINK LMODS, LINK MODULE, RECEIVE, or RESTORE processing.

LINK LMODS,

A common parameter list is used to pass information between SMP/E and the exit routines. It is pointed to by register 1 and is mapped by macro GIMMPUXP in SYS1.MACLIB. Table 52 shows the format and contents of the parameter list.

Table 52. GIMMPUXP: exit routine parameter list

The following sections describe the exit routines for RECEIVE and retry processing.

RECEIVE exit routine

The RECEIVE exit routine allows you to scan statements in the SMPPTFIN data set at RECEIVE time. This exit routine must be defined by a GIMEXITS control statement in the GIMEXITS member of SMPPARM, which tells SMP/E RECEIVE processing that an exit routine exists and should be called. Optionally, the GIMEXITS control statement may also specify the data set containing the exit routine. This exit routine must be a load module residing in an authorized library. For more information on specifying exit routines in GIMEXITS, see Chapter 3, “Defining control statements in SMPPARM members,” on page 129. The RECEIVE exit routine is loaded at the start of RECEIVE command processing and is deleted at the end of RECEIVE processing.
When this exit routine is called, the parameter list contains the values shown in Table 53 and Table 54.

Table 53. RECEIVE exit routine: parameter list values

<table>
<thead>
<tr>
<th>Field name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UXPUXNUM</td>

<td>X'04' – End-of-file on SMPPTFIN</td>
</tr>
<tr>
<td>UX001RCD</td>
<td>+ 1</td>
<td>+ 1</td>
<td>80</td>
<td>Record from SMPPTFIN</td>
</tr>
</tbody>
</table>

According to the input record, the RECEIVE exit may decide to continue RECEIVE processing, change the record, insert data after the record, or skip the record. Or, it may choose to stop processing for the SYSMOD, for the RECEIVE command, or for SMP/E.

When the exit routine returns control to SMP/E, it must set register 15 to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Continue normal RECEIVE processing.</td>
</tr>
<tr>
<td>8</td>
<td>Stop SYSMOD processing. SMP/E does not receive this SYSMOD, but continues to pass records from the SYSMOD to the exit routine.</td>
</tr>
<tr>
<td>12</td>
<td>Stop RECEIVE processing.</td>
</tr>
<tr>
<td>16</td>
<td>Stop SMP/E processing.</td>
</tr>
<tr>
<td>20</td>
<td>Insert a record after the current one in the buffer.</td>
</tr>
<tr>
<td>24</td>
<td>Skip the record in the buffer area.</td>
</tr>
</tbody>
</table>

If any other value is returned, SMP/E issues an error message and fails.

Changing records within SMPPTFIN

To change the current record within the SMPPTFIN data set, the exit routine must change the record currently in UX001RCD and set the return code in register 15 to 0 or 20. A return code of 0 indicates to SMP/E that the changed record should be processed and normal processing should continue. A return code of 20 indicates to SMP/E that the exit routine inserts records after this changed record. For more information, see Inserting records within SMPPTFIN.

Inserting records within SMPPTFIN

To insert one or more records within the SMPPTFIN data set after the current record in UX001RCD, the exit routine must set the return code in register 15 to 20.
SMP/E first processes the current record in UX001RCD; then it calls the exit routine again. On this call, the exit routine must place the record to be inserted into UX001RCD. If more records are to be inserted, the exit routine must set the return code in register 15 to 20. If this is the last record to be inserted, the exit routine must set the return code to 0.

When the exit routine passes a return code of 0, SMP/E processes the record in UX001RCD; then it continues processing with the next record in the SMPPTFIN data set.

**Inserting records at the end of SMPPTFIN**

To insert one or more records at the end of the SMPPTFIN data set, the exit routine must set the return code in register 15 to 20.

SMP/E then calls the exit routine again. On this call, the exit routine must place the record to be inserted into UX001RCD. If more records are to be inserted, the exit routine must set the return code in register 15 to 20. If this is the last record to be inserted, the exit routine must set the return code to 0. SMP/E processes the inserted records as if they were at the end of the SMPPTFIN data set.

When the exit routine passes a return code of 0, SMP/E processes the record in UX001RCD; then it continues with normal end-of-file processing.

**Note:** When you specify the SELECT operand during RECEIVE processing, and all selected SYSMODs have been processed, SMP/E indicates end-of-file to the exit routine. If the exit routine passes a return code of 20 at this point, the add request is ignored, and SMP/E continues with end-of-file processing.

**Skipping records in SMPPTFIN**

To skip a record in SMPPTFIN, the exit routine must set the return code in register 15 to 24. SMP/E does not process the current record in UX001RCD; instead, it processes the next record in SMPPTFIN.

**Retry exit routine**

The retry exit routine enables you to control retry processing when a data set runs out of space during ACCEPT, APPLY, GZONEMERGE, LINK LMODS, LINK MODULE, RECEIVE, or RESTORE processing. (In retry processing, the data set is compressed and the utility that failed is called again.) This exit routine must be defined by a GIMEXITS control statement in the GIMEXITS member of SMPPARM, which tells SMP/E retry processing that an exit routine exists and should be called. Optionally, the GIMEXITS control statement may also specify the data set containing the exit routine. This exit routine must be a load module residing in an authorized library. For more information on specifying exit routines in GIMEXITS, see Chapter 3, “Defining control statements in SMPPARM members,” on page 129.

The retry exit routine is loaded at the start of ACCEPT, APPLY, GZONEMERGE, LINK LMODS, LINK MODULE, RECEIVE, or RESTORE command processing and is deleted at the end of command processing.

**Note:** The processing of this routine is not affected by the debatching SMP/E does after retry processing fails, because this routine is called as part of the initial retry processing, before debatching is attempted.

When a data set runs out of space, an x37 abend occurs. If SMP/E determines that a retry can be attempted, it cancels the abend dump and calls the retry exit routine.
Retry exit routine

The parameter list contains these values:

Table 55. Retry exit routine: parameter list values

<table>
<thead>
<tr>
<th>Field name</th>

</tr>
<tr>
<td>UX002RCP</td>
<td>+23</td>
<td>+17</td>
<td>2</td>
<td>ABEND reason code (EBCDIC)</td>
</tr>
</tbody>
</table>

According to the input, the retry exit can either cancel retry processing or perform some other method of recovery.

When the exit routine returns control to SMP/E, it must set register 15 to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Continue normal retry processing.</td>
</tr>
<tr>
<td>12</td>
<td>Stop command processing and perform no retry.</td>
</tr>
<tr>
<td>16</td>
<td>Stop SMP/E processing and perform no retry.</td>
</tr>
<tr>
<td>20</td>
<td>Perform modified retry processing. Call the failing utility, but do not compress the failing data set.</td>
</tr>
</tbody>
</table>

If any other value is returned, SMP/E converts it to 12, and command processing fails.
Chapter 10. JCL statements required to invoke SMP/E

Unless you are using the SMP/E dialogs, you must provide the following JCL statements to invoke SMP/E:

- A JOB statement
- An EXEC statement
- DD (data definition) statements

**JOB statement**

The JOB statement describes your installation-dependent parameters. The JOB statement (or the EXEC statement, or both) can also include the REGION parameter to set the size of the region in which SMP/E runs. For details, see z/OS MVS JCL User's Guide SA22-7598 or z/OS MVS JCL Reference SA22-7597.

**Note:** To enable the SMP/E job step to get the maximum space above 16 megabytes, you can specify REGION=0M.

**EXEC statement**

The EXEC statement must specify PGM=GIMSMP or the name of your cataloged procedure for calling SMP/E. (For an example of a cataloged procedure, see SMP/E User's Guide.) The following can be specified in the EXEC statement PARM parameter:

- **COMPAT=WARNBYPASS** or **COMPAT=NOWARNBYPASS**
  - The COMPAT parameter is used to control incompatible behaviors of SMP/E processing.
  - **COMPAT(WARNBYPASS)** indicates that the APPLY and ACCEPT commands will issue warning messages to identify bypassed SYSTEM HOLD exceptions. This is the behavior for releases of SMP/E prior to V3R5.
  - **COMPAT(NOWARNBYPASS)** indicates that the APPLY and ACCEPT commands will issue informational messages to identify bypassed SYSTEM HOLD exceptions. If neither COMPAT(WARNBYPASS) or COMPAT(NOWARNBYPASS) is specified, the default is COMPAT(NOWARNBYPASS).

- **CSI=dsname**
  - where **dsname** is the name of the CSI data set containing the global zone. (This data set is also known as the master CSI.) This parameter is used to enable SMP/E to allocate the master CSI data set dynamically.

  **Note:** If there is an SMPCSI DD statement, the **CSI=dsname** operand is not allowed. If both are specified, SMP/E does not run.

- **DATE=date**
  - where **date** can be one of the following:
    - **U** or **IPL** To use the IPL date of the system.
### PROCESS=WAIT or PROCESS=END

The PROCESS parameter is used to control how long a job should wait if a CSI or PTS data set is not immediately available because it is currently being used either by another job or by a dialog.

- **WAIT** causes the job to wait until the data set is available. A message is issued to the system operator every 30 minutes while the job is waiting.
- **END** causes the job to wait for 10 minutes. If the data set is still not available after the 10-minute wait, the command requiring the data set is stopped.

If **PROCESS** is not specified, the default is **PROCESS=WAIT**.

For more information on obtaining and sharing CSI data sets, see the “Sharing SMP/E Data Sets” appendix in [SMP/E Commands](#).

Processing of the PTS data set is also affected by the WAITFORDSN value specified in its DDDEF entry. WAITFORDSN determines whether SMP/E should wait to allocate a data set that is not immediately available. If the DDDEF entry specifies WAITFORDSN=NO (or lets this value default to NO) and the data set is not available, allocation of the data set fails, regardless of the PROCESS value specified on the EXEC statement. If WAITFORDSN=NO, SMP/E does not wait to retry allocation of the data set.

For example, suppose a PTS with a disposition of OLD is already being used by a job, and a second job tries to access the same PTS data set by allocating it through a DDDEF entry. The DDDEF entry used by the second job for the PTS specifies WAITFORDSN=NO. As a result, allocation of the PTS fails for the second job.
DD statements

DD statements define the data sets that can be used in SMP/E processing. For information on the data sets required for each command, see the chapters on individual SMP/E commands in *SMP/E Commands*.

**Note:** You can use DDDEF entries, rather than DD statements, to allocate many of the necessary data sets. For more information, see "DDDEF entry (distribution, target, and global zone)" on page 197.
Sample cataloged procedure
Chapter 11. Service routines

SMP/E provides several service routines:

- GIMCPTS
- GIMDTS
- GIMGTPKG
- GIMUNZIP
- GIMXSID
- GIMXTRX
- GIMZIP

**GIMCPTS: SYMSPD compaction service routine**

The GIMCPTS service routine is used to compact or expand inline element data within SYMSPDs. The inline element data can be compacted prior to receiving a SYMSPD or SYMSPDs already received can be compacted.

SYMSPDs with their inline element data compacted require less space, so the space requirements of the SMPPTS data set should be reduced. Of course, SMP/E APPLY and ACCEPT processing will expand any compacted inline element data prior to installing the element in a target or distribution library respectively.

GIMCPTS can also be used to expand the inline element data within a SYMSPD. This could be useful if you need to send the SYMSPD to another system where the SMP/E installed on the other system cannot handle compacted inline element data. It could also be useful for viewing inline data. Note that the SMP/E Query Dialogs can be used to view MCS entries from the SMPPTS data set and that SMP/E expands the inline element data before displaying it.

**Note:** GIMCPTS is a separate load module residing in the MIGLIB library that runs independently from the rest of SMP/E processing.

**Calling GIMCPTS**

Following are the JCL statements needed to call GIMCPTS:

```jcl
//JOBx JOB ...
//STEP1 EXEC PGM=GIMCPTS,PARM='options'
//SYSPRINT DD SYSOUT=* 
//SYSUT1 DD DSN=aaaaaaa,DISP=SHR
//SYSUT2 DD DSN=bbbbbbb,DISP=OLD
```

*Figure 84. JCL to call GIMCPTS*

**EXEC**

is the statement used to call GIMCPTS. The EXEC statement must specify

**PGM=GIMCPTS.** The following options may be specified on the EXEC statement PARM operand:

**COMPACT**

The COMPACT option indicates to GIMCPTS the input data is to be
compacted. **COMPACT** is mutually exclusive with **EXPAND**. If neither **COMPACT** nor **EXPAND** is specified, the default is **COMPACT**.

**EXPAND**

The **EXPAND** option indicates to GIMCPTS the input data is to be expanded. **EXPAND** is mutually exclusive with **COMPACT**. If neither **EXPAND** or **COMPACT** is specified, the default is **COMPACT**.

**LANGUAGE=***xxx***

where *xxx* can be one of the following:

- **ENU** US English
- **JPN** Japanese

The **LANGUAGE** option defines which language to use for GIMCPTS messages. **LANGUAGE** can also be specified as **L**. If **LANGUAGE** is not specified, the default is **LANGUAGE=ENU**.

**SYSPRINT**

is used by GIMCPTS for messages.

The record format (RECFM) of SYSPRINT must be FBA, and the record length (LRECL) may be either 81 or 121. GIMCPTS will format messages to 80 characters or 120 characters in length, based on the record length of the SYSPRINT data set.

**SYSUT1**

points to the sequential or partitioned input data. Sequential input data may be a sequential data set or a single member of a partitioned data set. Partitioned input data is an entire partitioned data set (PDS) whose members each contain input data. The actual input data must be the MCS of one or more SYSMODs.

The inline element data within the SYSMODs will be either compacted or expanded, as determined by the **COMPACT** and **EXPAND** options.

The record format (RECFM) of SYSUT1 must be fixed (F), fixed-block (FB), or fixed-block standard (FBS), and the record length (LRECL) must be 80.

**SYSUT2**

points to the sequential or partitioned output destination. If the input is sequential, then SYSUT2 must also be sequential. If the input is partitioned, then SYSUT2 must also be partitioned. The output will contain the input SYSMODs with either compacted or expanded inline element data.

The record format (RECFM) of SYSUT2 must be fixed (F), fixed-block (FB), or fixed-block standard (FBS), the record length (LRECL) must be 80, and the BLKSIZE value must be a multiple of 80.

IBM recommends that SYSUT2 be allocated the same size as the original SMPPTS data set. The amount of compaction that can be achieved will vary depending on the content and packaging method of the SYSMOD in the originating SMPPTS data set. For example, if the originating SMPPTS data set contained only functions packaged in RELFILE format, no compaction would occur.

After GIMCPTS is run, you can release the unused space using ISPF (or other methods). You could also specify RLSE on the SPACE parameter of the SYSUT2 data set (if it is being allocated when GIMCPTS is being run) and z/OS will free unused space when it is closed.
Example

Suppose your system has an existing SMPPTS data set that is quite large and requires the space of an entire physical volume. You can use the SMP/E GIMCPTS compaction service routine to compact data within the members of the SMPPTS. In this example, the existing SMPPTS data set is compacted in place. However, a new data set could be allocated and used to receive the compacted data.

```plaintext
//JOBx  JOB ...
//COMPACT   EXEC PGM=GIMCPTS,PARM='COMPACT,LANGUAGE=ENU'
//*       SYSPRINT DD SYSOUT**
//SYSUT1  DD DSN=SMP.ZOSR1.SMPPTS,DISP=SHR
//SYSUT2  DD DSN=SMP.ZOSR1.SMPPTS,DISP=OLD
```

Figure 85. Sample GIMCPTS jobstream

When this is executed, the GIMCPTS service routine will compact the inline element data within all SYSMOD members in the SMPPTS data set and re-write them to the SMPPTS data set.

**Note**: You should only attempt to compact a partitioned data set in place if it is a PDSE. If the data set is a simple PDS however, it is likely the data set will get an out of space condition during the operation, unless a large amount of free space is available.

Return codes

To help you diagnose errors, GIMCPTS issues messages and return codes. The messages are documented in [SMP/E Messages, Codes, and Diagnosis](#). Here is a description of the return codes:

<table>
<thead>
<tr>
<th>Return code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The input data was processed successfully.</td>
</tr>
<tr>
<td>8</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>• Syntax errors were found in an input SYSMOD.</td>
</tr>
<tr>
<td></td>
<td>• An unsupported compaction dictionary was used to compact data.</td>
</tr>
<tr>
<td></td>
<td>• Compacted data is incomplete.</td>
</tr>
<tr>
<td>12</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>• Data sets were missing.</td>
</tr>
<tr>
<td></td>
<td>• Data sets could not be opened.</td>
</tr>
<tr>
<td></td>
<td>• Data set organization of SYSUT1 and SYSUT2 is not sequential or partitioned.</td>
</tr>
<tr>
<td></td>
<td>• Data set organizations of SYSUT1 and SYSUT2 did not match.</td>
</tr>
<tr>
<td></td>
<td>• SYSUT2 data set had incorrect RECFM or LRECL.</td>
</tr>
<tr>
<td></td>
<td>• SYSUT2 and SYSUT1 data sets are the same data set and they are sequential or members of a PDS.</td>
</tr>
<tr>
<td></td>
<td>• Directory space for SYSUT2 was exceeded.</td>
</tr>
<tr>
<td></td>
<td>• Compression and expansion services are not supported.</td>
</tr>
<tr>
<td>16</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>• An I/O error occurred.</td>
</tr>
<tr>
<td></td>
<td>• Syntax error was found on the EXEC statement parameters.</td>
</tr>
<tr>
<td>20</td>
<td>SYSPRINT data set is missing.</td>
</tr>
<tr>
<td>&gt; 20</td>
<td>Internal error. Report the error to the IBM Support Center.</td>
</tr>
</tbody>
</table>
GIMDTS: Data transformation service routine

Elements may have any of a variety of record formats, depending on how they are meant to be used. However, when elements are packaged inline in a SYSMOD, they must contain fixed-block 80 records. To help you package inline elements, SMP/E provides the GIMDTS service routine. GIMDTS is a background utility program that transforms data into fixed-block 80 records. For example, it can be used to format inline replacements for data elements. Although GIMDTS is packaged as part of SMP/E, it is a separate load module residing in SYS1.MIGLIB and runs independently from the rest of SMP/E processing.

The input for GIMDTS must meet these requirements:

- It must be a sequential data set or a member of a partitioned data set (PDS).
- It can contain either variable-length or fixed-length records.

The output from GIMDTS is in this format:

- It is a sequential data set or a member of a partitioned data set.
- It has these attributes:
  
  RECFM=FB
  LRECL=80
  BLKSIZE=a multiple of 80

After using GIMDTS to transform an element into the required format, you can package the transformed data inline in a SYSMOD, following the associated data element MCS. Later, when the element is installed, it is changed back to its original format.

The following sections describe:

- Statements used to call GIMDTS
- Processing done by GIMDTS
- Return codes issued by GIMDTS

Calling GIMDTS

Here are the JCL statements that are required to call GIMDTS:

```
//JOB JOB 'account','name',MSGLEVEL=(1,1)
//STEP1 EXEC PGM=GIMDTS
//SYSPRINT DD SYSOUT=A
//SYSUT1 DD DSN=aaaaaaa,DISP=SHR
//SYSUT2 DD DSN=bbbbbbb,DISP=SHR
EXEC
    is the statement used to call GIMDTS.
SYSPRINT
    is used by GIMDTS for messages.
SYSUT1
    points to the sequential data set or PDS member containing the data to be transformed.
    The record format (RECFM) must be F, FA, FM, FB, FBA, FBM, V, VA, VM, VB, VBA, VBM, VS, or VBS.
SYSUT2
    points to the sequential data set or PDS member that will contain the transformed data. This data set must be on DASD.
```
The record format of this file should be fixed-block (RECFM=FB) with a
BLKSIZE value that is a multiple of 80.

Processing
GIMDTS first checks for the required data sets, opens the SYSUT1 and SYSUT2
data sets, and makes sure these data sets have the correct attributes. If necessary,
GIMDTS changes the RECFM value of the SYSUT2 data set to FB and the BLKSIZE
value to 3200. Next, GIMDTS reads records from the SYSUT1 data set and
transforms the data.

After processing the data, GIMDTS writes the output records to the SYSUT2 data
set. GIMDTS also issues messages to SYSPRINT indicating the input data set, the
output data set, and the return code. If any errors occur during processing,
GIMDTS issues messages describing the errors and stops processing. If an abend
occurs, normal system abend processing is done.

If SYSUT1 is already fixed-block with LRECL=80 and the data has no "++" characters in columns 1 and 2, then the data needs no transformation and is
simply copied from SYSUT1 to SYSUT2.

Return codes
GIMDTS may issue the following return codes:

<table>
<thead>
<tr>
<th>Return code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>The input data was processed successfully.</td>
</tr>
<tr>
<td>04</td>
<td>The SYSUT2 data set was reblocked.</td>
</tr>
<tr>
<td>08</td>
<td>The input data was not processed successfully.</td>
</tr>
<tr>
<td>16</td>
<td>An I/O error occurred.</td>
</tr>
</tbody>
</table>

GIMGTPKG service routine
The GIMGTPKG service routine is used to get a GIMZIP package from a remote
FTP server in a TCP/IP network and store the package on a local z/OS host.
GIMGTPKG performs the functions of the SMP/E RECEIVE FROMNETWORK
TRANSFERONLY command, but does so independently of SMP/E. It uses FTP to
transport the files of a GIMZIP package from a remote FTP server to a local host,
thus it will provide the following capabilities (which are also available with the
RECEIVE FROMNETWORK command):
• Industry standard FTP protocol.
• Secure transmission using the capabilities of the z/OS FTP client.
• Ensured integrity of the transported files.

GIMGTPKG requires input to define the FTP server and package to be obtained
and to control local host processing. GIMGTPKG depends on the z/OS FTP client
for its FTP operations and on either ICSF or Java 2 Version 1 Release 4 to perform
SHA-1 hash calculations.

GIMGTPKG is an independent load module residing in the MIGLIB library. It has
an addressing mode of 31 (AMODE=31), a residence mode of 24 (RMODE=24),
and requires no special authorization (AC=0). GIMGTPKG runs independently
from the rest of SMP/E processing.
Calling GIMGTPKG

Following are the JCL statements required to call GIMGTPKG.

```
//job      JOB ...
//step     EXEC PGM=GIMGTPKG,PARM='options'
//SMPOUT   DD SYSOUT=
//SYSPRINT DD SYSOUT=
//SMPNTS   DD PATH='package_directory',PATHDISP=KEEP
//SMPCPATH DD PATH='smpclasses_directory', PATHDISP=KEEP
//SMPJHOME DD PATH='javaruntime_directory', PATHDISP=KEEP
//SMPJHOME DD *    server tag and attributes
//SMPCLNT DD *
//client tag and attributes
/*
```

Figure 86. JCL to call GIMGTPKG

EXEC is the statement used to call GIMGTPKG. The EXEC statement must specify PGM=GIMGTPKG. The following option may be specified on the EXEC statement PARM operand:

```
  LANGUAGE=xxx
```

where `xxx` can be either ENU (US English) or JPN (Japanese). The LANGUAGE option defines which language to use for GIMGTPKG messages. LANGUAGE can also be specified as L. If LANGUAGE is not specified, the default is LANGUAGE=ENU.

SMPOUT

used for GIMGTPKG messages. SMPOUT may be sequential, a member of a partitioned data set, or a file in the UNIX file system. See “SMPOUT” on page 155 for information on allocating SMPOUT. GIMGTPKG will format messages to 80 characters in width, regardless of the LRECL for SMPOUT.

SYSPRINT

is used for FTP output. SYSPRINT may be sequential, a member of a partitioned data set, or a file in the UNIX file system. See “SYSPRINT” on page 167 for information on allocating SYSPRINT. GIMGTPKG will format output to 80-characters in width, regardless of the LRECL for SYSPRINT.

SMPNTS

specifies a directory in the UNIX file system where the package to be obtained is to be stored.

SMPCPATH

specifies a directory in the UNIX file system where the SMP/E Java classes reside. The SMPCPATH DD statement is optional and only required to calculate SHA-1 hash values if ICSF is not available.

SMPJHOME

specifies a directory in the UNIX file system where the Java runtime resides. The SMPJHOME DD statement is optional and only required to calculate SHA-1 hash values if ICSF is not available.

SMPSRVR

provides the necessary information about the FTP server from which a package is to be obtained and about the package itself. This package and FTP server
information is specified with the <SERVER> tag. For information on using the <SERVER> tag, see "Content of SERVER Data Set" in [SMP/E Commands].

SMPSRVR may be sequential, a member of a partitioned data set, or a file in the UNIX file system. See "SMPSRVR" on page 160 for information on allocating SMPSRVR.

**SMPCCLNT**

provides information about the local FTP client host, such as information about local firewall navigation. The local FTP client host information is specified with the <CLIENT> tag. For information on using the <CLIENT> tag, see "Content of CLIENT Data Set" in [SMP/E Commands].

SMPCCLNT is an optional DD statement. SMPCCLNT may be sequential, a member of a partitioned data set, or a file in the UNIX file system. See "SMPCCLNT" on page 143 for information on allocating SMPCCLNT.

**Example of using GIMGTPKG**

```
//job  JOB ...
//step EXEC PGM=GIMGTPKG
//SMPOUT DD SYSOUT=*  
//SYSPRINT DD SYSOUT=*  
//SMPNTS DD PATH='/u/usr01/pkgs/',PATHDISP=KEEP
//SMPCPATH DD PATH='/usr/lpp/smp/classes/',PATHDISP=KEEP
//SMPJHOME DD PATH='/*'/usr/lpp/java/J1.4/',PATHDISP=KEEP
//SMPSRVR DD *
<SERVER host="host.sample.com"
  user="usr01"
  pw="n0peekng">
  <PACKAGE file="CBPROC/O12345/RIMTAPE/GIMPAF.XML"
    hash="1234567890123456789012345678901234567890"
    id="O12345">
  </PACKAGE>
</SERVER>
/*
//SMPCCLNT DD *
<CLIENT retry="3">
</CLIENT>
/*
```

*Figure 87. GIMGTPKG example*

In this example, a GIMZIP package residing on the host.sample.com FTP server is transferred onto the local z/OS host and stored in the /u/usr01/pkgs/ directory. The <SERVER> tag and attributes in the SMPSRVR data set describe the FTP server and the package to be obtained. The <CLIENT> tag and attributes in the optional SMPCCLNT data set indicate FTP operations should be retried a maximum of three times if necessary in order to obtain full and accurate package files.

**GIMGTPKG processing**

GIMGTPKG checks the required and optional DD statements that were specified, opens the data sets, and ensures they have the correct attributes.

The remainder of GIMGTPKG processing is much like that for the RECEIVE FROMNETWORK command with TRANSFERONLY (see the RECEIVE Command chapter in [SMP/E Commands]). Briefly, this processing includes the following activities:
GIMGTPKG

- The SMPSRVR and SMPCLNT data sets are read and analyzed. For comparison to the RECEIVE FROMNETWORK command, SMPSRVR is analogous to the SERVER data set and SMPCLNT is analogous to the CLIENT data set.
- The package directory is a specific subdirectory of the SMPNTS directory and is the destination on the local host for the GIMZIP package files to be stored. The name of this subdirectory is the package-id value from the SMPSRVR data set. If the package directory does not already exist, then it is created.
- Each of the files in the GIMZIP package on the FTP server are retrieved and stored in the package directory created in the previous step. Each file is verified by computing an SHA-1 hash value for the file.
- After all files have been transferred successfully, then, if any archive files in the package have been segmented, the segments are combined to create complete archive files.

Return codes
GIMGTPKG may complete with any of the following return codes.

<table>
<thead>
<tr>
<th>Return code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>GIMGTPKG processing completed successfully.</td>
</tr>
</tbody>
</table>
| 12          | One of the following:  
  - Required data sets were missing or could not be opened.  
  - Required modules could not be loaded.  
  - Syntax error was found in the SMPSRVR or SMPCLNT tags.  
  - An FTP error was detected.  
  - Neither ICSF or Java 2 Version 1 Release 4 is available. |
| 16          | One of the following:  
  - An I/O error occurred.  
  - Syntax error was found on the EXEC statement parameters. |
| 20          | The SMPOUT data set is missing. |

GIMUNZIP file extraction service routine

The GIMUNZIP service routine is used to extract data sets, files, and directories from archive files in GIMZIP packages created by the GIMZIP service routine. These packages typically contain software and associated materials in the form of SYSMODs, RELFILE data sets, HOLDDATA, and other materials such as documentation, samples, and text files. These GIMZIP packages may be transported through a network, processed by the GIMUNZIP service routine, and then processed by the SMP/E RECEIVE command.

More specifically, the GIMUNZIP service routine extracts data sets, files, and directories from the archive files that compose the GIMZIP package. An archive file consists of a portable image of a sequential, partitioned, or VSAM data set, or a file or directory in a UNIX file system, and the information needed to create that data set, file, or directory from the portable image. The data set, file, or directory into which the archive file is to be extracted can already exist or GIMUNZIP can create a new one of the appropriate type. New sequential and partitioned data sets created by GIMUNZIP are always catalogued.

Notes:
1. GIMUNZIP is a separate load module residing in the MIGLIB library and runs independently from the rest of SMP/E processing.
2. GIMUNZIP optionally requires either the Integrated Cryptographic Services Facility (ICSF) One-Way Hash Generate callable service or Java Version 1 Release 4 to be available for its use in order to compute an SHA-1 hash value.

**Calling GIMUNZIP**

The following figure shows the job control statements for GIMUNZIP:

```plaintext
//JOBx JOB ...
//STEP1 EXEC PGM=GIMUNZIP,PARM='options'
//SMPDIR DD PATH='package_directory',PATHDISP=KEEP
//SMPKDIR DD PATH='work_directory',PATHDISP=KEEP
//SMPJPATH DD PATH='smpclasses_directory',PATHDISP=KEEP
//SMPJHOME DD PATH='javaruntime_directory',PATHDISP=KEEP
//SMPOUT DD SYSOUT=*  
//SYSPRINT DD SYSOUT=*  
//SYSUT3 DD UNIT=SYSALLDA,SPACE=(CYL,(50,10)) 
//SYSUT4 DD UNIT=SYSALLDA,SPACE=(CYL,(25,5))  
//SYSIN DD *  
// package control statements
/*
Figure 88. JCL to call GIMUNZIP
```

**EXEC**

is the statement used to call GIMUNZIP. The EXEC statement must specify PGM=GIMUNZIP. The following options may be specified on the EXEC statement PARM operand:

**LANGUAGE=xxx**

where xxx can be one of the following:

- **ENU** US English
- **JPN** Japanese

The LANGUAGE option defines the language to use for GIMUNZIP messages.LANGUAGE can also be specified as L. If LANGUAGE is not specified, the default is LANGUAGE=ENU.

**HASH=xxx**

where xxx can be one of the following:

- **YES** indicates GIMUNZIP is to perform SHA-1 hash checking for the archive files specified in the SYSIN data set.

  **Note:** GIMUNZIP requires either the Integrated Cryptographic Services Facility (ICSF) One-Way Hash Generate callable service or Java 2 Version 1 Release 4 to be available in order to compute an SHA-1 hash value.

- **NO** indicates GIMUNZIP is not to perform SHA-1 hash checking for the archive files specified in the SYSIN data set.

  HASH can also be specified as H. If HASH is not specified, the default is HASH=NO.

**SYSIN**

specifies a control data set that contains the package control tags to control GIMUNZIP processing (see "GIMUNZIP package control tags” on page 456). The control data set may be a sequential data set or a single member of a partitioned data set, and its attributes must be LRECL=80 and RECFM=F or FB.
GIMUNZIP package control tags

GIMUNZIP service routine processing is controlled by package control tags. The package control tags identify the archive files to be extracted by GIMUNZIP and are specified in the SYSIN data set. The package control tags follow XML syntax rules and their format is as follows:
<GIMUNZIP> Tag syntax
The <GIMUNZIP> and corresponding </GIMUNZIP> tags identify the beginning and end of a set of archive retrieval requests.

<ARCHDEF> Tag syntax
The <ARCHDEF> and corresponding </ARCHDEF> tags identify the beginning and end of a specific archive retrieval request. The following attributes may be found on the <ARCHDEF> tag:

name="archive name"
specifies the path name for an archive file to be extracted by GIMUNZIP. The path name may include a subdirectory name (provided by the subdir attribute when the archive was created by GIMZIP). The path name value is a relative value and it is relative to the package directory specified on the SMPDIR DD statement. The name attribute is mutually exclusive with the archid attribute.

Note: If the archive file has been segmented in the package, you should specify the name of the archive file, not the names of the archive segment files. GIMUNZIP will combine the associated archive segment files to extract the complete archive.

archid="archive id"
specifies a unique archive id associated with an archive file to be extracted by GIMUNZIP. GIMUNZIP will search the package attribute file looking for the archive file with this unique archid. The archid attribute is mutually exclusive with the archive name attribute.

tvolume="data set volume | *"
specifies the volume serial number of the volume on which GIMUNZIP is to request the allocation of the data set to be extracted from the archive file. The volume identifier must be from 1 to 6 alphanumeric characters or an asterisk (*).
GIMUNZIP

Notes:

1. If you are extracting a sequential, partitioned, or VSAM data set into an existing cataloged data set, you should not specify the volume attribute.

2. If you are extracting a sequential or partitioned data set:
   - Into a new data set to be allocated on a specific volume, or into an existing, uncataloged data set on a specific volume, you must specify volume=data set volume. If you specify volume=* it is ignored.
   - Into an existing, uncataloged data set on a specific volume, you must specify volume=data set volume. If you specify volume=* it is ignored.
   The data set is first allocated with a disposition of (OLD,KEEP) using the specified volume. If the data set is not on the volume, the data set is allocated again with a disposition of (OLD,KEEP) without specifying a volume, to see if there is an existing cataloged data set that should be used for the extraction. If an existing cataloged data set is allocated, the archive is extracted into the cataloged data set, even though the volume on which it is allocated is different from the volume specified.

3. If you are extracting a VSAM data set:
   - Into a new data set, you can specify volume=data set volume,
     Or,
     You can specify volume*, GIMUNZIP uses the value on the VOLUMES parameter on the IDCAMS DEFINE command that GIMUNZIP will generate to create the new VSAM data set. Using the VOLUMES(*) parameter on the generated IDCAMS DEFINE command may allow SMS to assign a volume for the new VSAM data set if the automatic class selection (ACS) routines allow it.
   - Into an existing destination data set, a data set volume you specify on the volume attribute is ignored.
     Since VSAM data sets must be cataloged, the catalog is checked first to see if the VSAM destination data set already exists.

4. If you specify volume=data set volume, GIMUNZIP will use the specified volume to dynamically allocate work space to the SYSUT1 ddname during the processing of the archive. If you do not specify the volume attribute or you specify volume*, then you must make available at least one volume of mounted storage or the allocation to the SYSUT1 ddname will fail.

5. If you are extracting a UNIX file or directory, you do not need to specify the volume attribute. It is ignored. However, if you specify a volume attribute, it must be syntactically correct.

newname="name"

specifies the data set name or absolute pathname to use for the data set or file to be extracted from the archive file. This name replaces the original name of the data set or file that is recorded in the archive’s file attribute file.

The newname specified must identify the same type of data as the file being unzipped. That is, if the file being unzipped is a data set, newname must represent a data set. If the file being unzipped is a file or directory in the UNIX file system, newname must represent a file or directory in the UNIX file system.

The first character of an absolute pathname of a file or directory in the UNIX file system must be a slash (/). If the newname value does not begin with a slash, GIMUNZIP processing will assume that it is an MVS data set name and that it will conform to the MVS data set naming conventions. If the newname value does begin with a slash, it is assumed to be a file or directory in the
UNIX file system. When a file or directory in the UNIX file system is specified, the newname value can be from 1 to 1023 bytes long with 255 characters between delimiters (/). The value can be any character from X'40' through X'FE', except less than (<) and greater than (>) signs, ampersands (&), and double quotation marks ("). All data beyond column 72 is ignored, including blanks. The pathname of a file or directory in the UNIX file system is case sensitive and will not be converted to uppercase alphabetic during processing of the GIMUNZIP package control tags.

The newname specified may identify an existing data set, directory, or file. In this case, the archived file is unzipped into the existing data structure specified on the newname attribute. If the newname attribute is not specified for a file or directory in the UNIX file system, the original name for the file or directory is used. If neither the prefix nor the newname attributes are specified when a data set is being extracted, the original name for the data set is used.

prefix="data set prefix"

specifies a data set prefix to use for the data set to be extracted from the archive file. This prefix replaces the high-level qualifier of the original name for the data set as recorded in the archive's file attribute file. The specified data set prefix can be up to 26 characters long and must conform to standard data set naming conventions.

The resolved name using the prefix attribute may be for an existing data set. In this case, the archived data is extracted into the existing data set specified using the prefix attribute.

A prefix value has no meaning when the file being unzipped is a file or directory in the UNIX file system. In this case, the prefix value is parsed but ignored.

If neither the prefix nor the newname attributes are specified, the original name for the data set is used.

replace="YES | NO"

indicates whether data in an existing data set, file or directory should be replaced by data from the archive file. A value of YES indicates the data in the existing data set, file or directory should be replaced. A value of NO is equivalent to not specifying the replace attribute and indicates the data should not be replaced. The replace attribute is not meaningful when the data set, file or directory does not already exist.

- For an archive of a partitioned data set or directory in the UNIX file system, replace="YES" indicates that existing members in a partitioned data set and files in a directory will be replaced by members or files with the same name from the archive file. If replace="NO" is specified, or if the replace attribute is not specified at all, existing members and files will not be replaced.
- For an archive of a sequential data set or a file in the UNIX file system, replace="YES" indicates the existing data set or file and its attributes will be replaced with the data from the archive file. If replace="NO" is specified, or if the replace attribute is not specified at all, the existing sequential data set or file will not be replaced with the data from the archive file.

Note: GIMUNZIP will not check if a sequential data set or file is empty. If the data set or file exists, it will not be replaced unless replace="YES" is specified.

- For a VSAM data set (cluster), replace="YES" indicates that an existing VSAM cluster should be populated with the data from the archive file. If
replace="NO" is specified, or if the replace attribute is not specified at all, there will be no attempt to populate the existing VSAM cluster with the data from the archive.

Notes:
1. The existing VSAM cluster must be of the same type as the archived cluster (ESDS, KSDS, LDS, or RRDS).
2. The existing VSAM cluster must have characteristics that are compatible with the archived cluster (such as, record size, key size, and key offset). GIMUNZIP does not verify the compatibility of these characteristics.
3. To replace the contents of an existing cluster, the cluster is altered to a reusable state by using an IDCAMS ALTER command, if necessary, before the data from the VSAM archive is copied into the cluster by using an IDCAMS REPRO command. The REPRO command will use both the REPLACE and REUSE operands. Following the REPRO operation, the cluster is altered back to a nonreusable state if that was its state to begin with.

preserveid="YES | NO"
indicates whether the UID and GID of the extracted file or directory should:
  Remain as defined when the archive was created, or
  Inherit the UID and GID of the userid performing the extract operation (GIMUNZIP).

A value of YES indicates that the UID and GID from when the archive was created will be preserved. A value of NO is equivalent to not specifying the preserveid attribute and indicates that the UID and GID should be inherited from the userid performing the extract operation (GIMUNZIP).

Notes:
1. Preserving the UID and GID defined when the archive was created may cause GIMUNZIP to fail if the installer does not have the proper permissions.
2. The preserveid attribute applies only when extracting a UNIX file or directory from an archive. When extracting a data set, preserveid is parsed for syntax but otherwise ignored.

Syntax notes
1. GIMUNZIP ignores columns 73 through 80. If data is specified beyond column 72, GIMUNZIP ignores it, which may lead to the diagnosis of an error in a following tag.
2. Package control tags may contain comments. Comments start with <!-- (hex 4C5A6060) and end with --> (hex 60606E). The first --> encountered after the initial <!-- will end the comment. A comment may appear between a start-tag and its matching end-tag, but never within a tag.

Example of using GIMUNZIP
Suppose a GIMZIP package contains a set of archive files and you want to extract the data sets and files from those archive files. In addition, you wish to verify the integrity of the archive files and rename the destination data sets and files in the process. The following job stream can be used to perform such an operation.
GIMUNZIP processing

The GIMUNZIP service routine extracts data sets and files from the archive files that compose the GIMZIP package. An archive file consists of a portable image of a data set or file and the information needed to reload the data from the portable image (see "Archive files" on page 492 for details on archive file contents and construction).

GIMUNZIP uses the UNIX System Services pax command to expand the following component files from an archive file temporarily into a UNIX file system:
1. the portable image of the original data set or file, and
2. the file attribute file that contains the information necessary to reload the data from the archived data set or file.

GIMUNZIP then reads the file attribute file and uses the information recorded there, along with information specified on the <ARCHDEF> tag, such as volume, newname, or prefix, to allocate a new or existing data set or file. The portable image of the original data set or file is stored in the data set or file just allocated for that purpose.

Figure 89. GIMUNZIP example

Note: Blank lines and spaces have been added to the package control tags for clarity, but are not required.
GIMUNZIP

When GIMUNZIP encounters a package that contains archive segments, GIMUNZIP reassembles the archive segments into the original archive form, optionally verifies the integrity of the archive, and recreates the original data.

If the HASH=YES option was specified, then GIMUNZIP performs SHA-1 hash checking for the archive files. Specifically, GIMUNZIP reads the package attribute file for the package. The package attribute file, GIMPAF.XML, is found in the package directory, and contains the known hash values for the archives. These hash values were recorded by GIMZIP when the package and archives were created. GIMUNZIP then uses either ICSF services or Java 2 programs to compute the current hash values for the archive files, and compares this value to the known hash values for the archive files.

If the computed hash value matches the known hash value, then the integrity of the archive file is ensured. However, if the computed hash value does not match the known hash value, GIMUNZIP processing stops. This condition indicates the archive file has been corrupted since it was produced by GIMZIP when the package was created.

Sample RECEIVE job for GIMUNZIP output

After GIMUNZIP has been run, the SMP/E RECEIVE command can be used to process the data sets and files extracted by GIMUNZIP. Here is a sample RECEIVE job that would process the SMPMCS and RELFILE data sets and files extracted by GIMUNZIP in the sample in Figure 2:

```verbatim
//JOBx  JOB ...
/STEP1  EXEC OPM=GIMSMP
//SMPCSI  DD DSN=SMPE.GLOBAL.CSI,DISP=SHR
//SMPPFIN  DD DSN=USERID.FMID001.SMPMCS,DISP=SHR
//SMPCNTL  DD *
  SET BDY(GLOBAL).
  RECEIVE SYSMDS
  RFPPREFIX(USERID).
/*
```

Figure 90. Sample RECEIVE job for GIMUNZIP

Return codes

GIMUNZIP may end with the following return codes:

<table>
<thead>
<tr>
<th>Return code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>The input data was processed successfully.</td>
</tr>
<tr>
<td>04</td>
<td>A call to a system service may not have completed successfully.</td>
</tr>
<tr>
<td>12</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>• Required file attributes could not be obtained.</td>
</tr>
<tr>
<td></td>
<td>• Input files were not sequential, partitioned, or VSAM data sets,</td>
</tr>
<tr>
<td></td>
<td>or files and directories in the UNIX file system</td>
</tr>
<tr>
<td></td>
<td>• Call to a required system service failed.</td>
</tr>
<tr>
<td></td>
<td>• Syntax errors in the SYSIN data set.</td>
</tr>
<tr>
<td></td>
<td>• Data sets could not be opened.</td>
</tr>
<tr>
<td></td>
<td>• SMPDIR was not allocated to a UNIX directory.</td>
</tr>
<tr>
<td></td>
<td>• Data sets, files, or directories were missing.</td>
</tr>
<tr>
<td></td>
<td>• Required modules could not be loaded.</td>
</tr>
<tr>
<td></td>
<td>• Existing data set, file, or directory is not compatible.</td>
</tr>
<tr>
<td></td>
<td>• Existing data set, file, or directory could not be replaced.</td>
</tr>
</tbody>
</table>
One of the following:
- An I/O error occurred.
- A syntax error was found on the EXEC statement parameters.

SMPOUT data set is missing.

Internal error. Report the error to the IBM Support Center.

GIMXSID software inventory data service routine

GIMXSID is an SMP/E service routine to be used as part of the ShopzSeries offering. GIMXSID creates a single data source required by ShopzSeries to place customized software product and service orders. The data source created by GIMXSID, the software inventory data, is a composite of three kinds of information as follows:

Feature list
   a list of FEATUREs found in the SMPCSI data sets. The Feature List is used by ShopzSeries to perform product requisite checking and also to prime the order checklist when ordering a ServerPac.

FMID list
   a list of the FMIDs found in the SMPCSI data sets. The FMID List is used by ShopzSeries to scope service orders to the PTFs applicable solely to the user's desired configuration of target and global zones.

PTF bitmap
   a bitmap representation of the PTFs found in the specified target zones and global zones. The PTF Bitmap is used by ShopzSeries to produce service packages that do not contain PTFs that are already present in the user's configuration.

GIMXSID is an independent load module residing in the MIGLIB library. It has an addressing mode of 31 (AMODE=31), a residence mode of 24 (RMODE=24), and is not authorized (AC=0). GIMXSID runs independently from the rest of SMP/E processing.

Calling GIMXSID

The JCL statements needed to call GIMXSID are:

```
//job JOB ...
//step EXEC PGM=GIMXSID,PARM='options'
//SMPOUT DD SYSOUT=*
//SMPXTOUT DD DSN=output.dataset,DISP=(NEW,CATLG),
// SPACE=(TRK,(1,1)),UNIT=SYSALLDA
//SYSSIN DD *
//input control statements
/*
```

Figure 91. JCL to call GIMXSID

EXEC

is the statement used to call GIMXSID. The EXEC statement must specify
PGM=GIMXSID. The following options may be specified on the EXEC statement PARM operand:

```
LANGUAGE=ENU | JPN
```

The LANGUAGE option defines which language to use for GIMXSID
GIMXSID

messages. ENU is for US English, and JPN is for Japanese. LANGUAGE can also be specified as L. If LANGUAGE is not specified, the default is LANGUAGE=ENU.

WAIT=minutes MIN
where minutes is a decimal number between 0 and 9999. The WAIT option is used to control how long GIMXSID should wait if an SMPCSI data set is unavailable because it is in use by another SMP/E task.

WAIT=minutes MIN causes GIMXSID to wait for a data set for the specified number of minutes. If a data set is still not available after the specified number of minutes, then GIMXSID stops. If WAIT is not specified, the default is WAIT=60MIN.

WAIT may be specified as WAIT=minutes MIN or WAIT=minutes. The MIN keyword is optional.

SMPOUT
used for GIMXSID messages. The RECFM must be FBA and the LRECL must be 81 or 121. GIMXSID formats messages to 80 characters in length, regardless of the LRECL for SMPOUT.

SMPXTOUT
the output specification for the software inventory data collected by GIMXSID. The output can be a sequential data set, a member of a partitioned data set, or a file in a UNIX file system. If a data set, the RECFM must be FB and the LRECL must be 12560. If a file in a UNIX file system, then FILEDATA=BINARY and PATHOPTS(OWRONLY) must be specified on the DD statement.

SYSIN
specifies an input data set that contains the GIMXSID control statements. The input data set may be sequential, or a member of a partitioned data set. The RECFM must be F or FB and the LRECL must be 80.

GIMXSID control statements
Following are the control statements used to direct the processing for GIMXSID. These control statements are specified in the SYSIN data set.

CSI=dsname
indicates the data set name for an SMPCSI data set containing a global zone. This is a required control statement. There can be multiple CSI statements to identify multiple SMPCSI data sets and global zones to be processed.

dsname can be up to 44 characters long and must conform to standard data set naming conventions

TARGET=zone, zone, ...
indicates the target zones controlled by the global zone identified on the preceding CSI statement that are to be processed. There can be multiple instances of the TARGET statement to allow many target zones to be specified. The zone values can be from 1 to 7 characters and must be separated by a comma and zero or more blank characters, or, one or more blank characters.

This is an optional control statement. If a TARGET statement is not specified following a CSI control statement, all target zones controlled by the global zone identified on the preceding CSI statement are processed.

Syntax notes
1. Control statements must each start on a new line.
2. Control statements can begin in any column of a line.
GIMXSID

3. Control statements must end on the same line on which they begin (control statements cannot span records).
4. SMP/E ignores columns 73 through 80 of lines in the SYSIN data set.

Example of using GIMXSID

```
//job
//BITMAP EXEC PGM=GIMXSID
//SMPOUT DD SYSOUT=* 
//SMPXTOUT DD DSN=userid.GIMXSID.OUTPUT,DISP=(NEW,CATLG), 
//SPACE=(TRK,(1,1)),UNIT=SYSALLDA 
//SYSIN DD *
CSI=SMPE.ZOS.GLOBAL.CSI 
TARGET=ZOS14, JES314 
CSI=SMPE.DB2.GLOBAL.CSI 
/*
```

Figure 92. GIMXSID example

In this example, the ZOS14 and JES314 target zones are processed from the global zone in the SMPE.ZOS.GLOBAL.CSI data set. In addition, all target zones from the global zone in the SMPE.DB2.GLOBAL.CSI data set are processed.

Processing

There are several phases of GIMXSID processing described below in detail.

Initialization

GIMXSID first verifies that the SMPOUT data set, which is used for messages, is available. If SMPOUT is not allocated or cannot be opened, there is nowhere to write a message. Therefore, GIMXSID terminates with a return code of 20.

GIMXSID then checks for the required data sets, opens these data sets, and ensures they have the correct attributes.

Read and verify control statements

After the required data sets have been verified, GIMXSID reads the input control statements from the SYSIN data set. The CSI control statement is a required control statement and must precede any TARGET control statements. For each data set specified on a CSI control statement, GIMXSID ensures that the data set exists.

Verifying the target zones

For each SMPCSI data set specified on a CSI control statement, a list of target zones may be specified on one or more TARGET control statements. If target zones are specified, GIMXSID ensures that the specified zones exist and are in fact target zones.

Accessing resources

When reading SMPCSI data sets, it is possible one or more data sets are unavailable for use by GIMXSID because the data sets are being used by another SMP/E task. If so, GIMXSID waits for the data sets to become available based on the value of the WAIT option (see "Calling GIMXSID" on page 463).

If a global zone data set or a target zone data set is not available, then GIMXSID will wait until the data set is available, or until the number of minutes specified on the WAIT option have elapsed (or 60 minutes by default). During the WAIT time, GIMXSID attempts to read the data set every 30 seconds, just in case it becomes available.
available. If the specified number of minutes elapses and one or more of the data sets are still not available, processing stops.

If \texttt{WAIT=0MIN} was specified, GIMXSID does not wait for SMPCSI data sets to become available. The initial attempt is made to access the data sets, and if they are not available, GIMXSID does not wait or make additional access attempts.

The number of minutes specified on the \texttt{WAIT} option (or defaulted) is the total time GIMXSID waits for all data sets. For example, if \texttt{WAIT=60MIN} was specified and the first SMPCSI data set causes a wait of 40 minutes, GIMXSID waits only a maximum of 20 additional minutes for all subsequent SMPCSI data sets.

**Building the GIMXSID record**

To identify itself as the creator of the software inventory data, GIMXSID creates a GIMXSID record and writes it to the output data set. This GIMXSID record is the first record in the output data set, but will be written only if there is software inventory data to produce (that is, if there are other records to be written). This GIMXSID record provides the name and service level of the program that produced the software inventory data, as well as the date and time it was produced. Table 57 shows the format of the GIMXSID record.

**Table 57. GIMXSID record format**

<table>
<thead>
<tr>
<th>Field</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header</td>
<td>60</td>
<td>The value is “GIMXSID” padded to the right with blanks, to indicate the record type, and to identify the name of the program used to create the software inventory data.</td>
</tr>
<tr>
<td>Version</td>
<td>2</td>
<td>Two character representation of the version level of GIMXSID.</td>
</tr>
<tr>
<td>Release</td>
<td>2</td>
<td>Two character representation of the release level of GIMXSID.</td>
</tr>
<tr>
<td>Modification</td>
<td>2</td>
<td>Two character representation of the modification level of GIMXSID.</td>
</tr>
<tr>
<td>PTF</td>
<td>3</td>
<td>Two character representation of the PTF level of GIMXSID, padded to the right with a blank.</td>
</tr>
<tr>
<td>Date</td>
<td>9</td>
<td>The date the software inventory data was created, padded to the right with a blank. The date value is of the form \texttt{mm/dd/yy}.</td>
</tr>
<tr>
<td>Time</td>
<td>8</td>
<td>The time the software inventory data was created. The time value is of the form \texttt{hh:mm:ss}.</td>
</tr>
<tr>
<td>Reserved</td>
<td>12474</td>
<td>Reserved field, padded with blanks.</td>
</tr>
</tbody>
</table>

**Building the feature list**

The Feature List segment of the software inventory data contains the combined Feature information from all specified SMPCSI data sets. For each SMPCSI data set specified on a CSI control statement:

- If target zones were specified on one or more TARGET control statements for an SMPCSI data set, then the Feature List for that SMPCSI contains all FEATURE subentries found in FUNCTION SYSMOD entries from all specified target zones.
- If no target zones were specified for an SMPCSI data set, then the Feature List for that SMPCSI contains the name of all FEATURE entries found in the global zone, in addition to all FEATURE subentries found in FUNCTION SYSMOD entries from all target zones in the SMPCSI data set.

No regard is paid to the ERROR status of the FUNCTION SYSMOD entries; if a FUNCTION SYSMOD entry happens to be in ERROR, then it is assumed an overt
GIMXSID

A single FEATURE may be represented in the output data set with more than one
FEATURE record. Although an unlikely case, it is necessary only to accommodate a
FEATURE that contains more FMID s than can fit in the FMID List field of a single
FEATURE record.

**Building the FMID list**
The FMID List segment of the software inventory data contains the combined
FMID information from all specified SMPCSI data sets. For each SMPCSI data set
specified on a CSI control statement:

---

**Table 58. FEATURE record format**

<table>
<thead>
<tr>
<th>Field</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header</td>
<td>8</td>
<td>Value is “FEATURE” to indicate the record type, padded to the right with blanks.</td>
</tr>
<tr>
<td>Feature Name</td>
<td>52</td>
<td>Feature name, padded to the right with blanks.</td>
</tr>
<tr>
<td>Product-id</td>
<td>9</td>
<td>The product identifier of the feature’s associated product, padded to the right with blanks.</td>
</tr>
<tr>
<td>VRM</td>
<td>9</td>
<td>The version, release, and modification level of the feature’s associated product, padded to the right with blanks. This field is of the form vv:rr:mm where vv is the version, rr is the release, and mm is the modification level. This field may be all blank if the FEATURE entry is not found in a global zone in an SMPCSI data set.</td>
</tr>
<tr>
<td>reserved</td>
<td>5</td>
<td>This field is reserved for future use.</td>
</tr>
<tr>
<td>Description</td>
<td>65</td>
<td>A text description for the feature, padded to the right with blanks. This field may be all blank if the FEATURE entry is not found in a global zone in an SMPCSI data set.</td>
</tr>
<tr>
<td>FMID List</td>
<td>12412</td>
<td>List of function SYSMODs that make up this feature. This field is a list of 7-byte FMID names separated by one blank space, padded to the right with blanks. This field may be all blank if the FEATURE entry is not found in a global zone in an SMPCSI data set, or the FMID subentry is not found for the FEATURE entry.</td>
</tr>
</tbody>
</table>
If target zones were specified on one or more TARGET control statements for an SMPCSI data set, then the FMID List for that SMPCSI contains the names of all FUNCTION SYSMODs found in all specified target zones.

If no target zones were specified for an SMPCSI data set, then the FMID List for that SMPCSI contains the names of all FUNCTION SYSMODs found in the global zone, in addition to the names of all FUNCTION SYSMODs found in all target zones for the SMPCSI data set.

No regard is paid to the ERROR status of the FUNCTION SYSMOD entries; if a FUNCTION SYSMOD entry happens to be in ERROR, then it is assumed an overt attempt was made to install the FUNCTION and therefore its presence should be noted. However, if a FUNCTION SYSMOD in a target zone has been superseded or deleted, then it is ignored.

The individual FMID Lists from each specified SMPCSI are then merged to create the total FMID List. That is, the total FMID List set is the union of the individual sets.

The total FMID List is represented in the output data set using the definition for PRODLIST records. Multiple PRODLIST records may be produced in order to contain the complete list of FMIDs.

Table 59. PRODLIST record format

<table>
<thead>

</tr>
<tr>
<td>FMID List</td>
<td>12500</td>
<td>List of 7-byte FMID names separated by one blank space, padded to the right with blanks.</td>
</tr>
</tbody>
</table>

**Building the PTF bitmap**

The PTF Bitmap segment of the software inventory data contains a composite of PTF information from all specified SMPCSI data sets. The point of the PTF Bitmap is to identify all PTFs that are already "on-site" and therefore do not need to be included in a service order. That is, there is no need to deliver PTFs that are already applied in all target zones in which they could be applied, or are already in the global zones and could be applied to any target zone as needed.

For each SMPCSI data set specified on a CSI control statement, the individual zones to be processed when creating the PTF information are determined as follows:

- If target zones were specified on one or more TARGET control statements for an SMPCSI data set, then those target zones are the current set of zones to be processed.
- If no target zones were specified for an SMPCSI data set, then all target zones in the global zone, and the global zone itself, are the current set of zones to be processed.

For this discussion, a PTF is considered applicable to a target zone if the PTF’s FMID is applied in that target zone. A PTF is considered applicable to a global zone if the PTF’s FMID is received in the global zone. A PTF is considered applicable to an SMPCSI data set if the PTF is applicable to any of the zones in the current set, as determined above.
The PTF information for an individual SMPCSI data set contains all PTFs that are received in the global zone, or are applied in all target zones of the current set in which they are applicable. Such PTFs are deemed "present" in an SMPCSI data set. That is, such PTFs can be considered already present and therefore no need exists to deliver such PTFs on behalf of this SMPCSI, because they are either already in the global zone and can be applied to any target zone, or they are already applied in all target zones in which they could be applied.

A PTF is considered applied in a target zone whether or not it is superseded. A PTF is not considered applied in a target zone, or received in a global zone, if it’s SYMMD entry is in ERROR status. Further, it is not always possible to know the SYMMD TYPE for a SYMMD that has been superseded in a target zone. Therefore, if the name of such a SYMMD follows the IBM naming convention for PTFs, then it is assumed to be a PTF and its presence is noted. Specifically, if the first character of the name of such a SYMMD is a character in the set “LMNOPQRSTU” and the last five characters of the name are numeric, then it is assumed to be a PTF.

The PTF information from each individual SMPCSI data set is combined to create the total PTF Bitmap. A PTF is included in the PTF Bitmap if and only if it is present in all SMPCSI data sets in which it is applicable. Stated another way, if a PTF is applicable to n SMPCSI data sets, but it is present in only \( n-1 \) or fewer SMPCSI data sets, then that PTF cannot be included in the PTF Bitmap.

The total PTF Bitmap is represented in the output data set using the definition for BITPTF records. Multiple BITPTF records may be produced in order to contain the total PTF Bitmap.

**Table 60. BITPTF record format**

<table>
<thead>
<tr>
<th>Field</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header</td>
<td>6</td>
<td>Value is &quot;BITPTF&quot; to indicate the record type. BITPTF indicates the record contains a PTF identification bit-string.</td>
</tr>
<tr>
<td>PTF Prefix</td>
<td>54</td>
<td>A two-character PTF prefix value, padded to the right with blanks. The PTF prefix value is the first two alphabetic characters in a PTF name. For example, &quot;UR&quot; or &quot;UW&quot;.</td>
</tr>
<tr>
<td>Bit-String</td>
<td>12500</td>
<td>Bit-string where each bit represents a number from 00001 to 99999. The numbers from 00001 to 99999 correspond to the last five numeric characters in a PTF name. The position of a particular bit corresponds to a particular number from 00001 to 99999. This number, combined with the PTF prefix, represent a specific PTF name. For example, if the PTF prefix is &quot;UW&quot; and the 12345th bit is on, then the PTF with the name &quot;UW12345&quot; is represented.</td>
</tr>
</tbody>
</table>

**Zone and data set sharing considerations**

GIMXSID uses the system enqueue facility to control access to SMPCSI data sets. The following identifies the phases of GIMXSID processing and the zones and data sets GIMXSID may require for shared use during those phases.
1. Initialization
Global zones (as specified on CSI control statements) Read with shared enqueue.

2. Processing
Global zones (as specified on CSI control statements) Read with shared enqueue.
Target zones (as specified on TARGET control statements) Read with shared enqueue.

3. Termination
All resources are freed.

Return codes
GIMXSID may complete with any of the following return codes.

Return code   Meaning
00             GIMXSID processing completed successfully.
12             One of the following:
               • Required data sets were missing or could not be opened.
               • Required modules could not be loaded.
               • Syntax error was found in the SYSIN control statements.
               • SMP CSI data sets were not available.
               • Specified zones were not defined or are not target zones.
16             One of the following:
               • An I/O error occurred.
               • Syntax error was found on the EXEC statement parameters.
20             The SMPOUT data set is missing.

GIMXTRX service routine
GIMXTRX is intended for use as part of an offering called ShopzSeries. It provides two basic functions:

List target zone names (LSTTZN)
Generate a list of target zone names associated with a given GLOBAL zone SMP CSI data set name.

Create a BITMAP of an SMP CSI (BMPTZN)
Generate a BITMAP representation of FUNCTION and PTF SYSMODs found in a given list of target zone names associated with a given GLOBAL zone SMP CSI data set name.

The input to GIMXTRX is the name of a data set that contains the input parameters. See "Input parameter data set contents" on page 471.

The results of each function are written to a data set created by GIMXTRX. See "Processing" on page 474.

Note: GIMXTRX is a separate load module residing in the MIGLIB library and runs independently from the rest of SMP/E, and is executable on a z/OS, OS/390, or MVS system; it will not run on VM.
Calling GIMXTRX

GIMXTRX has normal standard linkage and expects an input parameter that is a character string that is a data set name. Following are the JCL statements needed to call GIMXTRX:

```
//JOBx JOB ...
//XTRX EXEC PGM=GIMXTRX,PARM='parmdsn'
//SYSTSPRT DD SYSOUT=(*)
//SMPXTOUT DD DSN=outputsdsn,DISP=(NEW,CATLG),
//    UNIT=unit,SPACE=(TRK,(2,1))
```

*Figure 93. JCL to call GIMXTRX*

**EXEC**

is the statement used to call GIMXTRX. The EXEC statement must specify PGM=GIMXTRX. The following option must be specified on the EXEC statement PARM operand:

```
parmdsn
```

name of the data set that contains the input parameters required for the GIMXTRX function. See [Input parameter data set contents] for a description of the data contained in the input parameter data set.

**SYSTSPRT**

is used by GIMXTRX for messages. The record format (RECFM) of SYSTSPRT must be FBA, and the record length (LRECL) must be 121. GIMXTRX will format messages to 120 characters in length.

**Note:** GIMXTRX messages are only issued in the U.S. English language.

**SMPXTOUT**

is the output data set. This DD statement is optional. If SMPXTOUT is specified, GIMXTRX writes the output to the identified data set. If SMPXTOUT is not specified, GIMXTRX allocates a new data set for the output. SMPXTOUT must be a sequential data set, the record format (RECFM) must be FB, and the record length (LRECL) must be 12560. If incorrect attributes are specified for SMPXTOUT, GIMXTRX will change the attributes to the required values.

**Input parameter data set contents**

The input parameter data set is a fixed-block 80-byte record sequential data set. Each input parameter consists of a keyword and an associated value. The rules for the input parameter data set are as follows:

- There must be one keyword with its associated parameter data per 80-byte record.
- All keywords must begin in column one of the records.
- No blanks are allowed after the keyword and before the equal sign.
- No blanks are allowed after the equal sign and before the first parameter value.
- Any data read from the input parameter data set that is not a recognized keyword parameter is ignored and processing continues.

The keywords and parameters passed to the GIMXTRX program are as follows:
GIMXTRX

GIMXTRX input parameters

**SUFFNC keyword:**

- **SUFFNC=**
  - LSTTZN
  - BMPTZN

**SUFGBL keyword:**

- **SUFGBL=**
  - globaldsn

**SUFUNIT keyword:**

- **SUFUNIT=**
  - unit

**SUFVOL keyword:**

- **SUFVOL=**
  - volume

**SUFTGT keyword:**

- **SUFTGT=**
  - tzone

**SUFFNC**

This is the name of the function to be processed by the GIMXTRX program. The two allowable values are

- **LSTTZN**
  - Generate a list of target zone names.

- **BMPTZN**
  - Create a BITMAP of a set of target zones.

This is a required parameter.

There can only be one function executed per invocation of GIMXTRX.

**SUFGBL**

This is the data set name containing the GLOBAL zone to be processed. This parameter is 44 characters long. This is a required parameter.

**SUFUNIT**

This is the UNIT value used to allocate a new output data set. The value is up to 8 characters long. This parameter is optional. If no UNIT value is specified, GIMXTRX uses a default UNIT value of SYSALLDA when allocating a new output data set.

**SUFVOL**

This is the work volume used to allocate the output data set. The value is six characters long, and must be a valid MVS volume name. This is an optional...
GIMXTRX

parameter. If no volume is specified, GIMXTRX will attempt to allocate the
output data set without a volume serial.

SUFTGT

This is the list of target zone names that will be queried. Each target zone
name is 7 characters long separated by one blank space. If a target zone name
is less than 7 characters long it must be left-justified and padded with blanks.
Each SUFTGT record can contain up to nine target zones. This is a required
parameter when SUFFNC=BMPTZN. It is not required when
SUFFNC=LSTTZN.

There can be multiple instances of the SUFTGT record to allow for situations
where a single 80-byte record cannot contain the required input data.

Examples of using GIMXTRX

In the following examples, the input data set is created in the job stream. In the
first example, the output of GIMXTRX is written to a new data set created by
GIMXTRX.

In the second example, the output of GIMXTRX is written to the data set specified
on the SMPXOUT DD statement.

Chapter 11. Service routines 473
GIMXTRX

//SMPXTOUT DD DSN=userid.dataset.OUT,DISP=(NEW,CATLG),
// UNIT=unit,SPACE=(TRK,(2,1))
//SYSTSPRT DD SYSOUT=*  
//SYSPRINT DD SYSOUT=*  

Processing

GIMXTRX obtains the input parameter data set name from the PARM value passed to it on the EXEC statement.

If the SMPXTOUT DD statement is specified, GIMXTRX uses the data set specified for the output. If the SMPXTOUT DD statement is not specified, GIMXTRX allocates a new data set for the output. GIMXTRX constructs the name of the output data set using the input parameter data set name as a base. The last qualifier of the input parameter data set name is changed to ‘OUT’ and this becomes the name of the output data set. For example, if the input parameter data set name is TEST.GIMXTRX.DATA.IN, the output data set name will be TEST.GIMXTRX.DATA.OUT.

The output data set is allocated and cataloged as follows:

DSNAME=dsn.OUT
DSORG=PS
RECFM=FB
LRECL=12560
BLKSIZE=0
SPACE=(TRK,(10,1),RLSE)
UNIT=unit (supplied as SUFUNIT= on input) or default of SYSALLDA
VOLUME=volume name (supplied as SUFVOL= on input).

If the SMPXTOUT DD statement is not specified, GIMXTRX attempts to create the output data set, which therefore must not exist at the time that GIMXTRX is initiated. If there is no volume supplied as input, GIMXTRX will attempt the allocation without a volume serial. If there is no unit supplied as input, GIMXTRX will attempt the allocation with UNIT=SYSALLDA.

GIMXTRX then allocates and opens all of the required data sets and extracts the input parameters from the input parameter data set.

Once the input parameters have been read and the output data set created, GIMXTRX continues processing based on the function requested (LSTTZN or BMPTZN).

List target zone names (LSTTZN)

This function of GIMXTRX produces a list of target zone names associated with a given GLOBAL zone SMPCSI data set name. The results are written to the output data set.

Inputs: The inputs to the List Target Zone Names function are:

SUFINC
Name of the function to be executed (LSTTZN)

SUFGBL
GLOBAL zone SMPCSI data set name

SUFINIT
UNIT to be used for output data set (optional)

SUFWOL
VOLUME to be used for output data set (optional)
GIMXTRX

A sample of the parameters contained in the input parameter data set for the List Target Zone Names function is:

```
1 2 3 4 5 6 7 8
----+----+----+----+----+----+----+----+----
SUFFNC=LSTTZN
SUFGBL=TEST.GLOBAL.VSAM.CSI
SUFVOL=VOL111
```

**Figure 94. Sample input parameter data set for function LSTTZN**

Using the SMP/E GIMAPI, GIMXTRX obtains the names of all of the target zones associated with the specified global zone. GIMXTRX then writes the list of target zone names to the output data set in 12560-byte records defined as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>header</td>
<td>60-byte header character string starting with the literal &quot;TARGETZN&quot; in upper case. The remaining 52 bytes are set to blanks.</td>
</tr>
<tr>
<td>Target zone name list</td>
<td>7-character target zone names each separated by one blank space, up to 12500 bytes in length. For target zone names that are less than 7 characters long, the field is left-justified and padded to the right with blanks. When the list is less than 12500 bytes long, the remaining bytes contain blanks.</td>
</tr>
</tbody>
</table>

**Example of a target zone name record:** The following example indicates an SMPCSI that has target zones MVST1, JESTGT1, CICTGA, DB2TG2.

```
1 2 3 4 5 6 7 8 9
----+----+----+----+----+----+----+----+----+----
TARGETZN  MVST1  JESTGT1  CICTGA  DB2TG2
```

**Figure 95. TARGETZN record**

**Create a BITMAP of an SMPCSI (BMPTZN)**

This function of GIMXTRX produces a BITMAP representation of the PTF service present in a user’s SMPCSI. This information is intended for shipment to IBM where it can be analyzed to create a custom-built service package to be delivered to the user over the internet.

The intent of the Create a BITMAP of an SMPCSI function is to identify and record in a set of BITMAP records:
- All FMIDs and PTFs applied in the target zones identified in the input data set (SUFTGT parameter).
- All PTFs received in the GLOBAL zone identified in the input data set (SUFGBL parameter) that are associated with the FMIDs applied in the specified target zones.

A PTF is considered applicable to a target zone if its FMID is applied in that target zone. If a PTF is applied in all selected target zones to which it is applicable, it is recorded in a BITMAP record. If a PTF is not applied in all of the selected target zones to which it is applicable, then it is not recorded in a BITMAP record. For example, if an FMID is applied in 4 of the selected target zones, but a PTF associated with that FMID is applied in only 3 of those zones, the PTF is not recorded in the BITMAP record.
All PTFs that are received in the GLOBAL zone are checked against the FMIDs applied in the selected target zones to determine if the PTFs are associated with the applied FMIDs. All PTFs received in the GLOBAL zone that are applicable to the FMIDs applied in the selected target zones are recorded in a BITMAP record.

**Inputs:** The inputs to the Create a BITMAP of an SMPCSI function are:

**SUFFNC**
Name of the function to be executed (BMPTZN)

**SUFGBL**
GLOBAL zone SMPCSI data set name

**SUFUNIT**
UNIT to be used for output data set (optional)

**SUFVOL**
VOLUME to be used for output data set (optional)

**SUFTGT**
Target zone names selected by the user

A sample of the input parameters contained in the input parameter data set for the create a BITMAP of an SMPCSI function is:

```
SUFFNC=BMPTZN
SUFGBL=TEST.GLOBAL.VSAM.CSI
SUFVOL=VOL111
SUFTGT=TARGET1 TGT2 TARGET3 TGT4 TARGET5 TARGET6 TGT7
```

**Figure 96. Sample input parameter data set for function BMPTZN**

The output records created by GIMXTRX for the BMPTZN function represent the functions applied in the target zones selected by the user (PRODLIST record) and the PTFs that are either applied or received (BITMAP records). GIMXTRX then writes the PRODLIST and BITMAP records to the output data set in 12560-byte records defined as follows:

**PRODLIST record:** The PRODLIST record contains the list of FMIDs applied in the target zones identified by the user in the input data set. Following is the definition of the PRODLIST record that is placed in the output data set by GIMXTRX.

**PRODLIST record**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>header</td>
<td>60-byte header starting with the literal &quot;PRODLIST&quot; in upper case. The remaining 52 bytes are set to blank.</td>
</tr>
</tbody>
</table>

**FMID list**
list of 7-character FMIDs each separated by one blank space. This field is 12500 bytes long. When the FMID list is less than 12500 bytes long, the remaining bytes will be made blanks.

The following example of a PRODLIST record indicates an SMPCSI that has FMIDs HBB6602, HMP1B00, JMP1B01 present.
The PRODLIST record will be placed before any BITMAP bitstring records in the output data set.

**BITMAP records:** The BITMAP records represent the PTFs applied in the target zones or received in the GLOBAL zone that are associated with the FMIDs listed in the PRODLIST record.

The BITMAP bitstring logic is based on the following PTF naming convention:
- PTF names are architected by IBM to consist of a 2 character prefix followed by 5 decimal digits providing 100000 possible PTF numbers per prefix (00000-99999).
- A BITMAP bitstring record simply contains 100000 bits and a 2-character PTF prefix in the record header.
- For example, if the prefix is "UR", then the first bit in the bitstring represents PTF UR00000, the second bit represents PTF UR00001, the third represents PTF UR00002 and so on. The last bit in the bitstring represents UR99999.
- The bits representing the URnnnnn PTF numbers received or applied on the customer system are turned on while the remaining bits are set to zero.
- One bitstring is required for each PTF prefix in the SMPCSI

Following is the definition of the BITMAP records that are placed in the output data set by GIMXTRX.

**BITMAP bitstring Record**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>header</td>
<td>60-byte header starting with the literal &quot;BITPTF&quot; in upper case, followed by the 2-character PTF prefix for each unique PTF prefix present in the zones being queried. This field is in upper case. The remaining 52 bytes in the header are set to blank.</td>
</tr>
<tr>
<td>bitstring</td>
<td>12500 bytes with 100000 bits representing PTF numbers present in the SMPCSI associated with the two-character PTF prefix in this record. A bit is set on to indicate a PTF number exists. All remaining bit positions are set to zero.</td>
</tr>
</tbody>
</table>

The following example of a BITMAP bitstring record indicates an SMPCSI that has PTFs UR00001 and UR00005 present.

```
1 2 3 4 5 6 7 8
-----+-----+-----+-----+-----+-----+-----+-----+
 0 0 0 0 0 0 0 0
```

**Figure 98. BITMAP record**
The bitstring section of the BITMAP record is expanded as follows (where each mark of the scale line represents one bit position of the BITMAP record):

```
 6 6 6 6 6 6 6 6 6 7
1-------2-------3-------4-------5-------6-------7-------8-------9-------0
01000100000000000000000000000000000000000000000000000000000000000000000000
```

*Figure 99. Bitstring section of BITMAP record*

**Return codes**

To help you diagnose errors, GIMXTRX issues messages and return codes. The messages are documented in [SMP/E Messages, Codes, and Diagnosis](#).

All non-zero return codes indicate unsuccessful completion of GIMXTRX. Here is a description of the return codes:

<table>
<thead>
<tr>
<th>Return code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The requested GIMXTRX function was processes successfully.</td>
</tr>
<tr>
<td>4</td>
<td>A warning condition was encountered in a program called by GIMXTRX.</td>
</tr>
<tr>
<td>8</td>
<td>An error condition was encountered in a program called by GIMXTRX.</td>
</tr>
</tbody>
</table>
| 12          | One of the following  
  • A required parameter is missing or incorrect.  
  • An allocation error occurred.  
  • An I/O error occurred.  
  • An error occurred while opening or closing a data set.  
  • GIMXTRX could not load either GIMAPI, GIMSGENU, or GIMKXENU.  
  • SMP/E could not obtain enough storage for processing. |

If an error occurs with SYSTSPRT, there will be no message issued. Only a return code will be returned through standard linkage.

GIMXTRX does not provide an ESTAE routine for recovery when an ABEND occurs. Normal system ABEND processing occurs.

---

**GIMZIP packaging service routine**

The GIMZIP service routine creates portable packages of software and associated materials. Typically the packages will contain SYSMODs, RELFILE data sets, HOLDDATA, and associated materials such as documentation, samples, and text files. These GIMZIP packages may be transported through a network, processed by the GIMUNZIP service routine, and then processed by the SMP/E RECEIVE command.

More specifically, a GIMZIP package consists of a single package definition file, a set of archive files, and text files. The package definition file describes the total package and identifies the archive files and text files contained in the package. An archive file consists of:

1. a portable image of any of the following:
   • a sequential data set
   • a partitioned data set

2. and the information necessary to reload the data from the portable image.

A single GIMZIP package typically consists of several archive files.

Notes:
1. GIMZIP is a separate load module residing in the MIGLIB library and runs independently from the rest of SMP/E processing.
2. GIMZIP requires either the Integrated Cryptographic Services Facility (ICSF) One-Way Hash Generate callable service or Java 2 Version 1 Release 4 to be available for its use in order to compute an SHA-1 hash value.

Calling GIMZIP

The following figure shows the job control statements for GIMZIP:

```
//JOBx JOB ...
//STEP1 EXEC PGM=GIMZIP,PARM='option'
//SMPDIR DD PATH='package_directory',PATHDISP=KEEP
//SMPWDIR DD PATH='work_directory',PATHDISP=KEEP
//SMPCPATH DD PATH='smpclasses_directory',PATHDISP=KEEP
//SMPHOME DD PATH='javaruntime_directory',PATHDISP=KEEP
//SMPOUT DD SYSOUT=''
//SYSPRINT DD SYSOUT=''
//SYSUT2 DD UNIT=SYSALDDA,SPACE=(CYL,(200,20))
//SYSUT3 DD UNIT=SYSALDDA,SPACE=(CYL,(50,10))
//SYSUT4 DD UNIT=SYSALDDA,SPACE=(CYL,(25,5))
//SYSIN DD *
   package control tags
/*
```

Figure 100. JCL to call GIMZIP

EXEC is the statement used to start GIMZIP. The EXEC statement must specify PGM=GIMZIP. The following options may be specified on the EXEC statement PARM operand:

```
LANGUAGE=xxx
```

where xxx can be one of the following:

```
ENU US English
JPN Japanese
```

The LANGUAGE option defines which language to use for GIMZIP messages. LANGUAGE can also be specified as L. If LANGUAGE is not specified, the default is LANGUAGE=ENU.

```
SEGMENT=nnnnM
```

where nnnn is a decimal number between 1 and 9999. The SEGMENT option indicates the archive files produced by GIMZIP are to be divided into archive segments no larger than nnnn megabytes. If SEGMENT is not specified, the default is to perform no archive segmenting.

SYSIN specifies a control data set that contains the package control tags to direct GIMZIP processing (see "GIMZIP package control tags" on page 480). The control data set may be a sequential data set or a single member of a partitioned data set and its attributes must be LRECL=80 and RECFM=F or FB.
SMPDIR
specifies a directory in a UNIX file system that is to contain the package created by GIMZIP. All files and archives created by GIMZIP are stored in this directory. This directory is referred to as the package directory.

The package directory must be empty at the start of GIMZIP processing. If any files, including a previous package, already exist in the package directory, you must move them to another directory, delete them, or specify a different directory on the SMPDIR DD statement for the package directory.

SMPWKDIR
specifies a directory in a UNIX file system that is used by GIMZIP for temporary work files. This is an optional DD statement. If the SMPWKDIR DD statement is not provided, GIMZIP will use the package directory specified on the SMPDIR DD statement for temporary work files.

SMPCPATH
specifies a directory in the UNIX file system where the SMP/E Java classes reside. The SMPCPATH DD statement is optional and only required to calculate SHA-1 hash values if ICSF is not available.

SMPJHOME
specifies a directory in the UNIX file system where the Java runtime resides. The SMPJHOME DD statement is optional and only required to calculate SHA-1 hash values if ICSF is not available.

SMPOUT
specifies an output data set that will contain SMP/E messages issued during GIMZIP processing. The data set attributes are LRECL=81 or LRECL=121 and RECFM=FBA.

SYSUT2
specifies a work area for the IEBCOPY utility to use for the sequential unload data sets placed on DASD as the result of an IEBCOPY unload operation. This data set must be large enough to accommodate the largest partitioned data set being processed by the current execution of GIMZIP.

SYSUT3 and SYSUT4
specifies work areas for the IEBCOPY utility to use for spill data sets on DASD.

SYSPRINT
specifies a data set to contain output and messages from the utilities called by GIMZIP.

GIMZIP package control tags
GIMZIP service routine processing is controlled by package control tags. The package control tags define the GIMZIP package to be created and are specified in the SYSIN data set. The package control tags follow XML syntax rules and their format is as follows:
GIMZIP package control tags

GIMZIP:

```xml
<GIMZIP description="package description">
  <FILEDEF />
</GIMZIP>
```

FILEDEF:

```xml
<FILEDEF name="file name" archid="archive id">
  subdir="subdirectory name" description="file description"
</FILEDEF>
```

```
<FILEDEF type="README" volume="file volume">
  <SMPHOLD>
    <SMPPTFIN>
      <SMPRELF>
    </SMPPTFIN>
  </SMPHOLD>
</FILEDEF>
```

**<GIMZIP> Tag syntax**

The `<GIMZIP>` and corresponding `</GIMZIP>` tags identify the beginning and end of a GIMZIP package build request. The following attribute may be found on the `<GIMZIP>` tag:

- **description="package description"**
  
  specifies a text description for the package. The description can be up to 500 characters long.

**<FILEDEF> Tag syntax**

The `<FILEDEF>` and corresponding `</FILEDEF>` tags identify the beginning and end of a file definition. Each file described by a `<FILEDEF>` tag is input to GIMZIP and is to be a component of the GIMZIP package. The following attributes may be found on the `<FILEDEF>` tag:

- **name="file name"**
  
  specifies the name of a data set or file that is to be a component of the GIMZIP package. The **name** attribute can specify either a sequential, partitioned, or VSAM data set, or the absolute pathname for a file or directory in the UNIX file system.

  The first character of the absolute pathname of a file or directory in the UNIX file system must be a slash (/). If the name does not begin with a slash, GIMZIP processing will assume that it is an MVS data set name and that it will conform to the MVS data set naming conventions. When a file or directory in the UNIX file system is specified, the name can be from 1 to 1023 bytes long with 255 characters between delimiters (/). The value can contain any character from X'40' through X'FE', except '<', '>', '&', and the double quotation mark ("). All data beyond column 72 is ignored, including blanks. The pathname of a file or directory in the UNIX file system is case sensitive and will not be converted to uppercase alphabetic during GIMZIP processing. Data set names are not case sensitive and will be converted to uppercase alphabetic during GIMZIP processing.

```
```

Chapter 11. Service routines  481
Notes:

1. When a VSAM data set is being specified, the true cluster name must be used. Do not reference a VSAM data set by a path name. Although an alternate index may be defined to the cluster, the alternate index does not become part of the archive. If an alternate index is desired at the destination site after the archive is unzipped, then the alternate index must be defined and built at the destination site.

2. GIMZIP processing uses the UNIX System Services pax command for creating archive files. Although GIMZIP will attempt to process UNIX file and directory names of up to 1023 bytes in length, this processing is subject to the limitations of the pax command. See z/OS UNIX System Services Command Reference, SA22-7802 for information on the pax command.

archid="archive id"

specifies a unique archive id value to be associated with the archive file created for the data set, file, or directory identified by the associated name attribute. The value of this attribute will most likely be something like a ddbname or the low level qualifier of a MVS library name or some generic specification for a file or directory in the UNIX file system.

The value can be from 1 to 243 characters in length. The value can contain any character from X'40' through X'FE', except '<', '>', '&', '/' and the double quotation mark (" ). The archid value is case sensitive and will not be converted to uppercase alphabetic by GIMZIP processing.

The same archid value may not be used in more than one file definition group in the same package.

description="file description"

specifies a text description for the file. The description can be up to 500 characters long.

subdir="subdirectory name"

specifies the subdirectory in which to store the file specified by the corresponding name attribute. The subdirectory name can be from 1 to 500 bytes long with 255 characters between delimiters (/).

This attribute can only be specified if the file type attribute is either not specified or is README.

The subdirectory name is a relative pathname for the desired subdirectory, so the first character of the subdirectory name cannot be a slash (/). However, the subdirectory name may be specified with or without an ending slash.

"SMP", all capitalized, cannot be specified as the first three characters of the subdir attribute value. Other case variations are allowed.

type="file type"

specifies a file type indicator that describes the contents of the file, identifies how the file is to be processed by GIMZIP, and also how the file will be processed by the SMP/E RECEIVE command. Any of the following values may be specified:

- **README** indicates that the associated file is a sequential text data set or a file in the UNIX file system that is intended to be viewable text after it is placed in the package. These files are not placed in archives by GIMZIP and are not compressed. They are only copied into the package by GIMZIP. The file name specified on
the associated name attribute must identify a file in the UNIX file system or a sequential data set that does not have a record format of VS (variable spanned).

**SMPHOLD** indicates that the associated data set or file contains SMP/E HOLDDATA statements. These files are placed in archives by GIMZIP and compressed. The name specified on the associated name attribute must identify a sequential data set with a logical record length of eighty (80) bytes and a record format of FB (fixed block), or it must identify a file in the UNIX file system.

**SMPPTFIN** indicates that the associated data set or file contains SMP/E modification control statements (MCS). These files are placed in archives by GIMZIP and compressed. The name specified on the associated name attribute must identify a sequential data set with a logical record length of eighty (80) bytes and a record format of FB (fixed block), or it must identify a file in the UNIX file system.

**SMPRELF** indicates the data set specified on the name attribute is an SMP/E REFLFILE data set associated with a SYSMOD contained in the SMPPTFIN file. Data sets with the SMPRELF file type must be either a partitioned data set or an IEBCOPY unloaded sequential image of a partitioned data set. These data sets are placed in archives by GIMZIP and compressed.

The type attribute must not be specified when a VSAM data set or a UNIX file system directory is specified on the name attribute. If the type attribute is not specified, then the data set specified on the name attribute can be either a sequential, partitioned, or VSAM data set, or a file or directory in the UNIX file system.

volume="file volume"
specifies the volume serial number of the volume containing the data set specified on the name attribute. The volume identifier must be from 1 to 6 alphanumeric characters and should be specified only if the name attribute identifies an uncataloged data set.

If the associated name attribute identifies a file or directory in the UNIX file system (the name begins with a slash), the volume attribute will be checked for syntax, but it will be ignored otherwise.

**Note:** The volume is used to allocate data sets. However, VSAM data sets must be catalogued. Information needed for the archival of VSAM data sets is gathered from the catalog and related areas, such as the VVDS - VSAM volume data set.

**Syntax notes**
1. GIMZIP ignores columns 73 through 80. If data is specified beyond column 72, GIMZIP ignores it, which may lead to the diagnosis of an error in a following tag.
2. Package control tags may contain comments. Comments start with $<$$-$$-$$ (hex 4C5A6060) and end with $$->$$ (hex 60606E). The first $$->$$ encountered after the initial $<$$-$$-$$ will end the comment. A comment may appear between a start-tag and its matching end-tag, but never within a tag.
Example of using GIMZIP

Suppose a GIMZIP package is to be created containing the following data sets, files, and directories:

- `/SAMPLE/ORDER123/SMPMC` - an SMP/E MCS file
- `SAMPLE.IBM.FMID001.F1` - An SMP/E PDS relative file
- `SAMPLE.IBM.FMID001.F2` - An SMP/E PDSE relative file
- `SAMPLE.ORDER123.DOCLIB` - A PDS containing documents
- `SAMPLE.ORDER123.RIMLIB` - A PDS containing related installation materials
- `SAMPLE.ORDER123.MVS.GLOBAL.CSI` - A VSAM cluster
- `/SAMPLE/ORDER123/RootHFS/` - the root directory

The following job stream can be used to create such a GIMZIP package:
//JOB
JOB ...
//STEP1 EXEC PGM=GIMZIP,PARM='SEGMENT=12M'
//SMPDIR DD PATH='/u/smpe/GIMZIP/ORDER123/',PATHDISP=KEEP
//SMPCPATH DD PATH='/usr/lpp/smp/classes/',PATHDISP=KEEP
//SMPJHOME DD PATH='/usr/lpp/java/j1.4/',PATHDISP=KEEP
//SMPOUT DD SYSOUT=* 
//SYSPRINT DD SYSOUT=* 
//SYSUT2 DD UNIT=SYSALLDA,SPACE=(CYL,(200,20))
//SYSUT3 DD UNIT=SYSALLDA,SPACE=(CYL,(50,10))
//SYSUT4 DD UNIT=SYSALLDA,SPACE=(CYL,(25,5))
//SYSIN DD *
<GIMZIP description="This is a sample software package.">
</GIMZIP>

<FILEDEF name="/SAMPLE/ORDER123/readme.html"
    archid="readme.html"
    description="This is the README file for the package."
    subdir="README"
    type="README">
</FILEDEF>

<FILEDEF name="/SAMPLE/ORDER123/SMPMCS"
    description="This is the SMPMCS file for ORDER123."
    archid="SMPMCS"
    type="SMPPFTIN">
</FILEDEF>

<FILEDEF name="/SAMPLE/ORDER123/RootHFS/"
    description="This is the entire root directory.">
</FILEDEF>

Figure 101. GIMZIP example
**GIMZIP**

**Note:** Blank lines and spaces have been added to the package control tags for clarity, but are not required.

**GIMZIP processing**

The GIMZIP service routine processes the following data structures as input to create GIMZIP packages:
- sequential data sets
- partitioned (PDS and PDSE) data sets
- VSAM data sets
- UNIX files
- UNIX directory files

The packages produced are stored in the package directory in a UNIX file system. The package directory is specified by the SMPDIR DD statement.

GIMZIP collects various attributes for the input data sets and files specified in the package control tags. These attributes, along with portable images of the input data sets, are temporarily stored in a UNIX file system. These images are then archived and compressed to create archive files. Each GIMZIP package will contain one or more archive files.

For each package there are two additional files:
- The package attribute file, which describes the contents of the package itself. The package attribute file identifies the archives for a package and contains a hash value for each archive within the package. The hash value for each archive is used for data integrity purposes and can be checked when the original data set is re-created from the archive using the GIMUNZIP service routine.
- An extensible stylesheet language (XSL) file, which describes how to format the information found in the package attribute file. The XSL file is used for rendering (displaying on a browser) the package attribute file.

**Package attribute file**

Each package contains a package attribute file. The name of this file is **GIMPAF.XML** and it is stored in the package directory identified by the SMPDIR DD statement. The file contains package definition control tags that describe the contents of the package and how the package was created. The package definition control tags follow XML syntax rules.

The format of the package definition control tags is as follows:
GIMZIP

Package definition control tags

PKGDEF:

- date="yyyy.ddd"
- description="package description"
- files="filenum"
- gmt="hh:mm:ss"
- level="vv.rr.mm.pp"
- originalsize="original package size"
- size="package size"

ARCHDEF:

- name="archive name"
- archid="archive id"
- description="archive description"
- hash="archive hash value"
- originalsize="original file size"
- size="archive size"
- type="README"

ARCHSEG:

- name="segment name"
- hash="segment hash value"
- size="segment size"

PKGHASH:

- hash="package hash value"
### <PKGDEF> Tag syntax

The `<PKGDEF>` and corresponding `</PKGDEF>` tags identify the beginning and end of a GIMZIP package definition. The following attributes may be found on the `<PKGDEF>` tag:

- **date**="yyyy.ddd"
  - indicates the year and Julian day on which the package was created by the GIMZIP service routine.

- **description**="package description"
  - specifies a text description for the package. The value GIMZIP places here, is the same as the description value, if specified, on the input `<GIMZIP>` tag.

- **files**="filenum"
  - indicates the total number of files that compose the package. This number includes all archives, and any and all control files, such as the Package Attribute File.

- **gmt**="hh:mm:ss"
  - indicates the time at which the package was created by the GIMZIP service routine. The time value is expressed as Greenwich Mean Time (GMT).

- **level**="vv.rr.mm.pp"
  - indicates the service level of the GIMZIP service routine used to create this package. The individual values are as follows:
    - vv version
    - rr release
    - mm modification level
    - pp PTF level

- **originalsize**="original package size"
  - indicates the sum of all the values of `originalsize` attributes on ARCHDEF tags in this package definition. It is used to determine the amount of auxiliary storage required to retrieve all the archives in this package.

- **size**="package size"
  - indicates the total size of the package, in bytes. This size is the sum of the sizes of all files that compose the package.

### <ARCHDEF> Tag syntax

The `<ARCHDEF>` and corresponding `</ARCHDEF>` tags identify the beginning and end of a specific archive file definition. The following attributes may be found on the `<ARCHDEF>` tag:

- **name**="archive name"
  - specifies the relative path name for an archive file in the GIMZIP package. The path name value is relative to the package directory specified on the SMPDIR DD statement. See "[Archive files](#)" on page 492 for information on the proper naming convention for archive files.

- **archid**="archive id"
  - specifies a unique archive id associated with the archive specified in the archive `name` attribute. There can be only one `archid` attribute in an archive definition group. The value is taken from the `archid` value found on the file definition tag in the GIMZIP package control tags (if one was specified). This is an optional attribute.
GIMZIP

description="archive description"
specifies a text description for the archive. The value GIMZIP produces is
copied from the description value, if specified, on the corresponding input
<FileDef> tag.

hash="archive hash"
indicates an SHA-1 hash value for the archive file.

originalsize="original file size"
indicates the total size, in bytes, of the original data set, directory, or file stored
in the archive file.

size="archive size"
indicates the total size of the archive file, in bytes.

type="file type"
specifies an archive type indicator that describes the contents of the archive
and how the file will be processed by the SMP/E RECEIVE command. The
value is copied from the file type value, if specified, on the corresponding
<FileDef> statement, and may be any of the following values:

README indicates the archive contains text data.

SMPHOLD indicates the archive contains SMP/E HOLDDATA statements.

SMPPTFIN indicates the archive contains SMP/E modification control
statements (MCS).

SMPRELF indicates the archive contains an SMP/E RELFILE data set
associated with a SYSMOD contained in the SMPPTFIN file.

<ARCHSEG> Tag syntax
The <ARCHSEG> tag and matching </ARCHSEG> end tag identify a segment of
an archive file. The following attributes may be found on the <ARCHSEG> tag:

name="segment name"
specifies the path name of a segment file for an archive file in the GIMZIP
package. The path name value is a relative value and it is relative to the
package directory specified on the SMPDIR DD statement for GIMZIP. This
attribute and corresponding attribute value is always produced when archives
are to be segmented.

size="segment size"
indicates the total size of the segment file, in bytes. While GIMZIP always
produces a byte count when archives are to be segmented, this attribute and
attribute value is optional and is not used for GIMUNZIP or RECEIVE
processing.

hash="segment hash"
indicates an SHA-1 hash value for the segment file. This attribute and
corresponding attribute value is always produced when archives are to be
segmented.

<?PKGHASH> Tag syntax
hash="package hash"
indicates an SHA-1 hash value for the information in the package attribute file
between the starting <PKGDEF> tag and the ending </PKGDEF> tag.

Syntax notes
1. Data in columns 73 through 80 is ignored. If data is specified beyond column
72, it is ignored and an error in a following tag may be indicated.
GIMZIP

2. Package definition control tags may contain comments. Comments start with
   <!-- (hex 4C5A6060) and end with --> (hex 60606E). The first --> encountered
   after the initial <!-- will end the comment. A comment may appear between a
   start-tag and its matching end-tag, but never within a tag.

Package attribute file example
   The package attribute file for the package produced by GIMZIP in [Figure 101 on
   page 485] would look like the following:
Figure 102. Package attribute file (GIMPAF.XML) example (Part 1 of 2)
### GIMZIP

```xml
<ARCHDEF name="S0006.2003033543543234.pax.Z"
  description="This is the entire root directory."
  originalsize="155840"
  size="132256"
  hash="D0E84938CA2EE1BC57FAA2008EBA2289ECE1BC5">
</ARCHDEF>

<ARCHDEF name="GIMPAF.XSL"
  description="This is an Extensible Stylesheet Language (XSL) document used to render the package attribute file (GIMPAF.XML) on an internet browser. This file has not been archived and should not be included on the input control statements for GIMUNZIP processing."
  size="4800"
  originalsize="155840"
  hash="6DD284BE148DB4FA39CD5C3798F2171482D29553">
</ARCHDEF>
</PKGDEF>

<?PKGHASH hash="1C4DC48997B66271202887E3A1628EA2ADCCBDDE"?>
```

**Figure 102. Package attribute file (GIMPAF.XML) example (Part 2 of 2)**

**Note:** Spaces have been added to the example for clarity, but are not necessarily produced by GIMZIP, nor are they required. Some of the values, such as size, original size, and hash, are for illustration purposes only, and may not be accurate.

### Displaying the package attribute file

The package attribute file (GIMPAF.XML) can be rendered on an internet browser that supports XML and XSL (for example, Microsoft® Internet Explorer 5). The package directory containing the package attribute file must be accessible to the browser through your z/OS web server. The accessibility of the package directory is determined by your specific web server configuration.

For example, suppose `/userid/public/` is defined by your z/OS web server to be your publicly accessible directory. Further suppose, to view the contents of this directory, you must specify an URL of the form `http://host name/~userid`. Then, in order to view the package attribute file, your package directory must be contained within the `/userid/public/` directory, or a symbolic link that points to the package directory must be in the `/userid/public/` directory in a UNIX file system. Furthermore, your z/OS web server must be configured to recognize `.XML` and `.XSL` as text MIME types and, if appropriate, convert EBCDIC text to ASCII text.

The package attribute file can then be viewed on an internet browser by entering an URL similar to the following:

```
http://host name/~userid/GIMPAF.XML
```

### Archive files

The actual software and associated materials for a package are stored in archive files. GIMZIP creates an archive file for each input data set or file specified by a `<FILEDEF>` tag. An archive file consists of a portable image of the original data set or file and attributes of the original data set or file needed to reload the data from the portable image.

The attributes of the original data set or file are recorded in a file attribute file in the UNIX file system called `GIMFAF.XML`. For data sets, the portable image of the original data set is stored temporarily as a file in the UNIX file system (this step is not required for UNIX files and directories). The name of this temporary file is the
type attribute value for the archive (SMPPTFIN, SMPHOLD, SMPRELF) or the name MVSFILE if the archive has no type attribute specified. An archive file is then created by using the UNIX System Services `pax` command to combine the GIMFAF.XML file and the original data into an archive. Although a UNIX file is not first stored as a temporary file with a name matching its type attribute value, its name within the archive will be its type attribute value, or the name MVSFILE, if the archive has no type attribute specified. The GIMUNZIP service routine and the RECEIVE command both expect an archive file to contain the GIMFAF.XML component file, and the following, depending on the original content:

**For data sets:**
- a file named SMPPTFIN, SMPHOLD, SMPRELF, or MVSFILE

**For UNIX files:**
- a file named SMPPTFIN, SMPHOLD, or MVSFILE

**For UNIX directories:**
- the directory and its contents are stored in the archive using the original names.

Data sets and files with a type of `README` are an exception to the previously described archive processing. README data sets and files have no file attribute file and are not archived using `pax`, but rather are stored unchanged in a file in the package directory. Likewise, README data sets and files are not subject to archive segmentation.

The absolute names for archive and README files in the package directory use the following format:

/package_directory/subdir/Snmmm.original__name.pax.Z

The absolute names for archive segment files in the package directory use the following format:

/package_directory/subdir/date_timeofday.nofm

**package_directory**
- indicates the package directory specified on the SMPDIR DD statement.

**subdir**
- indicates the subdirectory into which the archive file is stored. GIMZIP creates this subdirectory based on the filetype or the subdir attributes specified on the `<FILEDEF>` tag for the data set. If neither attribute is specified, then no subdirectory is used. If the file type is `README`, the subdirectory is created only if the `subdir` attribute has been specified.

**Snmmm**
- specifies the sequence indicator for the archive file. The sequence indicator is necessary so the correct order can be determined for the SMPHOLD and SMPPTFIN files when eventually processed by the SMP/E RECEIVE command. GIMZIP processes the input data sets or files in the sequence in which they are specified in the package control tags and the indicator is assigned accordingly. All archive files, except those specified with a file type of `SMPRELF`, are assigned a sequence indicator. If the file type is `README` and an archid tag was specified, then no sequence number will be assigned.

**original_name**
- specifies the original name of the data set, file, or directory, as indicated on the `<FILEDEF>` tag. This could also be the archid for UNIX directories and README data sets or files, or the date and time for UNIX directories, if the archid is not specified.
pax.Z
is the file extension for all archive files, except those with a file type of
README. The pax.Z extension indicates a file that has been processed by the
UNIX System Services pax command with the compress option.
date_timeofday
  the date and time of day value, unique for each archive, but the same for each
  segment file of a particular archive.
n  segment number
m  the total number of segments for the archive.

File attribute file
The File Attribute File (FAF) is included in the archive file along with the data set,
file or directory when it is archived. The FAF contains control tags that:
• Describe the attributes of the original data set, file or directory
• Provide information needed by GIMUNZIP to process the archive

The GIMUNZIP service routine uses the information in a FAF to reload the data
from an archive file. The FAF for a file or directory in the UNIX file system is
created in the temporary working directory, just as it is for data sets. The FAF
control tags follow XML syntax rules, and their format is as follows:
File attribute file control tags

FILELIST:

<FILELIST>
  FILEATTR for MVS data set
  FILEATTR for UNIX file system
  FILEATTR for VSAM data set
</FILELIST>

FILEATTR for MVS data set:

<FILEATTR name="MVS data set name" description="file description" type="SMPHOLD">
  level="vv.rr.mm.pp" dsorg="PDS" recfm="recfm" lrecl="lrecl" lreclu="lreclu" length="lrecl" unlength="lreclu" prispace="primary" secspac="secondary" dirblocks="dirblocks">
</FILEATTR>

FILEATTR for UNIX file system:

<FILEATTR name="UNIX file system file or directory name" description="file description" type="SMPHOLD">
  level="vv.rr.mm.pp" dsorg="UFS" dsntype="FILE">
</FILEATTR>

FILEATTR for VSAM data set:

<FILEATTR name="VSAM cluster name" description="file description" type="SMPHOLD">
  level="vv.rr.mm.pp" dsorg="VSAM" recfm="recfm" prispace="primary" secspac="secondary" allocunits="allocunits" length="length" unlength="unlength" prispace="primary" secspac="secondary" dirblocks="dirblocks">
</FILEATTR>

<DEFINECLUSTER component="DATA">
</DEFINECLUSTER>

INDEX
<FILELIST> Tag syntax: The <FILELIST> and corresponding </FILELIST> tags identify the beginning and end of a group of file definitions.

<FILEATTR> Tag syntax: The <FILEATTR> and corresponding </FILEATTR> tags identify the beginning and end of a file attribute definition for an archive file. The following attributes may be found on the <FILEATTR> tag:

name="file name | pathname"

specifies one of the following:

- The name of the original MVS data set or VSAM cluster in this archive
- The pathname for the original UNIX file or directory in this archive

Notes:

1. The first character of the absolute pathname of a file or directory in the UNIX file system must be a slash (/).
2. If the value of the name attribute does not begin with a slash, it is assumed to be an MVS data set name (sequential, partitioned, and VSAM data sets) and must conform to the MVS data set naming conventions.
3. When a file or directory in the UNIX file system is specified, the name can be from 1 to 1023 bytes long with 255 characters between delimiters (/). The value can be any character from X'40' through X'FE' except '<', '>', '&', and double quotation mark ("). All data beyond column 72 is ignored, including blanks. The pathname of a file or directory in the UNIX file system is case sensitive and will not be converted to uppercase alphabetic during GIMUNZI processing. (Data set names are not case sensitive. They will be converted to uppercase alphabetic during GIMUNZI processing.)

description="file description"

specifies a text description for the file. The value GIMZIP produces is copied from the description value, if specified, on the corresponding input <FILEDEF> tag. The description can be up to 500 characters long.

type="file type"

specifies a file type indicator that describes the contents of the file, identifies how the file is to be processed by GIMZIP, and also how the file will be processed by the SMP/E RECEIVE command. Any of the following values may be specified:

SMPHOLD

indicates that the data set or file contains SMP/E HOLDDATA statements.

SMPPTFIN

indicates that the data set or file contains SMP/E modification control statements (MCS).

SMPRELF

indicates that the data set contains an SMP/E RELFILE data set associated with a SYSMOD contained in the SMPPTFIN file.

If the type attribute is not specified, then the data set specified on the name attribute can be either sequential or partitioned.

level="vvv.vv.mm.pp"

indicates the service level of the GIMZIP service routine used to create this file attribute file. The individual values are as follows:

vvv version

rr release
dsntype="type"
specifies the type of partitioned data set, VSAM cluster, or UNIX file or
directory for the original data.
  DIR     indicates a directory in the UNIX file system.
  FILE    indicates a file in the UNIX file system.
  ESDS    indicates a VSAM cluster that is an entry sequence data set.
  KSDS    indicates a VSAM cluster that is a keyed sequence data set.
  LDS     indicates a VSAM cluster that is a linear data set.
  RRDS    indicates a VSAM cluster that is a relative record data set.
  LIBRARY indicates a PDSE partitioned data set.
  PDS     indicates a PDS partitioned data set.

dsorg="organization"
specifies the organization of the original data set, file, or directory.
  PO      indicates a partitioned data set
  PS      indicates a sequential data set
  UFS     indicates a file or directory in the UNIX file system
  VSAM    indicates a VSAM cluster

recfm="format"
specifies:
  • When dsorg="PS" or dsorg="PO", the record format of the sequential or
    partitioned MVS data set in an archive
  • When dsorg="VSAM", the record format of the data set used to contain the
    REPROed VSAM data

The value can be from 1 to 3 alphabetic characters.

lrecl="length"
specifies the logical record length of the original data set. The value can be
from 1 to 5 decimal digits.

lreclu="length"
specifies:
  • When dsorg="PO", the logical record length of the IEBUCOPY unloaded
    format of the original data set
  • When dsorg="VSAM", the logical record length of the data set used to
    contain the REPROed VSAM data from the cluster

In either case, the value can be from 1 to 5 decimal digits.

blksize="size"
specifies the block size of the original data set. The value can be from 1 to 5
decimal digits in the range of 00000 through 32760.

blksizeu="size"
specifies:
  • When dsorg="PO", the block size of the IEBUCOPY unloaded format of the
    original data set
  • When dsorg="VSAM", the block size of the data set used to contain the
    REPROed VSAM data from the cluster

In either case, the value can be from 1 to 5 decimal digits in the range of 00000
through 32760.
**primary**="prispace"
specifies:
- When **dsorg**="PS" or **dsorg**="PO", the primary space needed to reload the sequential or partitioned MVS data set in an archive
- When **dsorg**="VSAM", the primary space needed to create a temporary data set to contain the REPROed VSAM data

The value must be non-zero and can be from 1 to 8 decimal digits.

**secondary**="secspace"
specifies:
- When **dsorg**="PS" or **dsorg**="PO", the secondary space needed to reload the sequential or partitioned MVS data set in an archive
- When **dsorg**="VSAM", the secondary space needed to create a temporary data set to contain the REPROed VSAM data

The value must be non-zero and can be from 1 to 8 decimal digits.

**dirblocks**="blocks"
specifies the number of directory blocks in the original data set. The value must be non-zero and can be from 1 to 5 decimal digits.

**allocunits**="units"
specifies:
- When **dsorg**="PS" or **dsorg**="PO", the units to be used when allocating the data set used to reload the sequential or partitioned MVS data set in an archive
- When **dsorg**="VSAM", the units to be used to create a temporary data set to contain the REPROed VSAM data

The value can be one of the following:

**BLOCK**
indicates space is to be allocated in blocks. The size of the blocks is specified on the **length** attribute.

**CYLINDER**
indicates space is to be allocated in cylinders.

**RECORD**
indicates space is to be allocated in records. The average length of these records is specified on the **length** attribute.

**TRACK**
indicates space is to be allocated in tracks.

**length**="average record length 1 block length"
specifies either the block length, or the average record length, used to allocate the primary and secondary space for reloading the data from the archive. If **allocunits**="BLOCK" is specified, then this value represents the block length. If **allocunits**="RECORD" is specified, then this value represents the average record length. The value of the **length** attribute must be from 1 to 5 decimal digits and must be non-zero.

**avgrec**="multiplier"
indicates the multiplier for the primary and secondary space allocation values only when **allocunits**="RECORD".

**U**
indicates that the primary and secondary space quantities represent the number of records in units (multiplier of 1).
K  indicates that the primary and secondary space quantities represent the number of records in thousands (multiplier of 1024 or 1K).
M  indicates that the primary and secondary space quantities represent the number of records in millions (multiplier of 1048576 or 1M).
- When dsorg=“PS” or dsorg=“PO”, this value represents the multiplier to be used for allocating the sequential or partitioned data set in an archive.
- When dsorg=“VSAM”, this value represents the multiplier to be used for allocating the temporary data set to contain the REPROed VSAM data.

<DEFINECLUSTER> Tag syntax: The <DEFINECLUSTER> tag and corresponding </DEFINECLUSTER> tag identify the beginning and end of information that is needed to define a new VSAM cluster during GIMUNZIP processing. The <DEFINECLUSTER> tag may be specified for the data component of a VSAM cluster. The <DEFINECLUSTER> tag may also be specified for the index component of a VSAM cluster if the cluster is a KSDS. The following attribute is found on the <DEFINECLUSTER> tag:

component=
  specifies the name of the component type of a VSAM cluster, and may be one of the following values:

  "DATA"
    indicates that the following <OPERAND> tags are providing information to define the data component of a VSAM cluster.

  "INDEX"
    indicates that the following <OPERAND> tags are providing information to define the index component of a VSAM KSDS cluster.

Following the <DEFINECLUSTER> tag is the <OPERAND> tag.

<OPERAND> Tag syntax: The <OPERAND> tag and corresponding </OPERAND> tag identify the beginning and end of a valid IDCAMS DEFINE command operand for GIMUNZIP processing when a new VSAM cluster must be created in order to extract a VSAM archive. The <OPERAND> and </OPERAND> tags can only be specified within a <DEFINECLUSTER> tag and corresponding </DEFINECLUSTER> tag.

A maximum of 50 characters is allowed between the <OPERAND> tag and its corresponding </OPERAND> end tag. Multiple <OPERAND> tags may be specified to provide IDCAMS DEFINE command information.

Note: A portable package of software can be built either using GIMZIP, or manually (without using GIMZIP). If a packager is building a GIMZIP-like package manually and always intends that the users of the package will redefine a VSAM cluster for usage by GIMUNZIP, the <DEFINECLUSTER> tag and its imbedded <OPERAND> tags may be omitted from the FAF.

Syntax notes:
1. Data in columns 73 through 80 is ignored. If data is specified beyond column 72, it is ignored and an error in a following tag may be indicated.
2. File definition control tags may contain comments. Comments start with <!-- (hex A5606E) and end with -- (hex 606E). The first --> encountered after the initial <!-- will end the comment. A comment may appear between a start-tag and its matching end-tag, but never within a tag.
3. The space allocation for an archived data set is stored in the File Attribute File in terms of AVGREC regardless of how the data set was originally allocated. GIMZIP converts the current allocation information for a data set (as obtained from its DSCBs) into record type allocation information using AVGREC (usually set to U, although K could be used for extremely large data sets) and an average record length equal to the data set block size. The data set allocated using this information when an archive is retrieved by GIMUNZIP will approximately equal in size (number of bytes) the original data set, but will not use the same allocation units as the original data set that was archived by GIMZIP.

**File attribute file examples:** The following is an example of a file attribute file for a sequential data set containing modification control statements.

```xml
<?xml version="1.0" ?>
<FILELIST>
  <FILEATTR name="SAMPLE.FMID001.SMPMCS"
    description="This is the SMPMCS file for FMID001."
    level="02.07.00.35"
    type="SMPPTFIN"
    dsorg="PS"
    recfm="FB"
    lrecl="80"
    blksize="6160"
    allocunits="RECORD"
    length="6160"
    avgrecl="U"
    primary="24000">
  </FILEATTR>
</FILELIST>
```

*Figure 103. File attribute file (GIMFAF.XML) example for a sequential data set*

The file attribute file included with the archive for file `/CPACTST/DO000029/SMPMCS` from the example in *Figure 102 on page 491* would look something like this:

```xml
<FILELIST>
  <FILEATTR name="/CPACTST/DO000029/SMPMCS"
    description="This is the SMPMCS file for DO000029"
    level="03.03.00.00"
    type="SMPPTFIN"
    dsntype="FILE"
    dsorg="UFS">
  </FILEATTR>
</FILELIST>
```

*Figure 104. File attribute file example for a UNIX file*

The file attribute file included with the archive for VSAM cluster `/CPACTST.DO000029.MVS.GLOBAL.CSI` from the example in *Figure 102 on page 491* would look something like this:
GIMZIP

Return codes

GIMZIP may end with the following return codes:

Return code
Meaning

00  The input data was processed successfully.

04  A call to a system service may not have completed successfully.

12  One of the following:
- Required file attributes could not be obtained.
- Input data sets were not sequential, partitioned, or VSAM data sets, nor
  files and directories in the UNIX file system.
- Call to a required system service failed.
- Syntax errors in the SYSIN data set.
- Data sets could not be opened.
- SMPDIR was not allocated to a UNIX directory.
- SMPDIR directory was not empty.
- Data sets, directories, or files were missing.
- Required modules could not be loaded.

16  One of the following:
- An I/O error occurred.
- A syntax error was found on the EXEC statement parameters.

20  SMPOUT data set is missing.

Note: Blank lines and spaces have been added to the file attribute file for clarity,
but are not necessarily produced by the GIMZIP service routine, nor are
they required.
GIMZIP

> 20 Internal error. Report the error to the IBM Support Center.
Chapter 12. GIMIAP: Copy utility invocation program

The SMP/E GENERATE command creates a job stream that builds a set of target libraries from a set of distribution libraries. For data elements or hierarchical file system elements, the GENERATE command builds a job (DEIINST for data elements or HFSINST for hierarchical file system elements) to invoke the appropriate copy utility for those elements. Each job step in the job installs multiple elements from multiple distribution libraries into a single target library. This is done by invoking the SMP/E program GIMIAP, which calls the appropriate copy utility to do the actual installation.

Although GIMIAP is to be used only by SMP/E, you may need to understand the control statements passed to the program. For example, you may need to diagnose errors detected by GIMIAP (such as syntax errors or missing information). To help you with this task, this chapter describes:

- The control statements used to invoke GIMIAP
- The return codes issued by GIMIAP
- The JCL statements used in the job that invokes GIMIAP

Control statements used to invoke GIMIAP

The GIMIAP program runs as a background job and is driven by control statements that identify the following:

- The copy utility to be invoked
- The distribution and target libraries to be used for each invocation of GIMIAP
- The elements to be installed
- The parameters to be passed to the copy utility

These control statements are created by SMP/E during GENERATE processing and are for use during GIMIAP processing. Each invocation of GIMIAP can install many elements through multiple invocations of the copy utility. Each invocation of the copy utility by GIMIAP installs a single element. These are the control statements used for input to a GIMIAP step:

- INVOKE
- COPY
- SELECT

The INVOKE control statement

The INVOKE control statement identifies the copy utility that GIMIAP should invoke.

The INVOKE control statement is always produced. There is one INVOKE control statement for each job step (that is, one INVOKE control statement for each invocation of GIMIAP). The INVOKE control statement must be the first control statement and must be a single-card image (one 80-byte record).
The following operands are required on the INVOKE statement:

**COPY**
Specifies the name of the copy utility to be used when copying data elements that do not need reformatting and are being installed into a partitioned data set. The value of COPY is either the value of the NAME operand in the UTILITY entry in effect at GENERATE time or the default of IEBCOPY.

**HFSCOPY**
Specifies the name of the copy utility to be used when copying hierarchical file system elements. The value of HFSCOPY is either the value of the NAME operand in the UTILITY entry in effect at GENERATE time or the default of BPXCOPY.

**LIST**
Applies only when copying data elements. It specifies whether member names should be listed during copy processing. This value is derived from the copy utility entry in effect when the GENERATE command was issued.

- **YES** Indicates that member names should be listed during copy processing. This is the default.
- **NO** Indicates that the list of member names should be suppressed during copy processing.

**PRINT**
Specifies the ddname that is to be used for print output generated by the specified copy utility. The value of PRINT is either the value of the PRINT operand in the UTILITY entry in effect at GENERATE time or the default of SYSPRINT.

**RC**
Specifies the highest acceptable return code from the specified copy utility. The value of RC is either the value of the RC operand in the UTILITY entry in effect at GENERATE time or the default of 0.

**REPLACE**
Applies only when copying data elements. It specifies whether existing members are to be replaced when copying an element. If REPLACE is specified on the GENERATE command, then it is specified on the INVOKE control statement for data elements.

### COPY control statement
A COPY control statement identifies the input and output libraries to be used for the SELECT control statements that follow it. Each COPY statement identifies a distribution library that has elements to be copied to a single target library. Multiple COPY statements can identify the same target library.
A COPY control statement must follow an INVOKE or SELECT control statement. Also, each COPY control statement must be followed by at least one SELECT control statement.

```
COPY control statement

COPY-FROMLIB(ddname)-TOLIB(ddname)
```

The following operands are required on the COPY statement:

**FROMLIB**
- is the ddname used by the copy utility as its input file for the source of the element (that is, the distribution library). The name can be 1 to 8 characters and must be composed of uppercase alphabetic, numeric, or national ($, #, @) characters.

**TOLIB**
- is the ddname used by the copy utility as its output file identifying where the element is to be installed (that is, the target library). The name can be 1 to 8 characters and must be composed of uppercase alphabetic, numeric, or national ($, #, @) characters.

**The SELECT control statement**

The SELECT control statement identifies the element to be installed and the operands to be passed to the copy utility or SMP/E to enable its installation. The SELECT control statement must follow a COPY control statement and may span multiple 80-byte records.

```
SELECT control statement

SELECT-type(name)

ALIAS-alias

EPARM-option

SHSCRIPT-'/directory/file'-PRE-POST
```

type
- is the type of the element to be processed. Any valid data element type or hierarchical file system element type, including those with national language identifiers, may be specified. An element type name is formed by stripping the ++ from the beginning of the name of the MCS for that element. For example, the element type for an element defined by a ++CLIST MCS is **CLIST**, while the element type for a ++HFSRMS MCS is **HFSRMS**. See “Data element MCS” on page 10 for a list of data element MCS and “Hierarchical file system element MCS” on page 26 for a list of hierarchical file system element MCS.

name
- is the name of element to be processed.
ALIAS
specifies the list of alias names for the data element. This operand applies only to data elements.

EPARM
is the parameter list to be passed for this invocation of the HFSCOPY utility. This operand applies only to hierarchical file system elements. The parameter list consists of an LL value and the actual execution parameters.
- LL represents a halfword hexadecimal length of the character string (the HFSCOPY utility execution parameters) immediately following it as part of the EPARM value. The length of the character string described does not include the opening parenthesis preceding the LL value nor the closing parenthesis following the last option specified.
- No blanks are allowed between the opening parenthesis and the LL value. The opening parenthesis and the LL value must be in the same record.
- Because the LL value is nondisplayable (ready-to-use) hexadecimal, it may appear as blanks or odd characters. This is valid data and should not be removed or modified.
- The option values are the execution parameters to be used by the HFSCOPY utility for this invocation of the utility. SMP/E always supplies execution parameters to the HFSCOPY utility, and the parameters are separated by commas with no intervening blanks.
- If the HFSCOPY UTILITY entry that is in effect supplies execution parameters, these values precede the SMP/E-generated information. For example, suppose the UTILITY entry has the following values:
  NAME
  MYHFSCPY
  PRINT
  MYPRINT
  PARM A-PARM-FOR-MYHFSCPY
The character string for the execution parameters would be generated as:
LLA-PARM-FOR-MYHFSCPY,ELEMENT(hfselm1),TYPE(TEXT),LINK('linknm01'))
If a PARM value of user_info is specified in an element’s MCS, the character string for the execution parameters would be generated as:
LLA-PARM-FOR-MYHFSCPY,user_info,ELEMENT(hfselm1),TYPE(TEXT),LINK('linknm01'))
These are the parameters that are generated by SMP/E, using information in the hierarchical file system element entry:
ELEMENT(element_name)
the name of the element to be installed in a UNIX file system. The element_name is an unquoted character string 1 to 8 bytes long. It is composed of uppercase alphabetic, numeric, or national ($) characters.

LINK('linkname1','linkname2','linkname3'...)
the alternate names by which this element can be known in the target library within a UNIX file system. A linkname can be up to 1023 characters long and can contain special characters other than just uppercase alphabetic, numeric, or national ($, #, and @) characters.
- SMP/E always puts apostrophes around each linkname and separates multiple values with commas with no intervening blanks.

SYMLINK('linkname1','linkname2','linkname3'...)
a list of symbolic links, which are file names that can be used as alternate names for referring to this element in a UNIX file system. Each
linkname listed here is associated with a pathname listed in the SYMPATH operand. A symbolic link can be up to 1023 characters long and can contain characters in the range 'X'40' through 'X'FE'.

SMP/E always puts apostrophes around each symbolic link and separates multiple values with commas with no intervening blanks.

SYMPATH('pathname1','pathname2','pathname3'...)  
a list of pathnames that are associated with symbolic links identified by the SYMLINK operand. A symbolic pathname can be up to 1023 characters long and can contain characters in the range 'X'40' through 'X'FE'.

SMP/E always puts apostrophes around each symbolic pathname and separates multiple values with commas with no intervening blanks.

SYMPATH appears if SYMLINK appears, otherwise it is omitted.

For information on how the pathnames and linknames are associated, see the description of the SYMPATH operand and "Example 3: Packaging a SYSMOD with a symbolic link" on page 36 in "Hierarchical file system element MCS" on page 26.

TYPE(TEXT | BINARY)  
the installation format for the element in a UNIX file system. SMP/E generates this parameter from information stored in the element entry in the target zone. If no setting exists for TEXT mode or BINARY mode, SMP/E does not pass this parameter to the HFS copy utility.

SHSCRIPT  
indicates that a UNIX shell script is to be invoked to complete the installation of the selected element. This operand applies only to hierarchical file system elements whose ELEMENT entry contains a SHSCRIPT subentry.

/directory/file  
is the full path specification for the shell script to be invoked. The /directory/file is derived from the SHELLSCR entry that matches the name in the hierarchical file system element's SHSCRIPT subentry. The SYSLIB subentry of the shell script identifies the ddname of the directory and the shell script name itself is the file.

PRE  
indicates the shell script is to be invoked before the selected element is copied to the directory in a UNIX file system. This value is obtained from the SHSCRIPT subentry of the selected element.

POST  
indicates the shell script is to be invoked after the selected element is copied to the directory in a UNIX file system. This value is obtained from the SHSCRIPT subentry of the selected element.

Return codes  
To help you diagnose errors, GIMIAP issues messages and return codes. The messages are documented in [SMP/E Messages, Codes, and Diagnosis] Here is a description of the return codes:

<table>
<thead>
<tr>
<th>Return code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>GIMIAP processing was successful. The message issued by GIMIAP states that the invocation of GIMIAP was successful.</td>
</tr>
</tbody>
</table>
GIMIAP

Return code  Meaning
04  GIMIAP processing was successful. The message issued by GIMIAP states
    that the invocation of GIMIAP was successful, but one or more of the
    following has occurred:
    • An ALIAS was not installed during element installation.
    • The COPY or HFSCOPY utility issued a non-zero return code that is less
      than or equal to the acceptable return code as defined in the RC operand
      of the INVOKE statement.
08  SMP/E processing errors occurred or a return code from the copy utility was
    higher than the acceptable return code specified on the INVOKE control
    statement. At least one element was not installed correctly, although an
    attempt was made to install all elements to the target library. Review the copy
    utility print output and SMPOUT output to determine the error. Correct the
    problem and rerun the job step.
12  GIMIAP encountered an invalid control statement. As a result, the elements in
    that job step were not installed. Once a control statement error is
    encountered, no more elements are processed for that job step. The statement
    must be corrected and the job step must be rerun. However, subsequent job
    steps will be processed. The message issued by GIMIAP indicates how many
    80-byte records had been processed when the syntax error was encountered.
16  A severe error was encountered. As a result, the elements in that job step
    were not installed. After correcting the problem, the job step must be rerun.
    However, subsequent job steps will be processed. The message issued by
    GIMIAP indicates the cause of the problem, such as an I/O error on SYSIN,
    an open failure on SYSIN or another ddname, a syntax error on the EXEC
    parm, a syntax error on the control cards, or the absence of the copy utility.
20  A terminating error was encountered. The SMPOUT data set is not allocated
    or cannot be opened. GIMIAP is terminated.

JCL statements used in the DEIINST or HFSINST job

JCL statements are created for the DEIINST or HFSINST job during the
GENERATE process. Along with the GIMIAP control statements for each job step,
the JCL is composed of:

• A JOB statement. The JOB statement describes current installation-dependent
  parameters. The jobname is “DEIINST” when GIMIAP is to install data elements
  or “HFSINST” for hierarchical file system elements.
• One or more EXEC statements. The EXEC statement specifies
  **PGM=GIMIAP,PARM=’option’.**
    The step name is the name of the target library.
    The following is an example of the EXEC statement to call GIMIAP:

```
//jobname JOB ...
//stepname EXEC PGM=GIMIAP,PARM=‘option’
```

**Figure 106. JCL to call GIMIAP**

EXEC

is the statement used to call GIMIAP. The EXEC statement must specify
**PGM=GIMIAP.** The following option may be specified on the EXEC
statement PARM operand:

**LANGUAGE=XXX**

where XXX can be one of the following:
**ENU**    US English
**JPN**    Japanese
The LANGUAGE option defines which language to use for GIMIAP messages. LANGUAGE can also be specified as L. The LANGUAGE value will be the same as was used on GIMSMP while the GENERATE command was executed. If LANGUAGE is not specified, the default is LANGUAGE=ENU.

**DD statements.** The DD statements define the data sets to be used by GIMIAP processing. The following ddnames are required:

- **dlib** The file identified by a FROMLIB operand on a COPY control statement.
- **syslib** The file identified by a TOLIB operand on a COPY control statement.
- **print** This ddname is used by the copy utility for messages and processing information. If no DDDEF is found for the print file during GENERATE processing, the default of SYSOUT=* is generated. The ddname is the same as is specified for the PRINT operand of the INVOKE statement being used for the current invocation of GIMIAP.
- **SYSIN** Defines the input control stream for GIMIAP.
- **SMPOUT** The file to be used by the GIMIAP for message writing.
- **SYSPRINT** Contains output when GIMIAP is processing data elements or hierarchical file system elements with shell scripts.

The following DD statements are required when processing data elements:

- **SYSUT1** The file identified for containing the input statements to the copy program.
- **SYSUT3** A work file to be used by the copy program.
- **SYSUT4** A work file to be used by the copy program.

The following DD statement is required when processing file system elements that require the invocation of a UNIX shell script, and the shell script uses Java commands:

- **SMPJHOME** Directory in the UNIX file system that contains the Java runtime.

  During GIMIAP processing (invoked from the JCL produced by the GENERATE command), SMP/E can invoke a UNIX shell script to perform installation activities on behalf of a ++HFS file. If the UNIX shell script issues a Java command, the SMPJHOME DD statement is required.

  An SMPJHOME DD statement is created in the HFSINST job by the GENERATE command, if an SMPJHOME DDDEF entry is defined at the time the GENERATE command is run.

Figure 107 on page 510 illustrates the JCL statements that could be generated to invoke GIMIAP processing for data elements and Figure 108 on page 511 illustrates the JCL statements that could be generated to invoke GIMIAP processing for hierarchical file system elements.
Notes:

1. The **job** name “DEIINST” is generated during the job creation process. A single job installs the data elements.

2. The **job step** name is the target library. Each job step installs multiple data elements from multiple distribution libraries into a single target library.

Figure 107. Sample DEIINST job for GIMIAP
//HFSINST  JOB 'accounting info', MSGLEVEL=(1,1)

//tghfs01  EXEC PGM=GIMIAP
//distlib1 DD distribution library DD info.  distlib1
//distlib2 DD distribution library DD info.  distlib2
//tghfs01 DD PATH='/Hierarchical/File/System/library1/DD/info/'  tghfs01
//SYSPRINT DD SYSOUT=** DEFAULT
//SYSIN  DD *  DEFAULT

INVOKE HFSCOPY(BPXCOPY) RC(0) PRINT(SYSPRINT)
COPY FROMLIB(distlib1) TOLIB(tghfs01)
SELECT HFS(hfselem1) EPARAM(LLELEMENT(hfselem1),LINK('linkname01','linkname thatislongerthanthefirstoneandshouldbeuserfriendly'),TYPE(BINARY))
SELECT HFS(hfselem2) EPARAM(LLELEMENT(hfselem2),LINK('linknm01'),TYPE(TEXT))
COPY FROMLIB(distlib2) TOLIB(tghfs01)
SELECT HFS(hfselem3) EPARAM(LLELEMENT(hfselem3),TYPE(TEXT))
SELECT HFS(hfselem4) EPARAM(LLELEMENT(hfselem4),LINK('linknm01','linknm02', 'linknm03','linknm04','linknm05'))
/*

//tghfs02  EXEC PGM=GIMIAP
//distlib3 DD distribution library DD info.  distlib3
//distlib4 DD distribution library DD info.  distlib4
//tghfs02 DD PATH='/Hierarchical/File/System/library2/DD/info/'  tghfs02
//SYSPRINT DD SYSOUT=** DEFAULT
//SYSIN  DD *  DEFAULT

INVOKE HFSCOPY(BPXCOPY) RC(0) PRINT(SYSPRINT)
COPY FROMLIB(distlib3) TOLIB(tghfs02)
SELECT HFS(hfselem3) EPARAM(LLELEMENT(hfselem3),LINK('linknm01','linknm02', 'linknm03','linknm04'),TYPE(TEXT))
SELECT HFS(hfselem4) EPARAM(LLELEMENT(hfselem4),LINK('linknm01'),TYPE(TEXT))
COPY FROMLIB(distlib4) TOLIB(tghfs02)
SELECT HFS(hfselem5) EPARAM(LLELEMENT(hfselem5),TYPE(TEXT))
SELECT HFS(hfselem6) EPARAM(LLELEMENT(hfselem6),LINK('linknm01','linknm02', 'linknm03','linknm04','linknm05'),TYPE(TEXT))
/*

Notes:

1. The job name “HFSINST” is generated during the job creation process. A single job installs all hierarchical file system elements.

2. The job step name on the EXEC statement is the target library within a UNIX file system. Each job step installs multiple hierarchical file system elements from multiple distribution libraries into a single target library within a UNIX file system.

Figure 108. Sample HFSINST job for invoking GIMIAP
# Appendix A. SMP/E naming conventions

This appendix describes the naming conventions used by SMP/E. Table 61 summarizes the naming conventions you need to follow when using SMP/E. After this table are details on the naming conventions IBM follows for:

- HOLD reason IDs and classes
- Source IDs
- SYSMODs

<table>
<thead>
<tr>
<th>Table 61. Summary of SMP/E naming conventions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Entry or value</strong></td>
</tr>
</tbody>
</table>
| DDDEF entry | 1–8 alphabetic (A–Z), national (@, #, or $), or numeric (0–9) characters | • The first character must be alphabetic or national  
  • Must match ddname of data set |
| DLIB zone or DLIBZONE entry | 1–7 alphanumeric (A–Z, 0–9) or national ($, #, @) characters | The first character must be alphabetic. |
| Element entry | 1–8 alphanumeric (A–Z, 0–9) characters | Naming convention for first character:
  A–I Used by IBM  
  J–Z Available for users |
| FMID see SYMID ID | | |
| FMIDSET entry | 1–8 alphanumeric (A–Z, 0–9) characters | |
| Global zone or GLOBALZONE entry | Must be GLOBAL | |
| Hold class | 1–7 alphanumeric (A–Z, 0–9) characters | Naming convention for first character:
  A Reserved for IBM use  
  V Reserved for user-assigned values  
  For a description of the hold classes used by IBM, see “Class values” on page 516 |
| Hold reason ID: error | 1–7 alphanumeric (A–Z, 0–9) characters | Number of the APAR used to report an error in a PTF  
  For details on the conventions IBM follows, see “Error reason IDs” on page 514 |
| Hold reason ID: system | 1–7 alphanumeric (A–Z, 0–9) characters | Naming convention for first character:
  A–U Reserved for IBM use  
  V–Z Reserved for user-assigned values  
  For a description of the system reason IDs used by IBM, see “System reason IDs” on page 514 |
| Hold reason ID: user | 1–7 alphanumeric (A–Z, 0–9) characters | To avoid conflicts with IBM reason IDs, follow the conventions for system reason IDs.  
  For details on the conventions IBM follows, see “User reason IDs” on page 516 |
| OPTIONS entry | 1–8 alphanumeric (A–Z, 0–9) characters | |
Naming conventions

<td>ZONESET entry</td>
<td>1–8 alphanumeric (A–Z, 0–9) characters</td>
<td>Avoid using the same name as any of the target or DLIB zones defined in the global zone containing the ZONESET entry.</td>
</tr>
</tbody>
</table>

Naming conventions for HOLD reason IDs and HOLD classes

The ++HOLD statement prevents SMP/E from installing a SYMMD until some special action is taken. The type of action is indicated by the reason ID or class specified on the ++HOLD statement. A reason ID or class value can contain from 1 to 7 alphanumeric characters. To prevent conflicts between IBM- and user-specified values, there are naming conventions for the three types of HOLD reason IDs (error, system, and user), as well as for HOLD classes.

Error reason IDs

The reason ID for an error HOLD is the number of the APAR used to report an error in a PTF. Therefore, error reason IDs follow the naming conventions for APARs. These are described under "PTF, APAR, and USERMOD SYMMD IDs" on page 518.

System reason IDs

The reason ID for a system HOLD is generally a brief indication of the kind of processing the SYMMD requires. These are the values currently used by IBM:

<table>
<thead>
<tr>
<th>ID</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTION</td>
<td>The SYMMD needs special handling before or during APPLY processing, ACCEPT processing, or both.</td>
</tr>
</tbody>
</table>
| AO     | The SYMMD may require action to change automated operations procedures and associated data sets and user exits in products or in customer applications. The PTF cover letter describes any
Naming conventions

changes (such as to operator message text, operator command syntax, or expected actions for operator messages and commands) that can affect automation routines.

**DB2BIND**  A DB2 application REBIND is required for the SYSMOD to become effective.

**DDDEF**  Data set changes or additions as required.

**DELETE**  The SYSMOD contains a ++DELETE MCS, which deletes a load module from the system.

**DEP**  The SYSMOD has a software dependency.

**DOC**  The SYSMOD has a documentation change that should be read before the SYSMOD is installed.

**DOWNLD**  Code that is shipped with maintenance that needs to be downloaded.

**DYNACT**  The changes supplied by the SYSMOD may be activated dynamically without requiring an IPL. The HOLD statement describes the instructions required for dynamic activation. If those instructions are not followed, then an IPL is required for the SYSMOD to take effect.

**EC**  The SYSMOD needs a related engineering change.

**ENH**  The SYSMOD contains an enhancement, new option or function. The HOLD statement provides information to the user regarding the implementation and use of the enhancement.

**EXIT**  The SYSMOD contains changes that may affect a user exit. For example, the interface for an exit may be changed, an exit may need to be reassembled, or a sample exit may be changed.

**EXRF**  The SYSMOD must be installed in both the active and the alternative Extended Recovery Facility (XRF) systems at the same time to maintain system compatibility. (If you are not running XRF, you should bypass this reason ID.)

**FULLGEN**  The SYSMOD needs a complete system or subsystem generation to take effect.

**IOGEN**  The SYSMOD needs a system or subsystem I/O generation to take effect.

**IPL**  The SYSMOD requires an IPL to become effective. For example, the SYSMOD may contain changes to LPA or NUCLEUS, the changes may require a CLPA, or a failure to perform an IPL might lead to catastrophic results, such as could be caused by activation of a partial fix.

**Note:** If you plan to perform an IPL with CLPA after the SYSMOD has been applied, then no further investigation of the HOLD is required; simply bypass the IPL reason ID. However, if you are not planning to perform an IPL with CLPA, then the details of the HOLD statement must be investigated to determine what kind of actions are required to activate the SYSMOD.
Naming conventions

MSGSKEL  This SYSMOD contains message changes that must be compiled for
translated versions of the message changes to become operational
on extended TSO consoles.

If you want to use translated versions of the messages, you must
run the message compiler once for the library containing the
English message outlines, and once for each additional language
you want to be available on your system. For details, see \textit{z/OS
MVS Planning: Operations}.

If you want to use \textit{only} the English version of the messages, you
do not need to run the message compiler. You should bypass this
reason ID.

MULTSYS  Identifies fixes that need to be applied to multiple systems, in one
of three cases: preconditioning, coexistence, or exploitation.

RESTART  To become effective, the SYSMOD requires a special subsystem
restart operation. The HOLD statement contains information
regarding the required restart actions.

User reason IDs

The reason ID for a user HOLD is whatever you think is appropriate to describe
why the SYSMOD should be held. Because IBM does not use these reason IDs,
there are no restrictions on the values you can use. However, to prevent possible
confusion with other IBM reason IDs, follow the naming conventions for system
reason IDs.

Class values

A class value indicates an alternative way to release a held SYSMOD. These are the
values currently used by IBM:

<table>
<thead>
<tr>
<th>Class</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERREL</td>
<td>The SYSMOD is held for an error reason ID but should be installed</td>
</tr>
<tr>
<td></td>
<td>anyway. IBM has determined that the problem the SYSMOD resolves is significantly</td>
</tr>
<tr>
<td></td>
<td>more critical than the error reflected by the holding APAR.</td>
</tr>
<tr>
<td>HIPER</td>
<td>The SYSMOD is held with a hold class of HIPER (High Impact)</td>
</tr>
<tr>
<td>PE</td>
<td>The SYSMOD is held with a hold class of “PTF in Error”.</td>
</tr>
<tr>
<td>UCLREL</td>
<td>UCLIN needed for the SYSMOD has been handled by IBM and no longer requires</td>
</tr>
<tr>
<td></td>
<td>your attention.</td>
</tr>
<tr>
<td>YR2000</td>
<td>Identifies PTFs that provide Year 2000 function, or fix a Year 2000-related</td>
</tr>
<tr>
<td></td>
<td>problem.</td>
</tr>
</tbody>
</table>

Naming conventions for source IDs

With the SOURCEID operand, you can associate a name (a source ID) with each
SYSMOD processed by a single RECEIVE command, and then later process those
SYSMODs as a group by using that source ID. The following values are currently
used by IBM:

\textit{RSUyyymm}  This is the indicator used to identify a Recommended Service
Upgrade. For more information on RSU, see \textit{SMP/E User's Guide}.

\textit{PUTyyymm}  Each PTF is assigned a source ID in the format PUTyyymm.

\textbullet  \textit{yy} is the year the PTF was made available as preventive service.
Naming conventions

- *mm* is the month the PTF was made available as preventive service.

The PUTyyymm source ID represents a monthly accumulation of PTFs that have been COR-closed (made available for corrective service) within a given month and assigned a RETAIN VOLID indicating this. The RETAIN VOLID reflects the monthly PUTyyymm level no later than the 15th of the following month. For example, PUT0706 represents PTFs that were COR-closed in June 2008 and assigned a RETAIN VOLID of 0706 between July 1 and July 15.

**SMCCOR**

This indicates a PTF that is approved for distribution, but has not been assigned a monthly PUTyyymm source ID at the time your order was created. SMCCOR PTFs are not necessary for installation; however, they are made available for corrective service. If you plan to install any of the PTFs with this source ID, refer to the CORPE PSP bucket or latest available PUT bucket for the most current HOLD information. These PTFs are provided in case you experience the problem they fix and need to install them as corrective service.

**SMCREC**

This indicates a PTF that is approved for distribution and is recommended for installation, but has not been assigned a monthly PUTyyymm source ID at the time your order was created. These PTFs should be installed on your system. They were assigned a source ID of SMCREC for one of the following reasons:

- The PTF is needed to install a product.
- The PTF is needed to support new hardware.
- The PTF resolves an error for another PTF (PE-PTF).

To further enhance your ability to selectively install PUTyyymm and SMCREC PTFs, the additional SOURCEIDs listed below are assigned to the applicable PTFs. (There will be PUTyyymm and SMCREC PTFs that do not fall into the categories below and, therefore, are not assigned multiple source IDs.)

- **HIPER** identifies PTFs resolving a high-impact APAR
- **SPE** identifies PTFs that are small programming enhancements
- **PRP** identifies PTFs that resolve PTFs in error

**OS390Rn**

This indicates a PTF that is at the integration tested level for OS/390 Release *n*.

**YR2000**

This identifies PTFs that provide Year 2000 function, or fix a Year 2000-related problem.

**Naming conventions for SYSMODs**

The specific naming conventions for a SYSMOD ID depend on the type of SYSMOD: function, PTF, APAR, or USERMOD. The following sections define IBM’s naming conventions for SYSMOD IDs. This information is provided to help you develop a naming scheme for your own SYSMODs and avoid conflicts with IBM-written SYSMODs. However, these conventions are not requirements for user-written SYSMODs, and SMP/E does not check whether a SYSMOD ID follows these conventions.
Naming conventions

Function SYSMOD IDs

The IBM convention for the SYSMOD ID of a function SYSMOD is \textit{tccrrr}, where:

\begin{itemize}
  \item \textit{t} is the type of function. These are the values used by IBM:
    \begin{itemize}
      \item A: Licensed vendor or business partner base function
      \item B: Licensed vendor or business partner dependent function
      \item C, D: Reserved for future use
      \item E: Unlicensed base function
      \item F: Unlicensed dependent function
      \item G: Reserved for future use
      \item H: Licensed base function
      \item I: Reserved for future use
      \item J: Licensed dependent function
      \item K: Reserved for future use
    \end{itemize}
  \item \textit{ccc} For functions provided by IBM, this is the product code. It must be three alphanumeric characters (no vowels).
  \item \textit{rrr} For functions provided by IBM, this is the release number. It identifies a specific function within a product. These three characters identify a specific release of a product function and must be alphanumeric.
\end{itemize}

\textbf{Note:} The former convention for the SYSMOD ID of a function was \textit{tvvrrr}.

PTF, APAR, and USERMOD SYSMOD IDs

The IBM convention for the SYSMOD ID of a service SYSMOD (APAR, APAR fix, PTF) or USERMOD is \textit{tannnn}, where:

\begin{itemize}
  \item \textit{t} identifies the type of SYSMOD. It is a single alphanumeric character. These are the values used by IBM:
    \begin{itemize}
      \item A–K: Used by IBM for various levels of an APAR fix
      \item L–T: Available for users
      \item U: Used by IBM for PTFs
      \item V–Z: Used by IBM for various levels of an APAR fix
    \end{itemize}
  \item \textit{a} is any alphabetic character (A–Z). Any valid character can be used for user SYSMODs.
  \item \textit{nnnnn} is an additional identifier for the SYSMOD. For PTFs and APAR fixes supplied by IBM, it is a number from 00001 to 99999. Any valid characters can be used for user SYSMODs.
\end{itemize}
Appendix B. Accessibility

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use software products successfully. The major accessibility features in z/OS enable users to:

- Use assistive technologies such as screen readers and screen magnifier software
- Operate specific or equivalent features using only the keyboard
- Customize display attributes such as color, contrast, and font size

Using assistive technologies

Assistive technology products, such as screen readers, function with the user interfaces found in z/OS. Consult the assistive technology documentation for specific information when using such products to access z/OS interfaces.

Keyboard navigation of the user interface

Users can access z/OS user interfaces using TSO/E or ISPF. Refer to [z/OS TSO/E Primer](http://www.ibm.com/systems/z/os/zos/bkserv/) and [z/OS ISPF User's Guide Vol I](http://www.ibm.com/systems/z/os/zos/bkserv/) for information about accessing TSO/E and ISPF interfaces. These guides describe how to use TSO/E and ISPF, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

z/OS information

z/OS information is accessible using screen readers with the BookServer/Library Server versions of z/OS books in the Internet library at:

Notices

This information was developed for products and services offered in the USA.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user’s responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not give you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
USA

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

IBM World Trade Asia Corporation
Licensing
2-31 Roppongi 3-chome, Minato-ku
Tokyo 106, Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law:

Mail Station P300
2455 South Road
Poughkeepsie, NY 12601-5400
USA

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement, or any equivalent agreement between us.

If you are viewing this information softcopy, the photographs and color illustrations may not appear.

Programming interface information

This publication is intended to help you understand the output from SMP/E processing.

This publication also documents intended Programming Interfaces that allow the customer to write programs to obtain the services of IBM SMP/E for z/OS, V3R5. This Programming Interface information is identified where it occurs by an introductory statement to a chapter or section.

This publication also documents information that is not intended to be used as a Programming Interface of IBM SMP/E for z/OS, V3R5. This information is identified where it occurs by an introductory statement to a chapter or section.

Policy for unsupported hardware

Various z/OS elements, such as DFSMS™, HCD, JES2, JES3, and MVS, contain code that supports specific hardware servers or devices. In some cases, this device-related element support remains in the product even after the hardware devices pass their announced End of Service date. z/OS may continue to service element code; however, it will not provide service related to unsupported hardware devices. Software problems related to these devices will not be accepted for service, and current service activity will cease if a problem is determined to be associated with out-of-support devices. In such cases, fixes will not be issued.

Trademarks

IBM, the IBM logo, and ibm.com® are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at "Copyright and trademark information" at www.ibm.com/legal/copytrade.shtml

Microsoft, Windows, Windows NT®, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.
UNIX is a registered trademark of The Open Group in the United States and other countries.

Java and all Java-based trademarks are trademarks of Sun Microsystems, Inc. in the United States, other countries, or both.

Other company, product, or service names may be trademarks or service marks of others.
