About this document

This document supports z/OS (5650-ZOS).

IBM® z/OS Language Environment (also called Language Environment) provides common services and language-specific routines in a single runtime environment for C, C++, COBOL, Fortran (z/OS only; no support for z/OS UNIX System Services or CICS®), PL/I, and assembler applications. It offers consistent and predictable results for language applications, independent of the language in which they are written.

Language Environment is the prerequisite runtime environment for applications generated with the following IBM compiler products:

- z/OS XL C/C++ (feature of z/OS)
- z/OS® C/C++
- OS/390® C/C++
- C/C++ for MVS/ESA
- C/C++ for z/VM®
- XL C/C++ for z/VM
- AD/Cycle C/370™
- VisualAge for Java, Enterprise Edition for OS/390
- Enterprise COBOL for z/OS
- Enterprise COBOL for z/OS and OS/390
- COBOL for OS/390 & VM
- COBOL for MVS & VM (formerly COBOL/370)
- Enterprise PL/I for z/OS
- Enterprise PL/I for z/OS and OS/390
- VisualAge® PL/I
- PL/I for MVS & VM (formerly PL/I MVS™ & VM)
- VS FORTRAN and FORTRAN IV (in compatibility mode)

Although not all compilers listed are currently supported, Language Environment® supports the compiled objects that they created.

Language Environment supports, but is not required for, an interactive debug tool for debugging applications in your native z/OS environment.

Debug Tool is also available as a standalone product as well as Debug Tool Utilities and Advanced Functions. For more information, see the Debug Tool for z/OS home page (http://ibm.co/1GOKBov).

Language Environment supports, but is not required for, VS FORTRAN Version 2 compiled code (z/OS only).

Language Environment consists of the common execution library (CEL) and the runtime libraries for C/C++, COBOL, Fortran, and PL/I.

For more information about VisualAge for Java, Enterprise Edition for OS/390, program number 5655-JAV, see the product documentation.

This publication provides application programmers with a detailed description of each Language Environment runtime option and callable service, as well as information about how to use them. It also provides programming examples that
illustrate how each callable service can be used in routines written in Language Environment-conforming high-level languages (HLLs) and assembler language. Before using Language Environment, you should be familiar with the HLLs in which your applications are written. You should also understand the operating systems and any subsystems in which you plan to run Language Environment applications.

**Using your documentation**

The publications provided with Language Environment are designed to help you:

- Manage the runtime environment for applications generated with a Language Environment-conforming compiler.
- Write applications that use the Language Environment callable services.
- Develop interlanguage communication applications.
- Customize Language Environment.
- Debug problems in applications that run with Language Environment.
- Migrate your high-level language applications to Language Environment.

Language programming information is provided in the supported high-level language programming manuals, which provide language definition, library function syntax and semantics, and programming guidance information.

Each publication helps you perform different tasks, some of which are listed in Table 1.

How to read syntax diagrams

This section describes how to read syntax diagrams. It defines syntax diagram symbols, items that may be contained within the diagrams (keywords, variables, delimiters, operators, fragment references, operands) and provides syntax examples that contain these items.

Syntax diagrams pictorially display the order and parts (options and arguments) that comprise a command statement. They are read from left to right and from top to bottom, following the main path of the horizontal line.

For users accessing the Information Center using a screen reader, syntax diagrams are provided in dotted decimal format.

Symbols

The following symbols may be displayed in syntax diagrams:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>►►◄◄◄</td>
<td>Indicates the beginning of the syntax diagram.</td>
</tr>
<tr>
<td>——-&gt;</td>
<td>Indicates that the syntax diagram is continued to the next line.</td>
</tr>
<tr>
<td>►——</td>
<td>Indicates that the syntax is continued from the previous line.</td>
</tr>
<tr>
<td>————</td>
<td>Indicates the end of the syntax diagram.</td>
</tr>
</tbody>
</table>

Syntax items

Syntax diagrams contain many different items. Syntax items include:

- Keywords - a command name or any other literal information.
- Variables - variables are italicized, appear in lowercase, and represent the name of values you can supply.
- Delimiters - delimiters indicate the start or end of keywords, variables, or operators. For example, a left parenthesis is a delimiter.
- Operators - operators include add (+), subtract (-), multiply (*), divide (/), equal (=), and other mathematical operations that may need to be performed.
- Fragment references - a part of a syntax diagram, separated from the diagram to show greater detail.
- Separators - a separator separates keywords, variables or operators. For example, a comma (,) is a separator.

Note: If a syntax diagram shows a character that is not alphanumeric (for example, parentheses, periods, commas, equal signs, a blank space), enter the character as part of the syntax.
Keywords, variables, and operators may be displayed as required, optional, or default. Fragments, separators, and delimiters may be displayed as required or optional.

**Item type**

**Definition**

**Required**

Required items are displayed on the main path of the horizontal line.

**Optional**

Optional items are displayed below the main path of the horizontal line.

**Default**

Default items are displayed above the main path of the horizontal line.

**Syntax examples**

The following table provides syntax examples.

<table>
<thead>
<tr>
<th>Table 2. Syntax examples</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Item</strong></td>
<td><strong>Syntax example</strong></td>
</tr>
<tr>
<td>Required item</td>
<td></td>
</tr>
<tr>
<td>Required items appear on the main path of the horizontal line. You must specify these items.</td>
<td>[KEYWORD]required_item</td>
</tr>
<tr>
<td>Required choice</td>
<td></td>
</tr>
<tr>
<td>A required choice (two or more items) appears in a vertical stack on the main path of the horizontal line. You must choose one of the items in the stack.</td>
<td>[KEYWORD]required_choice1 required_choice2</td>
</tr>
<tr>
<td>Optional item</td>
<td></td>
</tr>
<tr>
<td>Optional items appear below the main path of the horizontal line.</td>
<td>[KEYWORD]optional_item</td>
</tr>
<tr>
<td>Optional choice</td>
<td></td>
</tr>
<tr>
<td>An optional choice (two or more items) appears in a vertical stack below the main path of the horizontal line. You may choose one of the items in the stack.</td>
<td>[KEYWORD]optional_choice1 optional_choice2</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
<tr>
<td>Default items appear above the main path of the horizontal line. The remaining items (required or optional) appear on (required) or below (optional) the main path of the horizontal line. The following example displays a default with optional items.</td>
<td>[KEYWORD]default_choice1 optional_choice2 optional_choice3</td>
</tr>
<tr>
<td>Variable</td>
<td></td>
</tr>
<tr>
<td>Variables appear in lowercase italics. They represent names or values.</td>
<td>[KEYWORD]variable</td>
</tr>
</tbody>
</table>
Table 2. Syntax examples (continued)

<table>
<thead>
<tr>
<th>Item</th>
<th>Syntax example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repeatable item.</td>
<td><img src="image" alt="Syntax Example" /></td>
</tr>
</tbody>
</table>

An arrow returning to the left above the main path of the horizontal line indicates an item that can be repeated.

A character within the arrow means you must separate repeated items with that character.

An arrow returning to the left above a group of repeatable items indicates that one of the items can be selected, or a single item can be repeated.

Fragment.

The fragment symbol indicates that a labelled group is described below the main syntax diagram. Syntax is occasionally broken into fragments if the inclusion of the fragment would overly complicate the main syntax diagram.

```
fragment: [ ,required_choice1 ] [ ,required_choice2 ] [ ,default_choice ] [ ,optional_choice ]
```

z/OS information

This information explains how z/OS references information in other documents and on the web.

When possible, this information uses cross document links that go directly to the topic in reference using shortened versions of the document title. For complete titles and order numbers of the documents for all products that are part of z/OS, see [z/OS V2R2 Information Roadmap](http://www.ibm.com/support/knowledgecenter/SSLTBW/welcome).

To find the complete z/OS library, go to [IBM Knowledge Center](http://www.ibm.com/support/knowledgecenter/SSLTBW/welcome).
How to send your comments to IBM

We appreciate your input on this publication. Feel free to comment on the clarity, accuracy, and completeness of the information or provide any other feedback that you have.

Use one of the following methods to send your comments:

1. Send an email to mhvrcfs@us.ibm.com.
2. Send an email from the "Contact us" web page for z/OS (http://www.ibm.com/systems/z/os/zos/webqs.html).

Include the following information:
• Your name and address.
• Your email address.
• Your telephone or fax number.
• The publication title and order number:
  z/OS V2R2 Language Environment Programming Reference
  SA38-0683-02
• The topic and page number that is related to your comment.
• The text of your comment.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute the comments in any way appropriate without incurring any obligation to you.

IBM or any other organizations use the personal information that you supply to contact you only about the issues that you submit.

If you have a technical problem

Do not use the feedback methods that are listed for sending comments. Instead, take one of the following actions:
• Contact your IBM service representative.
• Call IBM technical support.
Summary of changes

This information includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations for the current edition are indicated by a vertical line to the left of the change.

Summary of changes for z/OS Version 2 Release 2 (V2R2) as updated December, 2015

New
- A new callable service, CEERCDM, was added. See “CEERCDM—Record information for an active condition” on page 22.

Changed
- Table 9 on page 109 was updated to include the new CEERCDM callable service.

Deleted
No content was removed from this information.

Summary of changes for z/OS Version 2 Release 2 (V2R2)

The following changes are made to z/OS Version 2 Release 2 (V2R2).

New
- The CEE_Version_ID parameter for CEEGPID was updated for V2R2. See “CEEGPID—Retrieve the Language Environment version and platform ID” on page 300.

Changed
- An usage note was updated in “PAGEFRAMESIZE64” on page 62.
- An usage note was updated in “PLIST (C only)” on page 65.

Deleted
No content was removed from this information.

z/OS Version 2 Release 1 summary of changes

See the following publications for all enhancements to z/OS Version 2 Release 1 (V2R1):
- z/OS V2R2 Migration
- z/OS Planning for Installation
- z/OS Summary of Message and Interface Changes
- z/OS V2R2 Introduction and Release Guide
Part 1. Language Environment runtime options

The following sections contain detailed information about how to use the Language Environment runtime options.
Chapter 1. Summary of Language Environment runtime options

The quick reference tables for each of the Language Environment runtime options and information help you read syntax diagrams and specify the runtime options. The tables list the location of the options and briefly state their function.

Quick reference table for AMODE 31 runtime options

Table 3 provides a quick reference of the Language Environment runtime options for AMODE 31 applications.

<table>
<thead>
<tr>
<th>Runtime options</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABPERC</td>
<td>Percolates a specified abend. See &quot;ABPERC&quot; on page 9.</td>
</tr>
<tr>
<td>ABTERMENC</td>
<td>Sets the enclave termination behavior for an enclave ending with an unhandled condition of severity 2 or greater. See &quot;ABTERMENC&quot; on page 10.</td>
</tr>
<tr>
<td>AIXBLD</td>
<td>NOAIXBLD</td>
</tr>
<tr>
<td>ALL31</td>
<td>Indicates whether an application does or does not run entirely in AMODE(31). See &quot;ALL31&quot; on page 12.</td>
</tr>
<tr>
<td>ANYHEAP</td>
<td>Controls allocation of library heap storage not restricted to below the 16M line. See &quot;ANYHEAP&quot; on page 14.</td>
</tr>
<tr>
<td>ARGPARSE</td>
<td>Specifies if arguments on the command line are to be parsed in the usual C format. See &quot;ARGPARSE</td>
</tr>
<tr>
<td>AUTOTASK</td>
<td>Specifies if Fortran Multitasking Facility is to be used by your program and the number of tasks that are allowed to be active. See &quot;AUTOTASK</td>
</tr>
<tr>
<td>BELOWHEAP</td>
<td>Controls allocation of library heap storage below the 16M line. See &quot;BELOWHEAP&quot; on page 17.</td>
</tr>
<tr>
<td>CBLOPTS</td>
<td>Specifies the format of the argument string on application invocation when the main program is COBOL. See &quot;CBLOPTS (COBOL only)&quot; on page 18.</td>
</tr>
<tr>
<td>CBLPSHPOP</td>
<td>Controls if CICS PUSH HANDLE and CICS POP HANDLE commands are issued when a COBOL subprogram is called. See &quot;CBLPSHPOP (COBOL only)&quot; on page 18.</td>

How to specify runtime options

When specifying runtime options, use commas to separate any suboptions of those options. If you do not specify a suboption, you must still include the comma to indicate the omission of the suboption. For example: STACK(,,ANYWHERE,FREE,,). Trailing commas, however, are not required. STACK(,,ANYWHERE,FREE) is valid. If you do not specify any suboptions, they are ignored. Either of the following is valid: STACK or STACK().

If you run applications that are invoked by one of the exec family of functions, such as a program executed under the z/OS UNIX System Services shell, you can also use the _CEE_RUNOPTS environment variable to specify runtime options.

Refer to z/OS Language Environment Programming Guide for a detailed description of the various ways in which you can specify Language Environment runtime options and program arguments, and use _CEE_RUNOPTS.

Restriction: The double quotes character (") may not be part of the runtime options string for applications running under Turkish code page 1026. Use the single quote character (’) instead.

Propagating runtime options with spawn and exec

When going from AMODE 31 to AMODE 64 and back through the spawn or exec functions, Language Environment rebuilds the _CEE_RUNOPTS environment variable as a way to propagate runtime options to the new program. In the situations where AMODE 31 specific options or AMODE 64 specific options would
be passed across to the other mode, Language Environment ignores these options. No messages are issued. For example, when the STACK option is sent across from AMODE 31 to AMODE 64, it is ignored. This is because the AMODE 64 application uses the STACK64 option. No attempt to convert the AMODE 31 option to the new AMODE 64 option is performed.
Chapter 2. Using the Language Environment runtime options

The Language Environment runtime options, their syntax, and their usage are described. IBM-supplied default keywords appear above the main path or options path in the syntax diagrams. In the parameter list, IBM-supplied default choices are underlined. The minimum unambiguous abbreviation of each Language Environment option is also indicated in its syntax diagram with capital letters (for example, ABP indicates that ABP is the minimum abbreviation).

ABPERC

**Derivation:** ABnormal PERColation

ABPERC percolates an abend whose code you specify. This provides Language Environment condition handling semantics for all abends, except for the one specified. TRAP(ON) must be in effect. When you run with ABPERC and encounter the specified abend:

- User condition handlers are not enabled.
- Under z/OS UNIX, POSIX signal handling semantics are not enabled for the abend.
- No storage report or the report for runtime option is generated.
- No Language Environment messages or Language Environment formatted dump output is generated.
- The assembler user exit is not driven for enclave termination.
- The abnormal termination exit, if there is one, is not driven.
- Files that are opened by HLLs are not closed by Language Environment, so records might be lost.
- Resources that are acquired by Language Environment are not freed.
- A debugging tool, if one is active, is not notified of the error.

**Tip:** You can also use the CEEBXITA assembler user exit to specify a list of abend codes for Language Environment to percolate. For more information about CEEBXITA, see [z/OS Language Environment Programming Guide](https://www.ibm.com/support/knowledgecenter/p7wj7f_9.1.0/com.ibm.zos docs.le.p210079/p210079.htm).

The default value for non-CICS applications is ABPERC(NONE).

ABPERC is ignored under CICS.

**Syntax**

```
ABPERC (NONE abcode)
```

- **NONE**
  - Specifies that all abends are handled according to Language Environment condition handling semantics.
ABPERC

abcode
Specifications the abend code to percolate. The abcode can be specified as:

Shhh A system abend code, where hhh is the hex system abend code
Udddt A user abend code, where ddd is a decimal user abend code. Any
4-character string can also be used as ddd.

z/OS UNIX consideration

ABPERC percolates an abend regardless of the thread in which it occurs.

Usage notes

• Language Environment ignores ABPERC(S0Cx). In this instance, no abend is
percolated, and Language Environment condition handling semantics are in
effect.
• You can identify only one abend code with this option. However, an abend
U0000 is interpreted in the same way as S000.

ABTERMENC

Derivation: ABnormal TERmination of the ENClave

ABTERMENC sets the enclave termination behavior for an enclave ending with an
unhandled condition of severity 2 or greater. TRAP(ON) must be in effect.

The default value for non-CICS applications is ABTERMENC(ABEND).

The default value for CICS applications is ABTERMENC(ABEND).

Syntax

►►ABTermenc(RETCODE)◄◄

ABEND

When an unhandled condition of severity 2 or greater is encountered,
Language Environment issues an abend to end the enclave. Default abend
processing occurs as follows:
• Language Environment sets an abend code value that depends on the type
of unhandled condition.
• Language Environment sets a reason code value that depends on the type of
unhandled condition.
• Language Environment does not request a system dump.
• Language Environment issues an abend to terminate the task.

RETCODE

When an unhandled condition of severity 2 or greater is encountered,
Language Environment issues a return code and reason code to end the
enclave.
**ABTERMENC**

**z/OS UNIX consideration**

In a multithreaded application with ABTERMENC(ABEND), Language Environment issues an abend on the task associated with the initial processing thread (IPT), regardless of which thread experienced the unhandled condition. All non-IPT threads are terminated normally. This means that the thread that encountered the unhandled condition is terminated normally if it is a non-IPT thread.

**Usage notes**

- You can use the assembler user exit, CEEAUE_ABND, to modify the behavior of this runtime option by setting the CEEAUE_ABND flag. See [z/OS Language Environment Programming Guide](z/OS Language Environment Programming Guide) for more information.
- To gather information about the unhandled condition, see “TERMTHDACT” on page 83.

**For more information**

For information about return code calculation and abend codes, see [z/OS Language Environment Programming Guide](z/OS Language Environment Programming Guide).

---

**AIXBLD (COBOL only)**

**Derivation:** Alternate IndeX BuilD

AIXBLD invokes the access method services (AMS) for VSAM indexed and relative data sets (KSDS and RRDS) to complete the file and index definition procedures for COBOL programs. AIXBLD conforms to the ANSI 1985 COBOL standard.

The default value for non-CICS applications is NOAIXBLD.

AIXBLD is ignored under CICS.

**Syntax**

```
AIXBLD
AIX
```

- **NOAIXBLD**
  - Does not invoke the access method services for VSAM indexed and relative data sets. NOAIXBLD can be abbreviated NOAIX.

- **AIXBLD**
  - Invokes the access method services for VSAM indexed and relative data sets. AIXBLD can be abbreviated AIX®.

**z/OS UNIX consideration**

If you also specify the MSGFILE runtime option, the access method services messages are directed to the MSGFILE *ddname* or to the default SYSOUT.
Performance consideration

Running your program under AIXBLD requires more storage, which can degrade performance. Therefore, use AIXBLD only during application development to build alternate indexes. Use NOAIXBLD when you have already defined your VSAM data sets.

For more information

- See the appropriate version of the COBOL programming guide in the COBOL library at Enterprise COBOL for z/OS library (http://www.ibm.com/support/docview.wss?uid=swg27036733).
- See “MSGFILE” on page 55 for information about the MSGFILE runtime option.

ALL31

Derivation: ALL AMODE 31

ALL31 specifies if an application can run entirely in AMODE 31 or if the application has one or more AMODE 24 routines.

Guideline: ALL31 should have the same setting for all enclaves in a process. Language Environment does not support the invocation of a nested enclave requiring ALL31(OFF) from an enclave running with ALL31(ON) in non-CICS environments.

The default value for non-CICS applications is ALL31(ON).

The default value for CICS applications is ALL31(ON).

Syntax

```
ON
```

If the initial routine of the Language Environment application is AMODE 31, this setting indicates that no other routines in the application will be AMODE 24.

If the initial routine of the Language Environment application is AMODE 24, ALL31 is dynamically switched to OFF. No message will be issued to indicate this action. However, if you generate a Language Environment runtime options report using the RPTOPTS runtime option, the ALL31 option will be reported as "override" under the LAST WHERE SET column.

When ALL31(ON) remains in effect:

- AMODE switching across calls to Language Environment common runtime routines is minimized. For example, no AMODE switching is performed on calls to Language Environment callable services.
- Language Environment allocates storage for the common anchor area (CAA) and other control blocks in unrestricted storage.
- COBOL EXTERNAL data is allocated in unrestricted storage.
Indicates that one or more routines of a Language Environment application are AMODE 24. When ALL31(OFF) is in effect:

- Language Environment uses more storage below the 16M line.
- AMODE switching across calls to Language Environment common runtime routines is performed. For example, AMODE switching is performed on calls to Language Environment callable services.
- Language Environment allocates storage for the common anchor area (CAA) and other control blocks in storage below the 16M line.
- COBOL EXTERNAL data is allocated in storage below the 16M line.

Restriction: If you use the setting ALL31(OFF), you must also use the setting STACK,,BELOW,,. AMODE 24 routines require stack storage below the 16M line.

z/OS UNIX considerations

- In a multithreaded environment, the ALL31 option applies to all threads in a process.
- In a multithreaded environment, the thread start routine specified in the C pthread_create() function call is invoked in AMODE 31.

Usage notes

- Restrictions: You must specify ALL31(OFF) if your COBOL applications contain one of the following programs:
  - VS COBOL II NORES
  - OS/VS COBOL (non-CICS)
  - If the Language Environment environment was initialized using ILBOSTP0
- PL/I considerations: For PL/I MTF applications, Language Environment provides AMODE switching. Therefore, the first routine of a task can be in AMODE 24.
- Fortran considerations: Use ALL31(ON) if all of the compile units in the enclave have been compiled with VS FORTRAN Version 1 or Version 2 and there are no requirements for 24-bit addressing mode. Otherwise, use ALL31(OFF).
- XPLINK considerations: When an application is running in an XPLINK environment (that is, either the XPLINK(ON) runtime option was specified, or the initial program contained at least one XPLINK compiled part), the ALL31 runtime option is forced to ON. No AMODE 24 routines are allowed in an enclave that uses XPLINK. No message is issued to indicate this action. If a Language Environment runtime options report is generated using the RPTOPTS runtime option, the ALL31 option is reported as "Override" under the LAST WHERE SET column.
- Guideline: ALL31 should have the same setting for all enclaves in a process. Language Environment does not support the invocation of a nested enclave requiring ALL31(OFF) from an enclave running with ALL31(ON) in non-CICS environments.

Performance consideration

If your application consists entirely of AMODE 31 routines, it will run faster and use less below-the-line storage with ALL31(ON) than with ALL31(OFF).
For more information
• See “STACK” on page 76 for information about the STACK runtime option.
• See “XPLINK” on page 103 for information about the XPLINK runtime option.

ANYHEAP

The ANYHEAP runtime option controls the allocation of unrestricted library heap storage (anywhere heap). Storage that is unrestricted can be located anywhere in 31-bit addressable storage.

The default value for non-CICS applications is ANYHEAP(16K,8K,ANYWHERE,FREE).

The default value for CICS applications is ANYHEAP(4K,4080,ANYWHERE,FREE).

Syntax

\[\text{Syntax} \]

\[
\text{ANYheap(} \text{init\_size, incr\_size, ANYWHERE|ANY, BELOW, FREE, KEEP)}
\]

\[\text{Syntax} \]

init\_size
Determines the initial size of the anywhere heap. This value can be specified as \(n\), \(nK\), or \(nM\) bytes of storage. The actual amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

incr\_size
Determines the minimum size of any subsequent increment to the anywhere heap. This value can be specified as \(n\), \(nK\), or \(nM\) bytes of storage. The actual amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

ANYWHERE|ANY
Specifies that anywhere heap can be allocated anywhere in 31-bit addressable storage. If there is no storage available above the 16M line, storage is acquired below the 16-MB line.

BELOW
Specifies that anywhere heap is allocated below the 16M line.

FREE
Specifies that an anywhere heap increment is released when the last of the storage within that increment is freed.

KEEP
Specifies that an anywhere heap increment is not released when the last of the storage within that increment is freed.
CICS consideration

- If ANYHEAP(0) is specified, the initial anywhere heap segment is obtained on the first use and will be based on the increment size.
- The maximum initial and increment size for the anywhere heap is 1 gigabyte (1024M).
- The default increment size is 4080 bytes, rather than 4096 bytes, to accommodate the 16 byte CICS storage check zone. Without this accommodation, an extra page of storage is allocated (only when the storage allocation is below the 16 MB line). If you choose to change the increment size, it is recommended that you adjust for the 16 byte CICS storage check zone.

z/OS UNIX considerations

- In a multithreaded environment, the anywhere heap is shared by all threads in the process.
- When ALL31(ON) is in effect, Language Environment allocates thread-specific control blocks from the anywhere heap.

Performance consideration

You can improve performance with the ANYHEAP runtime option by specifying values that minimize the number of times the operating system allocates storage. See "RPTSTG" on page 73 for information about how to generate a report you can use to determine the optimum values for the ANYHEAP runtime option.

For more information

For more information about heap storage and heap storage tuning with storage report numbers, see z/OS Language Environment Programming Guide.

ARGPARSE | NOARGPARSE (C only)

Derivation: ARGument PARSE

ARGPARSE specifies if command-line arguments to a C/C++ program are to be parsed. This option does not apply to non-C/C++ languages and can be specified with the #pragma runopts directive or the ARGPARSE or NOARGPARSE compiler option.

Restriction: You cannot set this option at the system level, region level, or in the CEEBXITA assembler user exit interface.

The default value for non-CICS applications is ARGPARSE.

ARGPARSE is ignored under CICS.

The default value for AMODE 64 applications is ARGPARSE.
ARGPARSE | NOARGPARSE

Syntax

```
ARGPARSE
NOARGPARSE
```

**ARGPARSE**

Specifies that arguments given on the command line are to be parsed and given to the `main()` function in the usual C argument format (`argv` and `argc`).

**NOARGPARSE**

Specifies that arguments given on the command line are not parsed but are passed to the `main()` function as one string. Therefore, `argc` has a value of 2, and `argv[1]` contains a pointer to the command-line string.

**Note:** NOARGPARSE is ignored for programs that utilize `spawn()` or `exec()` or for any program that is started by the z/OS UNIX System Services shell or by the BPXBATCH utility.

**Usage notes**

You must specify ARGPARSE for the REDIR runtime option to have an effect.

**For more information**

See "REDIR | NOREDIR (C only)" on page 71 for a description of REDIR.

AUTOTASK | NOAUTOTASK (Fortran only)

AUTOTASK specifies if Fortran multitasking facility (MTF) is to be used by your program and the number of tasks that are allowed to be active.

The default value for non-CICS applications is NOAUTOTASK.

AUTOTASK is ignored under CICS.

Syntax

```
NOAUTOTASK
AUTOTASK
{loadmod, numtasks}
```

**NOAUTOTASK**

Disables the MTF and nullifies the effects of previous specifications of AUTOTASK parameters.

`loadmod`

The name of the load module that contains the concurrent subroutines that run in the subtasks created by MTF.

`numtasks`

The number of subtasks created by MTF. This value can range from 1 through 99.
BELOWHEAP

The BELOWHEAP runtime option controls the allocation of restricted library heap storage (below heap). Storage that is restricted must be located below the 16M line (24-bit addressable storage).

The default value for non-CICS applications is BELOWHEAP(8K,4K,FREE).

The default value for CICS applications is BELOWHEAP(4K,4080,FREE).

Syntax

```
BELOWHEAP(init_size, incr_size, FREE, KEEP)
```

**init_size**

Determines the minimum initial size of the below heap storage. This value can be specified as \( n, nK, \) or \( nM \) bytes of storage. The actual amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**incr_size**

Determines the minimum size of any subsequent increment to the area below the 16M line, and is specified in \( n, nK, \) or \( nM \) bytes of storage. This value is rounded up to the nearest multiple of 8 bytes.

**FREE**

Specifies that storage allocated to BELOWHEAP increments is released when the last of the storage is freed.

**KEEP**

Specifies that storage allocated to BELOWHEAP increments is not released when the last of the storage within that increment is freed.

**CICS consideration**

The default increment size is 4080 bytes, rather than 4096 bytes, to accommodate the 16-byte CICS storage check zone. Without this accommodation, an extra page of storage is allocated (only when the storage allocation is below the 16-MB line). If you choose to change the increment size, it is recommended that you adjust for the 16-byte CICS storage check zone.

**z/OS UNIX considerations**

- In a multithreaded environment, the below heap is shared by all threads in the process.
- When ALL31(OFF) is in effect, Language Environment allocates thread-specific control blocks from the below heap.

**Usage notes**

If BELOWHEAP(0) is specified, the initial below heap segment is obtained on the first use and is based on the increment size.
Performance consideration

You can improve performance with the BELOWHEAP runtime option by specifying values that minimize the number of times the operating system allocates storage. See “RPTSTG” on page 73 for information about how to generate a report you can use to determine the optimum values for the BELOWHEAP runtime option.

For more information

For more information about heap storage and heap storage tuning with storage report numbers, see z/OS Language Environment Programming Guide.

CBLOPTS (COBOL only)

Derivation: COBOL OPTionS

CBLOPTS specifies the format of the parameter string on application invocation when the main program is COBOL. CBLOPTS determines if runtime options or program arguments appear first in the parameter string. You can only specify this option at the system level, region level, or in a CEEUOPT.

CBLPSHPOP (COBOL only)

Derivation: COBOL PUSH POP

CBLPSHPOP controls if CICS PUSH HANDLE and CICS POP HANDLE commands are issued when a COBOL subroutine is called. CBLPSHPOP is ignored in non-CICS environments.

Tip: Specify CBLPSHPOP(ON) to avoid compatibility problems when calling COBOL subroutines that contain CICS CONDITION, AID, or ABEND condition handling commands.

You can set the CBLPSHPOP runtime option on an enclave basis using CEEUOPT.

There is no default value for non-CICS applications because CBLPSHPOP is ignored.

The default value for CICS applications is CBLPSHPOP(ON).

Syntax

```
CBLPshpop (ON OFF)
```

ON Automatically issues the following when a COBOL subroutine is called:

- An EXEC CICS PUSH HANDLE command as part of the routine initialization.
- An EXEC CICS POP HANDLE command as part of the routine termination.
Does not issue CICS PUSH HANDLE and CICS POP HANDLE commands on a call to a COBOL subroutine.

**Performance consideration**

If your application calls COBOL subroutines under CICS, performance is better with CBLPSHPOP(OFF) than with CBLPSHPOP(ON).

**For more information**

- For more information about CEEUOPT, see [z/OS Language Environment Programming Guide](#).
- To determine where to locate information about CICS commands, see CICS Master Index.

---

**CBLQDA (COBOL only)**

**Derivation:** COBOL QSAM Dynamic Allocation

CBLQDA controls COBOL QSAM dynamic allocation on an OPEN statement.

The default value for non-CICS applications is CBLQDA(OFF).

CBLQDA is ignored under CICS.

**Syntax**

\[ \text{CBLQDA} \left( \begin{array}{c} \text{OFF} \\ \text{ON} \end{array} \right) \]

**OFF**

Specifies that COBOL QSAM dynamic allocation is not permitted.

**ON**

Specifies that COBOL QSAM dynamic allocation is permitted. ON conforms to the 1985 COBOL standard.

**Usage notes**

- CBLQDA(OFF) is the recommended default because it prevents a temporary data set from being created in case there is a misspelling in your JCL. If you specify CBLQDA(ON) and have a misspelling in your JCL, Language Environment creates a temporary file, writes to it, and then z/OS deletes it. You receive a return code of 0, but no output.
- CBLQDA does not affect dynamic allocation for the message file specified in MSGFILE or the Language Environment formatted dump file (CEEDUMP).

---

**CEEDUMP**

**Derivation:** Common Execution Environment DUMP
The CEEDUMP runtime option is used to specify options to control the processing of the Language Environment dump report.

The default value for non-CICS applications is CEEDUMP(60,SYSOUT=*,FREE=END,SPIN=UNALLOC).

The default value for CICS applications is CEEDUMP(60,SYSOUT=*,FREE=END,SPIN=UNALLOC).

The default value for AMODE 64 is CEEDUMP(60,SYSOUT=*,FREE=END,SPIN=UNALLOC).

Syntax

```plaintext
CEEDUMP(page_len), SYSOUT=*
  page_len
  FREE=END, FREE=CLOSE,
  SPIN=UNALLOC
  SPIN=NO,
  class
  form-name
```

**page_len**

Specifies the number of lines that a CEEDUMP report contains on each page. The number specified by `page_len` must be 0 or a whole number greater than 9. A value of 0 indicates that the dump report should contain no page breaks. The default is 60. The maximum length of `page_len` is limited to 9 digits.

**SYSOUT=**

Specifies SYSOUT attributes for a dynamically allocated CEEDUMP DD. SYSOUT has three possible parameters, but the second parameter should always be omitted:

- **class**
  Specifies a value that is one character in length. Valid values are A through Z, 0 through 9, and *. A SYSOUT class must not be specified inside quotation marks.
  - If `class` is not specified, it defaults to * for the dynamically allocated CEEDUMP.
  - If dynamic allocation for the specified SYSOUT class specified fails, SYSOUT=* is set and message CEE3785I is issued.

- **form-name**
  Provides a name assigned to an output form for dynamically allocated CEEDUMP DD. `form-name` is made up of 1-4 alphanumeric or national ($,#,@) characters according to JCL rules. If you want to allow separation of
CEEDUMP output from other SYSOUT output for the same class in the JES spool, specify a form in addition to a class for a dynamically allocated CEEDUMP.

**FREE=**

Specifies that dynamically allocated CEEDUMPs will have one of the following JCL DD attributes:

**END**

The FREE=END DD attribute requests that the system unallocates the data set at the end of the last step that references the data set. This is the default value for this suboption.

**CLOSE**

The FREE=CLOSE DD attribute requests that the system unallocates the data set when it is closed. Code the FREE=CLOSE suboption along with SYSOUT=class to make CEEDUMP a spinning data set.

**SPIN=**

Specifies that dynamically allocated CEEDUMPs will have one of the following attributes:

**UNALLOC**

The SPIN=UNALLOC attribute indicates the system should make the SYSOUT data set available for processing immediately when it is unallocated. This is the default value for this suboption.

**NO**

The SPIN=NO attribute indicates the system should make the SYSOUT data set available for processing as a part of the output at the end of the job, regardless of when the data set is unallocated.

**z/OS UNIX considerations**

The SYSOUT=, FREE= and SPIN= suboptions do not have any effect on a CEEDUMP report taken in a z/OS UNIX file system.

**CICS consideration**

The SYSOUT=, FREE= and SPIN= suboptions do not have any effect on a CEEDUMP report taken under CICS.

**Usage notes**

- If a CEEDUMP DD card is explicitly coded in a job step, Language Environment ignores any SYSOUT class, FREE, SPIN or form-name specified in the CEEDUMP runtime.
- The SYSOUT=class suboption is overridden by _CEE_DMPTARG when this environment variable is used at the same time to indicate the SYSOUT class.
- The page_len suboption is overridden by the CEE3DMP PAGESIZE option. For more information about CEE3DMP, see [z/OS Language Environment Customization](#).
- Language Environment supports the use of a CEEDUMP DDNAME dynamically allocated with the XTIOT, UCB nocapture, or DSAB-above-the-line options specified in the SVC99 parameters (S99TIOEX, S99ACUCB, S99DSABA flags).

**CICS considerations**

- CEED(SYSOUT=X,FREE=CLOSE)
CEEDUMP

This dynamically allocates a CEEDUMP with SYSOUT class X and the FREE=CLOSE DD attribute. The other implicit suboptions are page_len and SPIN, which default to whatever values are currently set in the CEEDUMP runtime option.

- CEEDUMP(40)
  The CEEDUMP report contains a page length of 40 lines. The other implicit suboptions are SYSOUT=, FREE=, and SPIN=, which default to whatever values are currently set in the CEEDUMP runtime option.

CEEDUMP (40)

The CEEDUMP report contains a page length of 40 lines. The other implicit suboptions are SYSOUT=, FREE=, and SPIN=, which default to whatever values are currently set in the CEEDUMP runtime option.

CEERCDM—Record information for an active condition

CEERCDM records information for an active condition so that the information can be retrieved later from the condition information block (CIB). Use this service only during condition handling.

Syntax

```
>>> CEERCDM(function_code, information, fc)
```

function_code (input)

A fullword integer that contains the function code of the following value:

1. Record the data set name of a dump for an active condition.

information (input)

The information to be recorded. When the function_code is 1, the information is a halfword length-prefixed EBCDIC character string that is expected to be the data set name of a dump for an active condition. Language Environment validates that the length is positive and that it does not exceed 44.

fc (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions are possible:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service was successfully completed.</td>
</tr>
<tr>
<td>CEE3LA</td>
<td>3</td>
<td>3754</td>
<td>Incorrect parameters were detected.</td>
</tr>
<tr>
<td>CEE35S</td>
<td>3</td>
<td>3260</td>
<td>No condition was active when a call was made to condition management.</td>
</tr>
</tbody>
</table>

Usage notes

- After the condition handling functions return control to the application, the CIB that represents the conditions is no longer valid and the recorded information is no longer accessible.
- If CEERCDM is called more than once for the same condition, the information of the last call is recorded.
Examples

1. Following is an example of CEERCDM called by C/C++.

```c
/*Module/File Name: EDCRCDM */
#include <stdio.h>
#include <leawi.h>
#include <stdlib.h>
#include <string.h>
#include <ceeedcct.h>

#ifdef __cplusplus
extern "C" {
#endif
void handler(_FEEDBACK *,_INT4 *,_INT4 *,_FEEDBACK *);
#ifdef __cplusplus
}
#endif

int main()
{
    _FEEDBACK fc;
    _ENTRY routine;
    _INT4 token;
    int x,y,z;
    /* set the routine structure to point to the handler */
    /* and use CEEHDLR to register the user handler */
    token = 99;
    routine.address = (_POINTER)&handler;  routine.nesting = NULL;
    CEEHDLR(&routine,&token,&fc);
    /* verify that CEEHDLR was successful */
    if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
        printf("CEEHDLR failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    x = 5;
    y = 0;
    z = x / y;
}

// handler is a user condition handler */
//******************************************************************************
void handler(_FEEDBACK *fc, _INT4 *token, _INT4 *result, _FEEDBACK *newFC) {
    _FEEDBACK lfc;
    _INT4 funcode;
    _VSTRING info;
    char *ds_name = "XXXX.YYYY";
    /* suppose we have taken a dump of this condition */
    /* into a dataset XXXX.YYYY. */
    info.length = strlen(ds_name);
    memcpy(info.string, ds_name, info.length);
    funcode = 1;
    CEERCDM(&funcode, &info, &lfc);
    if ( _FBCHECK ( lfc , CEE000 ) != 0 ) {
        printf("CEERCDM failed with message number %d\n", lfc.tok_msgno);
        ...
```

exit(2999);
}
*result = 10;
}

---

**CHECK (COBOL only)**

If your COBOL application was compiled with the SSRANGE compile option, specifying the CHECK(ON) runtime option enables range checking of each index, subscript, and reference modification.

The default value for non-CICS applications is CHECK(ON).

The default value for CICS applications is CHECK(ON).

---

**Syntax**

```plaintext
HELP CHECK (ON | OFF)
```

- **ON**  Specifies that runtime range checking is performed.
- **OFF** Specifies that runtime range checking is not performed.

---

**Usage notes**

CHECK(ON) has no effect if the NOSSRANGE COBOL compile option was specified.

---

**Performance consideration**

If your COBOL program was compiled with the SSRANGE compile option, and you are not testing or debugging an application, performance improves when you specify CHECK(OFF). For COBOL 4.2 and earlier you can disable the SSRANGE code with CHECK(OFF). For COBOL 5.1 and later, you cannot disable it.

---

**COUNTRY**

Specifying a `country_code` with the COUNTRY runtime option determines:

- Date and time formats
- The currency symbol
- The decimal separator
- The thousands separator

COUNTRY affects only the Language Environment NLS services, not the Language Environment locale callable services.

**Tip:** You can set the country value using the COUNTRY runtime option or the CEE3CTY callable service.

The default value for non-CICS applications is COUNTRY(US).
The default value for CICS applications is COUNTRY(US).

Syntax

```plaintext
COUNTRY(country_code)
```

**country_code**

A 2-character code that indicates to Language Environment the country on which to base the default settings. Table 32 on page 483 contains a list of valid country codes.

**Usage notes**

- If you specify an unsupported `country_code`, Language Environment accepts the value and issues an informational message.

  If an unsupported `country_code` is specified on the COUNTRY runtime option and one of the services listed in "National Language Support callable services" on page 114 is called with the optional `country_code` parameter omitted, the called service returns its specified default value.

- Language Environment provides locales used in C and C++ to establish default formats for the locale-sensitive functions and locale callable services, such as date and time formatting, sorting, and currency symbols. The COUNTRY setting does not affect these locale-sensitive functions and locale callable services.

  To change the locale, you can use the `setlocale()` library function or the CEESETL callable service. These affect only C/C++ locale-sensitive functions and Language Environment locale callable services, not the COUNTRY runtime option.

  To ensure that all settings are correct for your country, use COUNTRY and either CEESETL or `setlocale()`.

  The settings of CEESETL or `setlocale()` do not affect the setting of the COUNTRY runtime option. COUNTRY affects only Language Environment NLS and date and time services. `setlocale()` and CEESETL affect only C/C++ locale-sensitive functions and Language Environment locale callable services.

  The COUNTRY setting affects the format of the date and time in the reports generated by the RPTOPTS and RPTSTG runtime options.

**For more information**

- For more information about the CEE3CTY callable service, see "CEE3CTY—Set default country" on page 135.
- For more information about the RPTOPTS runtime option, see "RPTOPTS" on page 71.
- For more information about the RPTSTG runtime option, see "RPTSTG" on page 73.
- For a list of countries and their codes, see Appendix A, "IBM-supplied country code defaults," on page 483.
- For more information about the CEESETL callable service, see "CEESETL—Set locale operating environment" on page 413.
- For more information about `setlocale()`, see "C/OS XL C/C++ Programming Guide".
DEBUG (COBOL only)

DEBUG activates the COBOL batch debugging features specified by the USE FOR DEBUGGING declarative.

The default value for non-CICS applications is NODEBUG.

The default value for CICS applications is NODEBUG.

**Syntax**

```
NODEBUG  DEBUG
```

**NODEBUG**  
Suppresses the COBOL batch debugging features.

**DEBUG**  
Activates the COBOL batch debugging features. You must have the WITH DEBUGGING MODE clause in the environment division of your application in order to compile the debugging sections.

**Usage notes**

- For information about specifying this option at the system or region level, see [z/OS Language Environment Customization](http://www.ibm.com/support/docview.wss?uid=swg27036733).
- For information about specifying this option in CEEUOPT, see [z/OS Language Environment Programming Guide](http://www.ibm.com/support/docview.wss?uid=swg27036733).
- Use DEBUG and NODEBUG only on the command line.

**Performance consideration**

Because DEBUG gives worse runtime performance than NODEBUG, you should use it only during application development or debugging.

**For more information**

See the appropriate version of the COBOL programming guide in the COBOL library at Enterprise COBOL for z/OS library (http://www.ibm.com/support/docview.wss?uid=swg27036733) for more information about the USE FOR DEBUGGING declarative.

DEPTHCONDLMT

**Derivation:** DEPTH of nested CONDITION Limit

DEPTHCONDLMT specifies the extent to which conditions can be nested. Figure 1 on page 27 illustrates the effect of DEPTHCONDLMT(3) on condition handling. The initial condition and two nested conditions are handled in this example. The third nested condition is not handled.
The default value for non-CICS applications is `DEPTHCONDLMT(10)`.

The default value for CICS applications is `DEPTHCONDLMT(10)`.

### Syntax

```
DEPTHCONDLMT(limit)
```

**limit**

An integer of 0 or greater value. It is the depth of condition handling allowed. An unlimited depth of condition handling is allowed if you specify 0.

A `limit` value of 1 specifies handling of the initial condition, but does not allow handling of nested conditions that occur while handling a condition. With a `limit` value of 5, for example, the initial condition and four nested conditions are processed. In this case, there can be no further nesting of conditions.

If the number of nested conditions exceeds the `limit`, the application ends with abend 4087.

### z/OS UNIX considerations

The `DEPTHCONDLMT` option sets the limit for how many nested synchronous conditions are allowed for a thread. Asynchronous signals do not affect `DEPTHCONDLMT`.

### Usage notes

- PL/I consideration: `DEPTHCONDLMT(0)` provides PL/I compatibility.
- PL/I MTF consideration: In a PL/I MTF application, `DEPTHCONDLMT` sets the limit for how many nested synchronous conditions are allowed for a PL/I task. If the number of nested conditions exceeds the limit, the application ends abnormally.

### For more information

For more information about nested conditions, see [z/OS Language Environment Programming Guide](#).
DYNDUMP

Derivation: DYNamic DUMP

The DYNDUMP runtime option provides a way to obtain dynamic dumps of user applications that would ordinarily be lost due to the absence of a SYSMDUMP, SYSUDUMP, or SYSABEND DD statement. The dynamic dump is written when:

- Certain types of ABENDs occur. You can select if a U4039 ABEND or other U40xx ABEND types can cause a dump to be collected.
- The first suboption defines the high level qualifier of the dynamic dump data set name.
- The second suboption controls when dynamic dumps are taken for U4039 ABENDS.
- The third suboption controls when dynamic dumps are taken for other U40xx ABENDS.

Restriction: The dump is written to a z/OS data set. It cannot be part of a z/OS UNIX file system.

The non-CICS default value is DYNDUMP(*userid,NODYNAMIC,TDUMP).

DYNDUMP is ignored under CICS.

The AMODE 64 default value is DYNDUMP(*userid,NODYNAMIC,TDUMP).

Syntax

**DYNdump**

```
(DYNdump hlq,userid,tsoprefix,NODYNAMIC,DYNAMIC,FORCE,BOTH,TDUMP,NOTDUMP)
```

hlq

is a high level qualifier for the dynamic dump data set to be created. This is concatenated with a time stamp consisting of the Julian day and the time of the dump. The job name or PID can also be part of the name if the combined length of hlq and the time stamp is 35 characters or less. The hlq value is limited to 26 characters including dot (.) separators. hlq allows three keywords:

*USERID

tells Language Environment to use the user ID associated with the job step task as the high level qualifier for the dynamic dump data set.

*TSOPREFIX or TSOPRE

tells Language Environment to use the TSO/E prefix. Restriction: The prefix is only valid in a TSO/E environment. If the prefix is not available, the user ID is used.

Each keyword may be followed by additional characters to be used to create the dataset name. When appended to the USERID or the TSO prefix, they form the hlq used when creating the dump data set.
The data set name is limited to 44 characters. If the combined length of hlq and
the time stamp is 35 characters or less, the job name or PID is added to the
data set name. If the system is using multilevel security, the SECLABEL is used
as the second qualifier. If hlq contains multiple qualifiers, only the first is used,
followed by the SECLABEL. The format of the data set name is:

- When the application is not exec()ed and not multilevel security:
  hlq.Djjj.Thhmmst.jobname
- When the application is exec()ed and not multilevel security:
  hlq.Djjj.Thhmmst.Pppppppp
- When the application is multilevel security and not exec()ed:
  hlq.MLS-level.Djjj.Thhmmst.jobname
- When the application is both multilevel security and exec()ed:
  hlq.MLS-level.Djjj.Thhmmst.Pppppppp

For U4039 ABENDS
The following suboptions are used for U4039 ABENDS only:

**DYNAMIC**
Language Environment creates a dynamic dump automatically when the
application has not already specified one of the dump ddnames, (for
example, SYSUDUMP).

**NODYNAMIC**
Language Environment does not create a dynamic dump if no dump DD
names are specified.

**FORCE**
Language Environment always creates a dynamic dump even if other
dump DD names have been specified. The SYSnnnnn DD card is ignored if
it exists. FORCE should not be used as the default.

**BOTH**
Language Environment creates a dynamic dump and, if a SYSnnnnn DD
name exists, a dump is also written to the DD. BOTH should not be used
as the default.

For U40xx ABENDS
The following suboptions are used for other U40xx ABENDS only. Existing
SYSnnnnn DD statements are also honored.

**TDUMP**
Language Environment creates a dynamic dump automatically.

**NOTDUMP**
Language Environment does not create a dynamic dump.

**Usage notes**

- **Recommendations:**
  - Set up an hlq to which everyone can write.
  - Do not use FORCE or BOTH as the default for the U4039 ABENDS.
- The DYNDUMP runtime option is ignored under CICS.
- When an ABEND occurs during Language Environment initialization, the
dynamic dump is not created if runtime options have not been processed yet.
- When the dynamic dump fails, messages are written to the operator's console or
  the job log (for batch). These are written by the IEATDUMP system service, by
  Language Environment, or by RACF®.
- When an ABEND is issued without the DUMP option, no dump is generated.
DYNDUMP

- When Language Environment terminates with a U4038 abend, the U4038 abend is issued without the DUMP option. Therefore, no system dump is generated, and DYNDUMP does not collect a dump for this ABEND.
- The job name is taken from the JOBNAME system symbol.
  - A dump for a TSO application uses the user ID of the JOBNAME.
  - For a batch job, JOBNAME is taken from the JOB card in the JCL.
  - In the shell, JOBNAME is the user ID with a suffix.

CICS considerations

- DYNDUMP(smith, force, notdump)
  A dynamic dump is generated only for ABEND code U4039. Other SYSnnnnn DD cards are ignored. Other ABENDs might cause a dump to be created if a SYSnnnnn DD card exists. The dynamic dump data set name will be similar to SMITH.D012.T112245.JOB11.
- DYNDUMP(smith,DYNAMIC,TDUMP)
  A dynamic dump is created if no SYSnnnnn is specified and the ABEND code is U4039. The data set name will be similar to SMITH.D117.T235900.JOBZ2.
- DYNDUMP(*TSOPREFIX,NODYNAMIC,TDUMP)
  A dynamic dump is generated only for ABEND code U40xx. The data set name will be similar to SMITH.D287.T234560.JOBZ2.
- DYNDUMP(*USERID,NODYNAMIC,TDUMP)
  A dynamic dump for a U4039 ABEND is taken to SMITH.D109.T234512.JOBZ3.
- DYNDUMP(*USERID.HOT.DUMPS,NODYNAMIC,TDUMP)
- DYNDUMP(*TSOPRE.A1234567.B1234567,NODYNAMIC,TDUMP)

ENV (C only)

Derivation: ENVironment

ENV specifies the operating system for your C application. z/OS XL C++ users can get the same behavior by using the z/OS XL C++ compiler option TARGET(IMS™) to specify ENV(IMS).

Restriction: This option does not apply to non-C languages and can be specified only with the C #pragma runopts directive. You cannot set this option at the system level, region level, or in the CEEBXITA assembler user exit interface.

For non-CICS applications, the ENV option differs from other runtime options that it does not have a standard default. The default depends on the system (CMS, IMS, or MVS) in which compilation occurs.

ENV is ignored under CICS.

Syntax

```plaintext
ENV(CMS,IMS,MVS)
```
CMS
    Specifies that the C application runs in a CMS environment.

IMS
    Specifies that the C application runs in an IMS environment. You do not need to specify the ENV option if your application is invoked under IMS but does not actually use IMS facilities.

MVS
    Specifies that the C application runs in an MVS environment.

z/OS UNIX considerations
    • In a multithreaded environment, the ENV option is shared by all threads in the process.

ENVAR

Derivation: Environment Variables

ENVAR sets the initial values for the environment variables that can later be accessed or changed using the C functions getenv(), putenv, setenv, and clearenv.

The set of environment variables established by the end of runtime option processing reflects all the various sources where environment variables are specified, rather than just the one source with the highest precedence. However, if a setting for the same environment variable is specified in more than one source, the setting with the highest precedence is used.

The system() function can be used to create a new environment. Environment variables in effect at the time of the POSIX system() call are copied to the new environment. The copied environment variables are treated the same as those found in the ENVAR runtime option on the command level.

When you specify the RPTOPTS runtime option, the output for the ENVAR runtime option contains a separate entry for each source where ENVAR was specified with the environment variables from that source.

The default value for non-CICS applications is ENVAR('').

The default value for CICS applications is ENVAR('').

The default value for AMODE 64 applications is ENVAR('').

Syntax

```
$ENVAR
  
```

Is specified as name=value, where name and value are sequences of characters
that do not contain null bytes or equal signs. The string name is an environment variable, and value is its value.

Blanks are significant in both the name= and the value characters. You can enclose string in either single or double quotation marks to distinguish it from other strings. You can specify multiple environment variables, separating the name=value pairs with commas. Quotation marks are required when specifying multiple variables.

**z/OS UNIX considerations**

In a multithreaded environment, the environment variables are shared by all threads in the process.

**Usage notes**

- The entire value of the ENVAR operand, whether a single string or multiple strings, cannot exceed 250 characters.
- String cannot contain DBCS characters.
- If ENVAR is specified as part of the _CEE_RUNOPTS environment variable, it is ignored.
- The ENVAR option functions independently of the POSIX runtime option setting.
- C/C++ consideration—An application can access the environment variables using C function getenv() or the POSIX variable environ, which is defined as:
  ```c
  extern char **environ;
  ```
  **Guideline:** You should access environment variables through the getenv() function, especially in a multithread environment. getenv() serializes access to the environment variables.

Environment variables that are passed to the exec or spawn family of functions replace those established by the ENVAR option in the new environment.

**For more information**

- For more information about the RPTOPTS runtime option, see **“RPTOPTS” on page 71.**
- For more information about getenv(), putenv(), setenv(), clearenv(), system(), and the exec and spawn family of functions, see **z/OS XL C/C++ Runtime Library Reference.**
- For more information about the order of precedence of runtime option sources, see **z/OS Language Environment Programming Guide.**

---

### ERRCOUNT

**Derivation:** ERRor COUNTer

ERRCOUNT specifies how many conditions of severity 2, 3, or 4 can occur per thread before the enclave terminates abnormally. When the number specified in ERRCOUNT is exceeded, Language Environment ends with ABEND U4091 RC=B.

The default value for non-CICS applications is ERRCOUNT(0).

The default value for CICS applications is ERRCOUNT(0).
Syntax

```
number
```

number
An integer of 0 or greater value that specifies the number of severity 2, 3, and 4 conditions allowed for each thread. An unlimited number of conditions is allowed if you specify 0. If the number of conditions exceeds the limit, the application ends with abend 4091 RC=B.

**z/OS UNIX considerations**

Synchronous signals that are associated with a condition of severity 2, 3, or 4 affect ERRCOUNT. Asynchronous signals do not affect ERRCOUNT.

**Usage notes**

- Language Environment does not count severity 0 or 1 conditions toward ERRCOUNT.
- ERRCOUNT only applies when conditions are handled by a user condition handler, signal catcher, PL/I on-unit, or a language-specific condition handler. Any unhandled condition of severity 2, 3, or 4 causes the enclave to terminate.
- COBOL consideration: The COBOL runtime library separately counts its severity 1 (warning) messages. When the limit of 256 IGZnnnnW messages is reached, the COBOL runtime library will issue message IGZ0041W, which indicates that the limit of warning messages has been reached. Any further COBOL warning messages are suppressed and processing continues.
- PL/I consideration: You should use ERRCOUNT(0) in a PL/I environment to avoid unexpected termination of your application. Some conditions, such as ENDPAGE, can occur many times in an application.
- PL/I MTF consideration: In a PL/I MTF application, ERRCOUNT sets the threshold for the total number severity 2, 3, and 4 synchronous conditions that can occur for each task.
- C++ consideration: C++ throw does not affect ERRCOUNT.

**For more information**

For more information about condition handling, see [z/OS Language Environment Programming Guide](#).

---

**ERRUNIT (Fortran only)**

**Derivation:** ERRor UNIT

ERRUNIT identifies the unit number to which runtime error information is to be directed. This option is provided for compatibility with the VS Fortran version 2 runtime.

The default value for non-CICS applications is ERRUNIT(6).
ERRUNIT

ERRUNIT is ignored under CICS.

Syntax

```
ERRUnit(number)
```

[number]
A number in the range 0-99.

Usage notes

The Language Environment message file and the file connected to the Fortran error message unit are the same.

EXECOPS | NOEXECOPS (C only)

EXECOPS specifies if you can enter runtime options on the command line.

Restriction: This option does not apply to non-C languages and can be specified only with the C #pragma runopts directive. You cannot set this option at the system level, region level, or in the CEEBXITA assembler user exit interface.

The default value for non-CICS applications is EXECOPS.

This option is ignored under CICS.

The default value for AMODE 64 applications is EXECOPS.

Syntax

```
EXECOPS NOEXECOPS
```

EXECOPS
Specifies that you can enter runtime options on the command line. Language Environment parses the argument string to separate runtime options from application arguments. The runtime options are interpreted by Language Environment and the application arguments are passed to the application.

NOEXECOPS
Specifies that you cannot enter runtime options on the command line. Language Environment passes the entire argument string to the application.

For more information

For more information about the format of the argument string and how it is parsed, see z/OS Language Environment Programming Guide.
FILEHIST (Fortran only)

**Derivation:** FILE HISTory

FILEHIST specifies whether to allow the file definition of a file referred to by a ddname to be changed during run time. This option is intended for use with applications called by Fortran that reallocate Fortran’s supplied DD names.

The default value for non-CICS applications is FILEHIST.

FILEHIST is ignored under CICS.

**Syntax**

```plaintext
FILEHIST
NOFILEHIST
```

**FILEHIST**

Causes the history of a file to be used in determining its existence. It checks to see if:

- The file was ever internally opened (in which case, it exists)
- The file was deleted by a CLOSE statement (in which case, it does not exist).

**NOFILEHIST**

Causes the history of a file to be disregarded in determining its existence. If you specify NOFILEHIST, you should consider:

- If you change file definitions during runtime, the file is treated as if it were being opened for the first time.
- Before the file definition can be changed, the existing file must be closed.
- If you do not change file definitions during runtime, you must use STATUS='NEW' to reopen an empty file that has been closed with STATUS='KEEP', because the file does not appear to exist to Fortran.

FILETAG (C/C++ only)

**Derivation:** FILE TAGging

FILETAG controls automatic text conversion and automatic file tagging for z/OS UNIX files. It activates the automatic file tagging, on the first write, of new or empty z/OS UNIX file system files open with fopen() or freopen(), or upon the first I/O to a pipe created with popen(). You should be familiar with the concept of file tagging, automatic conversion, and the program and file CCSIDs to use the runtime option properly. See [z/OS XL C/C++ Programming Guide](#) for more information.

The default value for non-CICS applications is FILETAG(NOAUTOCVT,NOAUTOTAG).

FILETAG is ignored under CICS.

The default value for AMODE 64 applications is FILETAG(NOAUTOCVT,NOAUTOTAG).
FILETAG

Syntax

```
FILETAG ( NOAUTOCVT AUTOCVT , NOAUTOTAG AUTOTAG )
```

NOAUTOCVT

Disables automatic text conversion.

AUTOCVT

Enables automatic text conversion for untagged UNIX file system files opened using `fopen()` or `freopen()`. The conversion for an untagged file is from the program CCSID to the EBCDIC CCSID as specified by the `_BPXK_CCSIDS` environment variable. If the environment variable is unset, a default CCSID pair is used. See "z/OS XL C++ Programming Guide" for more information about the `_BPXK_CCSIDS` environment variable.

Restriction: Automatic conversion for untagged UNIX files can only take place between IBM-1047 and ISO8859-1 code sets. Other CCSID pairs are not supported. By default, automatic conversion for untagged UNIX file system files applies only to files opened in text mode. An untagged file opened in binary mode is not converted automatically. You can control the tagging by using the `_EDC_AUTOCVT_BINARY` environment variable. For more information about the `_EDC_AUTOCVT_BINARY` environment variable, see "z/OS XL C++ Programming Guide".

This suboption also indicates that the standard streams should be enabled for automatic text conversion to the EBCDIC IBM-1047 code page when they refer to an untagged terminal file (tty).

This suboption does not affect untagged UNIX file system files that are automatically tagged by the AUTOTAG suboption. A UNIX file system file that is automatically tagged is already enabled for automatic text conversion.

The automatic text conversion is performed only if one of the following situations is also true:

- The `_BPXK_AUTOCVT` environment variable value is set to ON.
- The `_BPXK_AUTOCVT` environment variable is unset and AUTOCVT(ON) was specified in the active BPXPRMxx member on your system.

For more information about the `_BPXK_AUTOCVT` environment variable, see "z/OS XL C++ Programming Guide".

NOAUTOTAG

Disables the automatic tagging of new or empty z/OS UNIX files.

AUTOTAG

Enables automatic file tagging, on the first write, of new or empty z/OS UNIX files opened with `fopen()`, `freopen()`, or `popen()`.

Usage notes

- Avoid the following situations:
  - Setting this runtime option at the system or region levels.
  - Setting this runtime option using `_CEE_RUNOPTS` in a default profile for the UNIX shell users.
  - Exporting `_CEE_RUNOPTS` that specifies this runtime option. It can cause unexpected behaviors for the unknowing user or application.
• The application programmer should define this runtime option with the assumption that the application is coded to behave based on the option’s setting.
• The application programmer should specify this runtime option at compile time using #pragma runopts or at bind using a CEEUOPT CSECT that has been previously created.
• The application user should not override this runtime option because it can change the expected behavior of the application.
• The default CCSID pair is (1047,819), where 1047 indicates the EBCDIC IBM-1047 codepage and 819 indicates the ASCII ISO8859-1 codepage.
• Automatic text conversion is enabled for the standard streams only when the application has been exec()ed, for example, when the UNIX shell gives control to a program entered on the command line, and the standard stream file descriptors are already open, untagged, and associated with a tty.
• For the UNIX shell-owned standard streams that are redirected at program execution time, the shell includes added environment variables that control if the redirected streams are tagged. See z/OS UNIX System Services Command Reference for more information.
• Automatic tagging for a z/OS UNIX file is done by the system at first write. The CCSID used for the tag is the program CCSID of the current thread. Both text and binary files are tagged.
• When FILETAG(AUTOTAG) is in effect, fopen() or freopen() of a z/OS UNIX file fails if it cannot determine if the file exists or if it cannot determine the size.

FLOW (COBOL only)

FLOW controls the FLOW output produced by OS/VS COBOL programs. You cannot set this option at the system or region levels.

The default value for non-CICS applications is NOFLOW.

The default value for CICS applications is NOFLOW.

```
Syntax

NOFLOW
FLOW
FLOW(n)
FLOW=n
FLOWn

NOFLOW
Suppresses the OS/VS COBOL FLOW output.

FLOW
Allows the OS/VS COBOL FLOW output.

n
Specifies the number of procedures traced. The number can be any integer from 1 to 99, inclusive.
```
HEAP controls the allocation of user heap storage and specifies how that storage is managed. Heaps are storage areas containing user-controlled dynamically allocated variables or data. Examples of these are:

- C data allocated as a result of the malloc(), calloc(), and realloc() functions
- COBOL WORKING-STORAGE data items
- PL/1 variables with the storage class CONTROLLED, or the storage class BASED
- Data allocated as a result of a call to the CEEGTST Language Environment callable service

The default value for non-CICS applications is

```
HEAP(32K,32K,ANYWHERE,KEEP,8K,4K).
```

The default value for CICS applications is

```
HEAP(4K,4080,ANYWHERE,KEEP,4K,4080).
```

**Syntax**

```
Heap (init_size, incr_size, ANYWHERE | ANY, BELOW, KEEP, FREE)
```

**init_size**

Determines the initial allocation of heap storage. This value can be specified as \( n \), \( nK \), or \( nM \) bytes of storage. If 0 is specified, the initial storage is obtained on the first use and is based on the increment size. The actual amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**incr_size**

Determines the minimum size of any subsequent increment to the user heap storage. This value can be specified as \( n \), \( nK \), or \( nM \) bytes of storage. The actual amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**ANYWHERE | ANY**

Specifies that user heap storage can be allocated anywhere in storage. If there is no available storage above the line, storage is acquired below the 16 MB line.

**BELOW**

Specifies that user heap storage is allocated below the 16M line in storage.

**Restriction:** The HEAPPOOLS option is ignored when the BELOW suboption is specified.

**KEEP**

Specifies that an increment to user heap storage is not released when the last of the storage within that increment is freed.
FREE
Specifies that an increment to user heap storage is released when the last of the storage within that increment is freed.

initsz24
Determines the minimum initial size of user heap storage that is obtained below the 16M line for AMODE 24 applications that specify ANYWHERE in the HEAP runtime option. This value can be specified as \(n\), \(nK\), or \(nM\) number of bytes. If 0 is specified, the initial storage is obtained on the first use and is based on the increment size. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

incrsz24
Determines the minimum size of any subsequent increment to user heap storage that is obtained below the 16M line for AMODE 24 applications that specify ANYWHERE in the HEAP runtime option. This value can be specified as \(n\), \(nK\), or \(nM\) number of bytes. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

CICS consideration
- If \(\text{HEAP}(\_\_\_, \text{ANYWHERE}, \_\_)\) is in effect, the maximum size of a heap segment is 1 gigabyte (1024 MB).
- The default increment size under CICS is 4080 bytes, rather than 4096 bytes, to accommodate the 16 bytes CICS storage check zone. Without this accommodation, an extra page of storage is allocated when the storage allocation is below the 16 MB line.
  
  Guideline: If you choose to change the increment size, you should adjust for the 16 byte CICS storage check zone.

z/OS UNIX considerations

In a multithreaded environment, user heap storage is shared by all threads in the process.

Usage notes
- Applications running in AMODE 24 that request heap storage get the storage below the 16M line regardless of the setting of \(\text{ANYWHERE} \mid \text{BELOW}\).
- COBOL consideration—You can use the HEAP option to provide function similar to the VS COBOL II space management tuning table.
- PL/I consideration—For PL/I, the only case in which storage is allocated above the line is when all of the following conditions exist:
  - The user routine requesting the storage is running in 31-bit addressing mode.
  - \(\text{HEAP}(\_\_\_, \text{ANY}, \_\_)\) is in effect.
  - The main routine runs in AMODE 31.
- PL/I MTF consideration—In a PL/I MTF application, HEAP specifies the heap storage allocation and management for a PL/I main task.

Performance consideration

You can improve performance with the HEAP runtime option by specifying values that minimize the number of times the operating system allocates storage. See “RPTSTG” on page 73 for information about how to generate a report you can use to determine the optimum values for the HEAP runtime option.
HEAP

For more information

- For more information about Language Environment heap storage, see z/OS Language Environment Programming Guide.
- For more information about the CEECRHP callable service, see “CEECRHP—Create new additional heap” on page 223.
- For more information about the CEEGTST callable service, see “CEEGTST—Get heap storage” on page 315.
- For more information about the RPTSTG runtime option, see “RPTSTG” on page 73.

HEAP64 (AMODE 64 only)

HEAP64 controls the allocation of user heap storage for AMODE 64 applications and specifies how that storage is managed. Heaps are storage areas containing user-controlled dynamically allocated variables or data. An example is C data allocated as a result of the malloc(), calloc(), and realloc() functions.

The default value for AMODE 64 applications is HEAP64(1M,1M,KEEP,32K,32K,KEEP,4K,4K,FREE).

Syntax

```
  HEAP64
  H64
  (init64, incr64, KEEP, FREE, FILL, init31),
  (incr31, KEEP, FREE, init24, incr24, KEEP)
```

*init64*

Determines the initial allocation of heap storage that is obtained above the 2G bar. Specify this value as nM bytes of storage. If a value of 0 or less is specified, the default is used.

*incr64*

Determines the minimum size of any subsequent increment to the user heap storage obtained above the 2G bar. Specify this value as nM bytes of storage. If a value less than 0 is specified, the default is used.

*KEEP*

Specifies that an increment to user heap storage is not released when the last of the storage within that increment is freed.

*FREE*

Specifies that an increment to user heap storage is released when the last of the storage within that increment is freed.

*FILL*

Specifies that an increment to user heap storage is released when the last of the storage within that increment is freed. In addition, when a storage request results in a new increment segment being created which is greater than the
**incr64** size, the entire segment is filled by the single storage request. This option is available only for user heap storage above the bar.

**init31**
Determines the minimum initial size of user heap storage that is obtained above the 16M line and below the 2G bar. This value can be specified as *n*, *nK*, or *nM* number of bytes. If 0 is specified, the initial storage is obtained on the first use and is based on the increment size. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**incr31**
Determines the minimum size of any subsequent increment to user heap storage that is obtained above the 16M line and below the 2G bar. This value can be specified as *n*, *nK*, or *nM* number of bytes. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**init24**
Determines the minimum initial size of user heap storage that is obtained below the 16M line. This value can be specified as *n*, *nK*, or *nM* number of bytes. If 0 is specified, the initial storage is obtained on the first use and is based on the increment size. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**incr24**
Determines the minimum size of any subsequent increment to user heap storage that is obtained below the 16M line. This value can be specified as *n*, *nK*, or *nM* number of bytes. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**z/OS UNIX considerations**
In a multithreaded environment, user heap storage is shared by all threads the process.

**Performance consideration**
You can improve performance with the HEAP64 runtime option by specifying values that minimize the number of times the operating system allocates storage. See “RPTSTG” on page 73 for information about how to generate a report you can use to determine the optimum values for the HEAP64 runtime option.

**For more information**
- For more information about heap storage and heap storage tuning with storage report numbers, see [z/OS Language Environment Programming Guide](#).
- For more information about the RPTSTG runtime option, see “RPTSTG” on page 73.

**HEAPCHK**

**Derivation:** **HEAP storage CHecKing**

HEAPCHK performs diagnostic tests against the user heap.

The default value for non-CICS applications is

HEAPCHK(OFF,1,0,0,0,1024,0,1024,0).

The default value for CICS applications is

HEAPCHK(OFF,1,0,0,0,1024,0,1024,0).
The default value for AMODE 64 applications is
HEAPCHK(OFF,1,0,0,1024,0,1024,0).

### Syntax

```
HEAPChk(on,OFF,31,1024,0,1024,0)
```

**OFF**
- Indicates that no heap checking or tracing is done regardless of the values of the remaining suboptions.

**ON**
- Indicates that heap checking or tracing is activated based on the values of the remaining suboptions.

**frequency**
- The frequency at which the user heap is checked for damage to the heap control information. It is specified as \(n, nK\) or \(nM\). A value of one (1) is the default and causes the heap to be checked at each call to a Language Environment heap storage management service. A value of \(n\) causes the user heap to be checked at every \(n\)th call to a Language Environment heap storage management service. A value of zero results in no check for damage to the user heap.

**delay**
- A value that causes a delay before user heap is checked for damage, and is specified in \(n, nK\) or \(nM\). A value of zero (0) is the default and causes the heap checking to begin with the first call to a Language Environment heap storage management service. A value of \(n\) causes the heap checking to begin following the \(n\)th call to a Language Environment heap storage management service.

**call depth**
- Specifies the depth of calls displayed in the traceback for the heap storage diagnostics report. A value of zero is the default that turns heap storage diagnostics reporting off. The heap storage diagnostics report consists of a set of treebacks. Each traceback is a snapshot of the stack (to a specified call depth) for each request to obtain user heap storage that has not had a corresponding free request. Use a value of 10 to ensure an adequate call depth is displayed so that you can identify the storage leak.

**pool call depth**
- Specifies the depth of calls in the traceback for each trace entry of a heap pools trace. A value of zero is the default that turns heap pools tracing off. The heap pools trace is an in-core wrapping trace. Each heap pool has a separate trace.
The heap pools trace is only formatted from a system dump using the IPCS verbexit LEDATA. Use a value of 10 to ensure an adequate call depth is displayed so that you can identify the storage leak.

**number of entries**
Specifies the number of entries to be recorded in one heap pool trace table for the main user heap in the application. Each pool has its own trace table. If the number of entries is 0, the heap pool trace table is not generated.

**pool number**
Specifies which pools are traced for the main user heap in the application. You can either trace one pool or all pools. The value should be a valid pool number from 1 to 12. If the pool number is 0, all pools will be traced.

**number of entries 31**
Specifies the number of entries to be recorded in one heap pool trace table when an AMODE 64 application is using heap storage from 31-bit addressable storage (__malloc31()). Each pool has its own trace table. If the number of entries is 0, the heap pool trace table is not generated. This value is only supported in an AMODE64 environment.

**pool number 31**
Specifies which pools are traced when an AMODE 64 application is using heap storage from 31-bit addressable storage (__malloc31()). You can trace either one pool or all pools. The value should be a valid pool number from 1 to 12. If the pool number is 0, all pools will be traced. This value is only supported in an AMODE64 environment.

**Usage notes**

- When user heap damage is detected, Language Environment immediately issues an ABEND U4042 RC=0. To obtain a system dump of this abend, either specify TDUMP for the third suboption of the DYNDUMP runtime option or ensure that a SYSMDUMP DD is available.
- If HEAPCHK(ON) is used with STORAGE(,heap_free_value), all free areas of the heap are also checked.
- To request only a heap storage diagnostics report, you must specify a zero for frequency, a zero for pool call depth and a number n greater than zero for call depth. For example (HEAPCHK(ON,0,0,10,0)).
- Under normal termination conditions, if the call depth is greater than zero, the heap storage diagnostics report is written to the CEEDUMP report, independent of the TERMTHDACT setting.
- You can also generate a heap storage diagnostics report by calling CEE3DMP with the BLOCKS option.
- **Guideline:** Since HEAPCHK does not validate individual cells within a cell pool, you should specify HEAPPools(OFF) when running HEAPCHK to diagnose storage overlays in the heap.
- To request heap pools tracing, set pool call depth to a nonzero value and number of entries (for AMODE 64 applications, number of entries, number of entries 31, or both) to a value. To request only heap pools tracing, in addition, set frequency to zero and call depth to zero. The heap pools trace is only formatted from a system dump using the IPCS verbexit LEDATA.
- For AMODE 64 applications, number of entries and pool number control tracing for the set of heap pools located in storage above the 2-GB bar. Number of entries 31 and pool number 31 control tracing for the set of heap pools located in storage above the 16-MB line and below the 2-GB bar. Pool call depth applies to both sets of heap pools.
There is no interaction between specifying the HEAPZONES and HEAPCHK runtime options, but setting both at the same time is not recommended by IBM.

**Performance consideration**

Specifying HEAPCHK(ON) can result in a performance degradation due to the user heap diagnostic testing that is performed.

**For more information**

For more information about creating and using the heap storage diagnostics report, see [z/OS Language Environment Debugging Guide](#).

### HEAPPOOLS (C/C++ and Enterprise PL/I only)

**Derivation:** HEAP storage POOLS

The HEAPPOOLS runtime option is used to control an optional user heap storage management algorithm, which is known as heap pools. This algorithm is designed to improve the performance of multithreaded applications with a high frequency of calls to malloc(), __malloc31(), calloc(), realloc(), free(), and operators new and delete. When active, heap pools virtually eliminate contention for user heap storage.

HEAPPOOLS runtime option can be used by AMODE 64 applications to manage user heap storage above the 16 M line and below the 2 G bar.

The default value for non-CICS applications is

```
HEAPPOOLS(OFF,8,10,32,10,128,10,256,10,1024,10,2048,10,0,10,0,10,0,10,0,10,0,10,0,10,0,10,0,10)
```

The default value for CICS applications is

```
HEAPPOOLS(OFF,8,10,32,10,128,10,256,10,1024,10,2048,10,0,10,0,10,0,10,0,10,0)
```

The default value for AMODE 64 applications is

```
HEAPPOOLS(OFF,8,10,32,10,128,10,256,10,1024,10,2048,10,0,10,0,10,0,10,0,10,0,10,0,10)
```

#### Syntax

```
HEAPPOOLS(ON(cell-size,pool-count),OFF(cell-size,percentage))
```

- **OFF** Specifies that the heap pools algorithm is not used.
- **ON** Specifies that the heap pools algorithm is used.
ALIGN

Specifies that Language Environment will structure the storage for cells in a heap pool so that a cell less than or equal to 248 bytes does not cross a cache line. For cells larger than 248 bytes, two cells never share a cache line.

cell size

Specifies the size of the cells in a heap pool, which is specified as n or nK. The cell size must be a multiple of 8, with a maximum of 65536 (64K).

pool-count

The number of pools to create for the cell size. The pool-count must be in a range from 1 to 255.

percentage

The size of this heap pool and any of its extents is determined by multiplying this percentage by the init_size value that was specified in the HEAP runtime option. The percentage must be in a range from 1 to 90.

Usage notes

- Cell pool sizes should be specified in ascending order.
- To use less than twelve heap pools, specify 0 for the cell size after the last heap pool to be used. For example, if four heap pools are desired, use 0 for the fifth cell size when setting the HEAPPOLS runtime option.
- If the percentage of the HEAP runtime option init size values does not allow for at least one cell, the system automatically adjusts the percentage to enable four cells to be allocated.
- The sum of the percentages may be more or less than 100 percent.
- Each heap pool is allocated as needed. The allocation of a heap pool can result in the allocation of a heap increment to satisfy the request.
- The FREE suboption on the HEAP runtime option has no effect on any heap segment in which a heap pool resides. Each cell in a heap pool can be freed, but the heap pool itself is only released back to the system at enclave termination.
- To avoid wasting storage, see the heap pool tuning tips specified in z/OS Language Environment Programming Guide.
- The HEAPPOLS runtime option has no effect when BELOW is specified as the location on the HEAP runtime option.
- Mixing of the storage management AWIs (CEEGTST(), CEEFRST() and CEECZST()) and the C/C++ intrinsic functions (malloc(), calloc(), realloc() and free() ) are not supported when operating on the same storage address. For example, if you request storage using CEEGTST(), then you may not use free() to release the storage.
- Using the ALIGN suboption might cause an increase in the amount of heap storage that is used by an application.
- You should examine the storage report and adjust storage tuning when first using the ALIGN suboption.
- The HEAPCHK runtime option does not validate individual heap pool cells.
- Use of a vendor heap manager (VHM) overrides the use of the HEAPPOLS runtime option.
- If the RPTSTG runtime option is specified while using HEAPPOLS, extra storage is obtained from the ANYHEAP and is used to complete the storage report on heappools. This extra storage is only allocated when both HEAPPOLS and RPTSTG are used.
- The HEAPPOLS runtime option can be used by AMODE 64 applications to manage user heap storage above the 16M line and below the 2G bar.
When cell-size is specified without parenthesis, pool-count defaults to 1 rather than being picked up from an earlier setting of pool-count. For example, specifying 128 is treated like specifying (128,1).

When cell-size is specified with parenthesis, pool-count must also be specified.

When pool-count is greater than 1, the size of each heap pool extent is determined by dividing the heap allocation for the cell-size by the pool-count.

Performance considerations

To improve the effectiveness of the heap pools algorithm, use the storage report numbers generated by the RPTSTG runtime option as an aid in determining optimum cell sizes, percentages, and the initial heap size.

Use caution when using cells larger than 2K. Large gaps between cell sizes can lead to a considerable amount of storage waste. Properly tuning cell sizes with the help of RPTSTG is necessary to control the amount of virtual storage needed by the application.

When there are many successful get requests for the same size cell and the maximum elements used in the cell pool is high, this could be an indication that there is excessive contention allocating elements in the cell pool. Specifying pool-count greater than 1 might help relieve some of this contention. Multiple pools are allocated with the same cell size and a portion of the threads are assigned to allocate cells out of each of the pools.

HEAPPOOLS64 (C/C++ and AMODE 64 only)

Derivation: HEAP storage POOLS for AMODE 64

The HEAPPOOLS64 runtime option is used to control an optional user heap storage management algorithm, known as heap pools, for AMODE 64 applications. This algorithm is designed to improve the performance of multithreaded C/C++ applications with a high frequency of calls to malloc(), calloc(), realloc(), free(), and operators new and delete. When active, heap pools virtually eliminates contention for user heap storage.

The default value for AMODE64 applications is

HEAPPOOLS64(OFF,8,4000,32,2000,128,700,256,350,1024,100,2048,50,3072,50,4096,50,8192,25,16384,10,32768,5,65536,5).

Syntax

OFF
  Specifies that the heap pools algorithm is not being used.

ON
  Specifies that the heap pools algorithm is being used.

ALIGN
  Specifies that Language Environment will structure the storage for cells in a
heap pool so that a cell less than or equal to 240 bytes does not cross a cache line. For cells larger than 240 bytes, two cells never share a cache line.

**cell-size**
Specifies the size of the cells in a heap pool, specified as n or nK. The cell size must be a multiple of 8, with a maximum of 65536 (64K).

**pool-count**
The number of pools to create for the cell size. The pool-count must be in a range from 1 to 255.

**count**
Specifies the number of cells of the corresponding size to be allocated initially. The minimum cell count is 4.

**Usage notes**
- Cell pool sizes should be specified in ascending order.
- To use less than twelve heap pools, specify 0 for the cell size after the last heap pool to be used. For example if four heap pools are desired, use 0 for the fifth cell size when setting the HEAPPOOLS64 runtime option.
- Each heap pool is allocated as needed. The allocation of a heap pool can result in the allocation of a heap increment to satisfy the request.
- Using the ALIGN suboption might cause an increase in the amount of heap storage used by an application.
- Examine the storage report and adjust storage tuning when first using the ALIGN suboption.
- The HEAPCHK runtime option does not validate individual heap pool cells.
- If you specify the RPTSTG runtime option while using HEAPPOOLS64, extra storage is obtained from the LIBHEAP64 and is used to complete the storage report on heappools. This extra storage is only allocated when both HEAPPOOLS64 and RPTSTG are used.
- HEAPPOOLS runtime option can be used by AMODE 64 applications to manage user heap storage above the 16M line and below the 2G bar.
- When cell-size is specified without parenthesis, pool-count defaults to 1 rather than being picked up from an earlier setting of pool-count. For example, specifying 128 is treated like specifying (128,1).
- When cell-size is specified with parenthesis, pool-count must also be specified.
- When pool-count is greater than 1, the size of each heap pool extent is determined by dividing the heap allocation for the cell-size by the pool-count.

**Performance considerations**
- To improve the effectiveness of the heap pools algorithm, use the storage report numbers generated by the RPTSTG runtime option as an aid in determining optimum cell sizes and count.
- Use caution when using cells larger than 2K. Large gaps between cell sizes can lead to a considerable amount of storage waste. Properly tuning cell sizes with the help of RPTSTG is necessary to control the amount of virtual storage needed by the application.

**For more information**
For more information about heap storage and heap storage tuning with storage report numbers, see z/OS Language Environment Programming Guide.
HEAPZONES

**Derivation:** HEAP check ZONES

The HEAPZONES runtime option is used to turn on overlay toleration and checking for user heaps. When activated, the runtime option affects any obtained storage that can be controlled by the HEAP or HEAP64 runtime options. HEAPZONES also affects storage obtained from a heap pool.

A heap check zone is an additional piece of storage that is appended to an allocated element during a storage request. The size of the check zone depends on the size31 and size64 suboptions of HEAPZONES. The check zone can be examined for overlays when the heap element is freed.

The default value for non-CICS applications is HEAPZONES(0,ABEND,0,ABEND).

The default value for CICS applications is HEAPZONES(0,ABEND,0,ABEND).

The default value for AMODE 64 applications is HEAPZONES(0,ABEND,0,ABEND).

---

**Syntax**

```
HEAPZones( size31 , QUIET , size-64 , QUIET )
```

- **size31**: Controls the size of the check zone for all user heap storage which is below the 2 G bar. The check zone size is rounded up to the nearest multiple of 8 bytes. The maximum size allowed for a check zone is 1024 bytes. Specifying a value of 0 indicates that no check zone is active.

- **size64**: Controls the size of the check zone for all user heap storage which is above the 2 G bar. The check zone size is rounded up to the nearest multiple of 8 bytes with a minimum size of 16 bytes. The maximum size allowed for a check zone is 1024 bytes. Specifying a value of 0 indicates that the check zone is not active.

- **ABEND**: Specifies that check zones are validated and if an overlay is detected, a U4042 ABEND reason code 3 is issued.

- **QUIET**: Specifies that a heap check zone is appended to every allocated element, but the check zone is not validated.

- **MSG**: Specifies that check zones are validated and if an overlay is detected, informational messages are issued. For more information about the output for the HEAPZONES runtime option, see z/OS Language Environment Debugging Guide.
TRACE
specifies that in addition to informational messages, a CEEDUMP containing only a traceback is produced.

Usage notes
- You cannot set HEAPZONES at the system level, region level, or in the CEEBXITA assembler user exit interface.
- You cannot specify an active HEAPZONES setting and RPTSTG(ON) simultaneously. An active HEAPZONES setting causes Language Environment to override RPTSTG to the value OFF and no storage report is produced.
- There is no interaction between specifying the HEAPZONES and HEAPCHK runtime options, but setting both at the same time is not recommended by IBM.

Performance considerations
Using heap check zones can result in a performance degradation and significant additional storage usage. IBM recommends setting the size of a heap check zone to the smallest amount feasible by the application.

INFOMSGFILTER

Derivation: INFOrmational MeSsaGe FILTER

INFOMSGFILTER allows you to activate a filter that eliminates unwanted informational messages. During normal operations, informational messages are sometimes written to the Language Environment message file. If these messages are routed to your terminal, you need to clear them often. If the messages are saved to a data set, they take up disk space and could make it difficult to browse the output for a specific message.

Informational messages are not limited to Language Environment (CEE) messages. They can also be written, using the CEEMSG interface, by other IBM program products or user-written applications.

The default value for non-CICS applications is INFOMSGFILTER(OFF,\ldots). The default value for CICS applications is INFOMSGFILTER(OFF,\ldots). The default value for AMODE 64 applications is INFOMSGFILTER(OFF,\ldots).

Syntax

\[
\text{INFOMsgfilter} (\text{ON}, \text{Foreground}, \text{Background})
\]

**OFF**
- Turns off message filtering for all environments.
ON  Turns on the message filtering for the specified environments.

**Foreground**
Selecting this keyword causes message filtering to be turned on for the TSO and z/OS UNIX environments.

**Background**
Selecting this keyword causes message filtering to be turned on for the MVS Batch environment.

**CICS**
Selecting this keyword causes message filtering to be turned on in the CICS environment. This option is ignored for AMODE 64 applications.

**INQPCOPN (Fortran only)**

**Derivation:** INQuire the Pre-Connected units that are OPENed

INQPCOPN controls if the OPENed specifier on an INQUIRE by unit statement can be used to determine if a preconnected unit has had any I/O statements directed to it.

The default for non-CICS applications is INQPCOPN.

INQPCOPN is ignored under CICS.

### Syntax

```plaintext
INQPCOPN
NOINQPCOPN
```

**INQPCOPN**
Causes the running of an INQUIRE by unit statement to provide the value `true` in the variable or array element given in the OPENED specifier if the unit is connected to a file. This includes the case of a preconnected unit, which can be used in an I/O statement without running an OPEN statement, even if no I/O statements have been run for that unit.

**NOINQPCOPN**
Causes the running of an INQUIRE by unit statement to provide the value `false` for the case of a preconnected unit for which no I/O statements other than INQUIRE have been run.

**INTERRUPT**

INTERRUPT causes attention interrupts to be recognized by Language Environment. When you cause an interrupt, Language Environment can give control to your application or to a debug tool.

The default value for non-CICS applications is INTERRUPT(OFF).

INTERRUPT is ignored under CICS.
**INTERRUPT**

Syntax

```
►►INTerrupt—(OFF, ON)◄◄
```

**OFF**
- Specifies that Language Environment does not recognize attention interrupts.

**ON**
- Specifies that Language Environment recognizes attention interrupts.

**z/OS UNIX considerations**
- In a multithreaded application, only one thread in the enclave is affected for a particular attention interrupt.

**Usage notes**
- PL/I consideration: Language Environment supports the PL/I method of polling code. The PL/I routine must be compiled with the INTERRUPT compiler option in order for the INTERRUPT runtime option to have an effect.
- PL/I MTF consideration: To receive the attention interrupt, the PL/I program must be compiled with the INTERRUPT compiler option, and the INTERRUPT runtime option must be in effect.
- PL/I MTF consideration: The INTERRUPT option applies to the enclave. However, only one thread in the enclave is affected for a particular attention interrupt.
- If you have specified the TEST(ERROR) or TEST(ALL) runtime option, the interrupt causes the debug tool to gain control. See “TEST | NOTEST” on page 89 for more information about the TEST runtime option.

**IOHEAP64 (AMODE 64 only)**

IOHEAP64 controls the allocation of I/O heap storage for AMODE 64 applications and specifies how that storage is managed. Language Environment uses this storage when performing I/O for AMODE 64 applications.

The default value for AMODE 64 applications is IOHEAP64(1M,1M,FREE,12K,8K,FREE,4K,4K,FREE).

Syntax

```
►►IOHEAP64—(init64, incr64, KEEP, init31, incr31, KEEP, init24, incr24, KEEP)◄◄
```

**init64**
- Determines the initial allocation of I/O heap storage obtained above the 2G bar. Specify this value as nM bytes of storage. If a value of 0 or less is specified, the default is used.
**incr64**
Determines the minimum size of any subsequent increment to the I/O heap storage obtained above the 2G bar. Specify this value as \( n \)M bytes of storage. If a value less than 0 is specified, the default is used.

**KEEP**
Specifies that an increment to I/O heap storage is not released when the last of the storage within that increment is freed.

**FREE**
Specifies that an increment to I/O heap storage is released when the last of the storage within that increment is freed.

**init31**
Determines the minimum initial size of I/O heap storage that is obtained above the 16M line and below the 2G bar. This value can be specified as \( n \), \( n \)K, or \( n \)M number of bytes. If 0 is specified, the initial storage is obtained on the first use and is based on the increment size. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**incr31**
Determines the minimum size of any subsequent increment to I/O heap storage that is obtained above the 16M line and below the 2G bar. This value can be specified as \( n \), \( n \)K, or \( n \)M number of bytes. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**init24**
Determines the minimum initial size of I/O heap storage that is obtained below the 16M line. This value can be specified as \( n \), \( n \)K, or \( n \)M number of bytes. If 0 is specified, the initial storage is obtained on the first use and is based on the increment size. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**incr24**
Determines the minimum size of any subsequent increment to I/O heap storage that is obtained below the 16M line. This value can be specified as \( n \), \( n \)K, or \( n \)M number of bytes. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

**Performance consideration**
You can improve performance with the IOHEAP64 runtime option by specifying values that minimize the number of times the operating system allocates storage. See “RPTSTG” on page 73 for information about how to generate a report you can use to determine the optimum values for the IOHEAP64 runtime option.

**For more information**
- For more information about heap storage and heap storage tuning with storage report numbers, see [z/OS Language Environment Programming Guide](#).
- For more information about the RPTSTG runtime option, see “RPTSTG” on page 73.

**LIBHEAP64 (AMODE 64 only)**
The LIBHEAP64 runtime option controls the allocation of heap storage that is used by Language Environment for AMODE 64 applications. Storage that is unrestricted can be located anywhere in 64-bit addressable storage.
The default value for AMODE 64 applications is
LIBHEAP64(1M,1M,FREE,16K,8K,FREE,8K,4K,FREE).

Syntax

\[
\text{LIBHEAP64} (init64, incr64, KEEP, FREE, init31, incr31, KEEP, FREE, init24, incr24, KEEP, FREE)
\]

init64
Determines the initial allocation of library heap storage that is obtained above the 2G bar. Specify this value as \(n\)M bytes of storage. If a value of 0 or less is specified, the default is used.

incr64
Determines the minimum size of any subsequent increment to the library heap storage obtained above the 2G bar. Specify this value as \(n\)M bytes of storage. If a value less than 0 is specified, the default is used.

KEEP
Specifies that an increment to library heap storage is not released when the last of the storage within that increment is freed.

FREE
Specifies that an increment to library heap storage is released when the last of the storage within that increment is freed.

init31
Determines the minimum initial size of library heap storage that is obtained above the 16M line and below the 2G bar. This value can be specified as \(n\), \(n\)K, or \(n\)M number of bytes. If 0 is specified, the initial storage is obtained on the first use and is based on the increment size. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

incr31
Determines the minimum size of any subsequent increment to library heap storage that is obtained above the 16M line and below the 2G bar. This value can be specified as \(n\), \(n\)K, or \(n\)M number of bytes. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

init24
Determines the minimum initial size of library heap storage that is obtained below the 16M line. This value can be specified as \(n\), \(n\)K, or \(n\)M number of bytes. If 0 is specified, the initial storage is obtained on the first use and is based on the increment size. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

incr24
Determines the minimum size of any subsequent increment to library heap storage that is obtained below the 16M line. This value can be specified as \(n\), \(n\)K, or \(n\)M number of bytes. The amount of allocated storage is rounded up to the nearest multiple of 8 bytes.
Performance consideration

You can improve performance with the LIBHEAP64 runtime option by specifying values that minimize the number of times the operating system allocates storage. See “RPTSTG” on page 73 for information about how to generate a report you can use to determine the optimum values for the LIBHEAP64 runtime option.

For more information

- For more information about heap storage and heap storage tuning with storage report numbers, see z/OS Language Environment Programming Guide.

LIBSTACK

Derivation: LIBrary STACK storage

LIBSTACK controls the allocation of the thread’s library stack storage. This stack is used by Language Environment routines that require save areas below the 16 M line.

The default value for non-CICS applications is LIBSTACK(4K,4K,FREE).

The default value for CICS applications is LIBSTACK(32,4080,FREE).

Syntax

```plaintext
LIBStack(init_size, incr_size, FREE|KEEP)
```

*init_size*
Determines the minimum size of the initial library stack storage. This value can be specified as \( n \), \( nK \), or \( nM \) bytes of storage. Language Environment allocates the storage rounded up to the nearest multiple of 8 bytes.

*incr_size*
Determines the minimum size of any subsequent increment to the library stack. This value can be specified as \( n \), \( nK \), or \( nM \) bytes of storage. The actual amount of allocated storage is the larger of 2 values—\( incr\_size \) or the requested size—rounded up to the nearest multiple of 8 bytes. If you specify 0 as \( incr\_size \), Language Environment gets only the amount of storage that is needed at the time of the request, rounded up to the nearest multiple of 8 bytes.

*FREE*
Specifies that Language Environment releases storage allocated to LIBSTACK increments when the last of the storage in the library stack is freed. The initial library stack segment is not released until the thread ends.

*KEEP*
Specifies that Language Environment does not release storage allocated to LIBSTACK increments when the last of the storage is freed.
CICS considerations

The default increment size under CICS is 4080 bytes, rather than 4096 bytes, to accommodate the 16-byte CICS storage check zone. Without this accommodation, an extra page of storage is allocated.

z/OS UNIX considerations

The LIBSTACK option sets the library stack characteristics on each thread.

Usage notes

Language Environment does not acquire the initial library stack segment until the first program that requires LIBSTACK runs.

Performance considerations

You can improve performance with the LIBSTACK runtime option by specifying values that minimize the number of times the operating system allocates storage. See “RPTSTG” on page 73 for information about how to generate a report you can use to determine the optimum values for the LIBSTACK runtime option.

For more information

- See “RPTSTG” on page 73 for more information about the RPTSTG runtime option.
- For more information about using the storage reports generated by the RPTSTG runtime option to tune the stacks, see z/OS Language Environment Programming Guide.

MSGFILE

Derivation: MeSsaGe FILE

MSGFILE specifies the ddname and attributes of the data set (message file) where Language Environment directs the following output:
- All Language Environment messages
- Reports generated by the RPTOPTS and RPTSTG runtime options
- Output produced by the CEEMSG and CEEMOUT callable services

The default value for non-CICS applications is MSGFILE(SYSOUT,FBA,121,0,NOENQ).

MSGFILE is ignored under CICS.
**Syntax**

\[ \text{MSGFile} \left( \begin{array}{c} \text{ddname}, \text{recfm}, \text{lrecl}, \text{blksize}, \text{NOENQ}, \text{ENQ} \end{array} \right) \]

*ddname*

The ddname of the message file where Language Environment directs the information listed above.

*recfm*

The record format (RECFM) for the message file. *recfm* is used when this information is not available either in a data set definition or in the label of an existing data set. The following record formats are acceptable: F, FA, FB, FBA, FBS, FBSA, U, UA, V, VA, VB, and VBA.

*lrecl*

The record length (LRECL) for the message file. *lrecl* is used when this information is not available either in a data set definition or in the label of an existing data set. *lrecl* is expressed as bytes of storage. The *lrecl* cannot exceed *blksize*. For variable-length record formats, the *lrecl* is limited to *blksize* minus 4.

*blksize*

The block size (BLKSIZE) for the message file. *blksize* is used when this information is not available either in a data set definition or in the label of an existing data set. *blksize* is expressed as bytes of storage and cannot exceed 32760.

*NOENQ*

Specifies that no serialization is performed on *ddname*.

*ENQ*

Specifies that serialization is performed on the *ddname* specified in case multiple Language Environment environments are running in the same address space and sharing the same message file.

**CICS consideration**

- MSGFILE output under CICS is directed to a transient data queue named CESE.

**z/OS UNIX considerations**

- When multiple threads write to the message file, the output is interwoven by line. To group lines of output, the application must serialize its own output.
- If the message file is allocated (whether POSIX or z/OS), Language Environment directs the output to this file. If the current message file is not allocated, and the application calls fork()/exec(), spawn(), or spawnp(), Language Environment checks if file descriptor 2 (fd2) exists.
  - If fd2 exists, Language Environment uses it.
  - If fd2 does not exist, Language Environment dynamically allocates the message file to the POSIX file system and attempts to open the file SYSOUT in the current working directory. If there is no current directory, SYSOUT is opened in the directory /tmp.
Usage notes

• Under most circumstances, the NOENQ suboption is sufficient and provides better performance. The ENQ suboption is only needed when multiple Language Environment environments are running in the same address space and share the same message file.

An instance when ENQ might be needed is a batch job that uses ATTACH to create sub-tasks. Each of the sub-tasks is potentially a distinct Language Environment environment, all running with the same default MSGFILE parameters. In this example, each of these environments shares the same message file.

To avoid conflicts while writing to the shared message file, use the ENQ suboption. Using a different ddname for each environment can remove the need to use the ENQ suboption.

• Compiler options, such as the COBOL OUTDD compiler option, can affect if your runtime output goes to MSGFILE ddname.

• If there is no blksize in the MSGFILE runtime option, in a data set definition, or in the label of an existing data set, the block size is determined as follows:
  - If recfm specifies unblocked fixed-length format records (F or FA) or undefined-format records (U or UA), blksize is the same as lrecl.
  - If recfm specifies unblocked variable-length format records (V or VA), blksize is lrecl plus 4.
  - If recfm specifies blocked records (FB, FBA, FBS, FBSA, VB, or VBA) for a DASD device on z/OS, Language Environment uses a blksize of 0 so the system can determine the optimum blksize.
  - If recfm specifies blocked fixed-length format records (FB, FBA, FBS, or FBSA) for a terminal, blksize is the same as lrecl.
  - If recfm specifies blocked variable-length format records (VB or VBA) for a terminal, blksize is lrecl plus 4.
  - For all other cases, blksize is calculated to provide the largest number of records per block, up to 100 records per block, that does not exceed the maximum blksize of 32760.

• Language Environment does not diagnose combinations of recfm, lrecl, and blksize that are not valid but the system can detect an error condition on the first attempt to write to the message file.

• Language Environment does not check the validity of the MSGFILE ddname. A ddname that is not valid generates an error condition on the first attempt to write to the message file.

• C/C++ consideration—C output directed to stderr and perror() messages go to the MSGFILE destination.

• PL/I consideration—runtime messages in PL/I programs are directed to the message file instead of to the PL/I SYSPRINT STREAM PRINT file. User-specified output is directed to the PL/I SYSPRINT STREAM PRINT file. To direct this output to the message file, specify MSGFILE(SYSPRINT).

Use of MSGFILE(SYSPRINT) restricts the LINESIZE for PL/I programs to a maximum of 255.

• Fortran consideration—To get the same message file function as with VS Fortran, specify MSGFILE(FTnnF001,UA,133) where nn is the unit number of the error unit. For more information, see Fortran runtime Migration Guide.

• Language Environment supports the use of a MSGFILE DDNAME dynamically allocated with the XTIOT, UCB nocapture, or DSAB-above-the-line options specified in the SVC99 parameters (S99TIOEX, S99ACUCB, S99DSABA flags).
For more information

- For more information about the RPTOPTS and RPTSTG runtime options, see "RPTOPTS" on page 71 and "RPTSTG" on page 73.
- For more information about the CEEMSG and CEEMOUT callable services, see "CEEMSG—Get, format, and dispatch a message" on page 375 and "CEEMOUT—Dispatch a message" on page 357.
- For details on how HLL compiler options affect messages, see information about HLL I/O statements and message handling in z/OS Language Environment Programming Guide.
- For examples of getting and formatting messages, including HLL runtime output, see "CEEMSG—Get, format, and dispatch a message" on page 375.
- For more information about perror() and stderr see the C message output information in z/OS Language Environment Programming Guide.
- For more information about the CESE transient data queue, see z/OS Language Environment Programming Guide.

MSGQ

**Derivation:** Message Queue

MSGQ specifies the number of instance specific information (ISI) blocks that Language Environment allocates on a per thread basis for use by the application. The ISI block contains information for Language Environment to use when identifying and reacting to conditions, providing access to q_data tokens, and assigning space for message inserts used with user-created messages. When an insufficient number of ISI blocks are available, Language Environment uses the least recently used ISI block.

The default value for non-CICS applications is MSGQ(15).

MSGQ is ignored under CICS.

**Syntax**

```
MSGQ(number)
```

**number**

An integer that specifies the number of ISI blocks to maintain on a per thread basis.

**Usage notes**

- PL/1 MTF consideration—In a PL/1 MTF application, MSGQ sets the number of message queues allowed for each task.
- The CEECMI callable service allocates storage for ISI blocks if necessary. For information about using the CEECMI callable service, see "CEECMI—Store and load message insert data" on page 218.
NATLANG

Derivation: NATional LANGUAGE

NATLANG specifies the initial national language Language Environment uses for the runtime environment, including error messages, month names, and day of the week names. Message translations are provided for Japanese and for uppercase and mixed-case U.S. English. NATLANG also determines how the message facility formats messages.

The default value for non-CICS applications is NATLANG(ENU).

The default value for CICS applications is NATLANG(ENU).

The default value for AMODE 64 applications is NATLANG(ENU).

Syntax

\[
\text{NATlang} (\text{ENU}, \text{UEN}, \text{JPN})
\]

ENU
A 3-character ID specifying mixed-case U.S. English. Message text consists of SBCS characters and includes both uppercase and lowercase letters.

UEN
A 3-character ID specifying uppercase U.S. English. Message text consists of SBCS characters and includes only uppercase letters.

JPN
A 3-character ID specifying Japanese. Message text can contain a mixture of SBCS and DBCS characters.

Usage notes

• Restriction: CEE3LNG and CEESETL are not available to AMODE 64 applications.
• You can use the CEE3LNG callable service to set the national language.
• If you specify a national language that is not available on your system, Language Environment uses the IBM-supplied default ENU (mixed-case U.S. English).
• Language Environment is sensitive to the national language when it writes storage reports, option reports, and dump output.

When the national language is uppercase U.S. English or Japanese, the environment variable _CEE_UPPERCASE_DATA can be used to determine if variable data in storage reports, options reports and dump output is in uppercase.
When this environment variable is set to YES, variable data (entry point names, program unit names, variable names, Trace Entry in EBCDIC data, hexadecimal/EBCDIC displays of storage) will be in uppercase.

When this environment variable is not set or set to a value other than YES, variable data will not be in uppercase. Variable data is never in uppercase when the national language is mixed-case U.S. English.

- Language Environment provides locales used in C/C++ to establish default formats for the locale-sensitive functions and locale callable services, such as date and time formatting, sorting, and currency symbols. To change the locale, you can use the setlocale() library function or the CEESETL callable service.

The settings of CEESETL or setlocale() do not affect the setting of the NATLANG runtime option. NATLANG affects the Language Environment NLS and date and time services. setlocale() and CEESETL affect only C/C++ locale-sensitive functions and Language Environment locale callable services.

To ensure that all settings are correct for your country, use NATLANG and either CEESETL or setlocale().

- PL/I MTF consideration—NATLANG affects every task in the application. The SET function of CEE3LNG is supported for the relinked OS PL/I or PL/I for MVS & VM MTF applications only.

For more information
- For more information about the CEE3LNG callable service, see “CEE3LNG—Set national language” on page 174.
- For more information about the CEESETL callable service, see “CEESETL—Set locale operating environment” on page 413.
- For more information about setlocale(), see z/OS XL C/C++ Programming Guide.

**OCSTATUS (Fortran only)**

**Derivation:** Open Close STATUS

OCSTATUS controls the verification of file existence and if a file is actually deleted based on the STATUS specifier on the OPEN and CLOSE statement, respectively.

The default value for non-CICS applications is OCSTATUS.

OCSTATUS is ignored under CICS.

**Syntax**

```
OCstatus
```

**OCSTATUS**

Specifies that file existence is checked with each OPEN statement to verify that the status of the file is consistent with STATUS='OLD' and STATUS='NEW'. It also specifies that file deletion occurs with each CLOSE statement with STATUS='DELETE' for those devices which support file deletion. Preconnected files are included in these verifications. OCSTATUS consistency checking applies to DASD files, PDS members, VSAM files, MVS labeled tape files, and
dummy files only. For dummy files, the consistency checking occurs only if the file was previously opened successfully in the current program.

In addition, when a preconnected file is disconnected by a CLOSE statement, an OPEN statement is required to reconnect the file under OCSTATUS. Following the CLOSE statement, the INQUIRE statement parameter OPENED indicates that the unit is disconnected.

NOOCSTATUS

Bypasses file existence checking with each OPEN statement and bypasses file deletion with each CLOSE statement.

If STATUS='NEW', a new file is created; if STATUS='OLD', the existing file is connected. If STATUS='UNKNOWN' or 'SCRATCH', and the file exists, it is connected; if the file does not exist, a new file is created.

In addition, when a preconnected file is disconnected by a CLOSE statement, an OPEN statement is not required to reestablish the connection under NOOCSTATUS. A sequential READ, WRITE, BACKSPACE, REWIND, or ENDFILE will reconnect the file to a unit. Before the file is reconnected, the INQUIRE statement parameter OPENED will indicate that the unit is disconnected; after the connection is reestablished, the INQUIRE statement parameter OPENED will indicate that the unit is connected.

PAGEFRAMESIZE

Derivation: PAGE FRAME SIZE

PAGEFRAMESIZE specifies the preferred page frame size in virtual storage for HEAP, ANYHEAP, and STACK storage that is obtained during application initialization and runtime.

The default value for non-CICS applications is PAGEFRAMESIZE(4K,4K,4K).

PAGEFRAMESIZE is ignored under CICS.

Syntax

```
PAGeframesize( 4K heap_frame_size, 4K anyheap_frame_size)
```

heap_frame_size

Specifies the preferred page frame size in virtual storage for initial heap storage allocation and any subsequent heap increments. The page frame size can be specified as one of the following values:

- **4K** Requests the default value of 4-KB pages.
- **1M** Requests that 1-MB large pages be used, if available.
anyheap_frame_size
   Specifies the preferred page frame size in virtual storage for initial anywhere
   heap storage allocation and any subsequent anywhere heap increments. The
   page frame size can be specified as one of the following values:
   4K  Requests the default value of 4-KB pages.
   1M  Requests that 1-MB large pages be used, if available.

stack_frame_size
   Specifies the preferred page frame size in virtual storage for initial stack
   storage allocation and any subsequent stack increments. The page frame size
   can be specified as one of the following values:
   4K  Requests the default value of 4-KB pages.
   1M  Requests that 1-MB large pages be used, if available.

Usage notes
   • You cannot set PAGEFRAMESIZE at the system level or region level.
   • You cannot specify PAGEFRAMESIZE with the CEEBXITA assembler user exit
     interface.
   • In an XPLINK environment, the stack_frame_size suboption only applies to the
     upward-growing stack.
   • If 1-MB page frames are not available, the default 4-KB page frame size will be
     used. No message is issued to indicate this behavior.
   • Page frame sizes larger than 4 KB are not allowed below the 16-MB line. If a
     PAGEFRAMESIZE parameter specifies 1 MB but that storage type is allocated
     below the 16-MB line, then the default 4-KB page frames is used. No message is
     issued to indicate this behavior; however, the runtime options report will show
     the value that was specified.
   • If any PAGEFRAMESIZE parameter specifies 1M, then all of the storage
     preallocated to the enclave will request 1-MB page frames. The previous two
     usage notes apply as well.
   • By default, THREADSTACK storage comes from the library heap storage that is
     allocated with the ANYHEAP runtime option. To use 1-MB page frames for the
     THREADSTACK, ensure the anyheap_frame_size suboption specifies 1M.
   • When running in a preinitialized environment with an @GETSTORE service
     routine, a flag is passed to indicate that storage was requested to be backed by
     1-MB page frames. For more information about using 1-MB page frames with an
     @GETSTORE service routine, see z/OS Language Environment Programming Guide.

Performance considerations

Large pages are a special-purpose feature to improve performance; therefore, using
large pages is not recommended for all types of workloads. For more information
about large pages, see the following publications:
   • z/OS MVS Programming: Assembler Services Reference IAR-XCT
   • z/OS MVS Programming: Authorized Assembler Services Guide
   • z/OS MVS Programming: Assembler Services Guide

PAGEFRAMESIZE64

Derivation: PAGE FRAME SIZE for AMODE64
PAGEFRAMESIZE64 specifies the preferred page frame size in virtual storage for HEAP64, LIBHEAP64, IOHEAP64, and STACK64 storage that is obtained during application initialization and runtime.

The default value for AMODE 64 applications is PAGEFRAMESIZE64=(4K,4K,4K,4K,4K,4K,4K)

**Syntax**

```
PAGEFRAMESIZE64
( heap64_frame_size64, 4K
  heap64_frame_size31, 4K
  libheap64_frame_size64, 4K
  libheap64_frame_size31, 4K
  ioheap64_frame_size64, 4K
  ioheap64_frame_size31, 4K
  stack64_frame_size )
```

heap64_frame_size64

Specifies the preferred page frame size in virtual storage for initial heap storage allocation and any subsequent heap increments above the 2 GB bar. The page frame size can be specified as one of the following values:

- **4K** Requests the default 4 KB pages.
- **1M** Requests that 1 MB large pages be used, if available.

heap64_frame_size31

Specifies the preferred page frame size in virtual storage for initial heap storage allocation and any subsequent heap increments above the 16 MB line and below the 2 GB bar. The page frame size can be specified as one of the following values:

- **4K** Requests the default 4 KB pages.
- **1M** Requests that 1 MB large pages be used, if available.

libheap64_frame_size64

Specifies the preferred page frame size in virtual storage for initial library heap storage allocation and any subsequent library heap increments above the 2 GB bar. The page frame size can be specified as one of the following values:

- **4K** Requests the default 4 KB pages.
- **1M** Requests that 1 MB large pages be used, if available.

libheap64_frame_size31

Specifies the preferred page frame size in virtual storage for initial library heap storage allocation and any subsequent library heap increments above the 16 MB line and below the 2 GB bar. The page frame size can be specified as one of the following values:
PAGEFRAMESIZE64

4K  Requests the default 4 KB pages.
1M  Requests that 1 MB large pages be used, if available.

ioheap64_frame_size64
  Specifies the preferred page frame size in virtual storage for initial I/O heap
  storage allocation and any subsequent I/O heap increments above the 2 GB
  bar. The page frame size can be specified as one of the following values:

  4K  Requests the default of 4 KB pages.
  1M  Requests that 1 MB large pages be used, if available.

ioheap64_frame_size31
  Specifies the preferred page frame size in virtual storage for initial I/O heap
  storage allocation and any subsequent I/O heap increments above the 16 MB
  line and below the 2 GB bar. The page frame size can be specified as one of the
  following values:

  4K  Requests the default 4 KB pages.
  1M  Requests that 1 MB large pages be used, if available.

stack64_frame_size
  Specifies the preferred page frame size in virtual storage for initial stack
  storage allocation above the 2 GB bar. The page frame size can be specified as
  one of the following values:

  4K  Requests the default KB pages.
  1M  Requests that 1 MB large pages be used, if available.

Usage notes

- You cannot set PAGEFRAMESIZE64 at the system level or region level.
- You cannot specify PAGEFRAMESIZE64 with the CEEBXITA assembler user exit
  interface.
- If 1 MB page frames are not available, the default 4 KB page frame size is used.
  No message is issued to indicate this behavior.
- Page frame sizes larger than 4 KB are not allowed below the 16 MB line. If a
  PAGEFRAMESIZE parameter specifies 1 MB but that storage type is allocated
  below the 16 MB line, then the default 4 KB page frames is used. No message is
  issued to indicate this behavior, and the runtime options report shows the value
  that was specified.
- If the heap64_frame_size64 or hlibheap64_frame_size64 option is specified as 1M,
  then the initial storage allocation for both requests 1 MB page frames. The
  previous two usage notes apply as well.
- For THREADSTACK64 storage, the default 4 KB page frame size is used.
- When running in a preinitialized AMODE 64 (CELQPIPI) environment with an
  @GETSTORE service routine, a flag is passed to indicate that storage was
  requested to be backed by 1 MB page frames. For more information about using
  1 MB page frames with an @GETSTORE service routine, see z/OS V2R1.0
  Language Environment Programming Guide for 64-bit Virtual Addressing Mode

Performance considerations

Large pages are a special-purpose feature to improve performance; therefore, using
large pages is not recommended for all types of workloads. For more information
about large pages, see the following publications:

- z/OS MVS Programming: Assembler Services Reference IAR-XCT
PC (Fortran only)

**Derivation:** Private Common blocks

PC controls if Fortran status common blocks are shared among load modules.

The default value for non-CICS applications is NOPC.

PC is ignored under CICS.

### Syntax

```
NOPC
PC
```

**NOPC**

Specifies that Fortran static common blocks with the same name but in different load modules all refer to the same storage. NOPC applies only to static common blocks referenced by compiled code produced by any of the following compilers and that were not compiled with the PC compiler option:

- VS FORTRAN Version 2 Release 5
- VS FORTRAN Version 2 Release 6

**PC**

Specifies that Fortran static common blocks with the same name but in different load modules do not refer to the same storage.

PLIST (C only)

**Derivation:** Parameter LIST

PLIST specifies the format of the invocation parameters your C application receives when you invoke it. Although the CICS, CMS, IMS, MVS, and TSO suboptions of PLIST are supported for compatibility, you should use the HOST or OS suboptions of PLIST. Before using this runtime option, you should review the following restrictions:

- This option does not apply to non-C languages and can be specified only with the C #pragma runopts directive.
- You cannot set this option at the system level, region level, or in the CEEBXITA assembler user exit interface.

The default value for non-CICS applications is PLIST(HOST).

PLIST is ignored under CICS.
PLIST

Syntax

```
P(      )
H      C
L    I
S
```

HOST
The parameter list is a character string. The string is located differently under various systems, as follows:

CMS
If invoked by OSRUN, use the string presented in an MVS-like format located by the pointer held in R1. If not invoked by OSRUN, use the CMS extended parameter list.

TSO
If a command processor parameter list (CPPL) is detected, get the string from the command buffer. If a CPPL is not detected, assume a halfword-prefixed string in the MVS format.

MVS
Use the halfword-prefixed string.

CICS
The parameter list received by your C application is assumed to be in a CICS format.

CMS
The parameter list received by your C application is assumed to be in a CMS extended parameter list format.

IMS
The parameter list received by your C application is assumed to be in an IMS format.

MVS
The parameter list received by your C application is assumed to be in an MVS format.

OS
The parameter list received by your C application is assumed to be in an OS style.

TSO
The parameter list received by your C application is assumed to be in a CPPL format.

Usage notes
- The behavior of C applications with PLIST(HOST) in effect is the same for C++.
- When using the pre-Language Environment-conforming C interface for preinitialization, it is necessary to specify PLIST(MVS) in order to flag preinitialized routines.
- IMS considerations—If your C application runs under IMS, the suboption of PLIST that you specify depends on the version of the C compiler you used. Note that PLIST(IMS) is obsolete and should only be used with ADCycle C compiler Version 2.1 or earlier. For z/OS XL C/C++ compilers, you should specify the compiler options PLIST(OS) and TARGET(IMS) instead of runtime option PLIST(IMS).
• z/OS UNIX consideration—The PLIST option applies only to the main routine of the initial thread.

## PLITASKCOUNT (PL/I only)

**Derivation:** PL/I TASK COUNTer

PLITASKCOUNT controls the maximum number of tasks that can be active at one time while you are running PL/I MTF applications. PLITASKCOUNT(20) provides behavior compatible with the PL/I ISASIZE(,,20) option.

The default value for non-CICS applications is PLITASKCOUNT(20).

PLITASKCOUNT is ignored under CICS.

### Syntax

```
PLITaskcount(tasks)
```

- **tasks**
  - A decimal integer that is the maximum number of tasks allowed in a PL/I MTF application at any one time during execution. The total tasks include the main task and subtasks created directly or indirectly from the main task.

### Usage notes

- A value of zero (0) assumes the IBM-supplied default of 20.
- If tasks or the IBM-supplied default of 20 exceeds the z/OS UNIX installation default of the maximum number of threads, Language Environment assumes the z/OS UNIX installation default.
- If a request to create a task would put the number of currently active tasks over the allowable limit, condition IBM0566S is signalled and the task is not created.

## POSIX

**Derivation:** Portable Operating System Interface - X

POSIX specifies if the enclave can run with the POSIX semantics. POSIX is an application characteristic that is maintained at the enclave level. After you have established the characteristic during enclave initialization, you cannot change it.

The default value for non-CICS applications is POSIX(OFF).

POSIX is ignored under CICS.

The default value for AMODE 64 is POSIX(ON).
POSIX

Syntax

POSIX (OFF ON)

OFF  Indicates that the application is not POSIX-enabled.
ON   Indicates that the application is POSIX-enabled.

Usage notes

- When you set POSIX to ON, you can use functions that are unique to POSIX, such as pthread_create().
- POSIX(ON) applies to z/OS but explicitly excludes CICS. If you set POSIX to ON while an application is running under CICS, you receive a warning message, POSIX is set OFF, and the application continues to run. You can specify POSIX(ON) for both DB2® and IMS applications.
- When you set POSIX to ON while an application is running under CICS, you receive a warning message, POSIX is set OFF, and the application continues to run.
- One of the effects of POSIX(ON) is the enablement of POSIX signal handling semantics, which interact closely with the Language Environment condition handling semantics.
- ANSI C programs can access the z/OS UNIX file system on MVS independent of the POSIX setting. Where ambiguities exist between ANSI and POSIX semantics, the POSIX runtime option setting indicates the POSIX semantics to follow.
- Within nested enclaves, only one enclave can have the POSIX option set to ON. All other nested enclaves must have the POSIX option set to OFF. When a second nested enclave tries to specify the runtime option POSIX(ON) within one Language Environment process, Language Environment ends with abend U4093, reason code 172.

For more information

For more information about POSIX functions that have a kernel dependency or a POSIX ON dependency, see z/OS XL C/C++ Runtime Library Reference.

PROFILE

PROFILE controls the use of an optional PROFILER to collect performance data for the running application.

Restriction: An application cannot run with both the TEST and PROFILE options in effect. If both are specified, an informational message is generated and Language Environment forces the PROFILE option OFF.

The default value for non-CICS applications is PROFILE(OFF, ").

The default value for CICS applications is PROFILE(OFF,"}).
The default value for AMODE 64 applications is PROFILE(OFF,"").

**Syntax**

```plaintext
PROFILE(OFF, ON, string)
```

- **OFF** Indicates that the profile facility is inactive.
- **ON** Indicates that the profile facility is active.
- **string** Profile options that Language Environment passes to the profiler installed. You can enclose the string in either single or double quotation marks. The maximum length of the string is 250 bytes when specified on program invocation or from a compiler directive.

**For more information**

For details on the Performance Analyzer, see *Getting Started with C/C++ Productivity Tools for OS/390*, GC09-2918-00.

**PRTUNIT** (Fortran only)

**Derivation:** PRinT UNIT

PRTUNIT identifies the unit number used for PRINT and WRITE statements that do not specify a unit number.

The default value for non-CICS applications is PRTUNIT(6).

PRTUNIT is ignored under CICS.

**Syntax**

```plaintext
PRTunit(number)
```

- **number** A valid unit number in the range 0-99.

**PUNUNIT** (Fortran only)

**Derivation:** PUNch UNIT

PUNUNIT identifies the unit number used for PUNCH statements that do not specify a unit number.

The default value for non-CICS applications is PUNUNIT(7).
PUNUNIT

PUNUNIT is ignored under CICS.

**Syntax**

```plaintext
PUNunit (number)
```

*number*  
A valid unit number in the range 0-99.

---

**RDRUNIT (Fortran only)**

**Derivation:** ReaDeR UNIT

RDRUNIT identifies the unit number used for READ statements that do not specify a unit number.

The default value for non-CICS applications is RDRUNIT(5).

RDRUNIT is ignored under CICS.

**Syntax**

```plaintext
RDRunit (number)
```

*number*  
A valid unit number in the range 0-99.

---

**RECPAD (Fortran only)**

**Derivation:** RECorD PADding

RECPAD specifies if a formatted input record is padded with blanks.

The default value for non-CICS applications is NORECpad.

RECPAD is ignored under CICS.

**Syntax**

```plaintext
RECPad
```
Usage notes

- The PAD specifier of the OPEN statement can be used to indicate padding for individual files.

**REDIR | NOREDIR (C only)**

**Derivation:** REDIRection

REDIR specifies if you can redirect stdin, stdout, and stderr from the command line.

**Restriction:** This option can only be specified with the `#pragma runopts` directive or the REDIR and NOREDIR compiler options.

The default value for non-CICS applications is REDIR.

REDIR is ignored under CICS.

The default value for AMODE 64 applications is REDIR.

**Syntax**

```
REDIR
NOREDIR
```

**REDIR**

Specifies that you can redirect stdin, stdout, and stderr from the command line. REDIR applies only if ARGPARSE is also specified or defaulted.

**NOREDIR**

Specifies that you cannot redirect stdin, stdout, and stderr from the command line.

**For more information**

See “ARGPARSE | NOARGPARSE (C only)” on page 15 for a description of ARGPARSE.

**RPTOPTS**

**Derivation:** RePorT OPTionS

RPTOPTS generates, after an application has run, a report of the runtime options in effect while the application was running. RPTOPTS(ON) lists the declared runtime options in alphabetical order. The report lists the option names and shows where each option obtained its current setting. Language Environment writes options reports only in mixed-case U.S. English.

For an example and complete description of the options report, see z/OS Language Environment Debugging Guide.

The default value for non-CICS applications is RPTOPTS(OFF).
The default value for CICS applications is RPTOPTS(OFF).

The default value for AMODE 64 applications is RPTOPTS(OFF).

Default Value
Non-CICS
RPTOPTS(OFF)
AMODE 64
RPTOPTS(OFF)

Syntax

```
RPTOptsoff
```

**OFF**
Does not generate a report of the runtime options in effect while the application was running.

**ON**
Generates a report of the runtime options in effect while the application was running.

**Usage notes**
- For AMODE 64 applications, Language Environment writes the options report to stderr.
- In some cases, RPTOPTS will not generate the options report if your application ends abnormally.
- In a non-CICS environment, Language Environment directs the report to the `dbname` specified in the MSGFILE runtime option. Under CICS, with RPTOPTS(ON), Language Environment writes the options report to the CESE queue when the transaction ends successfully.
- If the RPTSTG runtime option is specified while using HEAPPOOLS, extra storage is obtained from the ANYHEAP and is used to complete the storage report on heappools. This extra storage is only allocated when both HEAPPOOLS and RPTSTG are used.

**Performance consideration**
This option increases the time it takes for the application to run. Therefore, use it only as an aid to application development.

**For more information**
- See “MSGFILE” on page 55 for more information about the MSGFILE runtime option.
- For an example and complete description of the options report, see z/OS Language Environment Debugging Guide.
RPTSTG

Derivation: RePorT SToraGe

RPTSTG generates, after an application has run, a report of the storage the application used. Language Environment writes storage reports only in mixed-case U.S. English.

You can use the storage report information to help you set the ANYHEAP, BELOWHEAP, HEAP, HEAP64, HEAPPOOLS, HEAPPOOLS64, IOHEAP64, LIBHEAP64, LIBSTACK, STACK, STACK64, THREADHEAP, THREADSTACK, and THREADSTACK64 runtime options for the best storage tuning. For an example and complete description of the storage report, see \textit{z/OS Language Environment Debugging Guide}.

The default value for non-CICS applications is RPTSTG(OFF).

The default value for CICS applications is RPTSTG(OFF).

The default value for AMODE 64 applications is RPTSTG(OFF).

### Syntax

\begin{verbatim}
RPTSTg
\end{verbatim}

<table>
<thead>
<tr>
<th>OFF</th>
<th>Generates a report of the storage used while the application was running.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ON</td>
<td>Does not generate a report of the storage used while the application was running.</td>
</tr>
</tbody>
</table>

### CICS consideration

- The phrases “Number of segments allocated” and “Number of segments freed” represent, on CICS, the number of EXEC CICS GETMAIN and EXEC CICS FREEMAIN requests, respectively.

### z/OS UNIX considerations

- The RPTSTG option applies to storage utilization for the enclave, including thread-level information about stack utilization, and heap storage used by multiple threads.

### Usage notes

- For AMODE 64 applications, Language Environment writes the storage report to stderr.
- When a vendor heap manager (VHM) is active, the Language Environment Storage Report will have a text line indicating that the user heap for C/C++ part of the enclave is managed separately. The VHM is expected to write its own storage report to the stderr stream.
- In some cases, RPTSTG will not generate the storage report if your application ends abnormally.
RPTSTG

- RPTSTG includes PL/I task-level information about stack and heap usage.
- The phrases “Number of segments allocated” and “Number of segments freed” represent the number of GETMAIN and FREEMAIN requests, respectively.

**Performance consideration**
- This option increases the time it takes for an application to run. Therefore, use it only as an aid to application development.
- The storage report generated by RPTSTG(ON) shows the number of system-level calls to obtain storage that were required while the application was running. To improve performance, use the storage report numbers generated by the RPTSTG option as an aid in setting the initial and increment size for stack and heap. This reduces the number of times that the Language Environment storage manager makes requests to acquire storage. For example, you can use the storage report numbers to set appropriate values in the HEAP init_size and incr_size fields for allocating storage.

**For more information**
- For more information about tuning your application with storage numbers, see `z/OS Language Environment Programming Guide`
- For more information about the MSGFILE runtime option, see `MSGFILE` on page 55.
- For an example and complete description of the storage report, see `z/OS Language Environment Debugging Guide`

**RTEREUS (COBOL only)**

**Derivation:** Run Time Environment REUSE

RTEREUS implicitly initializes the runtime environment to be reusable when the main program for the thread is a COBOL program. This option is valid only when specified at the system level, region level, in a CEEUOPT, or in the CEEBXITA assembler user exit.

The default value for non-CICS applications is NORTEREUS.

RTEREUS is ignored under CICS.

**Syntax**

```
NORTEREUS
RTEREUS
```

**NORTEREUS**

Does not initialize the runtime environment to be reusable when the first COBOL program is invoked.

**RTEREUS**

Initializes the runtime environment to be reusable when the first COBOL program is invoked.
Usage notes

• **Restriction:** Enterprise COBOL programs compiled with the THREAD compiler option do not run with RTEREUS(ON).

• **Guideline:** Avoid using RTEREUS(ON) as a system-level or region-level default. If you do use RTEREUS, use it for specific applications only.

• Under Language Environment, RTEREUS(ON) is only supported in a single enclave environment unless you modify the behavior using the IGZERREO CSECT. With the IBM supplied default setting for COBOL's reusable environment, applications that create multiple enclaves will terminate with error message IGZ0168S. Multiple enclaves can be created by applications that use SVC LINK or CMSCALL to invoke application programs. One example is when an SVC LINK is used to invoke an application program under ISPF that is using ISPF services (such as CALL 'ISPLINK' and ISPF SELECT).

• If a Language Environment reusable environment is established (using RTEREUS), any attempts to run a C or PL/I main program under Language Environment will fail. For example, when running on ISPF with RTEREUS(ON):
  – The first program invoked by ISPF is a COBOL program. A Language Environment reusable environment is established.
  – At some other point, ISPF invokes a PL/I or C program. The initialization of the PL/I or C program fails.

• If a large number of COBOL programs run (using RTEREUS) under the same MVS task, you can encounter out-of-region abends. This is because all storage acquired by Language Environment to run COBOL programs is kept in storage until the MVS task ends or the Language Environment environment is terminated.

• Language Environment storage and runtime options reports are not produced by Language Environment (using RTEREUS) unless a STOP RUN is issued to end the enclave.

• IMS consideration—RTEREUS is not recommended for use under IMS.

• The IGZERREO CSECT affects the handling of program checks in the non-Language Environment-enabled driver that repeatedly invokes COBOL programs. It also affects the behavior of running COBOL programs in a nested enclave when a reusable environment is active.

Performance consideration

• You must change STOP RUN statements to GOBACK statements to gain the benefits of RTEREUS. STOP RUN terminates the reusable environment. If you specify RTEREUS and use STOP RUN, Language Environment recreates the reusable environment on the next invocation of COBOL. Doing this repeatedly degrades performance, because a reusable environment takes longer to create than does a normal environment.

• The IGZERREO CSECT affects the performance of running with RTEREUS.

• Language Environment also offers preinitialization support in addition to RTEREUS.

For more information

• For information about specifying this option at the system or region level, see [z/OS Language Environment Customization](#).

• For information about specifying this option in a CEEUOPT, see [z/OS Language Environment Programming Guide](#).

• For more information about IGZERREO, see [z/OS Language Environment Customization](#).
SIMVRD (COBOL only)

**Derivation:** SIMulate Variable length Relative organization Data sets

SIMVRD specifies if your COBOL programs use a VSAM KSDS to simulate variable-length relative organization data sets.

The default value for non-CICS applications is NOSIMVRD.

SIMVRD is ignored under CICS.

### Syntax

```
NOSIMVRD
SIMVRD
```

**NOSIMVRD**

Do not use a VSAM KSDS to simulate variable-length relative organization.

**SIMVRD**

Use a VSAM KSDS to simulate variable-length relative organization.

**For more information**

See the appropriate version of the COBOL programming guide in the COBOL library at Enterprise COBOL for z/OS library (http://www.ibm.com/support/docview.wss?uid=swg27036733)

---

**STACK**

STACK controls the allocation of the thread’s stack storage for both the upward and downward-growing stacks. Typical items residing in the upward-growing stack are C or PL/I automatic variables, COBOL LOCAL-STORAGE data items, and work areas for runtime library routines. The downward-growing stack is allocated only in an XPLINK environment.

The default value for non-CICS applications is STACK(128K,128K,ANYWHERE,KEEP,512K,128K).

The default value for CICS applications is STACK(4K,4080,ANYWHERE,KEEP,4K,4080).
Syntax

```plaintext
STACK(usinit_size, usincr_size, ANYWHERE, ANY, BELOW)
KEEP, FREE, dsinit_size, dsincr_size)
```

`usinit_size`
Determines the initial allocation of the upward-growing stack storage. This value can be specified as \( n, nK, \) or \( nM \) bytes of storage. The actual amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

`usinit_size` can be preceded by a minus sign. In environments other than CICS, if you specify a negative number Language Environment uses all available storage minus the amount specified for the initial stack storage.

A size of "0" or "-0" requests half of the largest block of contiguous storage in the region below the 16-MB line.

`usincr_size`
Determines the minimum size of any subsequent increment to the upward-growing stack storage. This value can be specified as \( n, nK, \) or \( nM \) bytes of storage. The actual amount of allocated storage is the larger of two values—`usincr_size` or the requested size—rounded up to the nearest multiple of 8 bytes.

If you specify `usincr_size` as 0, only the amount of the storage needed at the time of the request, rounded up to the nearest multiple of 8 bytes, is obtained.

The requested size is the amount of storage a routine needs for a stack frame.

In the following example:
- `us incr size` is specified as 8K
- The requested size is 9000 bytes
- The currently allocated stack storage has less than 9000 bytes available

As a result, Language Environment allocates enough storage to hold the 9000 byte request.

If the requested size is smaller than 8K, Language Environment allocates 8K of stack storage.

`ANYWHERE|ANY`
Specifies that stack storage can be allocated anywhere in storage. If there is no available storage above the line, storage is acquired below the 16 MB line.

`BELOW`
Specifies that stack storage is allocated below the 16M line in storage.

`KEEP`
Specifies that an increment to stack storage is not released when the last of the storage within that increment is freed.
FREE
Specifies that an increment to stack storage is released when the last of the storage within that increment is freed.

dsinit_size
Determines the initial allocation of the downward-growing stack storage. This value can be specified as n, nK, or nM bytes of storage. The actual amount of allocated storage is rounded up to the nearest multiple of 16 bytes.

dsincr_size
Determines the minimum size of any subsequent increment to the downward-growing stack storage. This value can be specified as n, nK, or nM bytes of storage. The actual amount of allocated storage is the larger of two values—dsincr_size or the requested size—rounded up to the nearest multiple of 16 bytes.

CICS consideration
• dsinit_size and dsincr_size suboptions are ignored under CICS.
• The maximum initial and increment size for CICS above 16 MB is 1 gigabyte (1024 MB).
• The minimum for the initial size is 4K.
• STACK(0), STACK(-0), and STACK(-n) are all interpreted as STACK(4K) under CICS.
• The default increment size under CICS is 4080 bytes, rather than 4096 bytes, to accommodate the 16-bytes CICS storage check zone. Without this accommodation, an extra page of storage is allocated when the storage allocation is below the 16-MB line.

z/OS UNIX considerations
• The STACK option specifies the characteristics of the user stack for the initial thread. In particular, it gets the initial size of the user stack for the initial thread. The characteristics that indicate incr_size, ANYWHERE, and KEEP | FREE apply to any thread created using pthread_create. Language Environment gets the initial stack size from the threads attribute object specified in the pthread_create function. The default size to be set in the thread’s attribute object is obtained from the initial size of the STACK runtime option.
• The default setting for STACK under z/OS UNIX is STACK=(12K,12K,ANYWHERE,KEEP,512K,128K).

Usage notes
• Applications running with ALL31(OFF) must specify STACK(_,BELOW,_,) to ensure that stack storage is addressable by the application.
• When an application is running in an XPLINK environment, the STACK runtime option is forced to STACK(_,ANY,__). Only the third suboption of the STACK runtime option is changed by this action, to indicate that stack storage can be allocated anywhere in storage. No message is issued to indicate this action. In this case, if a Language Environment runtime options report is generated using the RPTOPTS runtime option, the STACK option will be reported as "Override" under the LAST WHERE SET column.
• If the initial routine of the Language Environment application is AMODE 24, the STACK runtime option is forced to STACK(_,BELOW). Only the third suboption of the STACK runtime option is changed by this action. No message is issued to indicate this action. However, if a Language Environment runtime options report
is generated using the RPTOPTS runtime option, the STACK option is reported as "Override" under the LAST WHERE SET column.

- The dsinit_size and dsincr_size values are not the actual amounts of storage obtained. The actual size of the storage obtained is 4K larger (8K if a 4K page alignment cannot be guaranteed) to accommodate the guard page.
- PL/I consideration—PL/I automatic storage above the 16-MB line is supported under control of the Language Environment STACK option. When the Language Environment stack is above, PL/I temporaries (dummy arguments) and parameter lists (for reentrant/recursive blocks) also reside above.

The stack frame size for an individual block is constrained to 16 MB. Stack frame extensions are also constrained to 16 MB. Therefore, the size of an automatic aggregate, temporary variable, or dummy argument cannot exceed 16 MB. Violation of this constraint might have unpredictable results.

If an OS PL/I application does not contain any edited stream I/O and if it is running with AMODE 31, you can relink it with Language Environment to use STACK(„ANY„). Doing so is particularly useful under CICS to help relieve below-the-line storage constraints.

- PL/I MTF consideration—The STACK option allocates and manages stack storage for the PL/I main task only.

Performance consideration

You can improve performance with the STACK runtime option by specifying values that minimize the number of times the operating system allocates storage. See "RPTSTG" on page 73 for information about how to generate a report you can use to determine the optimum values for the STACK runtime option.

For more information

- See "ALL31" on page 12 for more information about the ALL31 runtime option.
- See "RPTSTG" on page 73 for more information about the RPTSTG runtime option.
- For more information about using the storage reports generated by the RPTSTG runtime option to tune the stacks, see z/OS Language Environment Debugging Guide.
- See "XPLINK" on page 103 for more information about the XPLINK runtime option.

STACK64 (AMODE 64 only)

STACK64 controls the allocation of the thread’s stack storage for AMODE 64 applications. Storage required for the common anchor area (CAA) and other control blocks is allocated separately from, and prior to, the allocation of the initial stack segment and the initial heap.

The default value for AMODE 64 applications is STACK64(1M,1M,128M).
Syntax

```plaintext
STACK64 (initial, increment, maximum)
```

`initial`
Determines the size of the initial stack segment. The storage is contiguous. This value is specified as \( n \times M \) bytes of storage.

`increment`
Determines the minimum size of any subsequent increment to the downward-growing stack area. This value is specified as \( n \times M \) bytes of storage. The actual amount of allocated storage is the larger of two values—`increment` or the requested size—rounded up to the nearest 1MB. If you specify `increment` as 0, only the amount of the storage needed at the time of the request, rounded up to the nearest multiple of 1MB, is obtained. The requested size is the amount of storage a routine needs for a stack frame.

`maximum`
Specifies the maximum stack size. This value is specified as \( n \times M \) bytes of storage. When the maximum size is less than the initial size, `initial` is used as the maximum stack size.

**Usage notes**

- The 1MB guard page is not included in any of the sizes.
- The maximum stack segment is the maximum of STACK64 initial and maximum sizes.
- The default value of 128MB for the maximum stack size of the STACK64 and THREADSTACK64 runtime options can cause excessive use of system resources (such as real storage) when running a multithreaded application that creates many pthreads. For such applications, it is recommended to use the Language Environment Storage Report (RPTSTG runtime option) to determine your application’s actual pthread stack storage usage, and then use the THREADSTACK64 runtime option to set the maximum stack size to a value closer to the actual usage.

**Performance consideration**

You can improve performance with the STACK64 runtime option by specifying values that minimize the number of times the operating system allocates storage. See “RPTSTG” on page 73 for information about how to generate a report you can use to determine the optimum values for the STACK64 runtime option.

**For more information**

- See “RPTSTG” on page 73 for more information about the RPTSTG runtime option.
- For more information about heap storage and heap storage tuning with storage report numbers, see z/OS Language Environment Programming Guide.
- For more information about using the storage reports generated by the RPTSTG runtime option to tune the stacks, see z/OS Language Environment Debugging Guide.
STORAGE

STORAGE controls the initial content of storage when allocated and freed. It also controls the amount of storage that is reserved for the out-of-storage condition. If you specify one of the parameters in the STORAGE runtime option, all allocated storage processed by that parameter is initialized to the specified value. Otherwise, it is left uninitialized. You can use the STORAGE option to identify uninitialized application variables, or prevent the accidental use of previously freed storage. STORAGE is also useful in data security. For example, storage containing sensitive data can be cleared when it is freed.

The default value for non-CICS applications is STORAGE(NONE,NONE,NONE,0K).

The default value for CICS applications is STORAGE(NONE,NONE,NONE,0K).

The default value for AMODE 64 applications is STORAGE(NONE,NONE,NONE).

Syntax

```
STORAGE( heap_alloc_value, heap_free_value, dsa_alloc_value, reserve_size )
```

heap_alloc_value

The initialized value of any heap storage allocated by the storage manager. You can specify heap_alloc_value as:

- A single character enclosed in quotation marks. If you specify a single character, every byte of heap storage allocated by the storage manager is initialized to that character’s EBCDIC equivalent. For example, if you specify a as the heap_alloc_value, heap storage is initialized to X’818181...81’ or aaa...a.

- Two hex digits without quotation marks. If you specify two hex digits, every byte of the allocated heap storage is initialized to that value. For example, if you specify FE as the heap_alloc_value, heap storage is initialized to X’FEFEFE...FE’. A heap_alloc_value of 00 initializes heap storage to X’0000...00’.

- NONE If you specify NONE, the allocated heap storage is not initialized.

heap_free_value

The value of any heap storage freed by the storage manager is overwritten. You can specify heap_free_value as:

- A single character enclosed in quotation marks. For example, a heap_free_value of ‘f’ overwrites freed heap storage to X’868686...86’; ‘B’ overwrites freed heap storage to X’C2C2C2...C2’.

- Two hex digits without quotation marks. A heap_free_value of FE overwrites freed heap storage with X’FEFEFE...FE’.

- NONE If you specify NONE, the freed heap storage is not initialized.

dsa_alloc_value

The initialized value of stack frames from the Language Environment stack. A
stack frame is storage that was acquired dynamically and is composed of a standard register save area and the area available for automatic storage. The dsa_alloc_value has no effect on the XPLINK or AMODE 64 downwards growing stack.

If specified, all Language Environment stack storage, including automatic variable storage, is initialized to dsa_alloc_value. Stack frames allocated outside the Language Environment stack are never initialized.

You can specify dsa_alloc_value as:
- A single character enclosed in quotation marks. If you specify a single character, any dynamically acquired stack storage allocated by the storage manager is initialized to that character's EBCDIC equivalent. For example, if you specify 'A' as the dsa_alloc_value, stack storage is initialized to X'C1C1C1...C1'. A dsa_alloc_value of 'F' initializes stack storage to X'C6C6C6...C6', 'd' to X'848484...84'.
- Two hex digits without quotations. If you specify two hex digits, any dynamically-acquired stack storage is initialized to that value. For example, if you specify FE as the dsa_alloc_value, stack storage is initialized to X'FEFEFE...FE'. A dsa_alloc_value of 00 initializes stack storage to X'000000...00'.
- CLEAR If you specify CLEAR, any unused portion of the initial upward growing stack segment is initialized to binary zeros, just before the main procedure gains control. This value has no effect on any stack increments or on the XPLINK or AMODE 64 downward growing stack.
- NONE If you specify NONE, the stack storage is not initialized.

reserve_size
The amount of storage for the Language Environment storage manager to reserve in the event of an out-of-storage condition. You can specify the reserve_size value as n, nK, or nM bytes of storage. The amount of storage is rounded to the nearest multiple of 8 bytes.

Restriction: This option is ignored in a 64–bit environment.

If you specify reserve_size as 0, no reserve segment is allocated. The default reserve_size is 0, so no reserve segment is allocated. If you do not specify a reserve segment and your application exhausts storage, the application terminates with abend 4088 and a reason code of 1024.

If you specify a reserve_size that is greater than 0 on a non-CICS system, Language Environment does not immediately abend when your application runs out of storage. Instead, when the stack overflows, Language Environment uses the reserve stack as the new segment and signals a CEE0PD out of storage condition. This allows a user-written condition handler to gain control for this signal and release storage. If the reserve stack segment overflows while this is happening, Language Environment terminates with abend 4088 and reason code of 1004. The reserve stack segment is not freed until thread termination. It is acquired from 31-bit storage if the STACK(,,ANY,,) runtime option is set or 24-bit storage when STACK(,,BELOW,,) is requested. If a determination is made to activate the reserve stack, the reserve size should be set to a minimum of 32K to support Language Environment condition handling and messaging internal routines as well as the user condition handler. When using the reserve stack in a multithreaded environment, it is recommended that the ALL31(ON) and STACK(,,ANY,,) options also be in effect.
To avoid such an overflow, increase the size of the reserve stack segment with the \texttt{STORAGE(,reserve\_size)} runtime option. The reserve stack segment is not freed until thread termination.

**CICS consideration**

The out-of-storage condition is not raised under CICS.

**z/OS UNIX considerations**

A reserve stack of the size specified by the \texttt{reserve\_size} suboption of \texttt{STORAGE} is allocated for each thread.

**Usage notes**

- The \texttt{heap\_alloc\_value}, \texttt{heap\_free\_value}, and \texttt{dsa\_alloc\_value} can all be enclosed in quotation marks. To initialize heap storage to the EBCDIC equivalent of a single quote, double it within the string delimited by single quotes or surround it with a pair of double quotation marks. Both of the following are correct ways to specify a single quote:

  \begin{verbatim}
  STORAGE('""')
  STORAGE("'")
  \end{verbatim}

  Similarly, double quotation marks must be doubled within a string delimited by double quotation marks, or surrounded by a pair of single quotes. The following are correct ways to specify a double quotation mark:

  \begin{verbatim}
  STORAGE("**")
  STORAGE('**')
  \end{verbatim}

- CLEAR is not a valid option for AMODE 64 applications.
- COBOL consideration—If using WSCLEAR in VS COBOL II, \texttt{STORAGE(00,NONE,NONE,8K)} is recommended.

**Performance considerations**

- Use \texttt{STORAGE(NONE,NONE,NONE)} when you are not debugging.
- Using \texttt{STORAGE} to control initial values can increase program runtime. If you specify a \texttt{dsa\_alloc\_value}, performance is likely to be poor. Therefore, use the \texttt{dsa\_alloc\_value} option only for debugging, not to initialize automatic variables or data structures.
- You should not use \texttt{STORAGE(,00)} in any performance-critical application.

**TERMTHDACT**

**Derivation:** \texttt{TERMinating THeaD ACTions}

\texttt{TERMTHDACT} sets the level of information that is produced when Language Environment percolates a condition of severity 2 or greater beyond the first routine's stack frame. The Language Environment service \texttt{CEE3DMP} is called for the \texttt{TRACE}, \texttt{UATRACE}, \texttt{DUMP}, and \texttt{UADUMP} suboptions of \texttt{TERMTHDACT}.
The TRACE and UATRACE suboptions suppress the dumping of user storage and Language Environment control blocks.

The DUMP and UADUMP suboptions include the dumping of user storage and Language Environment control blocks.

If a message is printed, based upon the TERMTHDACT(MSG) runtime option, the message is for the active condition immediately prior to the termination imminent step. In addition, if that active condition is a promoted condition (was not the original condition), the original condition's message is printed.

If the TRACE runtime option is specified with the DUMP suboption, a dump containing the trace table, at a minimum, is produced. The contents of the dump depend on the values set in the TERMTHDACT runtime option.

The default value for non-CICS applications is TERMTHDACT(TRACE,CESE,96).

The default value for CICS applications is TERMTHDACT(TRACE,CESE,96).

The default value for AMODE 64 applications is TERMTHDACT(TRACE,,96).

**Syntax**

```
TERmthdact (TRACE QUIET MSG DUMP UATRACE UADUMP UAONLY UAIMM, CESE CICSDDS, reg_stor_amount)
```

**TRACE**

Specifies that when a thread terminates due to an unhandled condition of severity 2 or greater, Language Environment generates a message indicating the cause of the termination and a trace of the active routines on the activation stack.

**QUIET**

Specifies that Language Environment does not generate a message when a thread terminates due to an unhandled condition of severity 2 or greater.

**MSG**

Specifies that when a thread terminates due to an unhandled condition of severity 2 or greater, Language Environment generates a message indicating the cause of the termination.

**DUMP**

Specifies that when a thread terminates due to an unhandled condition of severity 2 or greater, Language Environment generates a message indicating the cause of the termination, a trace of the active routines on the activation stack, and a Language Environment dump.
**UATRACE**

Specifies that when a thread terminates due to an unhandled condition of severity 2 or greater, Language Environment generates a message indicating the cause of the termination, a trace of the active routines on the activation stack, and a U4039 system dump of the user address space. Under CICS, you will get a CICS transaction dump. Under non-CICS, if the appropriate DD statement is used, you will get a system dump of your user address space.

**UADUMP**

Specifies that when a thread terminates due to an unhandled condition of severity 2 or greater, Language Environment generates a message indicating the cause of the termination, a trace of the active routines on the activation stack, a Language Environment dump, and a U4039 system dump of the user address space. Under non-CICS, if the appropriate DD statement is used, you will get a system dump of your user address space. Under CICS, you will get a CICS transaction dump.

**UAONLY**

Specifies that when a thread terminates due to an unhandled condition of severity 2 or greater, Language Environment generates a U4039 system dump of the user address space. Under non-CICS, if the appropriate DD statement is used, you will get a system dump of your user address space. Under CICS, you will get a CICS transaction dump.

**UAIMM**

Specifies to Language Environment that prior to condition management processing, for abends and program interrupts that are conditions of severity 2 or higher, Language Environment will immediately request the operating system to generate a system dump of the original abend/program interrupt of the user address space. Due to an unhandled condition of severity 2 or greater, Language Environment generates a U4039 system dump of the user address space. Under non-CICS, if the appropriate DD statement is used, you will get a system dump of your user address space. After the dump is taken by the operating system, Language Environment condition manager can continue processing. If the thread terminates due to an unhandled condition of Severity 2 or higher, then Language Environment will terminate as if TERMTHDACT(QUIET) was specified.

**Note:** For software-raised conditions or signals, UAIMM behaves the same as UAONLY.

**CESE**

Specifies that Language Environment dump output are written to the CESE QUEUE as it has always been. This option is ignored in a 64–bit environment.

**CICSDDS**

Specifies that Language Environment dump output are written to the new CICS transaction dump that contains both CICS and CEEDUMP data. This option is ignored in a 64–bit environment.

**reg_stor_amount**

Controls the amount of storage to be dumped around registers. This amount can be in the range from 0 to 256 bytes. The amount specified will be rounded up to the nearest multiple of 32. The default amount is 96 bytes.
CICS consideration

All TERMTHDACT output is written to the data queue based on the setting of CESE or CICSDDS. See Table 5 for a summary of the results of the different options that are available.

          • Traceback written to CESE queue.  
          • U4039 transaction dump in CICS dump data set.  
          • U4038 abend issued. |
| UADUMP  | • Message written to CESE queue or MSGFILE.  
          • Traceback written to CESE queue.  
          • CEEDUMP written to CESE queue.  
          • U4039 transaction dump in CICS dump data set.  
          • U4038 abend issued. | • Invalid suboption combination. Not supported. |
| UAONLY  | • U4039 transaction dump in CICS dump data set.  
          • U4038 abend issued. | • No changes in behavior for CICSDDS. |
| UAIMM   | • U4039 transaction dump in CICS dump data set.  
          • U4038 abend issued. | • Incorrect suboption combination. Not supported. |

**Note:**

1. CICS is told about software-raised error conditions for DUMP and TRACE.
2. When assembling a CEEROPT or CEEUOPT, the CICSDDS option cannot be issued with DUMP or UADUMP. This results in a RC=8, CEEXOPT issues an MNOTE, and the setting is forced to TRACE:
3. Language Environment requests a CICS transaction dump via the U4039 abend.
4. See [z/OS Language Environment Runtime Messages](http://www.ibm.com) for more complete details regarding the U4039 abend.

**z/OS UNIX considerations**

The TERMTHDACT option applies when a thread terminates abnormally. Abnormal termination of a single thread causes termination of the entire enclave. If an unhandled condition of severity 2 or higher percolates beyond the first routine’s stack frame, the enclave terminates abnormally.

If an enclave terminates due to a POSIX default signal action, TERMTHDACT applies only to conditions that result from program checks or abends.
If running under a z/OS UNIX shell and Language Environment generates a system dump, a core dump is generated to a file based on the kernel environment variable, _BPXKDUMP.

Usage notes

- A runtime options report is generated and placed at the end of the enclave information whenever the TRACE, UATRACE, DUMP and UADUMP options are invoked.
- PL/I considerations—After a normal return from a PL/I ERROR ON-unit or from a PL/I FINISH ON-unit, Language Environment considers the condition unhandled. If a GOTO is not performed and the resume cursor is not moved, the thread terminates. The TERMTHDACT setting guides the amount of information that is produced. The message is not presented twice.
- PL/I MTF considerations—
  - TERMTHDACT applies to a task when the task terminates abnormally due to an unhandled condition of severity 2 or higher that is percolated beyond the initial routine’s stack frame.
  - When a task ends with a normal return from an ERROR ON-unit and other tasks are still active, a dump is not produced even when the TERMTHDACT option DUMP, UADUMP, UAONLY, or UAIMM is specified.
  - All active subtasks created from the incurring task also terminate abnormally, but the enclave can continue to run.
- The environment variable _CEE_DMPTARG allows a sysout class for a dynamically allocated CEEDUMP. You can set the _CEE_DMPTARG value string from a z/OS UNIX shell by:
  - Using the export command
  - Using the C functions setenv() or putenv()
  - Using the ENVAR runtime option

  _CEE_DMPTARG has the following format, _CEE_DMPTARG=value. The value is a null-terminated character string, SYSOUT(x), that defines a sysout class that Language Environment will set dynamically allocating the CEEDUMP. For example, you can specify: _CEE_DMPTARG=SYSOUT(A)

  To set the _CEE_DMPTARG value from a z/OS UNIX shell, you could issue the export command and specify the following run-options, for example:

  export _CEE_DMPTARG=SYSOUT(A).

  WHEN _CEE_DMPTARG is not set, then the sysout class will default to SYSOUT(*) for the dynamically allocated CEEDUMP. If the dynamic allocation for the specified SYSOUT class specified by _CEE_DMPTARG should fail, the default, SYSOUT(*) will be used.

For more information

- See “TRACE” on page 96, for more information about the TRACE runtime option.
- For more information about the CEE3DMP service and its parameters, see “CEE3DMP—Generate dump” on page 144.
- See z/OS Language Environment Programming Guide for more information about the TERMTHDACT runtime option and condition message.
- For more information about CESE, see z/OS Language Environment Programming Guide.
TEST specifies the conditions under which a debug tool (such as the Debug Tool supplied with z/OS) assumes control when the user application is being initialized. Parameters of the TEST and NOTEST runtime options are merged as one set of parameters.

The default value for non-CICS applications is NOTEST(ALL,*,PROMPT,INSPPREF).

The default value for CICS applications is NOTEST(ALL,*,PROMPT,INSPPREF).

The default value for AMODE 64 applications is NOTEST(ALL,*,PROMPT,INSPPREF).

**Syntax**

```
TEST | NOTEST
```

**ALL**

Specifies that any of the following causes the debug tool to gain control even without a defined AT OCCURRENCE for a particular condition or AT TERMINATION:
- The ATTENTION function
- Any Language Environment condition of severity 1 or above
- Application termination

**ERROR**

Specifies that only one of the following causes the debug tool to gain control without a defined AT OCCURRENCE for a particular condition or AT TERMINATION:
- The ATTENTION function
- Any Language Environment-defined error condition of severity 2 or higher
- Application termination

**NONE**

Specifies that no condition causes the debug tool to gain control without a defined AT OCCURRENCE for a particular condition or AT TERMINATION.

**commands_file**

A valid **ddname**, data set name (MVS), or file name (CMS), specifying the primary commands file for this run. If you do not specify this parameter all requests for commands go to the user terminal.
You can enclose commands_file in single or double quotation marks to distinguish it from the rest of the TEST | NOTEST suboption list. It can have a maximum length of 80 characters. If the data set name provided can be interpreted as a ddname, it must be preceded by a slash (/). The slash and data set name must be enclosed in quotation marks.

A primary commands file is required when running in a batch environment.

* (asterisk—in place of commands_file)
   Specifies that no commands_file is supplied. The terminal, if available, is used as the source of the debug tool commands.

PROMPT
   Specifies that the debug tool is invoked at Language Environment initialization.

NOPROMPT
   Specifies that the debug tool is not invoked at Language Environment initialization.

* (asterisk—in place of PROMPT/NOPROMPT)
   Specifies that the debug tool is not invoked at Language Environment initialization; equivalent to NOPROMPT.

; (semicolon—in place of PROMPT/NOPROMPT)
   Specifies that the debug tool is invoked at Language Environment initialization; equivalent to PROMPT.

command
   A character string that specifies a valid debug tool command. The command list can be enclosed in single or double quotation marks to distinguish it from the rest of the TEST parameter list; it cannot contain DBCS characters. Quotation marks are needed whenever the command list contains embedded blanks, commas, semicolons, or parentheses. The list can have a maximum of 250 characters.

INSPREF
   Specifies the default setting for preference_file.

preference_file
   A valid ddname, data set name (MVS), or file name (CMS), specifying the preference file to be used. A preference file is a type of commands file that you can use to specify settings for your debugging environment. It is analogous to creating a profile for a text editor, or initializing a terminal session.

   You can enclose preference_file in single or double quotation marks to distinguish it from the rest of the TEST parameter list. It can have a maximum of 80 characters.

   If a specified data set name could be interpreted as a ddname, it must be preceded by a slash (/). The slash and data set name must be enclosed in quotation marks.

* (asterisk—in place of preference_file)
   Specifies that no preference_file is supplied.

z/OS UNIX considerations

Language Environment honors the initial command string before the main routine runs on the initial thread.

The test level (ALL, ERROR, NONE) applies to the enclave.
Language Environment honors the preference file when the debug tool is initialized, regardless of which thread first requests the debug tool services.

**Usage notes**

- You can specify parameters on the NOTEST option. If NOTEST is in effect when the application gains control, it is interpreted as TEST(NONE,*,). If Debug Tool is initialized using a CALL CEETEST or equivalent, the initial test level, the initial commands_file, and the initial preference_file are taken from the NOTEST runtime option setting.

**Performance consideration**

To improve performance, use this option only while debugging.

**For more information**

See Debug Tool publications for details and examples of the TEST runtime option as it relates to Debug Tool.

---

**THREADHEAP**

**Derivation:** THREAD level HEAP storage

THREADHEAP controls the allocation and management of thread-level heap storage. Separate heap segments are allocated and freed for each thread based on the THREADHEAP specification.

For PL/I MTF applications, controlled and based variables declared in a subtask are allocated from heap storage specified by THREADHEAP. Variables in the main task are allocated from heap storage specified by HEAP.

Library use of heap storage in a substack is allocated from the enclave-level heap storage specified by the ANYHEAP and BELOWHEAP options.

The default value for non-CICS applications is THREADHEAP(4K,4K,ANY,KEEP).

THREADHEAP is ignored under CICS.

**Syntax**

```plaintext
THREADHeap(init_size, incr_size, ANYWHERE, KEEP, FREE)
```
**THREADHEAP**

*init_size*

The minimum initial size of thread heap storage, and is specified in \( n \), \( nK \), or \( nM \). Storage is acquired in multiples of 8 bytes. A value of zero (0) causes an allocation of 4K.

*incr_size*

The minimum size of any subsequent increment to the noninitial heap storage is specified in \( n \), \( nK \), or \( nM \). The actual amount of allocated storage is the larger of two values, *incr_size* or the requested size, rounded up to the nearest multiple of 8 bytes. If you specify *incr_size* as 0, only the amount of the storage needed at the time of the request (rounded up to the nearest 8 bytes) is obtained.

**ANYWHERE|ANY**

Specifies that the heap storage can be allocated anywhere in storage. If there is no available storage above the line, storage is acquired below the 16-MB line. The only valid abbreviation of ANYWHERE is ANY.

**BELOW**

Specifies that the heap storage must be allocated below the 16M line.

**KEEP**

Specifies that storage allocated to THREADHEAP increments is not released when the last of the storage in the thread heap increment is freed.

**FREE**

Specifies that storage allocated to THREADHEAP increments is released when the last of the storage in the thread heap increment is freed.

**CICS consideration**

Even though this option is ignored under CICS, the default increment size under CICS has changed from 4K (4096 bytes) to 4080 bytes, to accommodate the 16 bytes CICS storage check zone.

**Usage notes**

- If the requesting routine is running in 24-bit addressing mode and THREADHEAP(_,ANY) is in effect, THREADHEAP storage is allocated below the 16M line based upon the HEAP(_,initsz24,incrsz24) settings.
- PL/I MTF considerations—The thread-level heap is allocated only in applications that use the PL/I MTF. For PL/I MTF applications, controlled and based variables specified in subtasks are located in the thread-level heap. If the main program is running in 24-bit addressing mode and THREADHEAP(_,ANY) is in effect, heap storage is allocated below the 16M line. The only case in which storage is allocated above the line is when all of the following conditions exist:
  - The user routine requesting the storage is running in 31-bit addressing mode.
  - HEAP(_,ANY,_) is in effect.
  - The main routine is running in 31-bit addressing mode.
- When running PL/I with POSIX(ON) in effect, THREADHEAP is used for allocating heap storage for PL/I base variables declared in non-IPTs. Storage allocated to all THREADHEAP segments is freed when the thread terminates.
- THREADHEAP(4K,4K,ANYWHERE,KEEP) provides behavior compatible with the PL/I TASKHEAP option.
- The initial thread heap segment is never released until the thread terminates.
- THREADHEAP has no effect on C/C++ or Fortran for z/OS MTF applications.
THREADSTACK

**Derivation:** THREAD level STACK storage

THREADSTACK controls the allocation of the thread’s stack storage for both the upward and downward-growing stacks, except the initial thread in a multithreaded application. If the thread attribute object does not provide an explicit stack size, then the allocation values can be inherited from the STACK option or specified explicitly on the THREADSTACK option.

The default values for non-CICS applications is THREADSTACK(OFF,4K,4K,ANYWHERE,KEEP,128K,128K).

THREADSTACK is ignored under CICS.

**Syntax**

```
THREADStack (OFF, ON, usinit_size, usincr_size, ANYWHERE, ANY, BELOW, KEEP, FREE, dsinit_size, dsincr_size)
```

**OFF**
Indicates that the allocation suboptions of the STACK runtime option are used for thread stack allocation. Any other suboption specified with THREADSTACK is ignored.

**ON**
Controls the stack allocation for each thread, except the initial thread, in a multithreaded environment.

**usinit_size**
Determines the size of the initial upward-growing stack segment. The storage is contiguous. You specify the usinit_size value as \( n \), \( nK \), or \( nM \) bytes of storage. The actual amount of allocated storage is rounded up to the nearest multiple of 8 bytes.

The usinit_size value can be preceded by a minus sign. In environments other than CICS, if you specify a negative number Language Environment uses all available storage minus the amount specified for the initial stack segment.

A size of "0" or ",0" requests half of the largest block of contiguous storage in the region below the 16-MB line.

**usincr_size**
Determines the minimum size of any subsequent increment to the upward-growing stack area. You can specify this value as \( n \), \( nK \), or \( nM \) bytes of storage. The actual amount of allocated storage is the larger of two values—usincr_size or the requested size—rounded up to the nearest multiple of 8 bytes.

If you specify usincr_size as 0, only the amount of the storage needed at the time of the request, rounded up to the nearest multiple of 8 bytes, is obtained.
THREADSTACK

The requested size is the amount of storage a routine needs for a stack frame. For example, if the requested size is 9000 bytes, \textit{usincr\_size} is specified as 8K, and the initial stack segment is full, Language Environment gets a 9000 byte stack increment from the operating system to satisfy the request. If the requested size is smaller than 8K, Language Environment gets an 8K stack increment from the operating system.

\begin{itemize}
  \item \textsc{anywhere} | \textsc{any}
    \begin{itemize}
      \item Specifies that stack storage can be allocated anywhere in storage. On systems that support bimodal addressing, storage can be allocated either above or below the 16M line. If there is no storage available above the line, Language Environment acquires storage below the line. On systems that do not support bimodal addressing (for example, when VM/ESA is initial program loaded in 370 mode) Language Environment ignores this option and places the stack storage below 16M.
    \end{itemize}
  \item \textsc{below}
    \begin{itemize}
      \item Specifies that the stack storage must be allocated below the 16M line in storage that is accessible to 24–bit addressing.
    \end{itemize}
  \item \textsc{keep}
    \begin{itemize}
      \item Specifies that storage allocated to stack increments is not released when the last of the storage in the stack increment is freed.
    \end{itemize}
  \item \textsc{free}
    \begin{itemize}
      \item Specifies that storage allocated to stack increments is released when the last of the storage in the stack is freed. The initial stack segment is never released until the enclave terminates.
    \end{itemize}
\end{itemize}

\textit{dsinit\_size}

Determines the size of the initial downward-growing stack segment. The storage is contiguous. You specify the init\_size value as \textit{n}, \textit{nK}, or \textit{nM} bytes of storage. The actual amount of allocated storage is rounded up to the nearest multiple of 16 bytes.

\textit{dsincr\_size}

Determines the minimum size of any subsequent increment to the downward-growing stack area. You can specify this value as \textit{n}, \textit{nK}, or \textit{nM} bytes of storage. The actual amount of allocated storage is the larger of two values-- \textit{incr\_size} or the requested size--rounded up to the nearest multiple of 16 bytes.

**Usage notes**

\begin{itemize}
  \item The \textit{dsinit\_size} and \textit{dsincr\_size} values are the amounts of storage that can be used for downward-growing stack frames (plus the stack header, approximately 20 bytes). The actual size of the storage getmained will be 4K (8K if a 4K page alignment cannot be guaranteed) larger to accommodate the guard page.
  \item The downward-growing stack is only initialized in a XPLINK supported environment, that is, batch, TSO, z/OS UNIX, and only when a XPLINK application is active in the enclave. Otherwise the suboptions for the downward-growing stack are ignored.
  \item All storage allocated to \textsc{threadstack} segments are freed when the thread terminates.
  \item The initial stack segment of the thread is never released until the thread terminates, regardless of the \textsc{keep}/\textsc{free} state.
  \item You can specify suboptions with \textsc{threadstack}(OFF,...), but they are ignored. If you override the \textsc{threadstack}(OFF,...) suboption with \textsc{threadstack}(ON) and you omit suboptions, then the suboptions you
specified with THREADSTACK(OFF, ...) remain in effect. If you respecify THREADSTACK(OFF, ...) with different suboptions, they override the defaults.

- PL/I MTF consideration—THREADSTACK(ON, 4K, 4K, BELOW, KEEP, ...) remains in effect. If you respecify THREADSTACK(OFF, ...) with different suboptions, they override the defaults.
- PL/I considerations—For multitasking or multithreaded environments, the stack size for a subtask or non-Initial Process Thread (non-IPT) is taken from the THREADSTACK option unless THREADSTACK(OFF) is specified. THREADSTACK(OFF) specifies that the values in the STACK option be used.
- In the multithreaded environment, you can explicitly specify the stack size in the thread attribute object; it will be used instead of the value specified with THREADSTACK or STACK.
- The THREADSTACK option replaces the NONIPTSTACK and NONNONIPTSTACK options.

**THREADSTACK64 (AMODE 64 only)**

**Derivation:** THREAD level STACK storage for AMODE 64

THREADSTACK64 controls the allocation of the thread’s stack storage for AMODE 64 applications, except for the initial thread in a multithreaded environment.

The default value for AMODE 64 applications is THREADSTACK64(OFF, 1M, 1M, 128M).

**Syntax**

```
THREADSTACK64
(TS64)
```

- **OFF**
  - Indicates that the allocation suboptions of the STACK64 runtime option are used for thread stack allocation. Any other suboption specified with THREADSTACK64 is ignored.

- **ON**
  - Controls the stack allocation for each thread, except the initial thread, in a multithreaded environment.

- **initial**
  - Determines the size of the initial stack segment. The storage is contiguous. This value is specified as nM bytes of storage.

- **increment**
  - Determines the minimum size of any subsequent increment to the stack area. This value is specified as nM bytes of storage. The actual amount of allocated storage is the larger of two values—increment or the requested size—rounded up to the nearest multiple of 1MB.

If you specify increment as 0, only the amount of the storage needed at the time of the request, rounded up to the nearest multiple of 1MB, is obtained.

The requested size is the amount of storage a routine needs for a stack frame.
maximum

Specifies the maximum stack size. This value is specified as \( n \)M bytes of storage. When the maximum size is less than the initial size, initial is used as the maximum stack size.

Usage notes

- The 1 MB guard page is not included in any of the sizes.
- The maximum thread stack segment is the maximum of THREADSTACK64 initial and maximum sizes.
- The default value of 128 MB for the maximum stack size of the STACK64 and THREADSTACK64 runtime options can cause excessive use of system resources (such as real storage) when running a multithreaded application that creates many pthreads. For such applications, it is recommended to use the Language Environment Storage Report (RPTSTG runtime option) to determine your application's actual pthread stack storage usage, and then use the THREADSTACK64 runtime option to set the maximum stack size to a value closer to the actual usage.

For more information

For more information about heap storage and heap storage tuning with storage report numbers, see z/OS Language Environment Programming Guide.

TRACE

TRACE controls runtime library tracing activity, the size of the in-storage trace table, the type of trace events to record, and it determines whether a dump containing, at a minimum, the trace table should be unconditionally taken when the application terminates. When you specify TRACE(ON), user-requested trace entries are intermixed with Language Environment trace entries in the trace table.

Under normal termination conditions, if TRACE is active and you specify DUMP, only the trace table is written to the dump report, independent of the TERMTHDACT setting. Only one dump is taken for each termination. Under abnormal termination conditions, the type of dump taken (if one is taken) depends on the value of the TERMTHDACT runtime option and if TRACE is active and the DUMP suboption is specified.

The default value for non-CICS applications is TRACE(OFF,4K,DUMP,LE=0).

The default value for CICS applications is TRACE(OFF,4K,DUMP,LE=0).

The default value for AMODE 64 applications is TRACE(OFF,4K,DUMP,LE=0).

Syntax

```
TRACE(ON), table_size, DUMP, LE=0, LE=1, LE=2, LE=3, LE=20)
```
**OFF**
Indicates that the tracing facility is inactive.

**ON**
Indicates that the tracing facility is active.

**table_size**
Determines the size of the tracing table as specified in bytes (nK or nM). The upper limit is 16M - 1 (166777215 bytes). **Restriction:** This option is ignored in a 64-bit environment and the size is set to 1M.

**DUMP**
Requests that a Language Environment-formatted dump (containing the trace table) be taken at program termination regardless of the setting of the TERMTHDACT runtime option.

**NODUMP**
Requests that a Language Environment-formatted dump not be taken at program termination.

**LE=0**
Specifies that no trace events be recorded.

**LE=1**
Specifies that entry to and exit from Language Environment member libraries be recorded (such as, in the case of C, entry and exit of the printf() library function).

**LE=2**
Specifies that mutex init/destroy and locks/unlocks from Language Environment member libraries be recorded.

**LE=3**
Activates both the entry/exit trace and the mutex trace.

**LE=20**
Specifies that XPLINK/non-XPLINK transition should be recorded.

**Usage notes**
- **PL/I MTF consideration**—The TRACE(ON,,LE=2) setting provides the following trace table entries for PL/I MTF support:
  - Trace entry 100 occurs when a task is created.
  - Trace entry 101 occurs when a task that contains the tasking CALL statements is terminated.
  - Trace entry 102 occurs when a task that does not contain the tasking CALL statements is terminated.
- When running PL/I with POSIX(ON) in effect, no PL/I-specific trace information is provided.
- When you specify LE=20:
  - AMODE 64 applications have no transitions.
  - Transitions across OS_UPSTACK linkage are not recorded.
- When TRACE(OFF) is specified, Language Environment activates tracing when a pthread_create() is done and a debugger is being used.
- COBOL does not provide any Trace Table Entries.

**For more information**
- For more information about the dump contents, see “TERMTHDACT” on page 83.
TRAP

TRAP specifies how Language Environment programs handle abends and program interrupts (see Table 7). CEESGL is unaffected by this option.

TRAP(ON) must be in effect for the ABTERMENC runtime option to have effect. This option is similar to options that were offered by earlier versions of COBOL, C, and PL/I runtime libraries:

- STAE | NOSTAE runtime option of earlier COBOL, C, and PL/I
- SPIE | NOSPIE option offered by earlier C and PL/I

Table 7. TRAP runtime option settings

<table>
<thead>
<tr>
<th>If ...</th>
<th>Then ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>One option is specified in input</td>
<td>TRAP is set according to that option, TRAP(OFF) for NOSTAE or NOSPIE,</td>
</tr>
<tr>
<td></td>
<td>TRAP(ON) for STAE or SPIE.</td>
</tr>
<tr>
<td>Both options are specified in input</td>
<td>TRAP is set ON unless both options are negative. TRAP is set OFF if both</td>
</tr>
<tr>
<td></td>
<td>options are negative.</td>
</tr>
<tr>
<td>STAE is specified in one #pragma runopt statement, and NOSPIE in another</td>
<td>The option in the last #pragma runopt statement determines the setting</td>
</tr>
<tr>
<td></td>
<td>of TRAP.</td>
</tr>
<tr>
<td>Multiple instances of STAE</td>
<td>NOSTAE are specified</td>
</tr>
<tr>
<td>Multiple instances of SPIE</td>
<td>NOSPIE are specified</td>
</tr>
<tr>
<td>An options string has TRAP(ON) or</td>
<td>TRAP setting takes preference over all others.</td>
</tr>
<tr>
<td>TRAP(OFF) together with SPIE</td>
<td>NOSPIE, or STAE</td>
</tr>
</tbody>
</table>

The default value for non-CICS applications is TRAP(ON,SPIE).

The default value for CICS applications is TRAP(ON,SPIE).

The default value for AMODE 64 applications is TRAP(ON,SPIE).

Syntax

\[ \text{TRAP} (\begin{array}{c} \text{ON} \\ \text{OFF} \end{array}, \begin{array}{c} \text{SPIE} \\ \text{NOSPIE} \end{array}) \]

**ON** Fully enables the Language Environment condition handler.

**OFF** Prevents language condition handlers or handlers registered by CEEHDLR from being notified of abends or program checks; prevents application of POSIX signal handling semantics for abends and program checks.
SPIE
SPIE specifies that Language Environment issue an ESPIE macro to handle program interrupts. The SPIE suboption is ignored when specified with the OFF suboption.

NOSPIE
NOSPIE specifies that Language Environment will not issue the ESPIE macro. When you specify the ON, NOSPIE suboption, Language Environment will handle program interrupts and abends via an ESTAE. The NOSPIE suboption is ignored when specified with the OFF suboption.

Due to the restrictions and side-effects when running TRAP(OFF) stated in the Usage notes, IBM highly recommends running TRAP(ON,SPIE) in all environments.

CICS consideration
Since Language Environment never sets a SPIE or STAE, the SPIE|NOSPIE suboption is ignored on CICS.

z/OS UNIX considerations
The TRAP option applies to the entire enclave and all threads within.

Usage notes

- Use TRAP(OFF) only when you need to analyze a program exception before Language Environment handles it.
- When you specify TRAP(OFF) in a non-CICS environment, an ESPIE is not issued, but an ESTAE is issued. Language Environment does not handle conditions raised by program interrupts or abends initiated by SVC 13 as Language Environment conditions, and does not print messages for such conditions.
- Language Environment requires TRAP(ON) because it uses condition handling internally. As a result, running with TRAP(OFF) for exception diagnosis purposes can cause many side effects. If you run with TRAP(OFF), you can get side effects even if you do not encounter a software-raised condition, program check, or abend. If you do encounter a program check or an abend with TRAP(OFF) in effect, the following side effects can occur:
  - The ABTERMENC runtime option has no effect.
  - The ABPERC runtime option has no effect.
  - Resources acquired by Language Environment are not freed.
  - Files opened by HLLs are not closed by Language Environment, so records might be lost.
  - The abnormal termination exit is not driven for enclave termination.
  - The assembler user exit is not driven for enclave termination.
  - User condition handlers are not enabled.
  - The debugger is not notified of the error.
  - No storage report or runtime options report is generated.
  - No Language Environment messages or Language Environment dump output is generated.
  - In z/OS UNIX, POSIX signal handling semantics are not enabled for the abend.
  - The enclave terminates abnormally if such conditions are raised.
TRAP

- The COBOL ON SIZE ERROR clause may be disabled for arithmetic statements.

- TRAP(ON) must be in effect when you use the CEEBXITA assembler user exit for enclave initialization to specify a list of abend codes that Language Environment percolates.

- C++ consideration—TRAP(ON) must be in effect in order for the z/OS XL C++ try, throw, and catch condition handling mechanisms to work.

- When TRAP(ON) is in effect, and the abend code is in the CEEAU.E_A_AB_CODES list in CEEBXITA, Language Environment percolates the abend. Normal Language Environment condition handling is never invoked to handle these abends. This feature is useful when you do not want Language Environment condition handling to intervene for certain abends or when you want to prevent invocation of the abnormal termination exit for certain abends, such as when IMS issues a user abend code 777.

- When TRAP(ON,NOSPIE) is specified in a non-CICS environment, Language Environment will handle program interrupts and abends via an ESTAE. This feature is useful when you do not want Language Environment to issue an ESPIE macro.

  When TRAP(OFF), (TRAP(OFF,SPIE) or TRAP(OFF,NOSPIE) is specified and there is a program interrupt, the user exit for termination is not driven.

For more information

- See "ABTERMENC" on page 10 for more information about the ABTERMENC runtime option.

- See "CEESGL—Signal a condition" on page 417 for more information about the CEESGL callable service.

- For more information about the CEEHDLR callable service, see "CEEHDLR—Register user-written condition handler" on page 319.

- See z/OS Language Environment Programming Guide for more information about the CEEBXITA assembler user exit.

UPSI (COBOL only)

Derivation: User Programmable Status Indicator

UPSI sets the eight UPSI switches on or off for applications that use COBOL programs.

The default for non-CICS applications is UPSI(00000000).

The default for CICS applications is UPSI(00000000).

Syntax

```
UPS↓(nnnnnnnn)

nnnnnnnn
```

where:

- `n` represents one UPSI switch between 0 and 7, the leftmost `n` representing the first switch. Each `n` can either be 0 (off) or 1 (on).
For more information

- For more information about how COBOL programs access the UPSI switches, see the appropriate version of the COBOL programming guide in the COBOL library at Enterprise COBOL for z/OS library (http://www.ibm.com/support/docview.wss?uid=swg27036733).

**USRHDLR | NOUSRHDLR**

**Derivation:** _UseR condition _HanDLeR_

USRHDLR registers a user condition handler at stack frame 0, allowing you to register a user condition handler without having to include a call to CEEHDLR in your application and then recompile the application.

The default value for non-CICS applications is NOUSRHDLR.

The default value for CICS applications is NOUSRHDLR().

**Syntax**

```plaintext
NOUsrhdlr

USrhdlr( lmname, lmname2 )
```

**NOUSRHDLR**

Does not register a user condition handler without recompiling an application to include a call to CEEHDLR.

**USRHDLR**

Registers a user condition handler without recompiling an application to include a call to CEEHDLR.

**lmname**

The name of a load module (or an alias name of a load module) that contains the user condition handler that is to be registered at stack frame 0. This parameter is optional.

**lmname2**

The name of a load module (or an alias name of a load module) that contains the user condition handler that is to be registered to get control after the enablement phase and before any other user condition handler. This parameter is optional.

**CICS consideration**

When specifying USRHDLR under CICS, _lmname and _lmname2 must be defined in the CICS system definition data set (CSD) for your CICS region, rather than using program autoinstall. This includes the sample user-written condition handler CEEWUCHA.
**Usage notes**

- The user condition handler specified by the USRHDLR runtime option must be in a separate load module rather than be link-edited with the rest of the application.
- The user condition handler *lmname* is invoked for conditions that are still unhandled after being presented to condition handlers for the main program.
- The user condition handler *lmname2* is invoked for each condition after the condition completes the enablement phase but before any other registered user condition handlers are given control.
- You can use a user condition handler registered with the USRHDLR runtime option to return any of the result codes allowed for a user condition handler registered with the CEEHDLR callable service.
- A condition that is percolated or promoted by a user condition handler registered to handle conditions at stack frame 0 using the USRHDLR run time option is not presented to any other user condition handler.
- The loading of the user condition handlers *lmname* and *lmname2* occurs only when that user condition handler needs to be invoked the first time.
- If the load of either *lmname* or *lmname2* fails, an error message is issued.
- To turn off one of the suboptions previously specified by USRHDLR (*lmname* or *lmname2*), specify the option with either empty single quotes or empty double quotation marks. For example, to turn off the *lmname2* suboption after it had been previously specified, use either `USRHDLR(lmname, '')` or `USRHDLR(lmname, "")`.
- In SCEESAMP, IBM supplies a sample user-written condition handler, called CEEWUCHA. Under CICS, this handler will give you similar abend codes that existed in certain pre-Language Environment environments. The CEEWUCHA load module needs to be built using CEEWWCHA, which is also provided in SCEESAMP. This handler has support for both COBOL and PL/I; however, it is shipped with the PL/I-specific behavior commented out. If you want this PL/I behavior, modify the source before using CEEWWCHA.

**For more information**

For information about registering a user condition handler and its interfaces, see “CEEHDLR—Register user-written condition handler” on page 319.

---

**VCTRSAVE**

**Derivation:** VeCToR environment to be SAVEd

VCTRSAVE specifies if any language in the application uses the vector facility when user-written condition handlers are called.

The default values for non-CICS applications is VCTRSAVE(OFF).

VCTRSAVE is ignored under CICS.
Syntax

```
Vctrsave(ON|OFF)
```

**OFF**
No language in the application uses the vector facility when user-provided condition handlers are called.

**ON**
A language in the application uses the vector facility when user-provided condition handlers are called.

**CICS consideration**

VCTRSAVE is ignored under CICS.

**z/OS UNIX considerations**

The VCTRSAVE option applies to the entire enclave and all threads within the enclave.

**Performance consideration**

When a condition handler plans to use the vector facility (that is, run any vector instructions), the entire vector environment must be saved on every condition and restored on return to the application code. You can avoid this extra work by specifying VCTRSAVE(OFF) when you are not running an application under vector hardware.

**XPLINK**

**Derivation: eXtra Performance LINKage**

The XPLINK runtime option controls the initialization of the XPLINK environment. XPLINK resources such as the downward-growing stack and the C/C++ run time library are committed only when it is known that an XPLINK program will receive control. If the initial program in the enclave contains at least one function that was compiled using XPLINK conventions, then XPLINK resources will be committed during Language Environment initialization as if XPLINK(ON) had been specified. If the initial program is purely non-XPLINK, then no XPLINK resources will be committed. If it is known that an XPLINK function will be called at some point during the execution of the application, (for example, by calling a DLL function that has been compiled XPLINK), then XPLINK(ON) must be specified so the necessary XPLINK resources are available.

You cannot set this option at the system level, region level, or in the CEEBXITA assembler user exit interface. You can only specify XPLINK on application invocation (command-line interface or _CEE_RUNOPTS environment variable), or as an application default (CEEUOPT, C/C++ #pragma runopts, or PLIXOPT).

The default value for non-CICS applications is XPLINK(OFF).
XPLINK is ignored under CICS.

Syntax

```
XPLink ( OFF | ON )
```

**OFF**

Specifies that no programs containing XPLINK-compiled functions will be run. XPLINK resources will not be committed.

**ON**

Specifies that at some time during the execution of an application, an XPLINK-compiled function may be called. XPLINK resources will be committed so that when this occurs, the XPLINK function can properly execute.

**Usage notes**

The XPLINK(ON) runtime option is provided for application compatibility. It should be specified only for applications that:

- Have a non-XPLINK main(),
- Use XPLINK resources during their execution (for example, calls to an XPLINK function in a DLL), and have been tested to run in an XPLINK environment (that is, they do not use any resources or subsystems that are restricted in an XPLINK environment) Blindly running a non-XPLINK application in an XPLINK environment by specifying the XPLINK(ON) runtime option could result in performance degradation or application abends.

For these reasons, the XPLINK(ON) application should only be specified for individual applications that require it. That is why you cannot set XPLINK(ON) as a system-level or region-level default.

- If the XPLINK runtime option is not specified and the initial program contains at least one XPLINK-compiled part, then the XPLINK runtime option will be forced to (ON). No message will be issued to indicate this action.
- When an application is running in an XPLINK environment (that is, either the XPLINK(ON) runtime option was specified, or the initial program contained at least one XPLINK compiled part), the ALL31 runtime option will be forced to ON. No AMODE 24 routines are allowed in an enclave that uses XPLINK. No message will be issued to indicate this action. If a Language Environment runtime options report is generated using the RPTOPTS runtime option, the ALL31 option will be reported as "Override" under the LAST WHERE SET column.
- When an application is running in an XPLINK environment (that is, either the XPLINK(ON) runtime option was specified, or the initial program contained at least one XPLINK compiled part), the STACK runtime option will be forced to STACK(,,ANY). Only the third suboption is changed by this action to indicate that STACK storage can be allocated anywhere in storage. No message will be issued to indicate this action. If a Language Environment runtime options report is generated using the RPTOPTS runtime option, the STACK option will be reported as "Override" under the LAST WHERE SET column.
Performance considerations

- When XPLINK(ON) is in effect, resources required for the execution of an XPLINK-compiled function are committed. This includes, for example, allocation of a downward-growing stack segment. If no XPLINK functions are invoked, then these resources that are not available to an XPLINK function.
- If the application contains C or C++ and XPLINK(ON) is specified, then the XPLINK-compiled version of the C Runtime Library is loaded, which will run on the downward-growing stack. When non-XPLINK functions call C RTL functions in this environment, a swap from the upward-growing stack to the downward-growing stack will occur. This results in additional overhead that could cause performance degradation. Applications that make heavy use of the C RTL from non-XPLINK callers should be aware of this, and if necessary for performance reasons, either run in a pure non-XPLINK environment with XPLINK(OFF), or convert as much of the application to XPLINK as possible and run with XPLINK(ON).
- Applications that consist only of non-XPLINK functions (for example, COBOL or PL/I) should not specify the XPLINK(ON) runtime option, as just turning this on in these applications will result in a performance degradation.

XUFLOW

Derivation: eXponent Under FLOW

XUFLOW specifies if an exponent underflow causes a program interrupt. An exponent underflow occurs when a floating point number becomes too small to be represented. The underflow setting is determined at enclave initialization and is updated when new languages are introduced into the application (via fetch or dynamic call, for example). Otherwise, it does not vary while the application is running.

Language Environment preserves the language semantics for C/C++ and COBOL regardless of the XUFLOW setting. Language Environment preserves the language semantics for PL/I only when XUFLOW is set to AUTO or ON. Language Environment does not preserve the language semantics for PL/I when XUFLOW is set to OFF.

An exponent underflow caused by a C/C++ or COBOL program does not cause a condition to be raised.

The default value for non-CICS applications is XUFLOW(AUTO).

The default value for CICS applications is XUFLOW(AUTO).

Syntax

```
Xuflow(AUTO | ON | OFF)
```

**AUTO**

An exponent underflow causes or does not cause a program interrupt
dynamically, based on the HLLs that make up the application. Enablement is determined without user intervention. XUFLOW(AUTO) causes condition management to process underflows only in those applications where the semantics of the application languages require it. Normally, XUFLOW(AUTO) provides the best efficiency while meeting language semantics.

ON
An exponent underflow causes a program interrupt. XUFLOW(ON) causes condition management to process underflows regardless of the mix of languages; therefore, this setting might be less efficient in applications that consist of languages not requiring underflows to be processed by condition management.

OFF
An exponent underflow does not cause a program interrupt; the hardware takes care of the underflow. When you set XUFLOW to OFF, the hardware processes exponent underflows. This is more efficient than condition handling to process the underflow.

Usage notes
- PL/I consideration—When setting XUFLOW to OFF, be aware that the semantics of PL/I require the underflow to be signaled.
- z/OS UNIX consideration—The XUFLOW option applies to the entire enclave and all threads within.

Language runtime option mapping
Language Environment provides one set of runtime options for applications. These options are processed at the enclave level and allow you to control many aspects of the Language Environment environment.

Most options are applicable to all Language Environment-conforming languages. In addition, although Language Environment assists migration by mapping current HLL options to Language Environment’s options, the runtime options of a particular HLL product might change in the Language Environment-enabled version. However, Language Environment has attempted to maintain runtime options consistently across language products while minimizing required changes within each product.

Tables of pre-Language Environment, HLL-specific options and their Language Environment equivalents are provided in the z/OS V2R1.0 Language Environment Runtime Application Migration Guide. The mapping is performed automatically by Language Environment, except where noted.
Part 2. Language Environment callable services

The following sections contain detailed information about how to use the Language Environment callable services.
Chapter 3. Quick reference tables for Language Environment services

The following tables are a quick reference of the Language Environment callable services and math services.

Note: Language Environment callable services are not supported for AMODE 64 applications.

### Bit manipulation routines

</tr>
</tbody>
</table>
Chapter 4. Using Language Environment callable services

Restriction: Language Environment services are not supported for AMODE 64 applications.

This topic provides syntax and examples of Language Environment callable services, which you can invoke from applications generated with the following IBM compiler products:
• IBM z/OS XL C/C++
• C/C++ for MVS/ESA
• IBM SAA AD/Cycle C/370
• Enterprise COBOL for z/OS
• Enterprise PL/I for z/OS
• IBM COBOL for OS/390 & VM
• IBM COBOL for MVS & VM
• IBM PL/I for MVS & VM

You can invoke Language Environment callable services from assembler programs using the CEEENTRY and associated macros. While you cannot call these services directly from Fortran programs, you can use the Fortran routines AFHCEEN and AFHCEEF to invoke most of these services. (See Fortran Run-time Migration Guide.) You can use the other languages to perform these services on behalf of a Fortran program.

Note:
1. Customers using this information may not have pre-Language Environment runtime libraries.
2. You can use DYNAMIC calls from VS COBOL II programs to Language Environment Date/Time callable services. You can not use DYNAMIC calls from VS COBOL II programs to other Language Environment callable services. You can not use STATIC calls from VS COBOL II programs to any Language Environment callable services.
3. A Language Environment callable service used by application programmers can also be called an application writer interface (AWI).

Language Environment callable services provide functions that pre-Language Environment runtime libraries might not provide. You can use these services alone or with Language Environment runtime options, which customize your runtime environment. For guidelines about writing your own callable services, see Language Environment Programming Guide

Locating callable service information

The following sections help you use the Language Environment callable services. For a summary of Language Environment callable services, see Chapter 1, "Summary of Language Environment runtime options," on page 3.
• "General usage notes for callable services" on page 116
• "Invoking callable services" on page 116
• "Data type definitions" on page 121
• Chapter 5, "Callable services," on page 125
General usage notes for callable services

- You can invoke callable services from any Language Environment-conforming HLL except where otherwise noted.
- You might receive feedback codes from services other than the one you are invoking. This is because the callable services invoke other callable services that might return a feedback code.
- Callable services that are intended to be available on any platform that Language Environment supports are prefixed with CEE. Callable services defined only for S/370 are prefixed with CEE3.
- Routines that invoke callable services do not need to be in 31-bit addressing mode. 31-bit addressing mode switching is performed implicitly without any action required by the calling routine, if you specify the ALL31(OFF) runtime option (see "ALL31" on page 12).

However, if AMODE switching occurs and your program makes many calls to Language Environment callable services, the switching time can slow down your application. Run with AMODE(31), if possible, to avoid unnecessary mode switching.

- Under Language Environment, all parms are passed by reference, indirectly. The code in Figure 2 and Figure 3 might cause unpredictable results:

CALL CEEDATE USING X,Y,Z. **Invalid**

Figure 2. An invalid COBOL CALL that omits the fc parameter

DCL CEEDATE ENTRY OPTIONS(ASM);
CALL CEEDATE(x,y,z); /* invalid */

Figure 3. An invalid PL/I CALL that omits the fc parameter

Figure 4 and Figure 5 illustrate valid calls. The COBOL examples are valid only for COBOL for MVS & VM Release 2 or later.

CALL CEEDATE USING X,Y,Z,OMITTED.
CALL CEEDATE USING X,Y,Z,FC.

Figure 4. Valid COBOL CALLs that use the optional fc parameter

DCL CEEDATE ENTRY(*,*,*,* OPTIONAL) OPTIONS(ASM);
CALL CEEDATE(x,y,z,*); /* valid */
CALL CEEDATE(x,y,z,fc); /* valid */

Figure 5. Valid PL/I CALLs that use the optional fc parameter

Invoking callable services

You can invoke Language Environment callable services from assembler routines, HLL-generated object code, HLL library routines, other Language Environment library routines, and user-written HLL calls. When you want to access Language Environment library routines, you can use the same type of user-written HLL calls and functions you currently use for your HLL applications.
This topic provides syntax and examples to help you request callable services from C/C++, COBOL, and PL/I.

**Header, copy, or include files**

Many of the programming examples in this section imbed header, copy, or include files. (Whether you call the files header files, copy files, or include files depends on the language you are using.) These files can save you time by providing declarations for symbolic feedback codes and Language Environment callable services that you would otherwise need to code in your program. They can also help you reduce errors by verifying correct usage of Language Environment callable services at compile time.

Table 18 summarizes the names and descriptions of the files imbedded in the callable service examples in this section.

**Table 18. Files used in C/C++, COBOL, and PL/I examples**

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ceeedct.h</td>
<td>C declarations for Language Environment symbolic feedback codes</td>
</tr>
<tr>
<td>leawi.h</td>
<td>Declarations of Language Environment callable services and OMIT_FC, which is used to explicitly omit the fc parm, for routines written in C/C++</td>
</tr>
<tr>
<td>CEEIGZCI</td>
<td>Declarations for condition information block</td>
</tr>
<tr>
<td>CEEIGZCT</td>
<td>Declarations for Language Environment symbolic feedback codes</td>
</tr>
<tr>

<tr>
<td>CEEIBMD2</td>
<td>DTCONV structure needed for C99 support of CEEQDTC calls</td>
</tr>
<tr>
<td>CEEFORCT</td>
<td>Fortran declarations for Language Environment symbolic feedback codes</td>
</tr>
</tbody>
</table>

**Note:**

1. A symbolic feedback code is a symbolic representation of a condition token.
2. PL/I routines that imbed CEEIBMAW require the MACRO compiler option.
3. COBOL does not require declarations of external programs; therefore, you do not need declarations of Language Environment callable services for programs written in COBOL.
4. CEEIBMxx parts support PL/I applications.
5. CEEIGZxx parts support COBOL applications.

On z/OS, these files are contained in the Language Environment SCEESAMP partitioned data set, except for `leawi.h`, which is contained in the SCEEH.H partitioned data set. You can imbed these files using the statement appropriate for the language your routine is written in, as shown in Table 19. Examples of these statements are shown in the following topics on syntax.

**Table 19. Imbedding files in your routines**

<table>
<thead>
<tr>
<th>To imbed a file in a...</th>

</tr>
</thead>
<tbody>
<tr>
<td>C/C++ routine</td>
<td><code>#include</code></td>
</tr>
<tr>
<td>COBOL program</td>
<td><code>COPY</code></td>
</tr>
<tr>
<td>PL/I routine</td>
<td><code>%include</code></td>
</tr>
</tbody>
</table>

### Sample programs

Sample C/C++, COBOL, and PL/I programs are provided for most of the callable services. Sample Fortran programs are not provided because you cannot invoke Language Environment callable services from Fortran programs. However, you can use other languages to perform these services on behalf of a Fortran program. These sample programs are also provided online with the Language Environment product for your convenience. On MVS, the sample routines are located in the SCEESAMP partitioned data set.

### C/C++ syntax

In C or C++, use the following syntax to invoke a Language Environment callable service with a feedback code in effect:

```c
ceexxx((parm1, parm2, ..., parmn, fc);
```

**Note:** "..." is "and so on," not the C ellipsis operator.

Use the following syntax to invoke callable services with an omitted feedback code parameter:

```c
CEExxx((parm1, parm2, ..., parmn, NULL);
```
See “Parameter list for invoking callable services” on page 121 for a description of this syntax.

Language Environment callable services always have a return type of `void` and should be prototyped as such.

Input strings for callable services are **not** NULL terminated in C/C++.

You can use the SCEEH.H file `leawi.h` to declare Language Environment callable services, in conjunction with a C/C++ call to a Language Environment callable service, as shown in Figure 6.

```c
#include <leawi.h>
int main(void)
{
  CEExxxx(parm1, parm2, ... parmn, fc);
}
```

*Figure 6. Sample callable services invocation syntax for C/C++*

To help in checking the success of your applications, Language Environment provides FBCHECK in the `ceeedct.h` file. FBCHECK compares a feedback code against a condition token you supply to determine whether you receive the feedback code you should.

**COBOL syntax**

In COBOL, use the following syntax to invoke Language Environment callable services:

```
CALL "CEExxxx" USING parm1, parm2, ... parmn, fc
```

You can call Language Environment services either statically or dynamically from COBOL applications.

The Language Environment callable services are architected as low maintenance stubs that branch to the actual runtime routine that performs the service. Static CALL to these stubs is the preferred choice for best performance. This avoids the overhead of a COBOL dynamic call without the usual maintainability disadvantage of a more robust statically link-edited routine.

See “Parameter list for invoking callable services” on page 121 for a description of this syntax.

You can use the SCEESAMP file `CEEGZCT` to declare symbolic Language Environment feedback codes, in conjunction with a COBOL call to a Language Environment callable service to return a feedback code, as shown in Figure 7 on page 120.
COBOL for MVS & VM Release 2 or later also allows you to omit arguments. In place of the argument, use the OMITTED parameter, as shown below. See Figure 2 on page 116 and Figure 4 on page 116 for an example of omitting parameters in COBOL.

Syntax

```
CALL "CEExxxx" USING parm1, parm2, ..., parmn, OMITTED
```

PL/I syntax

In PL/I, use the following syntax to invoke a Language Environment callable service with a feedback code in effect:

Syntax

```
CALL CEExxxx (parm1, parm2, ..., parmn, *);
```

PL/I also allows you to omit arguments. In place of the argument, code an asterisk (*), as shown below:

Syntax

```
CALL CEExxxx (*, *, ..., *);
```

Note that you cannot invoke callable services as function references.

See “Parameter list for invoking callable services” on page 121 for a description of this syntax.

The value of register 15 upon return from any Language Environment callable service is undefined. Use of OPTIONS(RETCODE) is not recommended, because a subsequent use of the PLIRETV built-in function returns an undefined value.

If you code your own declarations for the Language Environment callable services, be sure to specify all required arguments in the CALL statement. Figure 3 on page 116 illustrates a call in which the feedback code to CEEDATE was incorrectly omitted.
You can use the SCEESAMP file CEEIBMAW to declare Language Environment callable services with a PL/I call to a Language Environment callable service, as Figure 8 shows.

```c
%INCLUDE CEEIBMAW;
CALL CEEExxxx(parm1, parm2, ... parmn, fc);
```

**Figure 8. Sample callable services invocation syntax for PL/I**

### Parameter list for invoking callable services

This section describes the syntax and parameters you need to invoke Language Environment callable services.

#### CEEExxxx

The name of the callable service. By including a reference to a header file in your code, you can avoid declaring each callable service as an external entry. See “Header, copy, or include files” on page 117 for these file names.

#### parm1 parm2 ... parmn

Optional or required parameters passed to or returned from the called service. Some callable service parameters are optional in C/C++ and PL/I only. If you do not want to pass the parm or you do not want the return value, you can omit the parm, using the appropriate syntax to indicate that the parm is omitted.

#### fc

A feedback code that indicates the result of the service. fc can be omitted when you use C/C++, PL/I, and COBOL (COBOL for MVS & VM Release 2 or later).

If you specify fc as an argument, feedback information in the form of a condition token is returned to the calling routine. The condition token indicates whether the service completed successfully or whether a condition was encountered while the service was running. In Language Environment you can decode the condition token so that it can be acted on.

If you omit fc as an argument, using the appropriate syntax to indicate fc is omitted, the condition is signaled if the service was not successful.

Because callable services call other services, these other services might generate feedback codes.

### Data type definitions

Parameters in Language Environment are defined as specific data types, such as:

- Fullword binary integer
- Short floating-point hexadecimal
- Long floating-point hexadecimal
- Fixed-length character string with a predefined length
- Entry variable
- Character string with a halfword prefix indicating its current length

Table 20 on page 122, Table 21 on page 123, and Table 22 on page 124 contain data type definitions and their descriptions for C/C++, COBOL, and PL/I, respectively.

### C/C++ data type definitions

Table 20 on page 122 includes data type definitions and their descriptions for C/C++.

Chapter 5. Callable services

This section lists the Language Environment callable services and shows examples of how to use them in C/C++, COBOL, and PL/I.

CEE3ABD—Terminate enclave with an abend

CEE3ABD requests that Language Environment terminate the enclave with an abend. The issuing of the abend can be either with or without clean-up. There is no return from this service, nor is there any condition associated with it.

Syntax

```
CEE3ABD(—abcode—,—clean-up—)
```

*abcode* (input)

A fullword integer, no greater than 4095, specifying the abend code that is issued. Under CICS, this fullword integer is converted to EBCDIC.

*clean-up* (input)

Indicates if the abend should result in clean-up of the enclave's resources. The acceptable values for *clean-up* are as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Issue the abend without clean-up</td>
</tr>
<tr>
<td>1</td>
<td>Issue the abend with normal enclave termination processing</td>
</tr>
<tr>
<td>2</td>
<td>Issue the abend with enclave termination processing honoring the TERMTHDACT runtime option for taking a system dump of the user address space but suppressing the CEEDUMP</td>
</tr>
<tr>
<td>3</td>
<td>Issue the abend with enclave termination processing suppressing both the CEEDUMP and system dump if requested by the TERMTHDACT runtime option</td>
</tr>
<tr>
<td>4</td>
<td>Issue the abend with enclave termination processing honoring the TERMTHDACT runtime option for taking a CEEDUMP but suppressing the system dump</td>
</tr>
<tr>
<td>5</td>
<td>Issue the abend with enclave termination processing forcing a system dump of the user address space and suppressing the CEEDUMP</td>
</tr>
</tbody>
</table>

If an illegal value for *clean-up* is passed, the abend is issued without clean-up.

If *clean-up* is 0, no Language Environment dump is generated. A system dump, however, is requested when issuing the abend. Under CICS, a transaction dump is taken. To get a dump under CMS, specify FILEDEF SYSABEND PRINTER or FILEDEF SYSUDUMP PRINTER.

If *clean-up* is 0, Language Environment condition handling is disabled for the current enclave and termination activities are not performed. Event handlers are not driven; Debug Tool is not invoked; user exits are not invoked; and user-written condition handlers are not invoked.
When clean-up is 1, the abend is processed in the same manner as if it were a non-Language Environment abend. Its processing is affected by the ABPERC and TRAP options, the filedef abends percolated in the assembler user exit, and other elements of the environment related to abend processing. In particular, the condition handler can intercept the abend and give the application a chance to handle the abend. If the condition remains unhandled, normal termination activities are performed: information such as a Language Environment dump is produced, depending on the setting of the TERMTHDACT option; event handlers are driven; Debug Tool is invoked; and user exits are invoked. Assembler user exit settings control if the application actually terminates with an abend.

When clean-up is 2, it follows the abend processing as when clean-up is 1 except the CEEDUMP is suppressed.

When clean-up is 3, it follows the abend processing as when clean-up is 1, however CEEDUMP and system dumps are both suppressed.

When clean-up is 4, it follows the abend processing as when clean-up is 1, however only the system dumps are suppressed.

When clean-up is 5, it follows the abend processing as when clean-up is 1, however forcing a system dump to be taken and suppressing the CEEDUMP.

z/OS UNIX considerations

- In a multithreaded environment, CEE3ABD applies to the enclave.
- When ALL31(ON) is in effect, Language Environment allocates thread-specific control blocks from the anywhere heap.

Usage notes

1. Recommendation: Language Environment abend codes are usually in the range of 4000 (X’F40’) to 4095 (X’FFF’). You should use the range of 0 to 3999 to avoid confusion with Language Environment abend codes. The value specified for the abend code is passed directly to the ABEND macro without further verification.

2. When TRAP(OFF) is specified, CEE3ABD behaves in a similar manner to clean-up 0.

3. In a non-CICS environment, a system dump of the user address space is taken only if a SYSMDUMP, SYSUDUMP, or SYSABEND DD card is present.

4. Users can look at CEE3AB2 to include user reason codes separately from abend codes.

For more information

- For more information about the ABPERC runtime option, see “ABPERC” on page 9.
- For more information about the TRAP runtime option, see “TRAP” on page 98.
- For more information about the TERMTHDACT runtime option, see “TERMTHDACT” on page 83.
- For more information about the CEE3AB2 callable service, see “CEE3AB2—Terminate enclave with an abend and reason code” on page 128.

**CEE3AB2—Terminate enclave with an abend and reason code**

CEE3AB2 requests that Language Environment terminate the enclave with an abend and user-defined reason code. The issuing of the abend can be either with or without clean-up, with the type of dumps the user requires. There is no return from this service, nor is there any condition that is associated with it.
**Syntax**

```
CEE3AB2(abcode, reasoncode, clean-up)
```

**abcode (input)**

A fullword integer, no greater than 4095, specifying the abend code that is issued. Under CICS, this fullword integer is converted to EBCDIC.

**reasoncode (input)**

A fullword integer, specifying the reason code that is issued by the user. If no reason code is specified, the reason code is 0.

**clean-up (input)**

Indicates if the abend should result in clean-up of the enclave’s resources. The acceptable values for clean-up are as follows:

0  Issue the abend without clean-up
1  Issue the abend with normal enclave termination processing
2  Issue the abend with enclave termination processing honoring the TERMTHDACT runtime option for taking a system dump of the user address space but suppressing the CEEDUMP
3  Issue the abend with enclave termination processing suppressing both the CEEDUMP and system dump if requested by the TERMTHDACT runtime option
4  Issue the abend with enclave termination processing honoring the TERMTHDACT runtime option for taking a CEEDUMP but suppressing the system dump
5  Issue the abend with enclave termination processing forcing a system dump of the user address space and suppressing the CEEDUMP

If an illegal value for clean-up is passed, the abend is issued without clean-up.

If clean-up is 0, no Language Environment dump is generated. A system dump, however, is requested when issuing the abend. Under CICS, a transaction dump is taken. To get a dump under CMS, specify FILEDEF SYSABEND PRINTER or FILEDEF SYSUDUMP PRINTER.

If clean-up is 0, Language Environment condition handling is disabled for the current enclave and termination activities are not performed. Event handlers are not driven; Debug Tool is not invoked; user exits are not invoked; and user-written condition handlers are not invoked.

When clean-up is 1, the abend is processed in the same manner as if it were a non-Language Environment abend. Its processing is affected by the ABPERC and TRAP options, the filedef abends percolated in the assembler user exit, and other elements of the environment related to abend processing. In particular, the condition handler can intercept the abend and give the application a chance to handle the abend. If the condition remains unhandled, normal termination activities are performed: information such as a Language Environment dump is produced, depending on the setting of the TERMTHDACT option; event handlers are driven; Debug Tool is invoked; and user exits are invoked. Assembler user exit settings control if the application actually terminates with an abend.
When clean-up is 2, it follows the abend processing as when clean-up is 1 except the CEEDUMP is suppressed.

When clean-up is 3, it follows the abend processing as when clean-up is 1, however CEEDUMP and system dumps are both suppressed.

When clean-up is 4, it follows the abend processing as when clean-up is 1, however only the system dumps are suppressed.

When clean-up is 5, it follows the abend processing as when clean-up is 1, however forcing a system dump to be taken and suppressing the CEEDUMP.

**z/OS UNIX consideration**

- In a multithreaded environment, CEE3AB2 applies to the enclave.

**Usage notes**

1. Language Environment abend codes are usually in the range of 4000 (X'F000') to 4095 (X'FFF'). Use the range of 0 to 3999 to avoid confusion with Language Environment abend codes. The value that is specified for the abend code is passed directly to the ABEND macro without further verification.

2. When TRAP(OFF) is specified, CEE3AB2 behaves in a similar manner to clean-up 0.

3. In a non-CICS environment, a system dump of the user address space is taken only if a SYSMDUMP, SYSUDUMP, or SYSABEND DD card is present.

- For more information about the TRAP runtime option, see "TRAP" on page 98.
- For more information about the TERMTHDACT runtime option, see "TERMTHDACT" on page 83.
- For more information about the ABEND macro, see z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO.
- For more information about the CEE3ABD callable service, see "CEE3ABD—Terminate enclave with an abend" on page 125.

**Examples**

1. Following is an example of CEE3AB2 called by C/C++.

   ```c
   /*Module/File Name: EDC3AB2 */
   /*********************************************************************/
   /*
   THIS EXAMPLE CALLS CEE3AB2 TO TERMINATE THE ENCLAVE WITH AN ABEND */
   /* AFTER CLEAN-UP TAKES PLACE. USER COULD ALSO SPECIFY THEIR OWN */
   /* REASON CODE. */
   /*
   /*********************************************************************/
   #include <leawi.h>

   int main(void) {
      _INT4 code,reason,cleanup;
      code = 1234; /* Abend code to issue */
      reason = 9; /* User defined reason code*/
      cleanup = 3; /* Specify 3, for an ABEND with cleanup & with no dumps*/
      CEE3AB2(&code,&reason,&cleanup);
   }
   ```

2. Following is an example of CEE3AB2 called by COBOL.
**Function:** CEE3AB2 - Terminate enclave with an abend and user defined reason code

**In this example, CEE3AB2 is called to terminate the enclave with an abend and a user defined reason code along with Language Environment cleanup.

**1234** is the abend code to be issued,
**9** is the reason code for the abend,
**A timing of four requests an abend with clean-up.**

---

**1234** is the abend code to be issued,
**9** is the reason code for the abend,
**A timing of four requests an abend with clean-up.**

---

**1234** is the abend code to be issued,
**9** is the reason code for the abend,
**A timing of four requests an abend with clean-up.**
/* reason code 9 with cleanup */
/**************************************************************************/
CALL CEE3AB2 ( ABDCODE, RESCODE, TIMING );
END PLI3AB2;

**CEE3CIB—Return pointer to condition information block**

CEE3CIB returns a pointer to a condition information block (CIB) associated with a
given condition token. Use this service only during condition handling.

For PL/I and COBOL applications, Language Environment provides called header,
COPY, or include files (in SCEESAMP) that map the CIB. For C/C++ applications,
the macros are in the header file leawi.h (in SCEEH.H).

The CIB contains detailed information about the condition and provides input to
your application’s condition handlers, which can then respond more effectively to a
given condition.

**Syntax**

```
CEE3CIB( cond_token, cib_ptr, fc )
```

*cond_token*  
The condition token passed to a user-written condition handler. If you do not
specify this parameter, Language Environment returns the address of the most
recently-raised condition.

*cib_ptr*  
The address of the CIB associated with the condition token.

*fc*  
A 12-byte feedback code, optional in some languages, that indicates the result
of this service. If you choose to omit this parameter, refer to "Invoking callable
services" on page 116 for the appropriate syntax to indicate that the feedback
code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE35S</td>
<td>1</td>
<td>3260</td>
<td>No condition was active when a call to a condition management routine was made.</td>
</tr>
<tr>
<td>CEE35U</td>
<td>1</td>
<td>3262</td>
<td>An invalid condition token was passed. The condition token did not represent an active condition.</td>
</tr>
</tbody>
</table>

**Usage notes**

- Because the CIB is used only for synchronous signals, you should not use
  CEE3CIB in signal catchers that are driven for asynchronous signals.
- After the condition handling functions return control to your application, *cib_ptr*
is no longer valid.
z/OS UNIX consideration—In multithread applications, CEE3CIB returns the CIB associated with the current token on only the current thread.

For more information

- For more information about the CEE3CIB callable service, see [z/OS Language Environment Programming Guide](#).

Examples

1. Following is example of CEE3CIB called by C/C++.

```c
/*Module/File Name: EDC3CIB */
#include <stdio.h>
#include <leawi.h>
#include <stdlib.h>
#include <string.h>
#include <ceeedcct.h>

#ifdef __cplusplus
extern "C"
{
#endif
void handler(_FEEDBACK *,_INT4 *,_INT4 *,_FEEDBACK *);
#ifdef __cplusplus
}
#endif

int main(void) {
  _FEEDBACK fc;
  _ENTRY routine;
  _INT4 token;
  int x,y,z;

  /* set the routine structure to point to the handler */
  /* and use CEEHDLR to register the user handler */

  token = 99;
  routine.address = (_POINTER)&handler;;
  routine.nesting = NULL;

  CEEHDLR(&routine,&token,&fc);
  /* verify that CEEHDLR was successful */
  if ( _FBCHECK ( fc, CEE000 ) != 0 ) {
    printf("CEEHDLR failed with message number %d\n", fc.tok_msgno);
    exit(2999);
  }
  x = 5;
  y = 0;
  z = x / y;

  /******************************************************************************/
  /* handler is a user condition handler */
  /******************************************************************************/
  void handler(_FEEDBACK *fc, _INT4 *token, _INT4 *result,
               _FEEDBACK *newfc) {
    _CEECIB *cib_ptr;
    _FEEDBACK cibfc;
    CEE3CIB(fc, &cib_ptr, &cibfc);
    /* verify that CEE3CIB was successful */
    if ( _FBCHECK ( cibfc, CEE000 ) != 0 ) {
```
printf("CEE3CIB failed with message number \%d\n", cibfc.tok_msgno);
exit(2999);
}

printf("%s \n",(*cib_ptr).cib_eye);
printf("%d \n",cib_ptr->cib_cond.tok_msgno);
printf("%s \n",cib_ptr->cib_cond.tok_facid);
*result = 10;
}

CEE3CTY—Set default country

CEE3CTY sets the default country. A calling routine can change or query the
current national country setting. The country setting affects the date format, the
time format, the currency symbol, the decimal separator, and the thousands
separator.

The current national country setting also affects the format of the date and time in
the reports generated by the RPTOPTS and RPTSTG runtime options.

CEE3CTY also affects the default symbols for the NLS and date and time callable
services.
CEE3CTY

CEE3CTY affects only the Language Environment NLS and date and time services, not the Language Environment locale callable services or C locale-sensitive functions.

The current default country setting, as well as previous default settings that have not been discarded, are stored on the stack on a LIFO (last in, first out) basis. The current default country setting is always on the top of the stack.

There are two methods of changing the default country setting with CEE3CTY:

- Specify the new default country setting and place it on top of the stack using a function value of 1 (SET). This discards the previous default setting.
- Specify the new default country setting and place it on top of the stack using a function value of 3 (PUSH). This pushes the previous default setting down on the stack so that you can later retrieve it by discarding the current setting.

To illustrate the second method, suppose you live in the United States and the code for the United States is specified as the default at installation. If you want to use the French defaults for a certain application, you can use CEE3CTY to PUSH France as the default country setting; then when you want the defaults for the United States, you can POP France from the top of the stack, making the United States the default setting.

Syntax

```plaintext
CEE3CTY(-function-, -country_code-, -fc-)
```

**function** (input)

A fullword binary integer specifying the service to be performed. The possible values for function are:

1—SET

Establishes the country_code parameter as the current country. The top of the stack is, in effect, replaced with country_code.

2—QUERY

Returns the current country code on the top of the stack to the calling routine. The current code is returned in the country_code parameter.

3—PUSH

Pushes the country_code parameter onto the top of the country code stack, making it the current country code. Previous country codes on the stack are retained on a LIFO basis, which makes it possible to return to a prior country code at a later time.

4—POP

Pops the current country code. The last country code that was affected by a PUSH now becomes the current country_code. On return to the calling routine, the country_code parameter contains the discarded country code. If the stack contains only one country code, the code cannot be popped because the stack would be empty after the call. Therefore, no action is taken and a feedback code indicating such is returned to the calling routine.
**country_code** *(input/output)*

A 2-character fixed-length string. `country_code` is not case-sensitive. Table 32 on page 483 contains a list of valid country codes. It is used in the following ways for the different functions:

<table>
<thead>
<tr>
<th>If function is:</th>
<th>then country_code:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 or 3</td>
<td>Contains the desired 2-character country code. In this case, it is an input parameter. Table 32 on page 483 contains a list of valid country codes.</td>
</tr>
<tr>
<td>2</td>
<td>Returns the current 2-character country code on top of the stack. In this case, it is an output parameter.</td>
</tr>
<tr>
<td>4</td>
<td>Returns the discarded 2-character country code. In this case, it is an output parameter.</td>
</tr>
</tbody>
</table>

**fc** *(output)*

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3BV</td>
<td>2</td>
<td>3455</td>
<td>Only one country code was on the stack when a POP request was made to CEE3CTY. The current country code was returned in the</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CEE3C0</td>
<td>3</td>
<td>3456</td>
<td>The country code <code>country-code</code> for the PUSH or SET function for CEE3CTY was invalid. No operation was performed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CEE3C1</td>
<td>3</td>
<td>3457</td>
<td>The function <code>function</code> specified for CEE3CTY was not recognized. No operation was performed.</td>
</tr>
</tbody>
</table>

**Usage notes**

- The default setting for `country_code` is already on the stack when you start a program. You do not have to PUSH it there.
- The bytes X'0E' and X'0F' representing shift-out and shift-in codes are not affected by any `country_code` setting.
- C/C++ consideration—Language Environment provides locales used in C and C++ to establish default formats for the locale-sensitive functions and locale callable services, such as date and time formatting, sorting, and currency symbols. To change the locale, you can use the `setlocale()` library function or the CEESETL callable service.

The settings of CEESETL or `setlocale()` do not affect the setting of the CEE3CTY callable service. CEE3CTY affects only Language Environment NLS and date and time services. `setlocale()` and CEESETL affect only C/C++ locale-sensitive functions and Language Environment locale callable services.

To ensure that all settings are correct for your country, use CEE3CTY and either CEESETL or `setlocale()`.

- z/OS UNIX consideration—CEE3CTY applies to the enclave. Every thread in the enclave has the same country setting.
For more information

- For more information about the RPTOPTS and RPTSTG runtime options, see "RPTOPTS" on page 71 and "RPTSTG" on page 73.
- For a list of the default settings for a specified country, see Table 32 on page 483.
- For more information about the COUNTRY runtime option, see “COUNTRY” on page 24.
- For more information about setlocale(), see z/OS XL C/C++ Programming Guide.

Examples

1. Following is an example of CEE3CTY called by C/C++.

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {

    _FEEDBACK fc;
    _INT4 function;
    _CHAR2 country;

    /* query the current country setting */
    function = 2; /* function 2 is query */
    CEE3CTY(&function,country,&fc);
    if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
        printf("CEE3CTY failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }

    /* if the current country is not Canada then set */
    /* it to Canada */
    if (memcmp(country,"CA",2) != 0) {
        memcpy(country,"CA",2);
        function = 1; /* function 1 is set */
        CEE3CTY(&function,country,&fc);
        if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
            printf("CEE3CTY failed with message number %d\n", fc.tok_msgno);
            exit(2999);
        }
    }
}

---

**CEE3DLY—Suspend processing of the active enclave in seconds**

CEE3DLY provides a service for Language Environment-conforming applications that suspends the processing of the active enclave for a specified number of seconds. The maximum is 1 hour.
Syntax

\[
\texttt{CEE3DLY\{(\textit{input\_seconds},\textit{fc})\}}
\]

\textit{input\_seconds}

A fullword binary value in the range of 0 to 3600 that specifies the total number of seconds during which the enclave should be suspended.

\textit{fc (output)}

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE3QQ</td>
<td>1</td>
<td>CEE3930W</td>
<td>The input value \textit{input_value} in a call to the callable service \textit{callable_service_name} was not within the valid range.</td>
</tr>
<tr>
<td>CEE3QS</td>
<td>1</td>
<td>CEE3932W</td>
<td>The system service \textit{system_service} failed with return code \textit{return_code} and reason code \textit{reason_code}.</td>
</tr>
</tbody>
</table>

\textbf{Usage notes}

- **CICS consideration**—CEE3DLY is available under CICS.
- **z/OS UNIX consideration**—CEE3DLY is handled by the z/OS UNIX System Services when POSIX is set to ON.
- This service is not intended for timing requests. Delays up to the nearest second might occur in some circumstances.
- In a multi-threaded application, only the calling thread is suspended.

\textbf{Examples}

1. An example of CEE3DLY called by C/C++:

```c
#include <time.h>
#include <stdio.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void)
{
    _INT4 seconds;
    _FEEDBACK fc;
    time_t ltime;

    /* Get the time in seconds */
    time(&ltime);
    printf("CEE3DLY Start time : %s", ctime(&ltime));

    seconds = 10;
```

Chapter 5. Callable services 141
CEE3DLY

CEE3DLY(&seconds,&fc);

if (_FBCHECK ( fc , CEE000 ) != 0 )
    printf("CEE3DLY failed with message number %d\n",fc.tok_msgno);
    exit(999);
}

time(&ltime);
printf("CEE3DLY Finish time : %s", ctime(&ltime));

CEE3DMP—Generate dump

CEE3DMP generates a dump of Language Environment and the member language libraries. Sections of the dump are selectively included, depending on options specified with the options parameter. When an error occurs that would cause a CEEDUMP to be taken, and this is a POSIX application, Language Environment writes this dump to the current directory. Output from CEE3DMP is written to one of the following (in top-down order):

- The directory found in _CEE_DMPTARG, if found.
- The current working directory, if this is not the root (/), and if the directory is writable, and if the dump pathname (made up of the cwd pathname plus the dump file name) does not exceed 1024 characters.
- The directory found in environment variable TMPDIR (if the temporary directory is not /TMP.
- /TMP

(See the Fname suboption of CEE3DMP in “Fname” on page 149 for more information about the dump output filename.)

If longer than 60 characters, the dump title is truncated to 60 characters in order to match the record size of the dump file. Only nested enclaves within a single process are supported.

CEE3DMP establishes a condition handler that captures all conditions that occur during dump processing. It terminates the section of the dump in progress when a condition occurs and inserts the following line into the dump (nnnnnnnnnn is the instruction address at the time of the exception). After this line is inserted in the report, dump processing continues for other member languages until CEE3DMP is complete.

Exception occurred during dump processing at nnnnnnnnn
If an abend occurs, or if any other condition occurs or is raised, the condition manager attempts to handle it. If the condition remains unhandled, and it is of sufficient severity, the condition manager might, based on if the TERMTHDACT TRACE or DUMP suboption is specified, invoke dump services and then terminate the program. You do not have to call CEE3DMP to use the dump services. Any routine can use them. To support this case, dump services are invoked as follows:

- The title is Condition processing resulted in the unhandled condition to indicate why the dump was produced.
- The dump options are 'TRACE COND THR(ALL) BLOCKS STOR NOENTRY' for dump output and 'TRACE COND THR(ALL) NOBLOCK NOSTOR NOENTRY' for trace output.

Reprinting of section title and control block name at the top of each page is suppressed. Only the main title CEE3DMP: ... is reprinted.

Syntax

```latex
\texttt{CEE3DMP(title, options, fc)}
```

title (input)

An 80-byte fixed-length character string containing a title printed at the top of each page of the dump.

options

A 255-byte fixed-length character string enclosed in single quotes containing options describing the type, format, and destination of dump information. Options are declared as a string of keywords separated by blanks or commas. Some options have suboptions that follow the option keyword and are contained in parentheses. The options can be specified in any order, but the last option declaration is honored if there is a conflict between it and any preceding options. The following options are recognized by Language Environment:

ENCLave(ALL | CURRENT | \textit{n})

Dumps the current enclave, a fixed number of enclaves, or all enclaves associated with the current process; \textit{n} is an integer ranging from 1 to $2^{31}-1$, inclusive, that indicates the maximum number of enclaves that should be dumped. ENCLAVE(CURRENT) and ENCLAVE(1) are equivalent.

THREAD(ALL | CURRENT)

Dumps the current thread (the thread that invoked this service) or all threads associated with the current enclave. When you specify THREAD(ALL) and more than one thread is running, the library quiesces all threads before writing the dump. Therefore, the state of the library changes from the time the dump is requested to the time the dump is written.

TRACEback

Includes a traceback of all routines on the call chain. The traceback shows transfers of control from either calls or exceptions. The traceback extends backwards to the main program of the current thread. PL/I transfers of control into BEGIN-END blocks or ON-units are considered calls.
**NOTRACEback**

Does not include a traceback.

**FILES**

Includes attributes of all open files and the buffer contents used by the files. The particular attributes displayed are defined by the member languages. File buffers are dumped when FILE and STORAGE are specified. File control blocks are dumped when FILE and BLOCKS are specified.

**NOFILES**

Does not include file attributes of open files.

**VARIABLEs**

Includes a symbolic dump of all variables, arguments, and registers. Variables include arrays and structures. Register values are those saved in the stack frame at the time of call. There is no way to print a subset of this information. Variables and arguments are printed only if the symbol tables are available. A symbol table is generated when a program is compiled with the options shown below for each HLL, except for PL/I, which does not support the VARIABLE option.

**Language**

**Compile-Time Option**

<table>
<thead>
<tr>
<th>Language</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>TEST(SYM)</td>
</tr>
<tr>
<td>C++</td>
<td>TEST</td>
</tr>
<tr>
<td>COBOL</td>
<td>TEST or TEST(h,SYM)</td>
</tr>
</tbody>
</table>

The variables, arguments, and registers are dumped, beginning with the routine that called CEE3DMP. The dump proceeds up the call chain for the number of routines specified by the STACKFRAME option. See below for a description of the STACKFRAME option.

**NOVARIABLEs**

Does not include a dump of variables, arguments, and registers.

**BLOCKs**

Dumps the control blocks used in Language Environment and member language libraries. Global control blocks, as well as control blocks associated with routines on the call chain, are printed. Control blocks are printed for the routine that called CEE3DMP. The dump proceeds up the call chain for the number of routines specified by the STACKFRAME option (see below). Control blocks for files are also dumped if the FILES option was specified. See the FILES option above for more information. If the TRACE runtime option is set to ON, the trace table is dumped when BLOCKS is specified. If the heap storage diagnostics report is requested through the HEAPCHK runtime option, the report is displayed when BLOCKS is specified.

**NOBLOCKs**

Suppresses the dump of control blocks.

**STORAGE**

Dumps the storage used by the program. The storage is displayed in hexadecimal and character format. Global storage, as well as storage associated with each routine on the call chain, is printed. Storage is dumped for the routine that called CEE3DMP, which proceeds up the call
chain for the number of routines specified by the STACKFRAME option. Storage for all file buffers is also dumped if the FILES option was specified (see above).

**NOSTORAGE**

Suppresses storage dumps.

**REGSTOR**

Controls the amount of storage (reg_stor_amount) that is dumped around registers. reg_stor_amount indicates storage in bytes to be dumped around each register and must be in the range of 0 to 256. The number is rounded up to the nearest multiple of 32. The default is REGSTOR(96).

**Restriction:** You must specify REGSTOR(0) as a CEE3DMP option if a dump storage around registers is not required.

**StackFrame(n|ALL)**

Specifies the number of stack frames dumped from the call chain. If STACKFRAME(ALL) is specified, all stack frames are dumped. No stack frame storage is dumped if STACKFRAME(0) is specified. The particular information dumped for each stack frame depends on the VARIABLE, BLOCK, and STORAGE option declarations specified for CEE3DMP. The first stack frame dumped is the one associated with the routine that called CEE3DMP, followed by its caller, and proceeding backwards up the call chain.

**Pagesize(n)**

Specifies the number of lines on each page of the dump. This value must be greater than 9. A value of 0 indicates that there should be no page breaks in the dump. The default setting is PAGESIZE(60). Refer to the CEEDUMP runtime option for an optional method of setting the number of lines on each page of the dump.

**FNAME(ddname)**

Specifies the ddname of the file to which the dump report is written. The ddname supplied in this option must be a valid ddname for the system on which the application is running. CEE3DMP does not check the ddname for validity, nor does CEE3DMP translate or modify the ddname. Supplying an invalid ddname can result in unpredictable behavior. The default ddname CEEDUMP is used if this option is not specified.

**CONDITION**

Specifies that for each active condition on the call chain, the following information is dumped from the CIB:

- The address of the CIB.
- The message associated with the current condition token.
- The message associated with the original condition token, if different from the current one.
- The location of the error.
- The machine state at the time the condition manager was invoked, if an abend or hardware condition occurred.
- The abend code and reason code, if the condition occurred as a result of an abend.
- Language-specific error information.

The information supplied by Language Environment-conforming languages differs. PL/I supplies DATAFIELD, ONCHAR, ONCOUNT,
CEE3DMP

ONFILE, ONKEY, and ONSOURCE built-in function (BIF) values, which are shown in the context of the condition raised.

This option does not apply to asynchronous signals.

**NOCONDition**

Does not dump condition information for active conditions on the call chain.

**ENTRY**

Includes in the dump a description of the routine that called CEE3DMP and the contents of the registers on entry to CEE3DMP.

**NOENTRY**

Does not include in the dump a description of the routine that called CEE3DMP and the contents of the registers on entry to CEE3DMP.

**GENOpts**

Includes in the dump a runtime options report like that generated by the use of the RPTOPTS runtime option.

**NOGENOpts**

Does not include in the dump a runtime options report like that generated by the use of the RPTOPTS runtime option.

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted. If specified as an argument, feedback information, in the form of a condition token, is returned to the calling routine. If not specified, and the requested operation was not successfully completed, the condition is signaled to the condition manager.

The following feedback codes can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE317</td>
<td>1</td>
<td>3111</td>
<td>CEDUMP was defined as a dummy data set. No Language Environment dump processing was performed.</td>
</tr>
<tr>
<td>CEE30U</td>
<td>2</td>
<td>3102</td>
<td>Invalid CEE3DMP options or suboptions were found and ignored.</td>
</tr>
<tr>
<td>CEE30V</td>
<td>3</td>
<td>3103</td>
<td>An error occurred in writing messages to the dump file.</td>
</tr>
</tbody>
</table>

**Usage notes**

- Language Environment is sensitive to the national language when it writes dump output.
  - When the national language is upper case U.S. English or Japanese, the environment variable _CEE_UPPERCASE_DATA can be used to determine if variable data in the dump output is in uppercase.
  - When this environment variable is set to YES, variable data (entry point names, program unit names, variable names, Trace Entry in EBCDIC data, hexadecimal/EBCDIC displays of storage) will be in uppercase.
  - When this environment variable is not set or set to a value other than YES, variable data will not be in uppercase. Variable data is never in uppercase when the national language is mixed-case U.S. English.
CICS consideration—Only ENCLAVE(CURRENT) and ENCLAVE(1) are supported on CICS.

MVS consideration—On MVS, all values for the ENCLAVE option are supported.

z/OS UNIX consideration—CEE3DMP applies to the enclave.
When you call CEE3DMP in a multithread environment, the current thread or all threads might be dumped. Enclave- and process-related storage (along with storage related to threads other than the current thread) might have changed in value from the time the dump request was issued.

If the CEEDUMP DD has a PATH= parameter, the dump is directed to the specified file system.

If your application is running under z/OS UNIX System Services and is either running in an address space created by using the fork() function or is invoked by one of the exec family of functions, the dump is written to the file system. Language Environment writes the dump to a file in your current working directory, unless that directory is the root directory, in which case the dump is written to a file in the directory /tmp.

The name of this file changes with each dump and uses the following format:

```
/path/Fname.Date.Time.Pid
```

- **path** The current working directory
- **Fname** The name specified in the FNAME parameter on the call to CEE3DMP (default is CEEDUMP)
- **Date** The date the dump is taken, appearing in the format YYYYMMDD (such as 19940325 for March 25, 1994)
- **Time** The time the dump is taken, appearing in the format HHMMSS (such as 175501 for 05:55:01 PM)
- **Pid** The process ID the application is running in when the dump is taken

When nested CEEPIPI main-DP environments are present, the traceback section includes all nested environments. The first environment contains all the usual sections as determined by the CEE3DMP options. For the chained parent main-DP environments, the dump output omits all sections other than the traceback.

The ENCLAVE option controls how many enclaves appear in the output for each CEEPIPI main-DP environment. The STACKFRAME option controls how many stack frames are dumped for each CEEPIPI main-DP environment.

When multiple CEEPIPI main-DP environments are present, and the chained parent Main-DP environments contain Language Environment member languages that are not present in the current active Main-DP environment (the one that caused the dump), the information dumped out might be incomplete.

If the assembler CEEPIPI driver program does not follow standard z/OS linkage conventions, the dumped traceback information might be incomplete or incorrect.

**For more information**
- See ["TERMTHDACT" on page 83](#) for more information about the TERMTHDACT runtime option.
- For more information about generating dumps, see [z/OS Language Environment Debugging Guide](#).
Examples

1. Following is an example of CEE3DMP called by C/C++.

```c
/*Module/File Name: EDC3DMP */

#include <stdio.h>
#include <leawi.h>
#include <stdlib.h>
#include <string.h>
#include <ceeedcct.h>

#define OPT_STR "THREAD(CURRENT) TRACEBACK FILES"

int main(void) {

    _CHAR80 title = "This is the title of the dump report";
    _CHAR255 options;
    FILE *f;
    _FEEDBACK fc;

    memset(options, ',', sizeof(options));
    memcpy(options, OPT_STR, sizeof(OPT_STR) - 1);

    f = fopen("my.file", "wb");
    fprintf(f, "my file record 1\n");

    CEE3DMP(title, options, &fc);
    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEE3DMP failed with msgno %d\n", fc.tok_msgno);
        exit(2999);
    }
}
```

2. Following is an example of CEE3DMP called by COBOL.

```cobol

GOBACK.
CEE3GRC—Get the enclave return code

CEE3GRC retrieves the current value of the user enclave return code. Use CEE3GRC in conjunction with CEE3SRC to get and then set user enclave return codes.

**Syntax**

\[\text{CEE3GRC}(\text{return\_code}, \text{fc})\]

- **return\_code (output)**
  - The enclave return code.

- **fc (output)**
  - A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

**Usage notes**

- z/OS UNIX consideration—CEE3GRC is not supported in multithread applications.
- PL/I MTF consideration—CEE3GRC is not supported in PL/I MTF applications.
- PL/I consideration—When running PL/I with POSIX(ON), CEE3GRC is not supported.

**For more information**

- See “CEE3SRC—Set the enclave return code” on page 208 for more information about the CEE3SRC callable service.
- See z/OS Language Environment Programming Guide for more information about the CEE3GRC and CEE3SRC callable services.

**Examples**

1. Following is an example of a C/C++ main routine that calls CEEHDLR and CEE3GRC.
void CERCDIV(int);

#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <ceeedcct.h>

void CERCDIV(int);

#include <leawi.h>

/******************************************
**
** Function: CEEHDLR - Register user condition handler
**
** : CEE3GRC - Get enclave return code
**
**
** 1. Register the user-written condition handler
**
** 2. Call CERCDIV, which performs a divide-by-zero.
**
** 3. CESETRC is entered, sets the enclave return code to 999998 and resumes.
**
** 4. The main routine regains control and retrieves the enclave return code
**
******************************************

Declaration of user-written condition handler
******************************************

#ifndef __cplusplus
extern "C"
{
#endif

if ( _FBCHECK ( feedback , CEE000 ) != 0 )
{
    printf("CEE3GRC failed with message number %d\n", feedback.tok_msgno);
    exit(2999);
}

Chapter 5. Callable services  153
if (enclave_RC != 999998)
    printf ("Error setting enclave return code");
}

2. Following is an example of a C/C++ user-written condition handler that sets a user enclave return code.

    #include <stdio.h>
    #include <string.h>
    #include <leawi.h>
    #include <ceeedcct.h>
    #define RESUME 10
    #define PERCOLATE 20

    void CESETRC (_FEEDBACK *cond, _INT4 *input_token,
                  _INT4 *result, _FEEDBACK *new_cond)
    {
        _INT4 enclave_RC;
        _FEEDBACK feedback;
        if ( _FBCHECK ( *cond, CEE349 ) == 0 )
        {
            enclave_RC = 999998;
            CEE3SRC(&enclave_RC, &feedback);
            *result = RESUME;
        }
        else
        {
            *result = PERCOLATE;
        }
    }

3. Following is an example of a C/C++ subroutine that generates the divide-by-zero condition.

    void CERCDIV (int Integer)
    {
        int num;
        num = 1/Integer;
    }

Chapter 5. Callable services  159
CEE3GRN—Get name of routine that incurred condition

CEE3GRN gets the name of the most current Language Environment-conforming routine where a condition occurred. If there are nested conditions, the most recently signaled condition is used.

Syntax

```
>>> CEE3GRN(name, fc)
```

name (output)

A fixed-length 80-character string (VSTRING), that contains the name of the routine that was executing when the condition was raised. name is left-justified within the field and right-padded with blanks. If there are nested conditions, the most recently activated condition is used to determine name.

fc (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE35S</td>
<td>1</td>
<td>3260</td>
<td>No condition was active when a call to a condition management routine was made.</td>
</tr>
</tbody>
</table>
Usage notes

- z/OS UNIX consideration—In multithread applications, CEE3GRN gets the name of the routine that incurred the condition on the current thread.

Examples

1. Following is an example of CEE3GRN called by C/C++.

```c
/*Module/FileName: EDC3GRN */

#include <stdio.h>
#include <string.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceeedcct.h>

#ifdef __cplusplus
extern "C"
{
#endif

void handler(_FEEDBACK *,_INT4 *,_INT4 *,_FEEDBACK *);

#ifdef __cplusplus
}
#endif

int main(void)
{

_SECRET routine;
_SECRET token,qdata;

CEE3GRO—Get offset of condition

The CEE3GRO service returns the offset within a failing routine of the most recent condition. If there are nested conditions, the most recently signaled condition is returned.

Syntax

CEE3GRO(—cond_offset—,—fc—)

cond_offset (output)

An INT4 data type that, upon completion of this service, contains the offset within a failing routine of the most recent condition.

fc (output, optional)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

CEE3INF—Query enclave information

CEE3INF queries and returns to the calling routine the information about the system/subsystem, the environment information, the member languages, and the version of Language Environment associated with this enclave.

Syntax

```plaintext
►► CEE3INF(—sys/subsys—,—env-info—,—member-id—,—gpid—,—fc—)◄◄
```

sys/subsys (input/output)
As input, sys/subsys is considered to be an address to a fullword. As output, the fullword is a 32-bit map that represents the operating system or subsystem on which the enclave is currently running.

- 0  Currently executing in the CICS environment
- 1  Currently executing in a CICS_PIPI environment
- 2-3 Reserved for other specific CICS environments
- 4  Currently executing in a TSO environment
- 5  Currently executing in a Batch environment
- 6  Currently executing in a z/OS UNIX environment
- 7-28 Reserved for future use
- 29 Currently executing on z/VSE®
- 30 Currently executing on z/OS
- 31 Reserved.

env-info (input/output)
As input, env-info is considered to be an address to a fullword. As output, the fullword is a 32-bit map representing the environments that are active in that enclave.

- 0  Currently executing in a PIPI environment
- 1  Currently executing in a PIPI-Main environment
- 2  Currently executing in a PIPI-Sub environment
- 3  Currently executing in a PIPI-Subdp environment
- 4  Currently executing in a PICI (Pre-init compatibility interface) environment. For more information, see z/OS XL C/C++ Programming Guide.
- 5  Currently executing in a nested enclave
- 6  LRR is active in the current enclave
- 7  Runtime reuse is active in the current environment
- 8  XPLINK(ON) is in effect in the current enclave
- 9  POSIX(ON) RTO in effect in the current enclave
- 10 At least one pthread has been created in this enclave
- 11 Currently executing on the IPT
- 12 Multithreaded fork is in effect in the current enclave
- 13-14 AMODE Init
  - B'00' AMODE 24
  - B'10' AMODE 31
- 15 Currently executing in a PIPI-Maindp environment
- 16-31 Reserved for future use
member-id (input/output)
As input, member-id is considered to be an address to a fullword. As output,
the fullword is a 32-bit map representing the member languages that are
initialized in that enclave.
0    Reserved
1    Reserved
2    Reserved
3    C/C++
4    Reserved
5    COBOL
6    Reserved
7    Fortran
8-9  Reserved
10   PL/I
11   Enterprise PL/I
12-14 Reserved
15   Reserved
16   Reserved
17-23 Reserved for future use
24-31 The current version number of CEE3INF. It is currently set to 0.

gpid (input/output)
A fullword integer representing the version of Language Environment that
created this thread. This fullword can be interpreted as a four-byte hex number
as follows:
  |PP|VV|RR|MM|
PP    product number
VV    version
RR    release
MM    modification

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result
of this service. If you choose to omit this parameter, refer to "Invoking callable
services" on page 116 for the appropriate syntax to indicate that the feedback
code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

Usage notes
• z/OS UNIX considerations — CEE3INF is allowed only in the thread.
• If you are not interested in any one of the parameters being passed, a 0 must be
  placed in the slot of those parameters. This indicates that no information is
  needed regarding that parameter.
• When the PIPI or nested enclave environment bit is on, a subsystem bit may not
  be set.

```

### CEE3LNG—Set national language

CEE3LNG sets the current national language. You can also use CEE3LNG to query the current national language. Changing the national language changes the languages in which error messages are displayed and printed, the names of the days of the week, and the names of the months. The current national language setting, as well as previous national language settings that have not been discarded, are recorded on the stack on a LIFO (last in, first out) basis. The current national language setting is always on the top of the stack.

There are two methods of changing the default national language setting with CEE3LNG:

- Specify the new national language setting and place it on top of the stack using a `function` value of 1 (SET). This discards the previous default setting.
- Specify the new national language setting and place it on top of the stack using a `function` value of 3 (PUSH). This pushes the previous national language setting down on the stack so that you can later retrieve it by discarding the current setting.

To illustrate the second method, suppose you live in the United States and the code for the United States is specified as a system-level default. If you want to use the French defaults for a certain application, you can use CEE3LNG to PUSH France as the national language setting; then when you want the defaults for the United States, you can POP France from the top of the stack, making the United States the national language setting.

If you specify a `desired language` that is not available on your system, Language Environment uses the IBM-supplied default ENU (mixed-case U.S. English). If an unknown national language code is specified as a system-level, region-level or CEEUOPT default, a return code of 4 and a warning message is issued.

You can also use the NATLANG runtime option to set the national language.
CEE3LNG affects only the Language Environment NLS and date and time services, not the Language Environment locale callable services or C locale-sensitive functions.

Syntax

$$\text{CEE3LNG} (\text{function}, \text{desired_language}, \text{fc})$$

function (input)
A fullword binary integer that specifies the service to perform. The possible values for function are:

1—SET
Establishes the desired_language specified in the call to CEE3LNG as the current language. In effect, it replaces the current language on the top of the stack with the desired_language that you specify. When setting the national language, the desired_language is folded to uppercase. "enu" and "ENU", for example, are considered to be the same national language.

2—QUERY
Identifies the current language on the top of the stack to the calling routine by returning it in the desired_language parameter of CEE3LNG. The desired_language retained as the result of the QUERY function is in uppercase.

3—PUSH
Pushes the desired_language specified in the call to CEE3LNG on to the top of the language stack, making it the current language. Previous languages are retained on the stack on a LIFO basis, making it possible to return to a prior language at a later time.

4—POP
Pops the current language off the stack. The previous language that was pushed on to the stack now becomes the new current language. Upon return to the caller, the desired_language parameter contains the discarded language. If the stack contains only one language and would be empty after the call, no action is taken and a feedback code indicating such is returned.

desired_language (input/output)
A 3-character fixed-length string. The string is not case-sensitive and is used in the following ways for different functions:

<table>
<thead>
<tr>
<th>If function is:</th>
<th>Then desired_language:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 or 3</td>
<td>Contains the desired national language identification. In this case, it is an input parameter. Table 23 on page 179 contains a list of national language identifiers.</td>
</tr>
<tr>
<td>Note: Language Environment supports only these national languages:</td>
<td></td>
</tr>
<tr>
<td>ENU Mixed-case U.S. English</td>
<td></td>
</tr>
<tr>
<td>UEN Uppercase U.S. English</td>
<td></td>
</tr>
<tr>
<td>JPN Japanese</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Returns the current language on top of the stack. In this case, it is an output parameter.</td>
</tr>
</tbody>
</table>
If function is: Then desired_language:

4 Returns the discarded national language. In this case, it is an output parameter.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3BQ</td>
<td>2</td>
<td>3450</td>
<td>Only one language was on the stack when a POP request was made to CEE3LNG. The current language was returned.</td>
</tr>
<tr>
<td>CEE3BR</td>
<td>3</td>
<td>3451</td>
<td>The desired language desired-language for the PUSH or SET function for CEE3LNG was invalid. No operation was performed.</td>
</tr>
<tr>
<td>CEE3BS</td>
<td>3</td>
<td>3452</td>
<td>The function function specified for CEE3LNG was not recognized. No operation was performed.</td>
</tr>
</tbody>
</table>

Usage notes
- PL/I MTF consideration—The CEE3LNG callable service is not supported in PL/I multitasking applications.
- PL/I consideration—When running PL/I with POSIX(ON), CEE3LNG is not supported.
- z/OS UNIX consideration
  - CEE3LNG applies to the enclave. Each enclave has a single current national language setting.
  - Language Environment provides z/OS UNIX-compliant locales as part of the C/C++ runtime library. The locales establish the cultural conventions for locale-sensitive functions in this runtime. The CEESETL callable service and other locale callable services depend on the loaded locale. To change the locale, you can use the setlocale() C/C++ library function or the CEESETL callable service. Locale values do not affect the settings used by the CEE3LNG callable service. For a complete list of locales, see z/OS Language Environment Programming Guide.
  - The CEE3LNG callable services, such as date and time formatting, sorting, and currency symbols are independent of the locale. CEE3LNG affects only Language Environment NLS and date and time services. Mixing CEE3LNG services and locale callable services might produce inconsistent results.

For more information
- See “NATLANG” on page 59 for more information about the NATLANG runtime option.
- For more information about the CEESETL callable service, see “CEESETL—Set locale operating environment” on page 413.
- For more information about setlocale(), see z/OS XL C/C++ Programming Guide.
Examples

1. Following is an example of CEE3LNG called by C/C++.

```c
/*Module/File Name: EDC3LNG */

#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {

_FEEDBACK fc;
_INT4 function;
_CHAR3 lang;

/* Query the current language setting */
function = 2; /* function 2 is query */
CEE3LNG(&function,lang,&fc);

if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
    printf("CEE3LNG failed with message number %d\n", fc.tok_msgno);
    exit(2999);
}

/* if the current language is not mixed-case */
/* American English set the current language to */
/* mixed-case American English */
if (memcmp(lang,"ENU",3) != 0) {
    memcpy(lang,"ENU",3);
    function = 1; /* function 1 is set */
    CEE3LNG(&function,lang,&fc);
    if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
        printf("CEE3LNG failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
}
}
```

CEE3MCS—Get default currency symbol

CEE3MCS returns the default currency symbol for the country you specify with country_code. For a list of the default settings for a specified country, see Table 32 on page 483.

Syntax

```
CEE3MCS(--country_code--,--currency_symbol--,--fc--)
```

country_code (input)
A 2-character fixed-length string representing one of the country codes found in Table 32 on page 483. country_code is not case-sensitive. If no value is specified, the default country code, as set by the COUNTRY runtime option or the CEE3CTY callable service, is used.

currency_symbol (output)
A 4-character fixed-length string returned to the calling routine. It contains the default currency symbol for the country specified. The currency symbol is left-justified and padded on the right with blanks, if necessary.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3C7</td>
<td>2</td>
<td>3463</td>
<td>The country code country_code was not valid for CEE3MCS. The default currency symbol currency_symbol was returned.</td>
</tr>
</tbody>
</table>

Usage notes

- If you specify a country_code that is not valid, the default currency symbol is X'9F404040'. In the United States, it is shown as a '$' followed by three blanks.
- z/OS UNIX considerations—CEE3MCS applies to the enclave. Every enclave has a single current country setting that has a single currency symbol. Every thread in every enclave has the same default.
- Euro considerations—For countries in the European Union that have adopted the Euro as the legal tender, the currency symbol is represented as a hexadecimal string in the default country settings. The value is the code point for the Euro sign, taken from a typical code page for the given country. Of course, the actual graphical representation depends on the code page in use. See Table 32 on page 483 for a list of country settings.

Language Environment supports the Euro as the default currency symbol in the following countries: Austria, Belgium, Finland, France, Germany, Greece, Ireland,
Italy, Luxembourg, the Netherlands, Portugal, and Spain. As more countries pass the economic and monetary union convergence criteria and adopt the Euro as the legal currency, the default currency symbol will replace the national currency symbol with the Euro sign.

For more information
- See “COUNTRY” on page 24 for an explanation of the COUNTRY runtime option.
- See “CEE3CTY—Set default country” on page 135 for an explanation of the CEE3CTY callable service.
- See “CEE3MC2—Get default and international currency symbols” on page 184 for an explanation of the CEE3MC2 callable service.

CEE3MC2—Get default and international currency symbols

CEE3MC2 returns the default currency symbol and international currency symbol for the country you specify with country_code. For a list of the default settings for a specified country, see Table 32 on page 483.

Syntax

►► CEE3MC2—(country_code—, currency_symbol—, international_currency_symbol—, fc—)

country_code (input)
A 2-character fixed-length string representing one of the country codes found in Table 32 on page 483. country_code is not case-sensitive. If no value is specified, the default country code, as set by the COUNTRY runtime option or the CEE3CTY callable service, is used.

currency_symbol (output)
A 4-character fixed-length string returned to the calling routine. It contains the default currency symbol for the country specified. The currency symbol is left-justified and padded on the right with blanks, if necessary.

international_currency_symbol (output)
A 3-character alphabetic fixed-length string returned to the calling routine. It contains the international currency symbol for the country specified.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>

CEE3MDS—Get default decimal separator

CEE3MDS returns the default decimal separator for the country specified by
\textit{country\_code}. For a list of the default settings for a specified country, see Table 32 on page 483.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
\textbf{Syntax} & \\
\hline
\multicolumn{2}{|c|}{\textasciitilde\textasciitilde CEE3MDS\{-country\_code-, -decimal\_separator-, -fc-\}} \textasciitilde\textasciitilde \\
\hline
\end{tabular}
\caption{CEE3MDS—Get default decimal separator}
\end{table}

\begin{description}
\item[country\_code (input)]
A 2-character fixed-length string representing one of the country codes found
in Table 32 on page 483. \textit{country\_code} is not case-sensitive. If no value is
specified, the default country code, as set by the COUNTRY runtime option or
the CEE3CTY callable service, is used.

\item[decimal\_separator (output)]
A 2-character fixed-length string containing the default decimal separator for
the country specified. The decimal separator is left-justified and padded on the
right with a blank.
\end{description}
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3C4</td>
<td>2</td>
<td>3460</td>
<td>The decimal separator 'decimal-separator' was truncated and was not defined in CEE3MDS.</td>
</tr>
<tr>
<td>CEE3C5</td>
<td>2</td>
<td>3461</td>
<td>The country code country-code was invalid for CEE3MDS. The default decimal separator 'decimal-separator' was returned.</td>
</tr>
</tbody>
</table>

Usage notes
- If you specify a country_code that is not valid, the default decimal separator is a period (.)
- z/OS UNIX considerations—CEE3MDS applies to the enclave. Every enclave has a single current country setting that has a single decimal separator. Every thread in every enclave has the same default.

For more information
- See “COUNTRY” on page 24 for an explanation of the COUNTRY runtime option.
- See “CEE3CTY—Set default country” on page 135 for an explanation of the CEE3CTY callable service.

Examples
1. Following is an example of CEE3MDS called by C/C++.

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {
  _FEEDBACK fc;
  _CHAR2 country,decimal;

  /* get the default decimal separator for Canada */
  memcpy(country,"CA",2);
  CEE3MDS(country,decimal,&fc);
  if (_FBCHECK (fc , CEE000 ) != 0 ) {
    printf("CEE3MDS failed with message number %d\n", fc.tok_msgno);
    exit(2999);
  }
  /* print out the default decimal separator */
  printf("The default decimal separator for":)
  printf("Canada is: %.2s",decimal);
}

CEE3MTS—Get default thousands separator

CEE3MTS returns the default thousands separator for the specified country with country_code.

Syntax

```
CEE3MTS(—country_code—,—thousands_separator—,—fc—)
```

**country_code (input)**

A 2-character fixed-length string representing one of the country codes found in Table 32 on page 483. country_code is not case-sensitive. If no value is specified, the default country code, as set by the COUNTRY runtime option or the CEE3CTY callable service, is used.

**thousands_separator (output)**

A 2-character fixed-length string representing the default thousands separator for the country specified. The thousands separator is left-justified and padded on the right with a blank.

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:
Usage notes

- If you specify a `country_code` that is not valid, the default thousands separator is a comma (,).
- z/OS UNIX considerations—CEE3MTS applies to the enclave. Every enclave has a single current country setting that has a single thousands separator. Every thread in every enclave has the same default.

For more information

- For a list of the default settings for a specified country, see Table 32 on page 483.
- See “COUNTRY” on page 24 for an explanation of the COUNTRY runtime option.
- See “CEE3CTY—Set default country” on page 135 for an explanation of the CEE3CTY callable service.

Examples

1. Following is an example of CEE3MTS called by C/C++.

```c
/*Module/File Name: EDC3MTS */

#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {
    _FEEDBACK fc;
    _CHAR2 country,thousand;

    /* get the default thousands separator for Canada */
    memcpy(country,"CA",2);
    CEE3MTS(country,thousand,&fc);
    if (_FBCHECK ( fc , CEE000 ) != 0 ) {
        printf("CEE3MTS failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    /* print out the default thousands separator */
    printf("The default thousands separator for Canada is: %.2s\n",thousand);
}
```

2. Following is an example of CEE3MTS called by COBOL.

```plaintext
CBL LIB,QUOTE

**CEE3PRM—Query parameter string**

CEE3PRM queries and returns to the calling routine the parameter string specified at invocation of the program. The returned parameter string contains only program arguments. If no program arguments are available, a blank string is returned.

### Syntax

```
>>>CEE3PRM(--char_parm_string--,--fc--)<<<
```

*char_parm_string* **(output)**

An 80-byte fixed-length string passed by CEE3PRM. On return from this service, the *char_parm_string* contains the parameter string specified at invocation of the program. If this parameter string is longer than 80 characters, it is truncated. If the parameter string is shorter than 80 characters, the returned string is padded with blanks. If the program argument passed to the service is absent, or is not a character string, *char_parm_string* is blank.

*fc* **(output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>
### Usage notes

- **C/C++ consideration**—C/C++ users can use the __osp11st to return a program argument longer than 80 characters.
- **z/OS UNIX considerations**—CEE3PRM is allowed only in the initial thread.
- You can use the CEE3PR2 callable service to return a program string that is longer than 80 characters.

### For more information

For more information about the CEE3PR2 callable service, see "CEE3PR2—Query parameter string long" on page 196.

### Examples

1. Following is an example of CEE3PRM called by C/C++.

   ```c
   /*Module/FileName: EDC3PRM */
   #include <stdio.h>
   #include <leawi.h>
   #include <stdlib.h>
   #include <string.h>
   #include <ceeedcct.h>

   int main() {
     _CHAR80 parm;
     _FEEDBACK fc;

     CEE3PRM(parm,&fc);
     if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
       printf("CEE3PRM failed with message number %d\n", fc.tok_msgno);
       exit(2999);
     }
     printf("%.80s\n",parm);
   }
   ```

2. Following is an example of CEE3PRM called by COBOL.

|| FC.MsgNo );
STOP;
END;

END PLI3PRM;

CEE3PR2—Query parameter string long

CEE3PR2 queries and returns to the calling routine the parameter string and its associated length specified at invocation of the program. The returned parameter string contains only program arguments. If no program arguments are available, a blank string is returned.

Syntax

►►CEE3PR2(—int_parm_length—,—char_parm_string—,—fc—)◄◄

int_parm_length (input/output)

A fullword integer that indicates the length of the parameter string.

- For input: If the value is less than or equal to 0, int_parm_length is a request for the length of the parameter string passed during program invocation. If the value is greater than 0, it is the actual size of the char_parm_string buffer passed by the caller.
- For output: CEE3PR2 returns the actual length of the parameter string passed during program invocation for any case, regardless of the input value in the int_parm_length field.

cchar_parm_string (input/output)

- For input: char_parm_string contains the address of a piece of storage that is obtained by the caller.

  Note: This storage is used as a varying string. It must be 2 bytes longer than the length of the parameter string passed during program invocation.
- For output: The storage pointed to by this address contains a varying string that contains the parameter string passed during program invocation. The parameter string is truncated when the actual length of the parameter string passed during invocation exceeds int_parm_length minus 2.

fc (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3K3</td>
<td>1</td>
<td>3715</td>
<td>The parameter string returned from CEE3PR2 was truncated due to insufficient storage space for the string provided by the caller.</td>
</tr>
</tbody>
</table>
Usage notes

- C/C++ consideration—C/C++ users can use the __osplist return a program argument longer than 80 characters.
- z/OS UNIX consideration—CEE3PR2 is allowed only in the initial thread.
- CICS consideration—CEE3PR2 always returns a blank string.

For more information

- For more information about the CEE3PRM callable service, see “CEE3PRM—Query parameter string” on page 193.

Examples

1. Following an example of CEE3PR2 called by C/C++.

```c
#include <stdio.h>
#include <leawi.h>
#include <stdlib.h>
#include <string.h>
#include <ceeedcct.h>

struct mystring{
    unsigned short int length;
    char string[298];
};
typedef struct mystring mystring;

int main() {
    int len;
    mystring parm;
    _FEEDBACK fc;

    /*Setting up the user defined space to store the retrieved string*/
    memset(&parm,0x00,sizeof(parm));
    len = sizeof(parm);

    /*Calling CEE3PR2 to retrieve the parameter string*/
    CEE3PR2(&len,&parm,&fc);

    if ( _FBCHECK (fc, CEE000) != 0 ){
        printf("CEE3PR2 failed with message number %d\n", fc.tok_msgno);
    }

    printf("Length field of the string : %d \n",len);
    printf("Parameter String is: %s\n",parm.string);
    return 0;
}
```

CEE3RPH—Set report heading

CEE3RPH sets the heading displayed at the top of the storage or options report generated when you specify the RPTSTG(ON) or RPTOPTS(ON) runtime options. For examples of these reports, see [z/OS Language Environment Debugging Guide]

Syntax

>>>CEE3RPH—(—report_heading—,—fc—)<<<

report_heading (input)
An 80-character fixed-length string, report_heading sets the identifying character string displayed at the top of the storage or options report. Language Environment uses only the first 79 bytes of report_heading; the last byte is ignored. report_heading can contain DBCS characters surrounded by X'OE' (shift-out) and X'0F' (shift-in).

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result
of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3JK</td>
<td>0</td>
<td>3700</td>
<td>The storage and options report heading replaced a previous heading.</td>
</tr>
</tbody>
</table>

Usage notes

- PL/I considerations—CEE3RPH is designed to provide an equivalent function to the special PL/I variable PLIXHD.
- z/OS UNIX considerations—CEE3RPH applies to the enclave.

For more information

- See “RPTSTG” on page 73 for more information about the RPTSTG runtime option.
- See “RPTOPTS” on page 71 for more information about the RPTOPTS runtime option.
- See PL/I for MVS & VM Programming Guide for further information about PLIXHD.

Examples

1. Following is an example of CEE3RPH called by C/C++.

```c
/*Module/File Name: EDC3RPH */

#pragma runopts(RPTOPTS(ON))
#include <string.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {
    _CHAR80 heading;
    /* initialize heading to blanks and then set the */
    /* heading */
    memset(heading, ' ',80);
    memcpy(heading,"User Defined Report Heading",27);
    /* set the report heading...do not need to check */
    /* feedback token because all return codes are */
    /* successful */
    CEE3RPH(heading,NULL);
    /* */

CEE3SPM—Query and modify Language Environment hardware condition enablement

CEE3SPM queries and modifies the enablement of Language Environment hardware conditions. You can use the CEE3SPM service to:

- Alter the settings of the Language Environment conditions, using an action value of 1 (SET), to those specified by the caller.
- Query the current settings of the Language Environment conditions and return the settings to the caller.
- Push the current settings of the Language Environment conditions on to the condition stack using an action value of 3 (PUSH). This pushes the current setting down on the stack for later retrieval, and, in effect, places a copy of the current setting on top of the stack. It does not alter the current condition settings.
- Pop the pushed settings of the Language Environment conditions from the condition stack using an action value of 4 (POP). This reinstates the previous condition settings as the current condition settings.
- Push the current settings of the Language Environment conditions on to the Language Environment-managed condition stack and alter the settings of the Language Environment conditions to those supplied by the caller.

The enabled or disabled Language Environment conditions are:

**fixed-overflow**
When enabled, raises the fixed-overflow condition when an overflow occurs during signed binary arithmetic or signed left-shift operations.

**decimal-overflow**
When enabled, raises the decimal-overflow condition when one or more nonzero digits are lost because the destination field in a decimal operation is too short to contain the results.

**underflow**
When enabled, raises the underflow condition when the result characteristic of a floating-point operation is less than zero and the result fraction is not zero. For an extended-format floating-point result, the condition is raised only when the high-order characteristic underflows.
When enabled, raises the significance condition when the resulting fraction in floating-point addition or subtraction is zero.

When you use the CEE3SPM callable service, maintenance of the condition stack is required. For example, one user-written condition handler can disable a hardware condition while another enables it. Therefore, do not assume that the program mask is at a given setting. The program mask is set differently based on different HLL requirements. You can find out what the current setting is by using the QUERY function of CEE3SPM.

Language Environment initialization sets conditions based on the languages in the initial load module. Each language present adds to the conditions that are enabled.

Some S/370 hardware interrupt codes and their matching Language Environment feedback codes appear in Table 24 on page 205.

Syntax

\[ \text{CEE3SPM}(\text{action}, \text{cond_string}, \text{fc}) \]

**action (input)**
The action to be performed. *action* is specified as a fullword binary signed integer corresponding to one of the numbers in the following list:

1—SET
   Alters the settings of the Language Environment conditions to those specified in the *cond_string* parameter.

2—QUERY
   Queries the current settings of the Language Environment conditions and return the settings in the *cond_string* parameter.

3—PUSH
   Pushes the current settings of the Language Environment conditions on to the Language Environment-managed condition stack.

4—POP
   Pops the pushed settings of the Language Environment conditions from the condition stack, discarding the current settings, and reinstating the previous condition settings as the current condition settings.

5—PUSH, SET
   Pushes the current settings of the Language Environment conditions on to the Language Environment-managed condition stack and alters the settings of the Language Environment conditions to those supplied by the caller in the *cond_string* parameter.

**cond_string (input/output)**
A fixed-length string of 80 bytes containing a sequence of identifiers representing the requested settings for the Language Environment conditions that can be enabled and disabled. A list of conditions enabled and disabled and their associated identifiers is given below:
Condition Identifier
fixed-overflow F (NOF for disablement)
decimal-overflow D (NOD for disablement)
underflow U (NOU for disablement)
significance S (NOS for disablement)

An identifier with the 'NO' prefix is used to disable the condition it represents. An identifier without the 'NO' prefix is used to enable the condition that it represents. For example, the token 'F' is used to enable the fixed-overflow condition. The identifier 'NOF' is used to disable the fixed-overflow condition. The rightmost option takes effect in the event of a conflict. Identifiers are separated by blanks or commas.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>

Usage notes
- PL/I MTF consideration—In PL/I MTF applications, CEE3SPM affects only the calling task.
- C/C++ consideration—C/C++ ignores the fixed-overflow, decimal-overflow, underflow, and significance interrupts, no matter what you specify in CEE3SPM.
- COBOL consideration—COBOL ignores the fixed-overflow and decimal-overflow interrupts, no matter what you specify in CEE3SPM.
- z/OS UNIX consideration—In multithread applications, CEE3SPM affects only the calling thread.
- You cannot use CEE3SPM to enable the fixed-overflow, decimal-overflow, underflow or significance interrupts. You can, however, query the settings of CEE3SPM.

Examples

1. Following is an example of CEE3SPM called by C/C++.

```c
#include <stdio.h>
#include <string.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceeedcct.h>

int main(void) {
  _FEEDBACK fc;
  _INT4 action;
  _CHAR80 cond_string;
  char *cond;

  /* query the current settings */
  action = 2;
  CEE3SPM(&action,cond_string,&fc);
  if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
    printf("CEE3SPM query failed with message \n", fc.tok_msgno);
    exit(2999);
  }
}
```

2. Following is an example of CEE3SPM called by COBOL.

```cobol

   END PLI3SPM; CALL CEE3SPM ( ACTION, CONDSTR, FC );
IF ~ FBCHECK( FC, CEE000) THEN DO;
   DISPLAY('CEE3SPM failed with msg ' || FC(MsgNo);
   STOP;
   END;
CEE3SRC—Set the enclave return code

CEE3SRC sets the user enclave return code. The value set is used in the calculation of the final enclave return code at enclave termination.

Syntax

```c
CEE3SRC( return_code, fc )
```

**return_code** (input)

An INT4 data type. The enclave return code to be set should be <= 999,999 and >= 0 to be in the Language Environment-preferred range. (The initial value is 0.)

**fc** (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE0HA</td>
<td>1</td>
<td>0554</td>
<td>A value outside the preferred range of 0 through 999,999 was supplied. However, the value was still used as the enclave return code.</td>
</tr>
</tbody>
</table>

**Usage notes**

- **z/OS UNIX consideration**—CEE3SRC is not supported in multithread applications.
- **PL/I MTF consideration**—For PL/I multitasking applications, the user return code value set during invocation of CEE3SRC affects the current task only. If a PL/I program causes an enclave to terminate, the value set by CEE3SRC at the associated task level is reflected in the final return code at enclave termination.
- **PL/I consideration**—When running PL/I with POSIX(ON), CEE3SRC is not supported.

**For more information**

- See [z/OS Language Environment Programming Guide](#) for more information about the CEE3SRC callable service.
Examples

CEE3SRC is used with CEE3GRC; see the examples for CEE3GRC show in “Examples” on page 152.

CEE3SRP—Set resume point

The CEE3SRP service sets the resume point at the next instruction in the calling routine. CEE3SRP works only in conjunction with the CEEMRCE service.

Syntax

```
CEE3SRP(resume_token, fc)
```

resume_token (output)

An INT4 data type that, upon completion of this service, contains a token that represents a machine state block, which Language Environment allocates from heap storage. Language Environment automatically frees the heap storage for the machine state block when the routine associated with the stack frame to which it points returns to its caller.

fc (output / optional)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE390</td>
<td>3</td>
<td>3360</td>
<td>The stack frame was not found on the call chain.</td>
</tr>
</tbody>
</table>

Usage notes

- An example for Service Label under COBOL follows:

```
SET-RECOVERY-POINT-PARAGRAPH.
   CALL 'CEE3SRP' USING RECOVERY-POINT FC.
   SERVICE LABEL.
ERROR-PARAGRAPH.
* code to do post-error processing
```

- Use the CEE3SRP service only with the CEEMRCE service from within a user condition handler. The token returned by this service is used as input to the CEEMRCE service.

- Language Environment automatically frees the heap storage for the machine state block when the routine associated with the stack frame to which it points returns to its caller. Attempts to use the machine state block after it is freed result in unpredictable behavior.

- COBOL considerations
CEE3SRP

- A Service Label compiler directive must be specified immediately after the call to CEE3SRP.
- When a resume occurs and control resumes to the next instruction following the call to CEE3SRP, the COBOL RETURN-CODE special register contains an unpredictable value.

Examples

For examples of how to use CEE3SRP in combination with CEEMRCE and CEEHDLR, see “CEEMRCE—Move resume cursor explicit” on page 360.

CEE3USR—Set or query user area fields

CEE3USR sets or queries one of two 4-byte fields known as the user area fields. The user area fields are associated with an enclave and are maintained on an enclave basis. A user area field can be used by vendor or application programs to store a pointer to a global data area or to keep a recursion counter.

Be careful not to confuse the Language Environment user area fields with the PL/I user area. The PL/I user area is a 4-byte field in the PL/I TCA and can be accessed only through assembler language. The PL/I user area continues to be supported for compatibility.

Language Environment initializes both user area fields to X'00000000' during enclave initialization.

Syntax

```plaintext
►► CEE3USR(function_code, field_number, field_value, fc) ◄◄
```

- **function_code** *(input)*
  A fullword binary integer representing the function performed:
  1—SET
  User area field according to the value specified in field_value.
  2—QUERY
  User area field; return current value in field_value.

- **field_number** *(input)*
  A fullword binary integer indicating the field to set or query. field_number must be specified as either 1 or 2.

- **field_value** *(input/output)*
  A fullword binary integer.
  If function_code is specified as 1 (meaning SET user area field), field_value contains the value to be copied to the user area field.
  If function_code is specified as 2 (meaning QUERY user area field), the value in the user area field is copied to field_value.

- **fc** *(output)*
  A 12-byte feedback code, optional in some languages, that indicates the result
of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3PS</td>
<td>3</td>
<td>3900</td>
<td>The function code passed to CEE3USR was not 1 or 2.</td>
</tr>
<tr>
<td>CEE3PT</td>
<td>3</td>
<td>3901</td>
<td>The field number passed to CEE3USR was not 1 or 2.</td>
</tr>
</tbody>
</table>

Usage notes

• z/OS UNIX consideration—CEE3USR applies to the enclave.

Examples

1. Following is an example of CEE3USR called by C/C++.

```c
/*Module/File Name: EDC3USR */

#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <leawi.h>
#include <ceeedcct.h>

typedef struct {
    int value1,value2,value3;
    char slot1_80;
} info_struct;

int main (void) {

    _INT4 function_code, field_number, field_value;
    _FEEDBACK fc;
    info_struct *info;

    info = (info_struct *)malloc(sizeof(info_struct));
    /*
     * Set User field 1 to point to info_struct */
    function_code = 1;
    field_number = 1;
    field_value = (int)info;

    CEE3USR(&function_code,&field_number,&field_value,&fc);
    if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
        printf("CEE3USR failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    /*
    */
    /* get the value of field 2 */
    function_code = 2;
    field_number = 1;

    CEE3USR(&function_code,&field_number,&field_value,&fc);
    if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
        printf("CEE3USR failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    /*
    */
    /*
    */
}
```

/* . . . */
*/
```

---

The `CEE3USR` is a user exit routine in the z/OS Language Environment that allows COBOL programs to set or query values of user-defined areas. This example demonstrates how to call `CEE3USR` twice: once to set the value of a user area, and once to query it. The `PARA-3USRSET` procedure shows how to call `CEE3USR` using specific parameters for setting and querying values.
3. Following is an example of CEE3USR called by PL/I.

*PROCESS MACRO;
/* Module/File Name: IBM3USR */

**CEECLBDY—Convert date to COBOL Integer format**

CEECLBDY converts a string representing a date into a COBOL Integer format, which is the number of days since 1 January 1601. This service is similar to CEEDAYS, except that it provides a string in COBOL Integer format, which is compatible with ANSI intrinsic functions. Use CEECLBDY to access the century window of Language Environment and to perform date calculations with COBOL intrinsic functions for programs compiled with the INTDATE(ANSI) compiler option.

Call CEECLBDY only from COBOL programs that use the returned value as input for COBOL intrinsic functions. You should not use the returned value with other Language Environment callable services, nor should you call CEECLBDY from any non-COBOL programs. Unlike CEEDAYS, there is no inverse function for CEECLBDY, because it is only for COBOL users who want to use the Language Environment century window service together with COBOL intrinsic functions for date calculations. The inverse function for CEECLBDY is provided by the DATE-OF-INTEGER and DAY-OF-INTEGER intrinsic functions.

To handle dates earlier than 1601, add 4000 to each year, convert to Integer, calculate, subtract 4000 from the result, and then convert back to character format. By default, 2-digit years lie within the 100-year range starting 80 years prior to the system date. Thus, in 1995, all 2-digit years represent dates between 1915 and 2014, inclusive. You can change this default range by using the CEESCEN callable service.

**Syntax**

```
CEECLBDY(input_char_date, picture_string, output_ANSI_date)
```

**input_char_date (input)**

A halfword length-prefixed character string (VSTRING) representing a date or timestamp, in a format conforming to that specified by picture_string. The character string must contain between 5 and 255 characters, inclusive. input_char_date can contain leading or trailing blanks. Parsing for a date begins with the first nonblank character (unless the picture string itself contains leading blanks, in which case CEECLBDY skips exactly that many positions before parsing begins). After parsing a valid date, as determined by the format of the date specified in picture_string, CEECLBDY ignores all remaining
characters. Valid dates range between and include 01 January 1601 to 31 December 9999. See Table 33 on page 489 for a list of valid picture character terms that can be specified in input_char_date.

**picture_string (input)**
A halfword length-prefixed character string (VSTRING), indicating the format of the date specified in input_char_date. Each character in the picture_string corresponds to a character in input_char_date. For example, if you specify MMDDYY as the picture_string, CEECBLDY reads an input_char_date of 060288 as 02 June 1988. If delimiters such as the slash (/) appear in the picture_string, leading zeros can be omitted. For example, the following calls to CEECBLDY would each assign the same value, 148155 (02 June 1988), to COBINTDATE:

```
MOVE '6/2/88' TO DATEVAL.
MOVE 'MM/DD/YY' TO PICSTR.
CALL CEECBLDY USING DATEVAL, PICSTR, COBINTDATE, fc);

MOVE '06/02/88' TO DATEVAL.
MOVE 'MM/DD/YY' TO PICSTR.
CALL CEECBLDY USING DATEVAL, PICSTR, COBINTDATE, fc);

MOVE '060288' TO DATEVAL.
MOVE 'MMDDYY' TO PICSTR.
CALL CEECBLDY USING DATEVAL, PICSTR, COBINTDATE, fc);

MOVE '88154' TO DATEVAL.
MOVE 'YYDDD' TO PICSTR.
CALL CEECBLDY USING DATEVAL, PICSTR, COBINTDATE, fc);
```

Whenever characters such as colons or slashes are included in the picture_string (such as HH:MI:SS YY/MM/DD), they count as placeholders but are otherwise ignored. See Table 33 on page 489 for a list of valid picture character terms and Table 34 on page 490 for examples of valid picture strings.

If picture_string includes a Japanese Era symbol <JJJJ>, the YY position in input_char_date is replaced by the year number within the Japanese Era. For example, the year 1988 equals the Japanese year 63 in the Showa era. See Table 34 on page 490 for an additional example. See also Table 35 on page 490 for a list of Japanese Eras supported by CEEDATE.

If picture_string includes era symbol <CCCC> or <CCCCCCCC>, the YY position in input_char_date is replaced by the year number within the era. See Table 34 on page 490 for an additional example.

**output_Integer_date (output)**
A 32-bit binary integer representing the COBOL Integer date, the number of days since 31 December 1600. For example, 16 May 1988 is day number 141485. If input_char_date does not contain a valid date, output_Integer_date is set to 0 and CEECBLDY terminates with a non-CEE000 symbolic feedback code. Date calculations are performed easily on the output_Integer_date, because output_Integer_date is an integer. Leap year and end-of-year anomalies do not affect the calculations.

**fc (output)**
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can arise from this service:
<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2EB</td>
<td>3</td>
<td>2507</td>
<td>Insufficient data was passed to CEEDAYS or CEESCS. The Lilian value was not calculated.</td>
</tr>
<tr>
<td>CEE2EC</td>
<td>3</td>
<td>2508</td>
<td>The date value passed to CEEDAYS or CEESCS was invalid.</td>
</tr>
<tr>
<td>CEE2ED</td>
<td>3</td>
<td>2509</td>
<td>The era passed to CEEDAYS or CEESCS was not recognized.</td>
</tr>
<tr>
<td>CEE2EH</td>
<td>3</td>
<td>2513</td>
<td>The input date passed in a CEEISEC, CEEDAYS, or CEESCS call was not within the supported range.</td>
</tr>
<tr>
<td>CEE2EL</td>
<td>3</td>
<td>2517</td>
<td>The month value in a CEEISEC call was not recognized.</td>
</tr>
<tr>
<td>CEE2EM</td>
<td>3</td>
<td>2518</td>
<td>An invalid picture string was specified in a call to a date/time service.</td>
</tr>
<tr>
<td>CEE2EO</td>
<td>3</td>
<td>2520</td>
<td>CEEDAYS detected non-numeric data in a numeric field, or the date string did not match the picture string.</td>
</tr>
<tr>
<td>CEE2EP</td>
<td>3</td>
<td>2521</td>
<td>The (&lt;JJJ&gt;) or (&lt;CCCC&gt;) year-within-era value passed to CEEDAYS or CEESCS was zero.</td>
</tr>
</tbody>
</table>

**Usage notes**

- The probable cause for receiving message number 2518 is a picture string that contains an invalid DBCS string. You should verify that the data in the picture string is correct.
- z/OS UNIX consideration—In multithread applications, CEECBLDY affects only the calling thread.

**For more information**

- See the INTDATE COBOL compiler installation option in the appropriate version of the COBOL programming guide in the COBOL library at [Enterprise COBOL for z/OS library](http://www.ibm.com/support/docview.wss?uid=swg27036733) for information about how to get ANSI integer values from COBOL Intrinsic Functions that are compatible with the Language Environment callable services CEEDAYS and CEEDATE.
- See "CEESCEN—Set the century window" on page 396 for more information about the CEESCEN callable service.
- See Table 33 on page 489 for a list of valid picture character terms that can be specified in input_char_date.

CEECMI—Store and load message insert data

CEECMI copies message insert data and loads the address of that data into the Instance Specific Information (ISI) associated with the condition being processed. CEECMI also allocates storage for the ISI, if necessary. The number of ISIs per thread is determined by the MSGQ runtime option. ISIs are released when the value specified in the MSGQ runtime option is exceeded. The least recently used ISI is overwritten.

If you plan on using a routine that signals a new condition with a call to the CEESGL callable service, you should first call CEECMI to copy any insert information into the ISI associated with the condition.

Syntax

```plaintext
►► CEECMI(cond_rep, insert_seq_num, insert_data, fc)◄◄
```

cond_rep (input/output)
A condition token that defines the condition for which the q_data_token is retrieved.

insert_seq_num (input)
A 4-byte integer that contains the insert sequence number (such as insert 1, insert 2). It corresponds to an insert number specified with an ins tag in the message source file created by the CEEBLDTX EXEC.

insert_data (input)
A halfword-prefixed length string that represents the insert data. The entire length described in the halfword prefix is used without truncation. DBCS strings must be enclosed within shift-out (X'0E') and shift-in (X'0F') characters. The maximum size for an individual insert data item is 254 bytes.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can arise from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>

<td>0463</td>
<td>The maximum size for an insert data item was exceeded.</td>
</tr>
<tr>
<td>CEE0H9</td>
<td>3</td>
<td>0553</td>
<td>An internal error was detected in creating the inserts for a condition.</td>
</tr>
</tbody>
</table>

Usage notes

- z/OS UNIX consideration—In multithread applications, CEECMI applies to message insert data for only the calling thread.

For more information

- See “MSGQ” on page 58 for more information about the MSGQ runtime option.
- For more information about CEEBLDTX, see z/OS Language Environment Programming Guide

Examples

1. Following is an example of CEECMI called by C/C++.

```
CEECRHP—Create new additional heap

CEECRHP lets you define additional heaps. It returns a unique heap_id. The heaps defined by CEECRHP can be used just like the initial heap (heap_id=0), below heap, and anywhere heap. Unlike the heaps created by these heap services, all heap elements within an additional heap can be quickly freed by a single call to CEEDSHP (discard heap). The number of heaps supported by Language Environment is limited only by the amount of virtual storage available.

Syntax

```
CEECRHP(heap_id,initial_size,increment,options,fc)
```

**heap_id (output)**

A fullword binary signed integer. heap_id is the heap identifier of the created heap. If a new heap cannot be created, the value of heap_id remains undefined. Storage obtained from heap_ids 79 and 80 is set to binary 0 independent of any initialization value specified by the STORAGE option.

**initial_size (input)**

A fullword binary signed integer. initial_size is the initial amount of storage, in bytes, allocated for the new heap. initial_size is rounded up to the nearest increment of 4096 bytes. If initial_size is specified as 0, then the init_size specified in the HEAP runtime option is used. If no HEAP runtime option was provided and initial_size is specified as 0, CEECRHP uses the system-level or region-level default.

**increment (input)**

A fullword binary signed integer. When it is necessary to enlarge the heap to satisfy an allocation request, increment represents the number of bytes by which the heap is extended. increment is rounded up to the nearest 4096 bytes. If increment is specified as 0, then the incr_size specified in the HEAP run time option is used. If no HEAP runtime option was provided and increment equals 0, CEECRHP uses the installation default.

**options (input)**

A fullword binary signed integer. options are specified with the decimal codes, as shown in Table 25.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>HEAP attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Use same attributes as the initial heap (copy them from the HEAP runtime option)</td>

</tbody>
</table>

fc (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can arise from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE0P2</td>
<td>4</td>
<td>0802</td>
<td>Heap storage control information was damaged.</td>
</tr>
<tr>
<td>CEE0P4</td>
<td>3</td>
<td>0804</td>
<td>The initial size value supplied in a create heap request was unsupported.</td>
</tr>
<tr>
<td>CEE0P5</td>
<td>3</td>
<td>0805</td>
<td>The increment size value supplied in a create heap request was unsupported.</td>
</tr>
<tr>
<td>CEE0P6</td>

</tr>
<tr>
<td>CEE0PD</td>
<td>3</td>
<td>0813</td>
<td>Insufficient storage was available to satisfy a get storage request.</td>
</tr>
</tbody>
</table>

Usage notes

- *z/OS UNIX consideration—CEECRHP applies to the enclave.*
- The heapid can only be used by the TCB on which the CEECRHP request was issued. Using the heapid on other TCBs is not supported and will generate unpredictable results.

For more information

- See "CEEDSHP—Discard heap" on page 258 for more information about the CEDSHP callable service.
- See "HEAP" on page 38 for more information about the HEAP runtime option and IBM-supplied defaults.
Examples

1. Following is an example of CEECRHP called by C/C++.

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {
    _INT4 heapid, size, increment, options;
    // Feedback output
    int fc;

    // Set heap identifier
    heapid = 0;
    // Initial size of heap
    size = 4096;
    // Increment to extend heap
    increment = 4096;
    // Options: set-up heap
    options = 72;

    // Create heap using CEECRHP
    CEECRHP(&heapid, &size, &increment, &options, &fc);

    // Check the first 4 bytes of the feedback token
    if (_FBCHECK(fc, CEE000) != 0) {
        printf("CEECRHP failed with message number %d\n", fc.tok_msgno);
        exit(99);
    }

    // Discard the heap
    CEEDSHP(&heapid, &fc);

    // Check the first 4 bytes of the feedback token
    if (_FBCHECK(fc, CEE000) != 0) {
        printf("CEEDSHP failed with message number %d\n", fc.tok_msgno);
        exit(99);
    }
}
```

2. Following is an example of CEECRHP called by COBOL.

CEECZST—Reallocate (change size of) storage

CEECZST changes the size of a previously allocated heap element. The address parameter points to the beginning of the heap element. The new_size parameter gives the new size of the heap element, in bytes. The contents of the heap element are unchanged up to the shorter of the new and old sizes.

The CEECZST service returns a pointer to the reallocated heap element. It can move the storage location of the heap element. As a result, the address parameter passed to CEECZST is not necessarily the same as the value returned.

Because the new storage might be allocated at a different location from the existing allocation, any pointers (specifically any addresses) that referred to the old storage become invalid. Continued use of such dangling pointers gives unpredictable, and almost certainly incorrect, results.

The heap identifier is inferred from the address. The new storage block is allocated from the same heap that contained the old block.

The contents of the old storage are preserved in the following manner:
- If new_size is greater than the old size, the entire contents of the old storage block are copied to the new block. The remaining bytes in the new element are left uninitialized unless an initialization suboption value was specified for the heap in the STORAGE option.
If new_size is less than the old size, the contents of the old block are truncated to the size of the new block.

If new_size is equal to the old size, no operations are performed; a successful feedback code is returned.

Syntax

```
►►CEECZST—(address,—new_size,—fc)—◄◄
```

address (input/output)
A fullword address pointer. On input, this parameter contains an address returned by a previous CEEGTST call. On output, the address of the first byte of the newly allocated storage is returned in this parameter.

new_size (input)
A fullword binary signed integer. new_size is the number of bytes of storage to be allocated for the new heap element.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE0P2</td>
<td>4</td>
<td>0802</td>
<td>Heap storage control information was damaged.</td>
</tr>
<tr>
<td>CEE0P8</td>
<td>3</td>
<td>0808</td>
<td>Storage size in a get storage request or a reallocate request was not a positive number.</td>
</tr>
<tr>
<td>CEE0PA</td>
<td>3</td>
<td>0810</td>
<td>The storage address in a free storage request was not recognized, or heap storage control information was damaged.</td>
</tr>
<tr>
<td>CEE0PD</td>
<td>3</td>
<td>0813</td>
<td>Insufficient storage was available to satisfy a get storage request.</td>
</tr>
</tbody>
</table>

Usage notes

• Storage that is reallocated maintains the same mark/release status as the old storage block. If the old storage block was marked, the new storage block carries the same mark and is released by a release operation that specifies that mark.

• z/OS UNIX consideration—CEECZST applies to the enclave.

• The _CEE_REALLOC_CONTROL environment variable provides additional levels of storage control, which can aid CEECZST to more efficiently use storage. For more information about _CEE_REALLOC_CONTROL, see z/OS XL C/C++ Programming Guide

For more information

• See “STORAGE” on page 81 for more information about the STORAGE runtime option.
• For information about CEEGTST, see “CEEGTST—Get heap storage” on page 315.

Examples

1. Following is an example of CEECZST called by C/C++.

```c
/*Module/File Name: EDCCZST */
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {  
  _INT4 heapid, size;
  _POINTER address;
  _FEEDBACK fc;
  
  heapid = 0; /* get storage from initial heap */
  size = 4000; /* number of bytes of heap storage */

  /* obtain the storage using CEEGTST */
  CEEGTST(&heapid,&size,&address,&fc);

  /* check the first 4 bytes of the feedback token */
  /* {0 if successful} */
  if ( _FBCHECK ( fc, CEE000 ) != 0 ) {  
    printf("CEEGTST failed with message number %d\n", fc.tok_msgno);
    exit(99);
  }
  
  size = 2000; /* new size of storage element */

  /* change the size of the storage element */
  CEECZST(&address,&size,&fc);

  /* check the first 4 bytes of the feedback token */
  /* {0 if successful} */
  if ( _FBCHECK ( fc, CEE000 ) != 0 ) {  
    printf("CEECZST failed with message number %d\n", fc.tok_msgno);
    exit(99);
  }
  
  /* free the storage that was previously obtained */
  /* using CEEGTST */
  CEEFRST(&address,&fc);

  /* check the first 4 bytes of the feedback token */
  /* {0 if successful} */
  if ( _FBCHECK ( fc, CEE000 ) != 0 ) {  
    printf("CEEFRST failed with message number %d\n", fc.tok_msgno);
    exit(99);
  }
}
```

---

**CEEDATE—Convert Lilian date to character format**

CEEDATE converts a number representing a Lilian date to a date written in character format. The output is a character string, such as 1993/09/09.

Do not use CEEDATE in combination with COBOL intrinsic functions.

The inverse of CEEDATE is CEE DAYS, which converts character dates to the Lilian format.

CEEDATE is affected only by the country code setting of the COUNTRY runtime option or CEE3CTY callable service, not the CEESETL callable service or the setlocale() function.

```
Syntax

CEE DATE(—input_Lilian_date—,—picture_string—,—output_char_date—)

—fc—
```
**input_Lilian_date** *(input)*

A 32-bit integer representing the Lilian date. The Lilian date is the number of days since 14 October 1582. For example, 16 May 1988 is Lilian day number 148138. The valid range of Lilian dates is 1 to 3,074,324 (15 October 1582 to 31 December 9999).

**picture_string** *(input)*

A halfword length-prefixed character string (VSTRING), representing the desired format of **output_char_date**, for example MM/DD/YY. Each character in **picture_string** represents a character in **output_char_date**. If delimiters such as the slash (/) appear in the picture string, they are copied to **output_char_date**.

See Table 33 on page 489 for a list of valid picture characters, and Table 34 on page 490 for examples of valid picture strings.

If **picture_string** is null or blank, CEEDATE gets **picture_string** based on the current value of the COUNTRY runtime option. For example, if the current value of the COUNTRY runtime option is US (United States), the date format would be MM/DD/YY. If the current COUNTRY value is FR (France), the date format would be MM/DD/YY HH:MM:SS AM (or PM), for example: 09/09/93 4:56:29 PM. This default mechanism makes it easy for translation centers to specify the preferred date, and for applications and library routines to use this format automatically.

If **picture_string** includes a Japanese Era symbol <JJJJ>, the YY position in **output_char_date** is replaced by the year number within the Japanese Era. For example, the year 1988 equals the Japanese year 63 in the Showa era. See Table 34 on page 490 for an additional example. Also see Table 35 on page 490 for a list of Japanese Eras supported by CEEDATE.

If **picture_string** includes an era symbol <CCCC> or <CCCCCCCC>, the YY position in **output_char_date** is replaced by the year number within the era. See Table 34 on page 490 for an example.

**output_char_date** *(output)*

A fixed-length 80-character string (VSTRING), is the result of converting **input_Lilian_date** to the format specified by **picture_string**. See Table 26 on page 237 for sample output dates. If **input_Lilian_date** is not valid, **output_char_date** is set to all blanks. CEEDATE terminates with a non-CEE000 symbolic feedback code.

**fc** *(output)*

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2EG</td>
<td>3</td>
<td>2512</td>
<td>The Lilian date value was not within the supported range.</td>
</tr>
<tr>
<td>CEE2EM</td>
<td>3</td>
<td>2518</td>
<td>An incorrect picture string was specified.</td>
</tr>
<tr>
<td>CEE2EQ</td>
<td>3</td>
<td>2522</td>
<td>&lt;JJJJ&gt;, &lt;CCCC&gt; or &lt;CCCCCCCC&gt; was used in a picture string passed to CEEDATE, but the Lilian date value was not within the supported range. The Era could not be determined.</td>
</tr>
<tr>
<td>CEE2EU</td>
<td>2</td>
<td>2526</td>
<td>The date string returned by CEEDATE was truncated.</td>
</tr>
</tbody>
</table>
Usage notes

- The probable cause for receiving message number 2518 is a picture string that contains a DBCS string that is not valid. You should verify that the data in the picture string is correct.
- To create a null VSTRING, set the length to zero; the content of the text portion does not matter. To create a blank VSTRING, any length greater than zero can be used; the content of the text portion must be spaces or blanks.
- z/OS UNIX consideration—In multithread applications, CEEDATE applies to the enclave.

For more information

- See the INTDATE COBOL compiler installation option in the appropriate version of the COBOL programming guide in the COBOL library at Enterprise COBOL for z/OS library (http://www.ibm.com/support/docview.wss?uid=swg27036733) for information about how to get Lilian integer values from COBOL intrinsic functions that are compatible with the Language Environment callable services CEEDAYS and CEEDATE.
- See "CEEDAYS—Convert date to Lilian format" on page 243 for more information about the CEEDAYS callable service.
- See "COUNTRY" on page 24 for more information about the COUNTRY runtime option.
- See "CEEFMDA—Get default date format" on page 270 for information about how to get the default format for a given country code.

Examples

1. Following is an example of CEEDATE called by C/C++.

```c
#include <leawi.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <ceeedcct.h>

int main(void) {
    _FEEDBACK fc;
    _INT4 lil_date = 139370; /* May 14, 1964 */
    _VSTRING date_pic,date;
    _CHAR80 date_out;
    strcpy(date_pic.string, "The date is Wwww, Mmmm ZD, YYYY");
    date_pic.length = strlen(date_pic.string);
    CEEDATE(&lil_date,&date_pic,date_out,&fc);
    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEEDATE failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    printf("%.80s\n",date_out);
}
```

CEEDATM—Convert seconds to character timestamp

CEEDATM converts a number representing the number of seconds since 00:00:00 14 October 1582 to a character string format. The format of the output is a character string timestamp, for example: 1988/07/26 20:37:00.

The inverse of CEEDA is CEESECS, which converts a timestamp to number of seconds.

CEEDATM is affected only by the country code setting of the COUNTRY runtime option or CEE3CTY callable service, not the CEESETL callable service or the setlocale() function.

Syntax

```
►►CEEDATM—(—input_seconds—,—picture_string—,—output_timestamp—,—fc—)
```

input_seconds (input)
A 64-bit double floating-point number representing the number of seconds since 00:00:00 on 14 October 1582, not counting leap seconds. For example, 00:00:01 on 15 October 1582 is second number 86,401 (24*60*60 + 01). The valid range of input_seconds is 86,400 to 265,621,679,999.999 (23:59:59.999 31 December 9999).

picture_string (input)
A halfword length-prefixed character string (VSTRING), representing the desired format of output_timestamp, for example, "MM/DD/YY HH:MI AP".

Each character in the picture_string represents a character in output_timestamp. If delimiters such as a slash (/) appear in the picture string, they are copied as is to output_timestamp.

See Table 33 on page 489 for a list of valid picture character terms and Table 34 on page 490 for examples of valid picture strings.

If picture_string is null or blank, CEEDATM gets picture_string based on the current value of the COUNTRY runtime option. For example, if the current value of the COUNTRY runtime option is US (United States), the date-time format would be "MM/DD/YY HH:MI:SS AP"; if the current COUNTRY value is FR (France), however, the date-time format would be "DD.MM.YYYY HH:MI:SS".

238  z/OS Language Environment Programming Reference
If `picture_string` includes the Japanese Era symbol `<JJJJ>`, the YY position in `output_timestamp` represents the year within Japanese Era. See Table 34 on page 490 for an example. See Table 35 on page 490 for a list of Japanese Eras supported by CEEDATM.

If `picture_string` includes era symbol `<CCCC>` or `<CCCCCCCC>`, the YY position in `output_timestamp` represents the year within the era. See Table 34 on page 490 for an example.

**output_timestamp (output)**

A fixed-length 80-character string (VSTRING), that is the result of converting `input_seconds` to the format specified by `picture_string`. If necessary, the output is truncated to the length of `output_timestamp`. See Table 27 on page 243 for sample output.

If `input_seconds` is not valid, `output_timestamp` is set to all blanks and CEEDATM terminates with a non-CEE000 symbolic feedback code.

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2E9</td>
<td>3</td>
<td>2505</td>
<td>The number-of-seconds value was not within the supported range.</td>
</tr>
<tr>
<td>CEE2EA</td>
<td>3</td>
<td>2506</td>
<td><code>&lt;JJJJ&gt;</code>, <code>&lt;CCCC&gt;</code> or <code>&lt;CCCCCCCC&gt;</code> was used in a picture string passed to CEEDATM, but the input number-of-seconds value was not within the supported range. The Era could not be determined.</td>
</tr>
<tr>
<td>CEE2EM</td>
<td>3</td>
<td>2518</td>
<td>An invalid picture string was specified.</td>
</tr>
<tr>
<td>CEE2EV</td>
<td>2</td>
<td>2527</td>
<td>The timestamp string returned by CEEDATM was truncated.</td>
</tr>
<tr>
<td>CEE3CF</td>
<td>2</td>
<td>3471</td>
<td>The country code <code>country-code</code> was not valid for CEEFMDT. The default date and time picture string <code>datetime-string</code> was returned.</td>
</tr>
</tbody>
</table>

**Usage notes**

- The probable cause for receiving message number 2518 is a picture string that contains a DBCS string that is not valid. You should verify that the data in the picture string is correct.
- To create a null VSTRING, set the length to zero; the content of the text portion does not matter. To create a blank VSTRING, any length greater than zero can be used; the content of the text portion must be spaces or blanks.
- z/OS UNIX consideration—In multithread applications, CEEDATM applies to the enclave.

**For more information**

- See “CEEDATM—Convert timestamp to seconds” on page 407 for more information about the CEESECS callable service.
- See “COUNTRY” on page 24 for more information about the COUNTRY runtime option.
CEEDATM

- See “CEEFMDT—Get default date and time format” on page 273 for information about how to get a default timestamp for a given country code.

Examples

1. Following is an example of CCEEDATM called by C/C++.

```c
#include <leawi.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <ceeedcct.h>

int main(void) {

    /* September 13, 1991 at 11:23:23 PM */
    _FLOAT8 seconds = 12904183403.0;
    _VSTRING date, date_pic;
    _CHAR80 out_date;
    _FEEDBACK fc;

    strcpy(date_pic.string, 
            "Mmmmmmmmmmmz DD, YYYY at ZH:MI:.SS AP");
    date_pic.length = strlen(date_pic.string);

    CCEEDATM(&seconds, &date_pic, out_date, &fc);

    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEEDATM failed with message number %d
", 
                fc.tok_msgno);
        exit(2999);
    }

    printf("%.80s\n", out_date);
}
```

2. Following is an example of CCEEDATM called by COBOL.

```cobol
IDENTIFICATION DIVISION.

CEEDAYS—Convert date to Lilian format

CEEDAYS converts a string representing a date into a Lilian format, which represents a date as the number of days from the beginning of the Gregorian calendar. CEEDAYS converts the specified input_char_date to a number representing the number of days since day one in the Lilian format: Friday, 14 October, 1582.

The inverse of CEEDAYS is CEEDATE, which converts output_Lilian_date from Lilian format to character format.

Do not use CEEDAYS in combination with COBOL intrinsic functions unless the programs are compiled with the INTDATE(LILIAN) compiler option. Use CEECBLDY for COBOL programs that use intrinsic functions and that are compiled with INTDATE(ANSI).
To handle dates earlier than 1601, it is possible to add 4000 to each year, convert to Lilian, calculate, subtract 4000 from the result, and then convert back to character format.

By default, 2-digit years lie within the 100-year range starting 80 years prior to the system date. Thus, in 1995, all 2-digit years represent dates between 1915 and 2014, inclusive. This default range is changed by using the callable service CEESCEN.

Syntax

```
CEEDAYS(input_char_date, picture_string, output_Lilian_date, fc)
```

**input_char_date (input)**

A halfword length-prefixed character string (VSTRING), representing a date or timestamp, in a format conforming to that specified by `picture_string`.

The character string must contain between 5 and 255 characters, inclusive. `input_char_date` can contain leading or trailing blanks. Parsing for a date begins with the first nonblank character (unless the picture string itself contains leading blanks, in which case CEEDAYS skips exactly that many positions before parsing begins).

After parsing a valid date, as determined by the format of the date specified in `picture_string`, CEEDAYS ignores all remaining characters. Valid dates range between and include 15 October 1582 to 31 December 9999. See Table 33 on page 489 for a list of valid picture character terms that can be specified in `input_char_date`.

**picture_string (input)**

A halfword length-prefixed character string (VSTRING), indicating the format of the date specified in `input_char_date`.

Each character in the `picture_string` corresponds to a character in `input_char_date`. For example, if you specify MMDDYY as the `picture_string`, CEEDAYS reads an `input_char_date` of 060288 as 02 June 1988.

If delimiters such as a slash (/) appear in the picture string, leading zeros can be omitted. For example, the following calls to CEEDAYS, would each assign the same value, 148155 (02 June 1988), to `lildate`.

```
CALL CEEDAYS('6/2/88', 'MM/DD/YY', lildate, fc);
CALL CEEDAYS('06/02/88', 'MM/DD/YY', lildate, fc);
CALL CEEDAYS('060288', 'MMDDYY', lildate, fc);
CALL CEEDAYS('068154', 'YYDDD', lildate, fc);
CALL CEEDAYS('1988154', 'YYYYDDD', lildate, fc);
```

Whenever characters such as colons or slashes are included in the `picture_string` (such as HH:MI:SS YY/MM/DD), they count as placeholders but are otherwise ignored. See Table 33 on page 489 for a list of valid picture character terms and Table 34 on page 490 for examples of valid picture strings.

If `picture_string` includes a Japanese Era symbol <JJJJ>, the YY position in `input_char_date` is replaced by the year number within the Japanese Era. For example, the year 1988 equals the Japanese year 63 in the Showa era. See
Table 34 on page 490 for an additional example. See also Table 35 on page 490 for a list of Japanese Eras supported by CEEDATE.

If picture_string includes era symbol <CCCC> or <CCCCCCCC>, the YY position in input_char_date is replaced by the year number within the era. See Table 34 on page 490 for an additional example.

output_Lilian_date (output)

A 32-bit binary integer representing the Lilian date, the number of days since 14 October 1582. For example, 16 May 1988 is day number 148138.

If input_char_date does not contain a valid date, output_Lilian_date is set to 0 and CEE DAYS terminates with a non-CEE000 symbolic feedback code.

Date calculations are performed easily on the output_Lilian_date, because it is an integer. Leap year and end-of-year anomalies do not affect the calculations.

fc (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2EB</td>
<td>3</td>
<td>2507</td>
<td>Insufficient data was passed to CEE DAYS or CEESECS. The Lilian value was not calculated.</td>
</tr>
<tr>
<td>CEE2EC</td>
<td>3</td>
<td>2508</td>
<td>The date value passed to CEE DAYS or CEESECS was not valid.</td>
</tr>
<tr>
<td>CEE2ED</td>
<td>3</td>
<td>2509</td>
<td>The era passed to CEE DAYS or CEESECS was not recognized.</td>
</tr>
<tr>
<td>CEE2EH</td>
<td>3</td>
<td>2513</td>
<td>The input date was not within the supported range.</td>
</tr>
<tr>
<td>CEE2EL</td>
<td>3</td>
<td>2517</td>
<td>The month value was not recognized.</td>
</tr>
<tr>
<td>CEE2EM</td>
<td>3</td>
<td>2518</td>
<td>An incorrect picture string was specified.</td>
</tr>
<tr>
<td>CEE2EO</td>
<td>3</td>
<td>2520</td>
<td>CEE DAYS detected non-numeric data in a numeric field, or the date string did not match the picture string.</td>
</tr>
<tr>
<td>CEE2EP</td>
<td>3</td>
<td>2521</td>
<td>The year-within-era value passed to CEE DAYS or CEESECS was zero.</td>
</tr>
</tbody>
</table>

Usage notes

- The probable cause for receiving message number 2518 is a picture string that contains a DBCS string that is not valid. You should verify that the data in the picture string is correct.
- z/OS UNIX consideration—In multithread applications, CEE DAYS applies to the enclave.

For more information

- See the INTDATE COBOL compiler installation option in the appropriate version of the COBOL programming guide in the COBOL library at Enterprise COBOL for z/OS library (http://www.ibm.com/support/docview.wss?uid=swg27036733) for information about how to get Lilian integer values from COBOL intrinsic functions that are compatible with the Language Environment callable services CEE DAYS and CEE DATE.
CEEDAYS

- See “CEEDATE—Convert Lilian date to character format” on page 232 for more information about the CEEDATE runtime option.
- See “CEESCEN—Set the century window” on page 396 for more information about the CEESCEN callable service.

Examples

1. Following is an example of CEEDAYS called by C/C++.

```c
#include <leawi.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <ceeedcct.h>

int main(void)
{
    _FEEDBACK fc;
    _INT4 lil_date1, lil_date2;
    _VSTRING date, date_pic;

    /* use CEEDAYS to get the Lilian format */
    strcpy(date.string, "05/14/64");
    date.length = strlen(date.string);
    strcpy(date_pic.string, "MM/DD/YY");
    date_pic.length = strlen(date_pic.string);
    CEEDAYS(&date, &date_pic, &lil_date1, &fc);
    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEEDAYS failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }

    /* use CEEDAYS to get the Lilian format */
    strcpy(date.string, "August 14, 1966");
    date.length = strlen(date.string);
    strcpy(date_pic.string, "MmmmmmmmmDD, YYYY");
    date_pic.length = strlen(date_pic.string);
    CEEDAYS(&date, &date_pic, &lil_date2, &fc);
    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEEDAYS failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }

    /* subtract the two Lilian dates to find out */
    /* difference in days */
    printf("The number of days between\n"  " May 14, 1964 and August 14, 1966\n"  " is: %d\n", lil_date2 - lil_date1);
}
```

CEEDCOD—Decompose a condition token

CEEDCOD alters an existing condition token. Language Environment-conforming HLLs can decompose or alter the condition token fields without using the CEEDCOD service. See the CEESGL HLL examples in “Examples” on page 419 for examples of how to alter the condition token field.

Syntax

CEEDCOD (cond_token, c_1, c_2, case, severity, control, facility_ID, i_s_info, fc)

cond_token (input)
A 12-byte condition token representing the current condition or feedback information.

c_1 (output)
A 2-byte binary integer representing the value of the first 2 bytes of the condition_ID.

c_2 (output)
A 2-byte binary integer representing the value of the second 2 bytes of the condition_ID. See “CEENCOD—Construct a condition token” on page 379 for a detailed explanation of the condition_ID.

case (output)
A 2-byte binary integer field defining the format of the condition_ID portion of the token. A value of 1 identifies a case 1 condition. A value of 2 identifies a case 2 condition. The values 0 and 3 are reserved.

severity (output)
A 2-byte binary integer representing the severity of the condition. severity specifies the following values:

0 Information only (or, if the entire token is zero, no information).
1 Warning—service completed, probably correctly.
2 Error detected—correction attempted; service completed, perhaps incorrectly.
3 Severe error—service not completed.
**CEEDCOD**

4 Critical error—service not completed; condition signaled. A critical error is a condition that jeopardizes the environment. If a critical error occurs during a Language Environment callable service, instead of returning synchronously to the caller, the condition manager is always signaled.

**control (output)**

A 2-byte binary integer containing flags describing aspects of the state of the condition. Valid values for the control field are 1 and 0.

- **1** Indicates that the *facility_ID* is assigned by IBM.
- **0** indicates the *facility_ID* is assigned by the user.

**facility_ID (output)**

A 3-character field containing three alphanumeric characters identifying the product generating the condition or feedback information.

**i_s_info**

A fullword binary integer that identifies the ISI associated with the given instance of the condition represented by the condition token where it is contained. If an ISI is not associated with a given condition token, the *i_s_info* field contains a value of binary zero.

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to *Invoking callable services* on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE036</td>
<td>3</td>
<td>0102</td>
<td>An unrecognized condition token was passed to routine and could not be used.</td>
</tr>
</tbody>
</table>

**Usage notes**

- C/C++ considerations—The structure of the condition token (type.Feedback) is described in the *leawi.h* header file shipped with Language Environment. C users can assign values directly to the fields of the token in the header file without using the CEENCOD service. The layout of the type.Feedback condition token in the header file is shown in Figure 12 on page 381.
- z/OS UNIX consideration—In multithread applications, CEEDCOD affects only the calling thread.

**For more information**

- See the CEESGL HLL examples starting in “Examples” on page 419 for examples of how to alter the condition token field.
- See “CEEDCOD—Construct a condition token” on page 379 for a detailed explanation of the condition_ID.
- See CEENCOD “Usage notes” on page 380 for a discussion of case 1 and case 2 types.
- See the *facility_ID* parameter of “CEEDCOD—Construct a condition token” on page 379 for more information.
- For more C user information about assigning values directly to the fields of the token in the header file without using the CEENCOD service, see the example for “CEESGL—Signal a condition” on page 417.
Examples

1. Following shows an example of CEEDCOD being called by C/C++.

   /*Module/File Name: EDCDCOD*/

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

/****************************************************/
/* In C/C++ it is not necessary to use this service.*/
/* The fields can be manipulated directly.  See the */
/* example for CEESGL to see how to manipulate       */
/* condition token fields directly.                 */
/****************************************************/

int main(void) {
    _FEEDBACK fc, newfc;
    _INT2 c_1, c_2, cond_case, sev, control;
    _CHAR3 facid;
    _INT4 isi, heapid, size;
    _POINTER address;

    heapid = 0;
    size = 4000;

    CEEGTST(&heapid, &size, &address, &fc);
    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEEGTST failed with msgno %d\n", fc.tok_msgno);
        exit(2999);
    }

    /* decompose the feedback token to check for errors */
    CEEDCOD(&fc, &c_1, &c_2, &cond_case, &sev, &control, facid, ;
             &isi, &newfc);
    if (_FBCHECK (newfc, CEE000) != 0) {
        printf("CEEDCOD failed with msgno %d\n", 
                newfc.tok_msgno);
        exit(2889);
    }

    if (c_1 != 0 || c_2 != 0)  
        printf("c_1 and c_2 returned from CEEDCOD should be 0\n");
    /* */
    /* */
}
```

CEEDLYM—Suspend processing of the active enclave in milliseconds

CEEDLYM provides a service for Language Environment-conforming applications that suspends the processing of the active enclave for a specified number of milliseconds. The maximum is 1 hour.

Syntax

CEEDLYM(—input_milliseconds—,—fc—)

input_milliseconds
A full-word binary value in the range of 0 to 3,600,000 that specifies the total number of milliseconds during which the enclave should be suspended.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE3QQ</td>
<td>1</td>
<td>CEE3930W</td>
<td>The input value input_value in a call to the callable service callable_service_name was not within the valid range.</td>
</tr>
<tr>
<td>CEE3QR</td>
<td>1</td>
<td>CEE3931W</td>
<td>CEEDLYM was invoked in a CICS environment.</td>
</tr>
</tbody>
</table>
Usage notes

- CICS consideration—CEEDLYM is not available under CICS.
- z/OS UNIX consideration—CEEDLYM is handled by the z/OS UNIX System Services when POSIX is set to ON.
- This service is not intended for timing requests. Delays up to the nearest millisecond might occur in some circumstances.
- In a multi-threaded application, only the calling thread is suspended.

Examples

1. Following is an example of CEEDLYM called by C/C++.

```c
int main(void)
{
    _INT4 millisecs, lil_date;
    _FLOAT8 local_date;
    _CHAR17 gregorian_date;
    _FEEDBACK fc1, fc2;

    /* Get current date and time */
    CEELOCT(&lil_date,&local_date,gregorian_date,&fc1);
    if ( _FBCHECK ( fc1 , CEE000 ) != 0 ) {
        printf("CEELOCT failed with message number %d\n", fc1.tok_msgno);
        exit(2999);
    }

    printf("CEEDLYM Start time : %.17s\n", gregorian_date);
    millisecs = 5000;
    CEEDLYM(&millisecs,&fc2);

    if ( _FBCHECK ( fc2 , CEE000 ) != 0 ) {
        printf("CEEDLYM failed with message number %d\n",fc2.tok_msgno);
        exit(999);
    }

    CEELOCT(&lil_date,&local_date,gregorian_date,&fc1);
    if ( _FBCHECK ( fc1 , CEE000 ) != 0 ) {
        printf("CEELOCT failed with message number %d\n", fc1.tok_msgno);
        exit(2999);
    }

    printf("CEEDLYM Finish time : %.17s\n",gregorian_date);
}

```

CEEDLYM

**CEEDSHP—Discard heap**

CEEDSHP discards an entire heap created by CEECHRHP or by CEEGTST. CEECHRHP and CEEGTST return a unique heap_id to the caller; use this ID in the CEEDSHP call. A heap_id of 0 is not permitted with CEEDSHP.

Discarding a heap with CEEDSHP immediately returns all storage allocated to the heap to the operating system, even if the KEEP suboption has been specified with the HEAP runtime option.

**Syntax**

```
CEEDSHP(—heap_id—,—fc—)
```

**heap_id (input)**

A fullword binary signed integer. heap_id is a token specifying the discarded heap. A heap_id of 0 is not valid; the initial heap is logically created during enclave initialization and cannot be discarded.

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to [“Invoking callable services” on page 116](#) for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE0P2</td>
<td>4</td>
<td>0802</td>
<td>Heap storage control information was damaged.</td>
</tr>
<tr>
<td>CEE0P3</td>
<td>3</td>
<td>0803</td>
<td>The heap identifier in a get storage request or a discard heap request was unrecognized.</td>
</tr>
<tr>
<td>CEE0PC</td>
<td>3</td>
<td>0812</td>
<td>An invalid attempt to discard the Initial Heap was made.</td>
</tr>
</tbody>
</table>

**Usage notes**

- After the call to CEEDSHP, any existing pointers to storage allocated from this heap are dangling pointers, that is, pointers to storage that is freed. Using these pointers can cause unpredictable results.
- z/OS UNIX considerations—CEEDSHP applies to the enclave. Language Environment frees all storage in the heap regardless of which thread allocated it.
For more information

- For more information about the CEEDSHP callable service, see "CEECRHP—Create new additional heap" on page 223.
- For more information about the CEEGTST callable service, and "CEEGTST—Get heap storage" on page 315.

Examples

1. Following is an example of CEEDSHP being called by C/C++.

```c
/*Module/File Name: EOCDSHP */

#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void)
{
  _INT4 heapid, size, increment, options;
  _FEEDBACK fc;
  /*
   * */
  /* heap identifier is set */
  /* by CEECRHP */
  heapid = 0;
  size = 4096;
  increment = 4096;
  options = 72;
  /* create heap using CEECRHP */
  CEECRHP(&heapid,&size,&increment,&options,&fc);
  /* check the first 4 bytes of the feedback token */
  /* (0 if successful) */
  if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
    printf("CEECRHP failed with message number %d\n", fc.tok_msgno);
    exit(99);
  }
  /*
   * */
  /* discard the heap that was previously created */
  /* using CEECRHP */
  CEEDSHP(&heapid,&fc);
  /* check the first 4 bytes of the feedback token */
  /* (0 if successful) */
  if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
    printf("CEEDSHP failed with message number %d\n", fc.tok_msgno);
    exit(99);
  }
  /*
   * */
  }
}

CEEDYWK—Calculate day of week from Lilian date

CEEDYWK calculates the day of the week on which a Lilian date falls. The day of
the week is returned to the calling routine as a number between 1 and 7. The
number returned by CEEDYWK is useful for end-of-week calculations.

Syntax

CEEDYWK(—input_Lilian_date—,—output_day_no—,—fc—)

input_Lilian_date (input)
A 32-bit binary integer representing the Lilian date, the number of days since
14 October 1582. For example, 16 May 1988 is day number 148138. The valid
range of input_Lilian_date is between 1 and 3,074,324 (15 October 1582 and 31
December 9999).

output_day_no (output)
A 32-bit binary integer representing input_Lilian_date's day-of-week: 1 equals
Sunday, 2 equals Monday, ..., 7 equals Saturday. If input_Lilian_date is invalid,
output_day_no is set to 0 and CEEDYWK terminates with a non-CEE000
symbolic feedback code.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result
of this service. If you choose to omit this parameter, refer to “Invoking callable
services” on page 116 for the appropriate syntax to indicate that the feedback
code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2EG</td>
<td>3</td>
<td>2512</td>
<td>The Lilian date value passed in a call to CEEDATE or CEEDYWK was not within the supported range.</td>
</tr>
</tbody>
</table>
Usage notes

- z/OS UNIX consideration—In multithread applications, CEEDYWK affects only the calling thread.
- COBOL consideration—The CEEDYWK callable service has different values than the COBOL ACCEPT statement with conceptual data item DAY-OF-WEEK. Use one or the other, not both.

Examples

1. Following is an example of CEEDYWK called by C/C++.

```c
#include <string.h>
#include <stdio.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceeedcct.h>

int main (void) {
    _INT4 in_date, day;
    _FEEDBACK fc;

    in_date = 139370; /* Thursday */
    CEEDYWK(&in_date,&day,&fc);
    if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
        printf("CEEDYWK failed with message number \%d\n", fc.tok_msgno);
        exit(2999);
    }
    printf("Lilian date %d, occurs on a ",in_date);
    switch(day) {
        case 1: printf("Sunday.\n"); break;
        case 2: printf("Monday.\n"); break;
        case 3: printf("Tuesday.\n"); break;
        case 4: printf("Wednesday.\n"); break;
        case 5: printf("Thursday.\n"); break;
        case 6: printf("Friday.\n"); break;
        case 7: printf("Saturday.\n"); break;
        default: printf("ERROR! DAY RETURN BY CEEDYWK UNKNOWN\n"); break;
    }
}
```

GOBACK.
```

3. Following is an example of CEEDYWK called by PL/I.

**CEEENV—Process environmental variables**

CEEENV processes environment variables depending on the function code passed in as input. Based on the input to this function, CEEENV can do the following:

- Obtain the value for an existing environment variable
- Create a new environment variable with a value
- Clear all environment variables
- Delete an existing environment variable
- Overwrite the value for an existing environment variable

**Syntax**

```plaintext
►►CEEENV(―function_code―,―name_length―,―name―,―value_length―,―value―,―fc―)►◄
```

**function_code (input)**

A fullword binary integer containing the function code of one of the following values:

1. Searches the environment table for environment variables specified by `name` and if found returns a pointer to `value`.
2. Adds an environment variable to the environment table. It does not overwrite an existing environment variable.
3. Clears all environment variables from the environment table.
4. Deletes an environment variable from the environment table.
5 Overwrites an existing environment variable in the environment table and adds the environment variable if it does not exist.

**name_length (input)**
A fullword binary integer containing the length of the name for the environment variable. If the request is for function code 3, this argument is ignored.

**name (input)**
Specifies the name of an environment variable. If the request is for function code 3, this argument is ignored.

**value_length (input/output)**
A fullword binary integer containing the length of the value for the environment variable. This argument is input for setting or modifying an environment variable and is output for getting an environment variable value. If the request is for function code 3 or 4, this argument is ignored.

**value (input/output)**
A field that contains the address of a string that contains the value of the environment variable. This argument is input for setting or modifying an environment variable and is output for getting an environment variable value. If the request is for function code 3 or 4, this argument is ignored. For function code 1 (get), the value address is 0 (NULL) if the name is not found in the environment.

**fc (output)**
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE51O</td>
<td>3</td>
<td>5176</td>
<td>Not enough memory available.</td>
</tr>
<tr>
<td>CEE51P</td>
<td>3</td>
<td>5177</td>

</tr>
<tr>
<td>CEE51S</td>
<td>0</td>
<td>5180</td>
<td>The specified environment variable name already exists.</td>
</tr>
</tbody>
</table>

**Usage notes**
- The environment array is searched sequentially and the first occurrence of name is used.
- Because an application can manipulate the environment using the environ pointer, Language Environment cannot guarantee a single instance of any particular environment variable.
- For a function code 1 request, the storage returned for the value character string is supplied by Language Environment. There is one buffer per thread, making it the user's responsibility to use or save the value before the next call for a function code 1 on that thread.
- Specifying 0 for value_length with function code 2 or 5 results in the environment variable being removed from the environment.
• Applications should not define environment variables that begin with the characters "_BPXK_", "_EDC_", or "_CEE_" because there might be conflicts with variable names reserved for z/OS that begin with those characters.

• name and value are copied into storage owned by Language Environment.

• If a function code 1 request is made and the variable name is not found in the environment, value_length is set to 0 upon return.

• A NULL character in name is not valid and causes feedback code CEE51P to be returned.

• A NULL character in value is interpreted as a string terminator. If a NULL character is imbedded, CEEENV will truncate the value string at the last character preceding the NULL.

Examples

1. Following is an example of CEEENV called by C/C++.  

```c
#include <stdio.h>  
#include <stdlib.h>  
#include <leawi.h>  

int main(void) {  
  _INT4 func_code;  
  _INT4 name_len;  
  _POINTER name = (_POINTER)malloc(255);  
  _INT4 value_len;  
  _POINTER value_ptr;  
  _FEEDBACK fc;  
  char value[255];  

  /* Clearing all the environment variables */  
  func_code = 3;  
  CEEENV(func_code,name_len,name,value_len,value_ptr,fc);  

  /* Setting a new environment variable */  
  func_code = 2;  
  strcpy(name,"ENVAR1");  
  strcpy(value,"DEFAULT");  
  name_len = strlen(name);  
  value_len = strlen(value);  
  value_ptr = value;  
  CEEENV(func_code,name_len,name,value_len,value_ptr,fc);  

  /* Getting the value of the new variable */  
  func_code = 1;  
  strcpy(name,"ENVAR1");  
  strcpy(value,""');  
  value_ptr = value;  
  CEEENV(func_code,name_len,name,value_len,value_ptr,fc);  

  if (value_len != 0)  
    printf("$s=%s\n",name,value_ptr);  
  else  
    printf("$s not found\n",name);  
}  
```

CEEFMDA—Get default date format

CEEFMDA returns to the calling routine the default date picture string for a
specified country. CEEFMDA is affected only by the country code setting of the
COUNTRY runtime option or CEE3CTY callable service, not the CEESETL callable
service or the setlocale() function.

Syntax

►►CEEFMDA(—country_code—,—date_pic_str—,—fc—)◄◄
country_code (input)
A 2-character fixed-length string representing one of the country codes found in Table 32 on page 483. The country_code is not case-sensitive. Also, if no value is specified, the default country code (as set by either the COUNTRY runtime option or the CEE3CTY callable service) is used. If you specify a country_code that is not valid, the default date format is 'YYYY-MM-DD'.

date_pic_str (output)
A fixed-length 80-character string (VSTRING), returned to the calling routine. It contains the default date picture string for the country specified. The picture string is left-justified and padded on the right with blanks if necessary.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3CB</td>
<td>2</td>
<td>3467</td>
<td>The country code country_code was invalid for CEEFMEDA. The default date picture string date_pic_string was returned.</td>
</tr>
</tbody>
</table>

Usage notes
- z/OS UNIX considerations—CEEFMDA applies to the enclave. Every enclave has a single current country setting that has a single date format. Every thread in every enclave has the same default.

For more information
- For a list of the default settings for a specified country, see Table 32 on page 483.
- See "COUNTRY" on page 24 for an explanation of the COUNTRY runtime option.
- See "CEE3CTY—Set default country" on page 135 for an explanation of the CEE3CTY callable service.

Examples
1. Following is an example of CEEFMDA called by C/C++.

C/C++ example of CEEFMDA
/*Module/File Name: EDCFMDA */

#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {
    _FEEDBACK fc;
    _CHAR2 country;
    _CHAR80 date_pic;

    /* get the default date format for Canada */
    memcpy(country,"CA",2);
    CEEFMDA(country,date_pic,&fc);
if (_FBCHECK (fc, CEE000) != 0) {
    printf("CEEFMDA failed with message number %d\n", fc.tok_msgno);
    exit(2999);
}

/* print out the default date format for Canada */
printf("%.80s\n", date_pic);
}

2. Following is an example of CEEFMDA called by COBOL.

CEEFMDT—Get default date and time format

CEEFMDT returns the default date and time picture strings for the country specified by country_code. CEEFMMDT is affected only by the country code setting of the COUNTRY runtime option or CEE3CTY callable service, not the CEESETL callable service or the setlocale() function.

Syntax

►► CEEFMMDT—(country_code—,datetime_str—,fc—)◄◄

country_code (input)
A 2-character fixed-length string representing one of the country codes found in Table 32 on page 483. The country_code is not case-sensitive. Also, if no value is specified, the default country code (as set by either the COUNTRY runtime option or by CEE3CTY) is used. If you specify a country_code that is not valid, the default date/time picture string is 'YYYY-MM-DD HH:MI:SS'.

datetime_str (output)
A fixed-length 80-character string (VSTRING), returned to the calling routine. It contains the default date and time picture string for the country specified. The picture string is left-justified and padded on the right with blanks, if necessary.
**CEEFDMDT**

*fc (output)*

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>

**CEEFMON—Format monetary string**

CEEFMON, analogous to the C function `strfmon()` , converts numeric values to monetary strings according to the specifications passed to it. These specifications work in conjunction with the format conversions set in the current locale. The current locale’s LC_MONETARY category affects the behavior of this service, including the monetary radix character, the thousands separator, the monetary grouping, the currency symbols (national and international), and formats.

CEEFMON is sensitive to the locales set by `setlocale()` or `CEESETL`, not to the Language Environment settings from COUNTRY or `CEE3CTY`.

**Syntax**

```
►► CEEFMON—(—omitted_parm—,—stringin—,—maxsize—,—format—,—stringout—,—result—,—fc—)
```

- **omitted_parm**
  This parameter is reserved for future expansion and must be omitted. For information about how to code an omitted parm, see “Invoking callable services” on page 116.

- **stringin** *(input)*
  An 8-byte field that contains the value of a double-precision floating point number.

- **maxsize** *(input)*
  A 4-byte integer that specifies the maximum number of bytes (including the string terminator) that can be placed in *stringout*.

- **format** *(input)*
  A halfword length-prefixed character string (VSTRING) of 256 bytes that contains plain characters and a conversion specification. Plain characters are
copied to the output stream. Conversion specification results in the fetching of the input stringin argument that is converted and formatted.

A conversion specification consists of a percent character (%), optional flags, optional field width, optional left precision, optional right precision, and a required conversion character that determines the conversion to be performed.

**Flags (optional)**

You can specify one or more of the following flags to control the conversion.

- **=f** An = followed by a single character f specifies that the character f should be used as the numeric fill character. The default numeric fill character is the space character. This option does not affect the other fill operations (such as field-width filling), which always use the space as the fill character.

- **^** Do not format the currency amount with the grouping characters. The default is to insert the grouping characters if defined for the current locale.

- **+ or (** Specifies the style of representing positive and negative currency amounts. You must specify either + or ( . If + is specified, the locale’s equivalent of + and - are used (for example, in USA: the empty (null) string if positive and -(minus sign) if negative). If ( is specified, the locale’s equivalent of enclosing negative amounts within a parenthesis is used. If this option is not included, a default specified by the current locale is used.

- **!** Suppresses the currency symbol from the output conversion.

**Field Width (optional)**

A decimal digit string w that specifies a minimum field width in which the result of the conversion is right-justified (or left-justified if -w is specified).

**Left Precision (optional)**

A # (pound sign) followed by the decimal digit string n, (specified as #n), indicates a maximum number of digits expected to be formatted to the left of the radix character. This option can be used to keep the formatted output from multiple calls to the CEEFMON service aligned in the same columns. It can also be used to fill unused positions with a special character as in $***123.45. This option causes an amount to be formatted as if it has the number of digits specified by n. If more digit positions are required than are specified, this conversion specification is ignored. Digit positions in excess of those actually required are filled with the numeric fill character. See the =f specification above.

If grouping is enabled, it is applied to the combined fill characters plus regular digits. However, if the fill character is not 0 (digit zero), grouping separators inserted after a fill character are replaced by the same fill character ($0,001,234.56 versus $****1,234.56).

**Right Precision (optional)**

A period (.) followed by the decimal digit string p, (specified as .p), indicates the number of digits after the radix character. If the value of the precision p is zero, no radix character appears. If this option is not included, a default specified by the current locale is used. The amount being formatted is rounded to the specified number of digits prior to formatting.
Conversion Characters (required)
One of the following conversion characters must be specified.

i  The double argument is formatted according to the locale’s international currency format (for example, in USA: USD 1,234.56).

n  The double argument is formatted according to the locale’s national currency format (for example, in USA: $1,234.56).

%  No argument is converted; the conversion specification %% is replaced by a single %.

stringout (output)
Contains the output of the CEEFMON service.

result (output)
Contains the number of characters placed in stringout, if successful. If unsuccessful, an error is reported.

fc (output/optional)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3T1</td>
<td>3</td>
<td>4001</td>
<td>General Failure: Service could not be completed.</td>
</tr>
<tr>
<td>CEE3VM</td>
<td>3</td>
<td>4086</td>
<td>Input Error: The number of characters to be</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>formatted must be greater than zero.</td>
</tr>
</tbody>
</table>

Usage notes
• PL/I MTF consideration—CEEFMON is not supported in PL/I MTF applications.
• This callable service uses the C/C++ runtime library. The C/C++ library must be installed and accessible even when this service is called from a non-C program.

For more information
• For more information about the setlocale() function, see “COUNTRY” on page 24, “CEE3CTY—Set default country” on page 135, and “CEE3LNG—Set national language” on page 174.
• For more information about the CEESETL callable service, see “CEESETL—Set locale operating environment” on page 413.

CEEFMTM—Get default time format

CEEFMTM returns to the calling routine the default time picture string for the
country specified by country_code. For a list of the default settings for a specified
country, see Table 32 on page 483 CEEFMTM is affected only by the country code
setting of the COUNTRY runtime option or CEE3CTY callable service, not the
CEESETL callable service or the setlocale() function.

Syntax

```
CEEFMTM(country_code, time_pic_str, fc)
```

country_code (input)
A 2-character fixed-length string representing one of the country codes found
in Table 32 on page 483 The country_code is not case-sensitive. Also, if no value
is specified, the default country code (as set by either the COUNTRY runtime
option or the CEE3CTY callable service) is used. If you specify a country_code
that is not valid, the default time picture string is 'HH:MI:SS'.

time_pic_str (output)
A fixed-length 80-character string (VSTRING), representing the default time
picture string for the country specified. The picture string is left-justified and
padded on the right with blanks if necessary.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result
of this service. If you choose to omit this parameter, refer to "Invoking callable
services" on page 116 for the appropriate syntax to indicate that the feedback
code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>
| CEE3CD    | 2        | 3469           | The country code country_code was invalid for CEEFMTM. The default time picture string
|           |          |                | time_pic_string was returned.                                               |
| CEE3CE    | 2        | 3470           | The date and time string datetime_str was truncated and was not defined in CEEFMDT. |

Usage notes

• z/OS UNIX considerations—CEEFMTM applies to the enclave. Every enclave
  has a single current country setting that has a single time format. Every thread
  in every enclave has the same default.
For more information

- See “COUNTRY” on page 24 for an explanation of the COUNTRY runtime option.
- See “CEE3CTY—Set default country” on page 135 for an explanation of the CEE3CTY callable service.

Examples

1. Following is an example of CEEFMTM called by C/C++.

```c
/*Module/File Name: EDCFMTM */

#include <stdio.h>
#include <string.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceeedcct.h>

int main(void)
{
    _FEEDBACK fc;
    _CHAR2 country;
    _CHAR80 time_pic;

    /* get the default time format for Canada */
    memcpy(country,"CA",2);
    CEEFMTM(country,time_pic,&fc);
    if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
        printf("CEEFMTM failed with message number %d\n",
                fc.tok_msgno);
        exit(2999);
    }

    /* print out the default time format */
    printf("%.80s\n",time_pic);
}
```

2. Following is an example of CEEFMTM called by COBOL.

```cobol

CEEFRST—Free heap storage

CEEFRST frees storage previously allocated by CEEGTST or by a language intrinsic function. Normally, you do not need to call CEEFRST because Language Environment automatically returns all heap storage to the operating system when the enclave terminates. However, if you are allocating a large amount of heap storage, you should free the storage when it is no longer needed. This freed storage then becomes available for later requests for heap storage, thus reducing the total amount of storage needed to run the application.

All requests for storage are conditional. If storage is not available, the feedback code (fc) is set and returned to you, but the thread does not abend. An attempt to free storage that was already marked as free produces no action and returns a non-CEE000 symbolic feedback code. An attempt to free storage at anything other than a valid starting address produces no action and returns a non-CEE000 symbolic feedback code. The application does not abend.

However, if you call CEEFRST for an invalid address, and you had specified TRAP(OFF), your application can abend. The reaction of Language Environment to this is undefined. Also, partial freeing of an allocated area is not supported.

When storage is allocated by CEEGTST, its allocated size is used during free operations. Storage allocated by CEEGTST, but not explicitly freed, is automatically freed at enclave termination.

CEEFRST generates a system-level free storage call to return a storage increment to the operating system only when:
• The last heap element within an increment is being freed, and
• The HEAP runtime option or a call to CEECRHP specifies FREE (note that KEEP is the IBM-supplied default setting for the initial heap).

Otherwise, the freed storage is simply added to the free list; it is not returned to the operating system until termination. The out-of-storage condition can cause freeing of empty increments even when KEEP is specified.

Syntax

```
CEEFRST(address, fc)
```

*address* (input)
A fullword address pointer. *address* is the address returned by a previous CEEGTST call or a language intrinsic function such as ALLOCATE or malloc(). The storage at this address is deallocated.

*fc* (output)
A 12-byte feedback code, optional in some languages, that indicates the result
of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following feedback codes can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE0P2</td>
<td>4</td>
<td>0802</td>
<td>Heap storage control information was damaged.</td>
</tr>
<tr>
<td>CEE0PA</td>
<td>3</td>
<td>0810</td>
<td>The storage address in a free storage (CEEFRST) request was not recognized, or heap storage (CEECZST) control information was damaged.</td>
</tr>
</tbody>
</table>

**Usage notes**

- If you specify heap_free_value in the STORAGE runtime option, all freed storage is overwritten with heap_free_value. Otherwise, it is simply marked as available. Portions of the freed storage area can be used to hold internal storage manager control information. These areas are overwritten, but not with heap_free_value.
- The heap identifier is inferred from the address of the storage to be freed. The storage is freed from the heap in which it was allocated.
- The address passed as the argument is a dangling pointer after a call to CEEFRST. The storage freed by this operation can be reallocated on a subsequent CEEGTST call. If the pointer is not reassigned, any further use of it causes unpredictable results.
- z/OS UNIX considerations—CEEFRST applies to the enclave. One thread can allocate storage, and another can free it.

**For more information**

- See “CEEGTST—Get heap storage” on page 315 for more information about the CEEGTST callable service.
- See “HEAP” on page 38 for further information about the HEAP runtime option.
- See “CEECRHP—Create new additional heap” on page 223 for more information about the CEECRHP callable service.
- See “STORAGE” on page 81 for further information about the STORAGE runtime option.

**Examples**

1. An example of CEEFRST called by C/C++:

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceedcct.h>

int main(void) {
    _INT4 heapid, size;
    _POINTER address;
    _FEEDBACK fc;
    /*
     * heapid = 0; /* get storage from initial heap */
```
2. An example of CEEFRST called by COBOL:

CEEFTDS—Format time and date into character string

CEEFTDS, analogous to the C function strftime(), converts the internal time and
date to character strings according to the specifications passed to it by the
TD_STRUCT. These specifications work in conjunction with the format conversions
set in the current locale. The current locale's LC_TIME category affects the behavior
of this service, including the actual values for the format specifiers. CEEFTDS is
sensitive to the locales set by setlocale() or CEESETL, not to the Language
Environment settings from COUNTRY or CEE3CTY.

Syntax

►►CEEFTDS—(omitted_parm—,-time_and_date—,-maxsize—,-format—,)->
►stringout—,-fc—)◄◄

288 z/OS Language Environment Programming Reference
omitted_parm
This parameter is reserved for future expansion and must be omitted. For information about how to code an omitted parm, see “Invoking callable services” on page 116.

time_and_date (input)
Points to the time structure that is to be converted. The structure has the following format:

\texttt{td\_sec}
A 4-byte integer that describes the number of seconds in the range of 0 through 59.

\texttt{td\_min}
A 4-byte integer that describes the number of minutes in the range of 0 through 59.

\texttt{td\_hour}
A 4-byte integer that describes the number of hours in the range of 0 through 23.

\texttt{td\_mday}
A 4-byte integer that describes the day of the month in the range of 1 through 31.

\texttt{td\_mon}
A 4-byte integer that describes the month of the year in the range of 0 through 12.

\texttt{td\_year}
A 4-byte integer that describes the year of an era.

\texttt{td\_wday}
A 4-byte integer that describes the day of the week in the range of 0 through 6.

\texttt{td\_yday}
A 4-byte integer that describes the day of the year in the range of 0 through 365.

\texttt{td\_isdst}
A 4-byte integer that is a flag for daylight savings time.

maxsize (input)
A 4-byte integer that specifies the maximum length (including the string terminator) of the string that can be placed in \texttt{stringout}.

format (input)
A halfword length-prefixed character string (VSTRING) of 256 bytes that contains the conversion specifications. The format parameter is a character string containing two types of objects: plain characters that are placed in the output string and conversion specifications that convert information from \texttt{time\_and\_date} into readable form in the output string. Each conversion specification is a sequence of this form:

\texttt{\%[-\{width\}][.precision]type}
\%
A percent sign (%) introduces a conversion specification. This character is required.

\texttt{width (optional)}
An optional decimal digit string that specifies a minimum field width. A converted value that has fewer characters than the field width is
padded with spaces to the left. If the decimal digit string is preceded by a minus sign, padding with spaces occurs to the right of the converted value.

If no width is given, for numeric fields the appropriate default width is used with the field padded on the left with zeros, as required. For strings, the output field is made exactly wide enough to contain the string.

**precision (optional)**
An optional value that specifies the maximum number of characters to be printed for the conversion specification. The precision value is a decimal digit string preceded by a period. If the value to be output is longer than the precision, it is truncated on the right.

**type** Specifies the type of conversion to be performed. The characters and their meanings are:

- %a The abbreviated weekday name (for example, Sun) defined by the abday statement in the current locale.
- %A The full weekday name (for example, Sunday) defined by the day statement in the current locale.
- %b The abbreviated month name (for example, Jan) defined by the abmon statement in the current locale.
- %B The full month name (for example, January) defined by the month statement in the current locale.
- %c The date and time format defined by the d_t_fmt statement in the current locale.
- %d The day of the month as a decimal number (01 to 31).
- %D The date in %m/%d/%y format (for example, 01/31/91).
- %e The day of the month as a decimal number (1 to 31). The %e field descriptor uses a two-digit field. If the day of the month is not a two-digit number, the leading digit is filled with a space character.
- %E The combined alternative era year and name, respectively, in %o %N format in the current locale.
- %F The ISO 8601:2000 standard date format, equivalent to %Y-%m-%d.
- %g The last 2 digits of the week-based year as a decimal number [00,99].
- %G The week-based year as a 4-digit decimal number.
- %h The abbreviated month name (for example, Jan) defined by the abmon statement in the current locale. This field descriptor is a synonym for the %b field descriptor.
- %H The 24-hour clock hour as a decimal number (00 to 23).
- %I The 12-hour clock hour as a decimal number (01 to 12).
- %j The day of the year as a decimal number (001 to 366).
- %m The month of the year as a decimal number (01 to 12).
- %M The minutes of the hour as a decimal number (00 to 59).
%n Specifies a new-line character.
%N The alternative era name in the current locale.
%o The alternative era year in the current locale.
%p The AM or PM string defined by the am_pm statement in the current locale.
%r The 12-hour clock time with AM/PM notation as defined by the t_fmt_ampm statement (%I:%M:%S [AM|PM]) in the current locale.
%S The seconds of the minute as a decimal number (00 to 60).
%t Specifies a tab character.
%T Represents 24-hour clock time in the format %H:%M:%S (for example, 16:55:15).
%u The week of the year as a decimal number (00 to 53). Sunday, or its equivalent as defined by the day statement, is considered the first day of the week for calculating the value of this field descriptor.
%w The day of the week as a decimal number (0 to 6). Sunday, or its equivalent as defined by the .day statement, is considered as 0 for calculating the value of this field descriptor.
%w The week of the year as a decimal number (00 to 53). Monday, or its equivalent as defined by the day statement, is considered the first day of the week for calculating the value of this field descriptor.
%x The date format defined by the d_fmt statement in the current locale.
%x The time format defined by the t_fmt statement in the current locale.
%y The year of the century (00 to 99).
%y The year as a decimal number (for example, 1989).
%z The offset from UTC in ISO8601:2000 standard format ( +hhmm or -hhmm ). For example, "-0430" means 4 hours 30 minutes behind UTC (west of Greenwich).
%Z The time-zone name, if one can be determined (for example, EST); no characters are displayed if a time zone cannot be determined.
%% Specifies a percent sign (%) character.

stringout (output)
A halfword length-prefixed character string (VSTRING) of 256 bytes that contains the formatted time and date output of the CEEFTDS service.

fc (output/optional)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:
### CEEFTDS

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3T1</td>
<td>3</td>
<td>4001</td>
<td>General Failure: Service could not be completed.</td>
</tr>
<tr>
<td>CEE3VM</td>
<td>3</td>
<td>4086</td>
<td>Input Error: The number of characters to be formatted must be greater than zero.</td>
</tr>
</tbody>
</table>

#### Usage notes

- PL/I MTF consideration—CEEFTDS is not supported in PL/I MTF applications.
- This callable service uses the C/C++ runtime library. The C/C++ library must be installed and accessible even when this service is called from a non-C program.

#### For more information

- For more information about the `setlocale()` function, see "COUNTRY" on page 24, "CEE3CTY—Set default country" on page 135, and "CEE3LNG—Set national language" on page 174.
- For more information about the CEESETL callable service, see "CEESETL—Set locale operating environment" on page 413.

CEEGMT—Get current Greenwich Mean Time

CEEGMT returns the current Greenwich Mean Time (GMT) as both a Lilian date and as the number of seconds since 00:00:00 14 October 1582. The returned values are compatible with those generated and used by the other Language Environment date and time services. In order for the results of this service to be meaningful, your system's TOD (time-of-day) clock must be set to Greenwich Mean Time and be based on the standard epoch. Use CEEGTMTO to get the offset from GMT to local time.
The values returned by CEEGMT are handy for elapsed time calculations. For example, you can calculate the time elapsed between two calls to CEEGMT by calculating the differences between the returned values.

Language Environment treats Coordinated Universal Time (UTC) and Greenwich Mean Time (GMT) as the same. You can use the CEEUTC service, which is an alias of the CEEGMT service, to get the same value.

### Syntax

```
CEEGMT(output_GMT_Lilian, output_GMT_seconds, fc)
```

#### output_GMT_Lilian (output)
A 32-bit binary integer representing the current time in Greenwich, England, in the Lilian format (the number of days since 14 October 1582). For example, 16 May 1988 is day number 148138. If GMT is not available from the system, `output_GMT_Lilian` is set to 0 and CEEGMT terminates with a non-CEE000 symbolic feedback code.

#### output_GMT_seconds (output)
A 64-bit double floating-point number representing the current date and time in Greenwich, England, as the number of seconds since 00:00:00 on 14 October 1582, not counting leap seconds. For example, 00:00:01 on 15 October 1582 is second number 86,401 (24*60*60 + 01). 19:00:01.078 on 16 May 1988 is second number 12,799,191,601.078. If GMT is not available from the system, `output_GMT_seconds` is set to 0 and CEEGMT terminates with a non-CEE000 symbolic feedback code.

#### fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2E6</td>
<td>3</td>
<td>2502</td>
<td>The UTC/GMT was not available from the system.</td>
</tr>
</tbody>
</table>

### Usage notes
- CEEDATE converts `output_GMT_Lilian` to a character date, and CEEDATM converts `output_GMT_seconds` to a character timestamp.
- CICS consideration—CEEGMT does not use the OS TIME macro.
- z/OS UNIX consideration—In multithread applications, CEEGMT affects only the calling thread.
- Setting the TOD (time-of-day) clock to anything before January 1, 1972 may produce unpredictable results in your applications.

### For more information
- See “CEEGMTO—Get offset from Greenwich Mean Time to local time” on page 297 for more information about the CEEGMTO callable service.
Examples

1. Following is an example of CEEGMT called by C/C++.

```c
#include <string.h>
#include <stdio.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceedcct.h>

int main(void) {
    _FEEDBACK fc;
    _INT4 lilGMT_date;
    _FLOAT8 secGMT_date;
    CEEGMT(&lilGMT_date,&secGMT_date,&fc);
    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEEGMT failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    printf("The current Lilian date in Greenwich,\n            England is %d\n", lilGMT_date);
}
```

2. Following is an example of CEEGMT called by COBOL.

CEEGMTO—Get offset from Greenwich Mean Time to local time 

CEEGMTO returns values to the calling routine representing the difference between the local system time and Greenwich Mean Time (GMT).
**Syntax**

```plaintext
►► CEEGMTO—(—offset_hours—,—offset_minutes—,—offset_seconds—,—fc—)►◄
```  

**offset_hours (output)**  
A 32-bit binary integer representing the offset from GMT to local time, in hours. For example, for Pacific Standard Time, offset_hours equals -8. If local time offset is not available, offset_hours equals 0 and CEEGMT0 terminates with a non-CEE000 symbolic feedback code.

**offset_minutes (output)**  
A 32-bit binary integer representing the number of additional minutes that local time is ahead of or behind GMT. The range of offset_minutes is 0 to 59. If the local time offset is not available, offset_minutes equals 0 and CEEGMT0 terminates with a non-CEE000 symbolic feedback code.

**offset_seconds (output)**  
A 64-bit double floating-point number representing the offset from GMT to local time, in seconds. For example, Pacific Standard Time is eight hours behind GMT. If local time is in the Pacific time zone during standard time, CEEGMT0 would return -28,800 (-8 * 60 * 60). offset_seconds can be used with CEEGMT to calculate local date and time. See “CEEGMT—Get current Greenwich Mean Time” on page 294 for more information.

**fc (output)**  
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2E7</td>
<td>3</td>
<td>2503</td>
<td>The offset from UTC/GMT to local time was not available from the system.</td>
</tr>
</tbody>
</table>

**Usage notes**

- CEEDATM is used to convert number of seconds to a character timestamp.
- CICS consideration—CEEGMT0 does not use the OS TIME macro.
- z/OS UNIX consideration—In multithread applications, CEEGMT0 affects only the calling thread.

**For more information**

- See “CEEDATM—Convert seconds to character timestamp” on page 238 for more information about the CEEDATM callable service.

**Examples**

1. An example of CEEGMT0 called by C/C++:
   ```c
   /*Module/File Name: EDCGMO */
   
   #include <string.h>
   ```
#include <stdio.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceeedcct.h>

int main(void) {
    _FEEDBACK fc;
    _INT4 GMT_hours, GMT_mins;
    _FLOAT8 GMT_secs;
    CEEGMTO(&GMT_hours, &GMT_mins, &GMT_secs, &fc);
    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEEGMTO failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    printf("The difference between GMT and the local time is:\n");
    printf("%d hours, %d minutes\n", GMT_hours, GMT_mins);
}

2. An example of CEEGMTO called by COBOL:

CEEGPID—Retrieve the Language Environment version and platform ID

CEEGPID retrieves the Language Environment version ID and the platform ID of
the version and platform of Language Environment that is processing the currently
active condition.
Syntax

```
|►►CEE_VERSION_ID, Plat_ID, fc◄◄ |
```

**CEE_Version_ID (output)**

A four-byte hexadecimal number representing the version of Language Environment that created this data block.

```
|pp|vv|rr|mm|
pp = Product Number
vv = Version
rr = Release
mm = Modification
```

The current value of this parameter is:

- X'04010800'
  Version 1 Release 8 Modification 0
- X'04010900'
  Version 1 Release 9 Modification 0
- X'04010A00'
  Version 1 Release 10 Modification 0
- X'04010B00'
  Version 1 Release 11 Modification 0
- X'04010C00'
  Version 1 Release 12 Modification 0
- X'04010D00'
  Version 1 Release 13 Modification 0
- X'04020100'
  Version 2 Release 1 Modification 0
- X'04020200'
  Version 2 Release 2 Modification 0

**Plat_ID (output)**

A fullword integer representing the platform used for processing the current condition. The current values of this parameter are:

- 3  z/OS or VM
- 4  AS/400

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

**Usage notes**

- z/OS UNIX consideration—In multithread applications, CEEGPID affects only the calling thread.
• To make a decision concerning Language Environment and z/OS levels at assembly time instead of runtime, use CEEGLOB instead. See z/OS Language Environment Programming Guide for more information.

Examples

1. Following is an example of CEEGPID called by C/C++.

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {
    _INT4 cee_ver_id, plat_id;
    _FEEDBACK fc;
    int Vmask= 0x00FF0000;
    int Rmask= 0x0000FF00;
    int Mmask= 0x000000FF;

    CEEGPID(cee_ver_id,plat_id,fc);
    if (_FBCHECK(fc,CEE000) != 0) {
        printf("CEEGPID failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }

    if ((plat_id == 3) && (cee_ver_id > 290)) {
        printf("The LE version id is %08X\n", cee_ver_id);
        printf("Version: %d\n", (Vmask & cee_ver_id)>>16);
        printf("Release: %d\n", (Rmask & cee_ver_id)>>8);
        printf("Modification: %d\n\n", (Mmask & cee_ver_id));
    }

    switch(plat_id) {
    case 3: printf("z/OS\n");
    break;
    case 4: printf("AS/400\n");
    break;
    default: printf("unrecognized platform id\n");
    }
}
```

2. Following is an example of CEEGPID called by COBOL.

**CEEGQDT—Retrieve q-data_token**

CEEGQDT retrieves the q-data_token from the Instance-Specific Information (ISI). CEEGQDT is particularly useful when you have user-written condition handlers registered by CEEHDLR.

### Syntax

```c
CEEGQDT((cond_rep, q_data_token, fc))
```

`cond_rep` *(input)*  
A condition token defining the condition for which the q-data_token is retrieved.

`q_data_token` *(output)*  
A pointer to the q-data associated with condition token `cond_rep`.

`fc` *(output)*  
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

### Usage notes

- z/OS UNIX consideration—In multithread applications, CEEGQDT affects only the calling thread.

### For more information

- For more information about the various types of q-data structures, see [z/OS Language Environment Programming Guide](#).
- For more information about the CEEHDLR callable service, see "CEEHDLR—Register user-written condition handler" on page 319.
- For more information about the CEESGL callable service, see "CEESGL—Signal a condition" on page 417.

### Examples

1. Following is an example of CEEGQDT called by C/C++.

   ```c
   /*Module/File Name: EDCGQDT */
   #include <stdio.h>
   #include <stdlib.h>
   #include <string.h>
   #include <leawi.h>
   ```
#include <ceeedcct.h>
#ifdef __cplusplus
extern "C"
#endif

void handler(_FEEDBACK *_,_INT4 *_,_INT4 *_,_FEEDBACK *);
#endif

typedef struct { /* condition info structure */
    int error_value;
    char err_msg_80;
    int retcode;
} info_struct;

int main(void) {
    _FEEDBACK fc, condtok;
    _ENTRY routine;
    _INT4 token, qdata;
    _INT2 c_1, c_2, cond_case, sev, control;
    _CHAR3 facid;
    _INT4 isi;
    info_struct *info;
    /* . . */
    /* register the condition handler */
    token = 99;
    routine.address = (_POINTER)&handler;:
    routine.nesting = NULL;
    CEEHDLR(&routine, &token, &fc);
    if (_FBCHECK(fc, CEE000) != 0) {
        printf("CEEHDLR failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    /* . . */
    /* set up the condition info structure */
    info = (info_struct *)malloc(sizeof(info_struct));
    if (info == NULL) {
        printf("error allocating info_struct\n");
        exit(2399);
    }
    info->error_value = 86;
    strcpy(info->err_msg, "Test message");
    info->retcode = 99;
    /* set qdata to be the condition info structure */
    qdata = (int)info;
    /* build the condition token */
    c_1 = 3;
    c_2 = 99;
    cond_case = 1;
    sev = 3;
    control = 0;
    memcpy(facid, "ZZZ", 3);
    isi = 0;
    CEENCOD(&c_1, &c_2, &cond_case, &sev, &control, &facid, &isi, &condtok, &fc);
    if (_FBCHECK(fc, CEE000) != 0) {
        printf("CEENCOD failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    /* signal the condition */
    CEESGL(&condtok, &qdata, &fc);
if (_FBCHECK (fc, CEE000) != 0) {
    printf("CEESGL failed with message number \%d\n", fc.tok_msgno);
    exit(2999);
}

void handler(_FEEDBACK *fc, _INT4 *token, _INT4 *result, _FEEDBACK *newfc) {
    _FEEDBACK qdatafc;
    _INT4 idata;
    info_struct *qdata;
    /* *
    * get the q_data_token from the ISI */
    CEEGQDT(fc, &idata, &qdatafc);
    if (_FBCHECK (qdatafc, CEE000) != 0) {
        printf("CEEGQDT failed with message number \%d\n", qdatafc.tok_msgno);
        *result = 20; /* percolate */
        return;
    }
    /***************************************************************************/
    /* set info_struct pointer to address return by */
    /* CEEGQDT */
    /***************************************************************************/
    qdata = (info_struct *)idata;
    /* use the condition info structure (qdata) */
    if (qdata->error_value == 86) {
        printf("%.12s\n", qdata->err_msg);
        printf("retcode = \%d\n", qdata->retcode);
        *result = 10; /* resume this is what we want */
        return;
    }
    /***************************************************************************/
    /* */
    /***************************************************************************/
    *result = 20; /* percolate */
}

END IBMGQDT;
CEEGTJS—Retrieves the value of an exported JCL symbol

CEEGTJS retrieves and returns to the caller the symbol value and length of the requested exported JCL symbol.

Syntax

```plaintext
function_code (input)
A fullword integer that contains the function code of the following value:

1  Retrieves the value and its associated length of an exported JCL symbol.

symbol_name (input)
A halfword length-prefix fixed character string (VSTRING), representing the name of an exported JCL symbol to be retrieved.

symbol_value (output)
A 255-byte fixed-length string. On return from this service, the `symbol_value` contains the value of the exported JCL symbol. If the length of the exported JCL symbol is shorter than 255 characters, the returned string is padded with blanks.

value_length (output)
A fullword integer that contains the length of the value of the specified JCL symbol.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3L9</td>
<td>0</td>
<td>3753</td>
<td>The input symbol cannot be found in the current job step.</td>
</tr>
<tr>
<td>CEE3LA</td>
<td>3</td>
<td>3754</td>
<td>Incorrect parameters detected.</td>
</tr>
<tr>
<td>CEE3QS</td>
<td>1</td>
<td>3932</td>
<td>The system service service failed with return code <code>return_code</code> and reason code <code>reason_code</code>.</td>
</tr>
</tbody>
</table>

Usage notes

- Lowercase characters in the `symbol_name` are converted to uppercase by CEEGTJS.
- For more information about JCL symbols, refer to the topic on system symbols and JCL symbols in Z/OS MVS JCL Reference.
CEEGTJS

Examples
1. This example uses CEEGTJS to retrieve the value of an exported JCL symbol.

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {
    _FEEDBACK fc;
    _INT4 funcode;
    _CHAR255 symvalue;
    _VSTRING symname;
    _INT4 valuelen;
    char *symbol="SYM1";

    /* Setting the function code */
    funcode=1;

    /* Preparing the JCL symbol */
    symname.length=strlen(symbol);
    memcpy(symname.string, symbol,strlen(symbol));

    /* Retrieving the value of the JCL symbol */
    CEEGTJS(&funcode,&symname,symvalue,&valuelen,&fc);
    if( _FBCHECK (fc, CEE000) !=0 ) {
        printf("CEEGTJS failed with message number %d\n", fc.tok_msgno);
        exit(1);
    }
    symvalue[valuelen]='\0';
    printf("The value of JCL symbol %s is %s. The length
          of the value is %d\n",symbol,symvalue,valuelen);
}
```

Use the following JCL to run EDCGTJS:

```jcl
//JOB1 JOB FELE,MSGLEVEL=(2,0)
//STEP1 EXEC PGM=EDCGTJS
//E1 EXPORT SYMLIST=(SYM1,SYM2,SYM3)
//S1 SET SYM1=XXXX
//S2 SET SYM2=YYYY
//STEPLIB DD DSN=USER.LOADLIB,DISP=SHR
//SYSPRINT DD SYSOUT=* 
//SYSPRINT DD SYSOUT=* 
```

Running this example would produce the following output:
The value of JCL symbol SYM1 is XXXX. The length of the value is 4.
CEEGTST—Get heap storage

CEEGTST gets storage from a heap whose ID you specify. It is used to acquire both large and small blocks of storage. CEEGTST always allocates storage that is addressable by the caller. Therefore, if the caller is in 24-bit addressing mode, or if HEAP(,,BELOW) is in effect, the storage returned is always below the 16M line. Above-the-line storage is returned only if the caller is in 31-bit addressing mode and HEAP(,,ANY) is in effect.

All requests for storage are conditional. If storage is not available, the feedback code (fc) is set and returned to you, but the thread does not abend. When storage is not available, the appropriate action in the member environment should be taken. One option is to use the CEESGL callable service to signal the Language Environment condition handler with the returned feedback code.

Storage obtained by CEEGTST can be freed by a call to CEEFRST or CEEDSHP. You can also free storage by using a language intrinsic function. If storage is not explicitly freed, it is freed automatically at termination.

If you have specified a heap_alloc_value in the STORAGE runtime option, all storage allocated by CEEGTST is initialized to heap_alloc_value. Otherwise, it is left uninitialized.

If the value specified in the size parameter of CEEGTST is greater than the size of an increment (as specified in the HEAP runtime option), all of the requested storage (rounded up to the nearest doubleword) is allocated in a single system-level call.

Heap storage is acquired by a system-level get storage call in increments of init_size and incr_size bytes as specified by the HEAP runtime option, or in the CEECRHP callable service. If the increment size is chosen appropriately, only a few of the calls to CEEGTST result in a system call. The storage report generated when the RPTSTG runtime option is specified shows the number of system-level get storage calls required. This helps you tune the init_size and incr_size fields in order to minimize calls to the operating system.

### Syntax

```
CEEGTST(—heap_id—,—size—,—address—,—fc—)
```

#### heap_id (input)

A fullword binary signed integer. heap_id is a token denoting the heap in which the storage is allocated. A heap_id of 0 allocates storage from the initial heap (or user heap). Any other heap_id must be a value obtained from the CEECRHP callable service. If the heap_id you specify is invalid, no storage is allocated. CEEGTST terminates with a non-CEE000 symbolic feedback code and the value of the address parameter is undefined.

#### size (input)

A fullword binary signed integer. size represents the amount of storage allocated, in bytes. If the specified amount of storage cannot be obtained, no storage is allocated, CEEGTST terminates with a non-CEE000 symbolic feedback code, and the value of the address parameter is undefined.
address (output)
A fullword address pointer. address is the main storage address of the first byte of allocated storage. If storage cannot be obtained, address remains undefined. Storage is always allocated on a doubleword boundary. This parameter contains an address that is returned as output to CEECZST.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE0P2</td>
<td>4</td>
<td>0802</td>
<td>Heap storage control information was damaged.</td>
</tr>
<tr>
<td>CEE0P3</td>
<td>3</td>
<td>0803</td>
<td>The heap identifier in a get storage request or a discard heap request was unrecognized.</td>
</tr>
<tr>
<td>CEE0P8</td>
<td>3</td>
<td>0808</td>
<td>Storage size in a get storage request (CEEGTST) or a reallocate request (CEECZST) was not a positive number.</td>
</tr>
<tr>
<td>CEE0PD</td>
<td>3</td>
<td>0813</td>
<td>Insufficient storage was available to satisfy a get storage (CEECZST) request.</td>
</tr>
</tbody>
</table>

Usage notes

- COBOL considerations—If you want to use the CEEGTST callable service in a 24-bit addressing mode COBOL program to request 24-bit heap storage, you can make a static call to CEEGTST without any additional changes. If you want to call it dynamically (either by using the COBOL DYNAM compiler option, or using the “CALL identifier” statement, where identifier is a variable that holds the name of the program you want to call), you must also specify HEAP("BELOW",") as a runtime option.

This runtime specification affects all programs in the enclave using the user heap, not just the 24-bit addressing mode program. If this is undesirable, one alternative is to use the CEECRHP callable service to create an additional heap, specifying for the options parameter a value that will create the heap BELOW. The 24-bit addressing mode COBOL program can then obtain storage from this additional heap using the CEEGTST callable service.

- PL/I considerations—Storage allocated within PL/I AREAs is managed by PL/I. Therefore, only PL/I language functions can allocate and free storage within a PL/I area.

Based upon the layout of a PL/I structure, PL/I might adjust the starting byte of the PL/I structure to a non-doubleword aligned byte. The difference between the doubleword boundary and the first byte of such a structure is known as the hang. Because Language Environment callable storage services do not adjust the starting byte, you must be careful using callable services to allocate storage for PL/I structures. Use either the PL/I ALLOCATE statement or fully defined structures and aggregates to avoid this problem.

- CICS considerations—In a CICS environment, size should not exceed 1024M (1 gigabyte or X'40000000') when running in AMODE ANY, and 65,504 bytes when running in 24-bit addressing mode. These CICS restrictions are subject to change from one release of CICS to another. Portable applications should respect current CICS limitations.
z/OS UNIX considerations—CEEGTST applies to the enclave. Any thread can free the allocated storage.

For more information

- See “HEAP” on page 38 for further information about the Language Environment HEAP runtime option.
- For more information about the CEESGL callable service, see “CEESGL—Signal a condition” on page 417.

- For more information about the CEECZST callable service, see “CEECZST—Reallocate (change size of) storage” on page 227.

Examples

1. Following is an example of CEEGTST called by C/C++.

   /*Module/File Name: EDCGTST */
   
   #include <stdio.h>
   #include <string.h>
   #include <stdlib.h>
   #include <leawi.h>
   #include <ceeedcct.h>

   int main(void) {
       _INT4 heapid, size;
       _POINTER address;
       _FEEDBACK fc;
       /* . */
       . */
       heapid = 0; /* get storage from initial heap */
       size = 4000; /* number of bytes of heap storage */
       /* obtain the storage using CEEGTST */
       CEEGTST(&heapid,&size,&address,&fc);

       /* check the first 4 bytes of the feedback token */
       /* (0 if successful) */
       if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
           printf("CEEGTST failed with message number %d\n", fc.tok_msgno);
           exit(99);
       }
       /* . */
       . */

   /* free the storage that was previously obtained */
   /* using CEEGTST */
CEEGTST

CEEFRST(&address,&fc);

/* check the first 4 bytes of the feedback token */
/* (0 if successful) */
if (_FBCHECK ( fc , CEE000 ) != 0 ) {
    printf("CEEFRST failed with message number %d\n", 
        fc.tok_msgno);
    exit(99);
}

CEEHDLR—Register user-written condition handler

CEEHDLR registers a user-written condition handler for the current stack frame. The user condition handler is invoked when:

- It is registered for the current stack frame by CEEHDLR, and
- The Language Environment condition manager requests the condition handler associated with the current stack frame handle the condition.
Language Environment places the user-written condition handlers associated with each stack frame in a queue. The queue can be empty at any given time. The Language Environment condition manager invokes the registered condition handlers in LIFO (last in, first out) order to handle the condition.

The opposite of CEEHDLR, which registers a user-written condition handler, is CEEHDLU, which unregisters the handler. You do not necessarily need to use CEEHDLU to remove user-written condition handlers you registered with CEEHDLR. Any user-written condition handlers created through CEEHDLR and not unregistered by CEEHDLU are unregistered automatically by Language Environment, but only when the associated stack frame is removed from the stack.

Language Environment condition handlers are driven only for synchronous conditions.

### Syntax

```
CEEHDLR(routine, token, fc)
```

**routine** *(input)*

An entry variable or entry constant for the routine called to process the condition. The entry variable or constant must be passed by reference. The routine must be an external routine; that is, it must not be a nested routine.

**token** *(input)*

A fullword integer of information you want passed to your user handler each time it is called. This can be a pointer or any other fullword integer you want to pass.

**fc** *(output)*

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE080</td>
<td>1</td>
<td>0256</td>
<td>The user-written condition handler routine specified was already registered for this stack frame. It was registered again.</td>
</tr>
<tr>
<td>CEE081</td>
<td>3</td>
<td>0257</td>
<td>The routine specified contained an invalid entry variable.</td>
</tr>
</tbody>
</table>

### Usage notes

- **PL/I MTF consideration**—CEEHDLR is not supported in PL/I MTF applications. This includes any CEEHDLR service called from a COBOL program in the application.
- **COBOL consideration**—You should not call CEEHDLR from a nested COBOL program.
- **z/OS UNIX consideration**—In multithread applications, CEEHDLR affects only the calling thread.
C consideration—The CEEHDLR service does not save Writeable Static Area (WSA) information about the user handler, so it's possible that the user handler will be given control with the wrong WSA. Specifically, the user handlers on the stack will be invoked with the WSA of the routine that incurred the condition. The preferred method of handling conditions from a C application is to use C signal handlers.

For more information

For more information about the CEEHDLU callable service, see “CEEHDLU—Unregister user-written condition handler” on page 328.

Examples

Chapter 5. Callable services 327
CEEHDLU—Unregister user-written condition handler

CEEHDLU unregisters a user condition handler for the current stack frame. You do not necessarily need to use CEEHDLU to remove user-written condition handlers you registered with CEEHDLR. Any user-written condition handlers created through CEEHDLR and not unregistered by CEEHDLU are unregistered automatically by Language Environment, but only when the associated stack frame is removed from the stack.

**Note:** For information about restrictions on the use of CEEHDLU with PL/I, see [z/OS Language Environment Programming Guide](#).

### Syntax

```
CEEHDLU(-routine-, -fc-)
```

#### routine (input)

An entry variable or constant for the routine to be unregistered as a user condition handler. This routine must be previously registered (with CEEHDLR) by the same stack frame that invokes CEEHDLU.

#### fc (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE07S</td>
<td>1</td>
<td>0252</td>
<td>CEEHDLU was unable to find the requested user-written condition handler routine.</td>
</tr>
</tbody>
</table>

### Usage notes

- **PL/I MTF consideration**—CEEHDLU is not supported in PL/I MTF applications. This includes any CEEHDLR service called from a COBOL program in the application.
- **z/OS UNIX consideration**—In multithread applications, CEEHDLU affects only the calling thread.

### For more information

- See “CEEHDLR—Register user-written condition handler” on page 319 for more information about specifying the routine parameter.

### Examples

1. Following an example of CEEHDLU called by C/C++.

```c
/*Module/File Name: EDCHDLU */

#include <stdio.h>
#include <string.h>
#include <stdlib.h>
```
#include <leawi.h>
#include <ceeedcct.h>

#ifdef __cplusplus
    extern "C"
#endif

void handler(_FEEDBACK *, _INT4 *, _INT4 *, _FEEDBACK *);
#ifdef __cplusplus
}
#endif

int main(void) {

    _FEEDBACK fc;
    _ENTRY routine;
    _INT4 token;

    /* set the routine structure to point to the handler */
    /* and use CEEHDLR to register the user handler */

    token = 99;
    routine.address = (POINTER)&handler;;
    routine.nesting = NULL;

    CEEHDLR(&routine, &token, &fc);

    /* verify that CEEHDLR was successful */
    if ( _FBCHECK ( fc, CEE000 ) != 0 ) {
        printf("CEEHDLR failed with message number %d\n", fc.tok_msgno);
        exit (2999);
    }

    /* Unregister the condition handler */
    CEEHDLU(&routine, &fc);

    /* verify that CEEHDLU was successful */
    if ( _FBCHECK ( fc, CEE000 ) != 0 ) {
        printf("CEEHDLU failed with message number %d\n", fc.tok_msgno);
        exit (2999);
    }

    void handler(_FEEDBACK *fc, _INT4 *token, _INT4 *result,
                 _FEEDBACK *newfc) {
        
    }

CEEISEC—Convert integers to seconds

CEEISEC converts separate binary integers representing year, month, day, hour, minute, second, and millisecond to a number representing the number of seconds since 00:00:00 14 October 1582. Use CEEISEC instead of CEESECS when the input is in numeric format rather than character format.

The inverse of CEEISEC is CEESECI, which converts number of seconds to integer year, month, day, hour, minute, second, and millisecond.

Syntax

```plaintext
CEEISEC(input_year,input_months,input_day,input_hours,input_minutes,input_seconds,input_milliseconds,fc)

input_year (input)
   A 32-bit binary integer representing the year. The valid range for input_year is 1582 to 9999, inclusive.
```
input_month  (input)
A 32-bit binary integer representing the month. The valid range for input_month is 1 to 12.

input_day  (input)
A 32-bit binary integer representing the day. The valid range for input_day is 1 to 31.

input_hours  (input)
A 32-bit binary integer representing the hours. The range of valid input_hours is 0 to 23.

input_minutes  (input)
A 32-bit binary integer representing the minutes. The range of valid input_minutes is 0 to 59.

input_seconds  (input)
A 32-bit binary integer representing the seconds. The range of valid input_seconds is 0 to 59.

input_milliseconds  (input)
A 32-bit binary integer representing milliseconds. The range of valid input_milliseconds is 0 to 999.

output_seconds  (output)
A 64-bit double floating-point number representing the number of seconds since 00:00:00 on 14 October 1582, not counting leap seconds. For example, 00:00:01 on 15 October 1582 is second number 86,401 (24*60*60 + 01). The valid range of output_seconds is 86,400 to 265,621,679,999,999 (23:59:59,999 31 December 9999). If any input values are invalid, output_seconds is set to zero. To convert output_seconds to a Lilian day number, divide output_seconds by 86,400 (the number of seconds in a day).

fc  (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td></td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2EE</td>
<td>3</td>
<td>2510</td>
<td>The hours value in a call to CEEISEC or CEESECS was not recognized.</td>
</tr>
<tr>
<td>CEE2EF</td>
<td>3</td>
<td>2511</td>
<td>The day parameter passed in a CEEISEC call was invalid for year and month specified.</td>
</tr>
<tr>
<td>CEE2EH</td>
<td>3</td>
<td>2513</td>
<td>The input date passed in a CEEISEC, CEEDAYS, or CEESECS call was not within the supported range.</td>
</tr>
<tr>
<td>CEE2EI</td>
<td>3</td>
<td>2514</td>
<td>The year value passed in a CEEISEC call was not within the supported range.</td>
</tr>
<tr>
<td>CEE2EJ</td>
<td>3</td>
<td>2515</td>
<td>The milliseconds value in a CEEISEC call was not recognized.</td>
</tr>
<tr>
<td>CEE2EK</td>
<td>3</td>
<td>2516</td>
<td>The minutes value in a CEEISEC call was not recognized.</td>
</tr>
<tr>
<td>CEE2EL</td>
<td>3</td>
<td>2517</td>
<td>The month value in a CEEISEC call was not recognized.</td>
</tr>
<tr>
<td>CEE2EN</td>
<td>3</td>
<td>2519</td>
<td>The seconds value in a CEEISEC call was not recognized.</td>
</tr>
</tbody>
</table>
**Usage notes**

- z/OS UNIX consideration—In multithread applications, CEEISEC affects only the calling thread.

**For more information**

- For more information about the CEESECS callable service, see "CEESECS—Convert timestamp to seconds" on page 407.
- See "CEESECI—Convert seconds to integers" on page 402 for more information about the CEESECI callable service.

**Examples**

1. Following is an example of CEEISEC called by C/C++.

   /*Module/File Name: EDCISEC */

   #include <string.h>
   #include <stdio.h>
   #include <leawi.h>
   #include <stdlib.h>
   #include <ceeedcct.h>

   int main(void) {
      _INT4 year, month, day, hours, minutes, seconds,
      - milliseecs;
      _FLOAT8 output;
      _FEEDBACK fc;

      year = 1991;
      month = 9;
      day = 13;
      hours = 4;
      minutes = 34;
      seconds = 25;
      milliseecs = 746;
      CEEISEC(&year,&month,&day,&hours,&minutes,&seconds,;
      &milliseecs,&output,&fc);

      if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
         printf("CEEISEC failed with message number %d\n",
         fc.tok_msgno);
         exit(2999);
      }
      printf("The number of seconds between 00:00:00.00";
      " 10/14/1582 and 04:34:25.746 09/13/1991";
      " is %.3f\n",output);
   }

---

**CEEITOK—Return initial condition token**

CEEITOK returns the condition that initially triggered the current condition. The current condition might be different from the initial condition if the initial condition has been promoted by a user-written condition handler.
Syntax

```
CEEITOK(--i_ctok--,--fc--)          
```

**i_ctok (output)**
A 12-byte condition token identifying the initial condition in the current active data block being processed.

**fc (output)**
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE35S</td>
<td>1</td>
<td>3260</td>
<td>No condition was active when a call to a condition management routine was made.</td>
</tr>
</tbody>
</table>

**Usage notes**

- z/OS UNIX considerations—In multithread applications, CEEITOK affects only the calling thread. CEEITOK returns the initial token for the condition of the thread.

**For more information**

- See "CEENCOD—Construct a condition token" on page 379, for more information about the CEENCOD callable service.

**Examples**

1. Following is an example of CEEITOKC called by C/C++.

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

#ifdef __cplusplus

CEELCNV—Query locale numeric conventions

CEELCNV, which calls the C function localeconv(), queries the numeric formatting information from the current locale and sets the components of a structure with values pertaining to the LC_NUMERIC and LC_MONETARY categories. It sets the components of an object of the type NM_STRUCT with the values appropriate for the formatting of the numeric quantities (monetary and otherwise) according to the rules of the current locale.

CEELCNV is sensitive to the locales set by setlocale() or CEESETL, not to the Language Environment settings from COUNTRY or CEE3CTY.

Syntax

```plaintext
CEELCNV(—version—,—num_and_mon—,—fc—)
```

**version**
This parameter points to a user supplied VERSION_INFO structure, in which the first four bytes contain the callable service version number.

**Requirement:** If the parameter does not point to a user supplied VERSION_INFO structure, it must be omitted. If the parameter points to a VERSION_INFO containing version number 2, CEELCNV returns a num_and_mon structure with the international monetary string formatting elements added for ISO/IEC 9899:1999 (C99). This corresponds to the current C language localeconv structure. If the parameter is omitted, CEELCNV returns the structure format used before C99. For information about how to code this parameter, see “Invoking callable services” on page 116.

**num_and_mon** (output)
Points to the numeric and monetary structure that is filled in by this service. If the service fails, the contents of the structure are undefined. num_and_mon has the following structure:

**NM_STRUCT**
A halfword length-prefixd character string (VSTRING). A pointer to the filled-in structure NM_STRUCT is returned. The structure pointed to by the return value should not be modified by the program but can be overridden by subsequent calls to CEELCNV. In addition, calls to CEESETL with the LC_ALL, LC_MONETARY or LC_NUMERIC categories can cause subsequent calls to CEELCNV to return different values based on the selection of the locale.

The members of the structure with the type VSTRING are strings, any of which (except decimal_point) can point to an empty string, to indicate that the value is not available in the current locale or is of zero length. The members with type VINT are non-negative numbers, any of which can be CHAR_MAX to indicate that the value is not available in the current locale. The members include the following:
VSTRING decimal_point
A halfword length-prefixed character string (VSTRING) of 22 bytes that is the decimal-point character used to format non-monetary quantities.

VSTRING thousands_sep
A halfword length-prefixed character string (VSTRING) of 22 bytes that is the character used to separate groups of digits to the left of the decimal point in formatted non-monetary quantities.

VSTRING grouping
A halfword length-prefixed character string (VSTRING) of 22 bytes whose elements indicate the size of each group of digits in formatted non-monetary quantities.

VSTRING int_curr_symbol
A halfword length-prefixed character string (VSTRING) of 22 bytes that is the international currency symbol applicable to the current locale, left justified within a four-character space-padded field.

VSTRING currency_symbol
A halfword length-prefixed character string (VSTRING) of 22 bytes that is the local currency symbol applicable to the current locale.

VSTRING mon_decimal_point
A halfword length-prefixed character string (VSTRING) of 22 bytes that is the decimal point character used to format monetary quantities.

VSTRING mon_thousands_sep
A halfword length-prefixed character string (VSTRING) of 22 bytes that is the separator for groups of digits to the left of the decimal point in formatted monetary quantities.

VSTRING mon_grouping
A halfword length-prefixed character string (VSTRING) of 22 bytes whose elements indicate the size of each group of digits in formatted monetary quantities.

VSTRING positive_sign
A halfword length-prefixed character string (VSTRING) of 22 bytes that indicates a non-negative-formatted monetary quantity.

VSTRING negative_sign
A halfword length-prefixed character string (VSTRING) of 22 bytes used to indicate a negative-formatted monetary quantity.

VINT int_frac_digits
A 1-byte integer that is the number of fractional digits (those to the right of the decimal point) to be displayed in an internationally-formatted monetary quantity.

VINT frac_digits
A 1-byte integer that is the number of fractional digits (those to the right of the decimal point) to be displayed in a formatted monetary quantity.

VINT p_cs_precedes
A 1-byte integer that is set to 1 if the currency_symbol precedes the value for a non-negative-formatted monetary quantity. It is set to 0 if it follows.
VINT p_sep_by_space
A 1-byte integer that is set to 1 if the currency_symbol is separated by a space from the value for a non-negative-formatted monetary quantity. It is set to 0 if it is not separated.

VINT n_cs_precedes
A 1-byte integer that is set to 1 if the currency_symbol precedes the value for a negative-formatted monetary quantity. It is set to 0 if it follows.

VINT n_sep_by_space
A 1-byte integer that is set to 1 if the currency_symbol is separated by a space from the value for a negative-formatted monetary quantity. It is set to 0 if it is not separated.

VINT p_sign_posn
A 1-byte integer that is set to a value indicating the positioning of the positive_sign for non-negative-formatted monetary quantity.

VINT n_sign_posn
A 1-byte integer that is set to a value indicating the position of the negative_sign for negative-formatted monetary quantity.

VSTRING left_parenthesis
A halfword length-prefixed character string (VSTRING) of 22 bytes that is used to denote a negative monetary quantity.

VSTRING right_parenthesis
A halfword length-prefixed character string (VSTRING) of 22 bytes that is used to denote a negative monetary quantity.

VSTRING debit_sign
A halfword length-prefixed character string (VSTRING) of 22 bytes that is the debit sign character in monetary formats.

VSTRING credit_sign
A halfword length-prefixed character string (VSTRING) of 22 bytes that is the credit sign character in monetary formats.

VINT int_p_cs_precedes
A 1-byte integer that is set to 1 if the currency_symbol precedes the value for a non-negative-formatted international monetary quantity. It is set to 0 if it follows.

VINT int_p_sep_by_space
A 1-byte integer that is set to 1 if the currency_symbol is separated by a space from the value for a non-negative-formatted international monetary quantity. It is set to 0 if it is not separated.

VINT int_n_cs_precedes
A 1-byte integer that is set to 1 if the currency_symbol precedes the value for a negative-formatted international monetary quantity. It is set to 0 if it follows.

VINT int_n_sep_by_space
A 1-byte integer that is set to 1 if the currency_symbol is separated by a space from the value for a negative-formatted international monetary quantity. It is set to 0 if it is not separated.
VINT int_p_sign_posn
A 1-byte integer that is set to a value indicating the positioning of the positive_sign for non-negative-formatted international monetary quantity.

VINT n_sign_posn
A 1-byte integer that is set to a value indicating the position of the negative_sign for negative-formatted international monetary quantity.

fc (output/optional)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3T1</td>
<td>3</td>
<td>4001</td>
<td>General Failure: Service could not be completed.</td>
</tr>
<tr>
<td>CEE3VN</td>
<td>3</td>
<td>4087</td>
<td>Input Error: The version_info control block contains a version number that is not valid.</td>
</tr>
</tbody>
</table>

Usage notes
- PL/I MTF consideration—CEELCNV is not supported in PL/I MTF applications.
- This callable service uses the C/C++ runtime library. The C/C++ library must be installed and accessible even when this service is called from a non-C program.
- CEELCNV does not return all numeric conventions.
- CHAR_MAX determines when no further grouping is to be performed. The elements of grouping and mon_grouping are interpreted according to the following CHAR_MAX settings:
  - 0 specifies that the previous element is to be repeatedly used for the remainder of the digits. Indicates that no further grouping is to be performed.
  - Any other value represents the number of digits comprising the current group. The next element is examined to determine the size of the next group of digits to the left of the current group.
- The value of p_sign_posn and n_sign_posn is interpreted according to the following:
  - 0 Parentheses surround the quantity and currency_symbol.
  - 1 The sign string precedes the quantity and currency_symbol.
  - 2 The sign string follows the quantity and currency_symbol.
  - 3 The sign string immediately precedes the currency_symbol.
  - 4 The sign string immediately follows the currency_symbol.

For more information
- See “CEEQRYL—Query active locale environment” on page 391 for a description of LC_NUMERIC and LC_MONETARY categories.
- See “CEESETL—Set locale operating environment” on page 413 for details on the CEESETL callable service.

END PLILCNV;

CEELCNV

CEELCNV returns the current local date or time in three formats:
  * Lilian date (the number of days since 14 October 1582)
  * Lilian seconds (the number of seconds since 00:00:00 14 October 1582)
  * Gregorian character string (in the form YYYYMMDDHHMISS999)

These values are compatible with other Language Environment date and time services, and with existing language intrinsic functions.

CEELCNV performs the same function as calling the CEEGMT, CEEGMT0, and CEEDATM date and time services separately. CEELCNV, however, performs the same services with much greater speed.

The character value returned by CEELCNV is designed to match that produced by existing language intrinsic functions. The numeric values returned can be used to simplify date calculations.
output_Lilian (output)
A 32-bit binary integer representing the current local date in the Lilian format, that is, day 1 equals 15 October 1582, day 148,887 equals 4 June 1990. If the local time is not available from the system, output_Lilian is set to 0 and CEELOCT terminates with a non-CEE000 symbolic feedback code.

output_seconds (output)
A 64-bit double-floating point number representing the current local date and time as the number of seconds since 00:00:00 on 14 October 1582, not counting leap seconds. For example, 00:00:01 on 15 October 1582 is second number 86,401 (24*60*60 + 01). 19:00:01.078 on 4 June 1990 is second number 12,863,905,201.078. If the local time is not available from the system, output_seconds is set to 0 and CEELOCT terminates with a non-CEE000 symbolic feedback code.

output_Gregoriant (output)
A 17-byte fixed-length character string in the form YYYYMMDDHHMISS999 representing local year, month, day, hour, minute, second, and millisecond. If the format of output_Gregoriant does not meet your needs, you can use the CEEDATM callable service to convert output_seconds to another format.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2F3</td>
<td>3</td>
<td>2531</td>
<td>The local time was not available from the system.</td>
</tr>
</tbody>
</table>

Usage notes
- z/OS consideration—The MVS command SET DATE will not affect the value returned by CEELOCT.
- CICS consideration—CEELOCT does not use the OS TIME macro.
- z/OS UNIX consideration—In multithread applications, CEELOCT affects only the calling thread.

For more information
- See "CEEDATM—Convert seconds to character timestamp" on page 238 for more information about the CEEDATM callable service.

Examples
1. Following is an example of CEELOCT called by C/C++.
**Module/FileName: EDCLOCT */

```c
#include <string.h>
#include <stdio.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {

_FEEBACK fc;
_INT4 lil_date;
_FLOAT8 local_date;
_CHAR17 gregorian_date;

CEELOCT(&lil_date,&local_date,gregorian_date,&fc);
if (_FBCHECK (fc, CEE000)! = 0) {
    printf("CEELOCT failed with message number %d\n", fc.tok_msgno);
    exit(2999);
}

printf("The current date is YYYYMMDDHHMISS999\n");
printf("%.17s\n", gregorian_date);
}
```

end pliloct;
```
CEEMGET

CEEMGET—Get a message

CEEMGET retrieves, formats, and stores in a passed message area a message corresponding to a condition token that is either returned from a callable service or passed to a user-written condition handler. The caller can later retrieve the message to change or to write as output.

Syntax

```plaintext
CEEMGET(cond_token, message_area, msg_ptr, fc)
```

`cond_token (input/output)`

A 12-byte condition token received or returned as the result of a Language Environment callable service.

`message_area (input/output)`

A fixed-length 80-character string (VSTRING), where the message is placed. The message is left-justified and padded on the right with blanks.

`msg_ptr (input/output)`

A 4-byte binary integer returned to the calling routine. The `msg_ptr` should be passed a value of zero on the initial call to CEEMGET. If a message is too large to be contained in the `message_area`, `msg_ptr` (containing the index) is returned into the message. This index is used on subsequent calls to CEEMGET to retrieve the remaining portion of the message. A feedback code is also returned, indicating that the message was truncated. When the entire message is returned, `msg_ptr` is zero.

The `msg_ptr` contains different results based on the length of the message:

- If a message contains fewer than 80 characters, the entire message is returned on the first call. `msg_ptr` contains 0.
- If a message contains exactly 80 characters, the entire message is returned on the first call. `msg_ptr` contains 0.
- If the message is too long, CEEMGET splits it into segments. The `msg_ptr` does not contain the cumulative index for the entire message returned so far, but contains only the index into the segment that was just returned. It is up to the user of CEEMGET to maintain the cumulative count if needed. When a message is too long, the following can occur:
  - If a message contains more than 80 characters and at least one blank is contained in the first 80 characters, the string up to and including the last blank is returned on the first call.
  - If the 80th character is nonblank (even if the 81st character is a blank), `msg_ptr` contains the index of the last blank (something less than 80), and the next call starts with the next character.
  - If the 80th character is a blank, `msg_ptr` contains 80 and the next call starts with the 81st character, blank or nonblank.
  - If a message contains more than 80 characters and at least the first 80 are all nonblank, the first 80 are returned and the next call does not add any blanks and starts with the 81st character. `msg_ptr` contains 80.

`fc (output)`

A 12-byte feedback code, optional in some languages, that indicates the result.
of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE036</td>
<td>3</td>
<td>0102</td>
<td>An unrecognized condition token was passed to routine and could not be used.</td>
</tr>
<tr>
<td>CEE0E2</td>
<td>3</td>
<td>0450</td>
<td>The message inserts for the condition token with message number message-number and facility ID facility-id could not be located.</td>
</tr>
<tr>
<td>CEE0E6</td>
<td>3</td>
<td>0454</td>
<td>The message number message-number could not be found for facility ID facility-id.</td>
</tr>
<tr>
<td>CEE0E7</td>
<td>1</td>
<td>0455</td>

</tr>
<tr>
<td>CEE0EA</td>
<td>3</td>
<td>0458</td>
<td>The message repository repository-name could not be located.</td>
</tr>
</tbody>
</table>

**Usage notes**

- z/OS UNIX considerations—In multithread applications, CEEMGET affects only the calling thread. However, CEEMGET uses the NATLANG value of the enclave. Any subsequent calls to CEEMGET, for a given condition, use the NATLANG value in effect at the time of the first call.

**For more information**

- See “CEENCOD—Construct a condition token” on page 379 for a description of the 12-byte condition token constructed by the CEENCOD callable service.

**Examples**

1. Following is an example of CEEMGET called by C/C++.

```c
#include <string.h>
#include <stdio.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceedcct.h>

int main(void) {
    ...     

    /* construct a token for CEE message 2523 */
    c_1 = 1;
    c_2 = 2523;
    cond_case = 1;
    sev = 1;
    control = 1;
    memcpy(facid,"CEE",3);
    isi = 0;
}
```
CEENCOD(&c_1,&c_2,&cond_case,&sev,&control,;
facid,&isi,&token,&fc);

if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
    printf("CEENCOD failed with message number %d\n", fc.tok_msgno);
    exit(2999);
}

msgindx = 0;
memset(msgarea, ' ',79);/* initialize the message area */
msgarea_80 = '\0';

/* use CEEMGET until all the message has been */
/* retrieved */
/* msgindx will be zero when all the message has */
/* been retrieved */
do {
    CEEMGET(&token,msgarea,&msgindx,&fc);
    if (fc.tok_sev > 1 ) {
        printf("CEEMGET failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    /* put out the message using CEEMOUT */
    memcpy(message.string,msgarea,80);
    message.length = 80;
    dest = 2;
    CEEMOUT(&message,&dest,&fc);

   || FC.MsgNo );
   STOP;
   END;

END PLIMGET;
CEEMOUT—Dispatch a message

CEEMOUT dispatches a user-defined message string to the message file.

Syntax

```
CEEMOUT(message_string, destination_code, fc)
```

message_string (input)
A halfword-prefixed printable character string containing the message. DBCS characters must be enclosed within shift-out (byte X'0F') shift-in (X'0E') characters. Insert data cannot be placed in the message with CEEMOUT. The halfword-prefixed message string (input) must contain only printable characters. For length greater than zero, unpredictable results will occur if the byte following the halfword prefix is X'00'.

destination_code (input)
A 4-byte binary integer. The only accepted value for destination_code is 2. Under systems other than CICS, Language Environment writes the message to the ddname of the file specified in the MSGFILE runtime option. Under CICS, the message is written to a transient data queue named CESE.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to the “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE0E3</td>
<td>3</td>
<td>0451</td>
<td>An invalid destination code destination-code was passed to routine routine-name.</td>
</tr>
<tr>
<td>CEE0E9</td>
<td>3</td>
<td>0457</td>
<td>The message file destination ddname could not be located.</td>
</tr>
</tbody>
</table>

Usage notes

- z/OS UNIX considerations—In multithread applications, CEEMOUT affects only the calling thread. When multiple threads write to the message file, the output is interwoven by line. To group lines of output, serialize MSGFILE access (by using a mutex, for example).
- If the message file is defined with an LRECL greater than 256, and the input to CEEMOUT is greater than 256 bytes, the output results in multiple records. The first 256 bytes of each record contains output data. The remaining bytes of each record, up to the LRECL size, might contain unpredictable data.

For more information

- See “MSGFILE” on page 55 for more information about the MSGFILE runtime option.
- See z/OS Language Environment Programming Guide for more information about CESE.

Chapter 5. Callable services 359
CEEMRCE—Move resume cursor explicit

The CEEMRCE service resumes execution of a user routine at the location established by CEE3SRP. CEEMRCE is designed to be called from a user condition handler and works only in conjunction with the CEE3SRP service.

Syntax

```
►►—CEEMRCE—(—resume_token—,—fc—)
```

resume_token (input)

An INT4 data type that contains a token, returned from the CEE3SRP service, representing the resume point in the user routine.

fc (output/optional)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>0</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE07V</td>
<td>2</td>
<td>0255</td>
<td>The first parameter passed to CEEMRCE was an unrecognized label.</td>
</tr>
</tbody>
</table>

Usage notes

- Exit DSA routines are invoked as the resume cursor is moved back across stack frames.
- When a resume is requested, the state of the machine indicated in the machine state block is established prior to entry at the resume point.

For more information

- See [z/OS Language Environment Programming Guide](z/OS Language Environment Programming Reference) for more information about the CEEMRCE callable service.

CEEMRCR—Move resume cursor

CEEMRCR moves the resume cursor to a position relative to the current position of the handle cursor. The actions supported are:

- Moving the resume cursor to the call return point of the routine registering the executing condition handler.
- Moving the resume cursor to the caller of the routine registering the executing condition handler.

Initially, the resume cursor is placed after the instruction that caused the condition. Whenever CEEMRCR moves the resume cursor and passes stack frames, associated exit routines are invoked. Note that "exit routine" refers to user condition handlers as well as language-specific condition handlers. In addition, any associated user condition handlers are unregistered. The movement direction is always toward earlier stack frames, never toward more recent stack frames. The movement occurs only after the condition handler returns to the Language Environment condition manager.

Multiple calls to CEEMRCR yield the net results of the calls; that is, if two calls move the resume cursor to different places for the same stack frame, the most restrictive call (that closest to the earliest stack frame) is used for that stack frame.

Moving the resume cursor to a particular stack frame:
- Cancels all stack frames from the previous resume point up to but not including the new resume point
- Unregisters any user condition handlers registered for the canceled stack frames

Syntax

```
CEEMRCR(—type_of_move—, —fc—)
```

type_of_move (input)
A fullword binary signed integer indicating the target of the resume cursor movement. The possible values for type_of_move are:

0  Move the resume cursor to the call return point of the stack frame associated with the handle cursor.
1  Move the resume cursor to the call return point of the stack frame prior to the stack frame associated with the handle cursor. The handle cursor is moved to the most recently established condition handler of the stack frame. The new resume cursor position now points to this condition handler for the stack frame. Do not use a type_of_move value of 1 if the caller of the stack frame associated with the handle cursor is a nested COBOL program.

Modifying the resume cursor to point to stack frame 0 is not allowed. You cannot move the resume cursor beyond the earliest stack frame.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE07U</td>
<td>1</td>
<td>0254</td>
<td>The first parameter passed to CEEMRCR was not 0 or 1.</td>
</tr>
<tr>
<td>CEE083</td>
<td>3</td>
<td>0259</td>
<td>A move to stack frame zero using CEEMRCR was attempted from a MAIN routine.</td>
</tr>
<tr>
<td>CEE084</td>
<td>3</td>
<td>0260</td>
<td>No condition was active when a call to a condition management routine was made. The requested function was not performed.</td>
</tr>
<tr>
<td>CEE08L</td>
<td>1</td>
<td>0277</td>
<td>CEEMRCR was called to perform an unnecessary move.</td>
</tr>
</tbody>
</table>

Usage notes

- PL/I MTF consideration—CEEMRCR is not supported in PL/I MTF applications. This includes any CEEHDLR service called from a COBOL program in the application.
- z/OS UNIX considerations—In multithread applications, CEEMRCR affects only the calling thread. You can use CEEMRCR only within the thread’s call chain.
Illustration of CEEMRCR Usage

The following three figures illustrate how you can move the resume cursor by using the CEEMRCR service.

In Figure 9, routine A calls routine B, which in turn calls C, which calls D. User condition handlers are registered in routines B and C.

When a condition is raised in routine D, the Language Environment condition manager passes control to the user condition handler established for routine C. The handle cursor now points to the stack frame for routine C. Routine C percolates the condition.

The handle cursor now points to the stack frame for routine B. The next user condition handler to gain control is that one established for routine B; it recognizes the condition and issues a resume by calling CEEMRCR.

A 0 type_of_move, meaning move the resume cursor to the stack frame associated with the handle cursor, causes control to resume at the call return point in routine B, the instruction immediately following the call to routine C. A 1 type_of_move, meaning move the resume cursor to the call return point of the stack frame immediately preceding the one to which the handle cursor points, moves the resume cursor to the instruction immediately following a call in routine A to routine B.

The same scenario is illustrated in Figure 10 on page 368, except that HDLR2 issues a resume for the signaled condition rather than percolating it. HDLR1 never
gains control. Because the handle cursor now points to the stack frame for routine C, a 0 type_of_move causes control to resume at the call return point in routine C, the instruction immediately following the call to routine D. A 1 type_of_move moves the resume cursor to the instruction immediately following a call in routine B to routine C.

![Diagram](image)

Figure 10. Second example moving resume cursor using CEEMRCR

In Figure 11 on page 369, the user condition handlers are established for routines C and D. When a condition is raised in routine D, only a 1 type_of_move is permitted. A 0 type_of_move results in error warning message CEE0277.
Examples

1. Following is an example of CEEMRCR called by C/C++.

/*Module/FileName: EDCMRCR */

#include <stdio.h>
#include <string.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceeedcct.h>

#ifdef __cplusplus
extern "C"
#endif

void handler(_FEEDBACK *,_INT4 *,_INT4 *,_FEEDBACK *);

#ifdef __cplusplus
}
#endif

void b(void);

int main(void) {
    /*
     
     */
    /*
     */
    b();
    /* the CEEMRCR call in the handler will place the */
    /* resume cursor at this point. */
    /*
    */
void b(void) {
    _FEEDBACK fc, condtok;
    _ENTRY routine;
    _INT4 token, qdata;
    _INT2 c_1, c_2, cond_case, sev, control;
    _CHAR3 facid;
    _INT4 isi;
    /* register the condition handler */
    token = 99;
    routine.address = (_POINTER)&handler;;
    routine.nesting = NULL;
    CEEHDLR(&routine, &token, &fc);
    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEEHDLR failed with message number %d\n", fc.tok_msgno);
        exit (2999);
    }
    /*
     *
     */
    /* set up the condition using CEENCOD */
    c_1 = 3;
    c_2 = 2523;
    cond_case = 1;
    sev = 3;
    control = 0;
    memcpy(facid, "CEE", 3);
    isi = 0;
    CEENCOD(&c_1, &c_2, &cond_case, &sev, &control,;
             facid, &isi, &condtok, &fc);
    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEENCOD failed with message number %d\n", fc.tok_msgno);
        exit (2999);
    }
    /* signal the condition */
    CEESGL(&condtok, &qdata, &fc);
    if (_FBCHECK (fc, CEE000) != 0) {
        printf("CEESGL failed with message number %d\n", fc.tok_msgno);
        exit (2999);
    }
    /*
     *
     */
    void handler(_FEEDBACK *fc, _INT4 *token, _INT4 *result, _FEEDBACK *newfc) {
        _FEEDBACK cursorfc, orig_fc;
        _INT4 type;
        /*
         */
        /* move the resume cursor to the caller of the */
/* routine that registered the condition handler */
type = 1;
CEEMRCR(&type,&cursorfc);
if ( _FBCHECK ( cursorfc , CEE000 ) != 0 ) {
    printf("CEEMRCR failed with message number %d\n", 
            cursorfc.tok_msgno);
    exit (2999);
}
printf("condition handled\n");
*result = 10;
return;
}

        end;
      end;
    else
      /* something besides div-zero token */
  do;
CEEMSG—Get, format, and dispatch a message

CEEMSG gets, formats, and dispatches a message corresponding to an input condition token received from a callable service or passed to a user-written condition handler. You can use this service to print a message after a call to any Language Environment service that returns a condition token.

Syntax

\[
\text{CEEMSG}(\text{cond\_token}, \text{destination\_code}, \text{fc})
\]

cond_token (input)
A 12-byte condition token received as the result of a Language Environment callable service.

destination_code (input)
A 4-byte binary integer. destination_code can be specified only as 2, meaning write the message to the ddname of the file specified in the MSGFILE runtime option.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE0E2</td>
<td>3</td>
<td>0450</td>
<td>The message inserts for the condition token with message number message-number and facility ID facility-id could not be located.</td>
</tr>
<tr>
<td>CEE0E3</td>
<td>3</td>
<td>0451</td>
<td>An invalid destination code destination-code was passed to routine routine-name.</td>
</tr>
<tr>
<td>CEE0E6</td>
<td>3</td>
<td>0454</td>
<td>The message number message-number could not be found for facility ID facility-id.</td>
</tr>
<tr>
<td>CEE0E9</td>
<td>3</td>
<td>0457</td>
<td>The message file destination ddname could not be located.</td>
</tr>
<tr>
<td>CEE0EA</td>
<td>3</td>
<td>0458</td>
<td>The message repository repository-name could not be located.</td>
</tr>
<tr>
<td>CEE3CT</td>
<td>3</td>
<td>3485</td>
<td>An internal message services error occurred while locating the message number within a message file.</td>
</tr>
<tr>
<td>CEE3CU</td>
<td>3</td>
<td>3486</td>
<td>An internal message services error occurred while formatting a message.</td>
</tr>
<tr>
<td>CEE3CV</td>
<td>3</td>
<td>3487</td>
<td>An internal message services error occurred while locating a message number within the ranges specified in the repository.</td>
</tr>
</tbody>
</table>
Usage notes

- z/OS UNIX considerations—In multithread applications, CEEMSG affects only the calling thread. When multiple threads write to the message file, the output is interwoven by line. To group lines of output, serialize MSGFILE access (by using a mutex, for example).

For more information

- See "CEENCOD—Construct a condition token" on page 379 for more information about the CEENCOD callable service.
- See "MSGFILE" on page 55 for more information about the MSGFILE runtime option.

Examples

1. Following is an example of CEEMSG called by C/C++.

```c
#include <string.h>
#include <stdio.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {
    _VSTRING message;
    _INT4 dest, msgindx;
    _CHAR80 msgarea;
    _FEEDBACK fc, token;

    strcpy(message.string, "This is a test message");
    message.length = strlen(message.string);
    dest = 5; /* invalid dest so CEEMOUT will fail */
    CEEMOUT(&message, &dest, &fc);

    if (_FBCHECK(fc, CEE000) != 0) {
        /* put the message if CEEMOUT failed */
        dest = 2;
        CEEMSG(&fc, &dest, NULL);
        exit(2999);
    }
}
```

2. Following is an example of CEEMSG called by COBOL.

```cobol
IDENTIFICATION DIVISION.
PROGRAM-ID. CBLMSG.
DATA DIVISION.
```

CEEMSG

IF ¬FBCHECK( FC2, CEE000) THEN DO;
    DISPLAY('CEEMSG failed with msg'
|| FC.MsgNo);
    STOP;
END;

END PLIMSG;
```
CEENCOD—Construct a condition token

CEENCOD dynamically constructs a 12-byte condition token that communicates a condition in Language Environment. The condition token communicates with the Language Environment message and condition handling callable services, and user routines. Also, all Language Environment callable services use the condition-token data type to return information to the user as a feedback code.

**Syntax**

```plaintext
CEENCOD(c_1, c_2, case, severity, control, facility_ID, i_s_info, cond_token, fc)
```

- **c_1 (input)**
  - c_1 and c_2 together make up the condition_ID portion of the condition token.
  - c_1 is a 2-byte binary integer representing the value of the first 2 bytes of the 4-byte condition_ID. For case 1, c_1 represents the severity; for case 2, it is the class_code.

- **c_2 (input)**
  - A 2-byte binary integer representing the value of the second 2 bytes of the condition_ID. For case 1, this is the Msg_No; for case 2, it is the cause_code.

- **case (input)**
  - A 2-byte binary integer defining the format of the condition_ID portion of the token.

- **severity (input)**
  - A 2-byte binary integer indicating the condition's severity. For case 1 conditions, the value of this field is the same as the severity value specified in the condition_ID. For case 1 and 2 conditions, this field is also used to test the condition's severity. **severity** can be specified with the following values:
    - 0 Information only (or, if the entire token is 0, no information).
    - 1 Warning; service completed, probably correctly.
    - 2 Error detected and correction attempted; service completed, perhaps incorrectly.
    - 3 Severe error; service not completed.
    - 4 Critical error; service not completed; condition signaled. A critical error is a condition jeopardizing the environment. If a critical error occurs during a Language Environment callable service, it is always signaled to the condition manager instead of returning synchronously to the caller.

- **control (input)**
  - A 2-byte binary integer containing flags describing or controlling various aspects of condition handling. Valid values for the control field are 1 and 0. 1 indicates the facility_ID is assigned by IBM. 0 indicates the facility_ID is assigned by the user.

- **facility_ID (input)**
  - A 3-character field containing three alphanumeric characters (A-Z, a-z and 0-9)
identifying the product or component of a product generating this condition or feedback information, for example, CEE.

The *facility_ID* is associated with the repository (for example, a file) of the runtime messages. If a unique ID is required (for IBM and non-IBM products), an ID can be obtained by contacting an IBM project office.

If you create a new *facility_ID* to use with a message file you created by using the CEEBLDTX utility, be aware that the *facility_ID* must be part of the message file name. It is therefore important to follow the naming guidelines described below in order to have a module name that does not cause your application to abend.

Begin a non-IBM assigned product *facility_ID* with letters J through Z. (See the preceding description control (input) parameter on how to indicate whether the *facility_ID* has been assigned by IBM.) Special characters, including blank spaces, cannot be used in a *facility_ID*. There are no other constraints (besides the alphanumeric requirement) on a non-IBM assigned *facility_ID*.

**i_s_info (input)**
A fullword binary integer identifying the ISI, that contains insert data. Whenever a condition is detected by the Language Environment condition manager, insert data is generated describing the instance of its occurrence is generated. This insert data is used, for example, to write to a file a message associated with that instance or occurrence of the condition.

**cond_token (output)**
The 12-byte representation of the constructed condition token.

**fc (output)**
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE0CH</td>
<td>3</td>

</tr>
<tr>
<td>CEE0E4</td>
<td>3</td>
<td>0452</td>
<td>An invalid facility ID <em>facility-id</em> was passed to routine <em>routine-name</em>.</td>
</tr>
</tbody>
</table>

**Usage notes**

- **C/C++ considerations**—The structure of the condition token (type_FEEDBACK) is described in the `leaw1.h` header file shipped with Language Environment. You can assign values directly to the fields of the token in the header file without using the CEENCOD service. Figure 12 on page 381 shows the layout of the type_FEEDBACK condition token in the header file.
z/OS UNIX consideration—In multithread applications, CEENCOD affects only the calling thread.

For more information

- For more information about case 1 and case 2, see CEENCOD "Usage notes" on page 380.

Examples

1. Following is an example of CEENCOD called by C/C++.

```c
typedef struct {
    short tok_sev ; /* severity */
    short tok_msgno ; /* message number */
    int tok_case ;2. /* flags-case/sev/cont */
    tok_sever:3,
    tok_ctrl :3 ;
    char tok_facid3]; /* fac ID */
    int tok_isi ; /* index in ISI block */
} _FEEDBACK;

Figure 12. type_FEEDBACK data type as defined in the leawi.h header file

2. Following is an example of CEENCOD called by COBOL.

typedef struct {
    short tok_sev ; /* severity */
    short tok_msgno ; /* message number */
    int tok_case ;2. /* flags-case/sev/cont */
    tok_sever:3,
    tok_ctrl :3 ;
    char tok_facid3]; /* fac ID */
    int tok_isi ; /* index in ISI block */
} _FEEDBACK;

CEEQCEN—Query the century window

CEEQCEN queries the century in which Language Environment contains the
2-digit year value. When you want to change the setting, use CEEQCEN to get the
setting and then use CEESCEN to save and restore the current setting.

Syntax

```
>>>CEEQCEN(---century_start---,---fc---)<<<
```

century_start (output)
An integer between 0 and 100 indicating the year on which the century
window is based. For example, if the Language Environment default is in
effect, all 2-digit years lie within the 100-year window starting 80 years prior to
the system date. CEEQCEN then returns the value 80. An 80 value indicates to
Language Environment that, in 1995, all 2-digit years lie within the 100-year
window starting 80 years before the system date (between 1915 and 2014,
inclusive).

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result
of this service. If you choose to omit this parameter, refer to "Invoking callable
services" on page 116 for the appropriate syntax to indicate that the feedback
code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

Usage notes

- z/OS UNIX considerations—CEEQCEN applies to the enclave, as does the
century window.
For more information

- See “CEESCEN—Set the century window” on page 396 for more information about the CEESCEN callable service.

Examples

1. Following is an example of CEEQCEN called by C/C++.

```c
#include <string.h>
#include <stdio.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceeedcct.h>

int main (void) {
    _INT4 century_start;
    _FEEDBACK fc;

    /* query the century window */
    CEEQCEN(&century_start,&fc);
    if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
        printf("CEEQCEN failed with message number %d\n",
                fc.tok_msgno);
        exit(2999);
    }

    /* if the century window is not 50 set it to 50 */
    if (century_start != 50) {
        century_start = 50;
        CEESCEN(&century_start,&fc);
        if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
            printf("CEESCEN failed with message number %d\n",
                    fc.tok_msgno);
            exit(2999);
        }
    }
}
```

2. Following is an example of CEEQCEN called by COBOL.

/* to check, so print result */
IF FBCHECK( FC, CEE000) THEN DO;
   PUT SKIP LIST ('The century window starts '||STARTCW||' years before today.');
CEEQDTC—Query locale date and time conventions

CEEQDTC, analogous to the C language function `localdtconv()`, queries the date and time conventions from the current locale and sets the components of a structure with values appropriate to the settings for the LC_TIME category. CEEQDTC is sensitive to the locales set by `setlocale()` or CEESETL, not to the Language Environment settings from COUNTRY or CEE3Cty.

**Syntax**

```
CEEQDTC(—version—,—localdt—,—fc—)
```

**version**

This parameter points to a user supplied VERSION_INFO structure, in which the first four bytes contain the callable service version number.

**Requirement:** If the parameter does not points to a user supplied VERSION_INFO structure, it must be omitted. If the parameter points to a VERSION_INFO containing version number 1, CEEQDTC returns a DTCONV structure with the new element showing the format of the ISO 8601:2000 standard date. If the parameter is omitted, CEEQDTC returns the DTCONV format used before C99. For information about how to code this parameter, see “Invoking callable services” on page 116.

**localdt** *(output)*

A pointer to the data structure containing the date and time formatting information from the current, active locale. The fields used to populate the structure come from the LC_TIME category. The LC_TIME category structure fields used to retrieve the date and time values are:

- **abmon**
  
  Abbreviated month names (12 instances of a halfword length-prefixed character string, VSTRING, of 22 bytes)

- **mon**
  
  Month names (12 instances of a halfword length-prefixed character string, VSTRING, of 62 bytes)

- **abday**
  
  Abbreviated day names (7 instances of a halfword length-prefixed character string, VSTRING, of 22 bytes)

- **day**
  
  Day names (7 instances of a halfword length-prefixed character string, VSTRING, of 62 bytes)

- **d_t_fmt**
  
  Date and time format (1 instance of a halfword length-prefixed character string, VSTRING, of 82 bytes)
**CEEQDTC**

- **d_fmt** Date format (1 instance of a halfword length-prefixed character string, VSTRING, of 42 bytes)
- **t_fmt** Time format (1 instance of a halfword length-prefixed character string, VSTRING, of 42 bytes)
- **am_fmt** AM string (1 instance of a halfword length-prefixed character string, VSTRING, of 22 bytes)
- **pm_fmt** PM string (1 instance of a halfword length-prefixed character string, VSTRING, of 22 bytes)
- **t_fmt_ampm** Time format ampm (1 instance of a halfword length-prefixed character string, VSTRING, of 42 bytes)
- **ISO_STD8601_2000** ISO8601:2000 standard date format (1 instance of a halfword length-prefixed character string, VSTRING, of 42 bytes)
- **fc** (output) A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3T1</td>
<td>3</td>
<td>4001</td>
<td>General Failure: Service could not be completed.</td>
</tr>
<tr>
<td>CEE3VN</td>
<td>3</td>
<td>4087</td>
<td>Input Error: The version_info control block contains a version number that is not valid.</td>
</tr>
</tbody>
</table>

**Usage notes**

- PL/I MTF consideration—CEEQDTC is not supported in PL/I MTF applications.
- If no call to CEESETL has been made, the default locale values to be used are determined at installation time for Language Environment.
- This callable service uses the C/C++ runtime library. The C/C++ library must be installed and accessible even when this service is called from a non-C program.

**For more information**

- See "CEESETL—Set locale operating environment” on page 413 for more information about the current locale.

                     DTCONV.D_T_FMT );
   END;
END PLIQDTC;

---

**CEEQRYL—Query active locale environment**

CEEQRYL, analogous to the C language function "localename=setlocale(category, NULL)" queries the environment for which locale defines the current setting for the locale category. CEEQRYL is sensitive to the locales set by setlocale() or CEESETL, not to the Language Environment settings from COUNTRY or CEE3CTY.

**Syntax**

```
►► CEEQRYL(category, localename, fc)◄◄
```

*category* (input)
A symbolic integer number that represents all or part of the locale for a
program. Depending on the value of the `localename`, these categories can be
initiated by the values of global categories of corresponding names. The
following values for the `category` parameter are valid; Language Environment
locale callable services do not support the LC_TOD and LC_SYNTAX
categories.

**LC_ALL**
A 4-byte integer (with a value of -1) that affects all locale categories
associated with a program's locale.

**LC_COLLATE**
A 4-byte integer (with a value of 0) that affects the behavior of regular
expression and collation subroutines.

**LC_CTYPE**
A 4-byte integer (with a value of 1) that affects the behavior of regular
expression, character classification, case conversion, and wide character
subroutines.

**LC_MESSAGES**
A 4-byte integer (with a value of 6) that affects the format and values for
positive and negative responses.

**LC_MONETARY**
A 4-byte integer (with a value of 3) that affects the behavior of subroutines
that format monetary values.

**LC_NUMERIC**
A 4-byte integer (with a value of 2) that affects the behavior of subroutines
that format non-monetary numeric values.

**LC_TIME**
A 4-byte integer (with a value of 4) that affects the behavior of time
conversion subroutines.

`localename` *(output)*

Returns the name of the locale that describes the current setting of the category
requested.

`fc` *(output)*

A 12-byte feedback code, optional in some languages, that indicates the result
of this service. If you choose to omit this parameter, refer to "Invoking callable
services" on page 116 for the appropriate syntax to indicate that the feedback
code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2KD</td>
<td>3</td>
<td>2701</td>
<td>An invalid category parameter was passed to a locale function.</td>
</tr>
<tr>
<td>CEE3T1</td>
<td>3</td>
<td>4001</td>
<td>General Failure: Service could not be completed.</td>
</tr>
</tbody>
</table>

**Usage notes**

- PL/I MTF consideration—CEEQRYL is not supported in PL/I MTF applications.
- CEEQRYL does not change the status of the active locales.
- This callable service uses the C/C++ runtime library. The C/C++ library must be
  installed and accessible even when this service is called from a non-C program.
If the active locale is not explicitly set with CEESETL or setlocale(category, localename), then the locale chosen is as follows:

- With POSIX(OFF), the SAA C locale is chosen, and querying the locale with CEEQRYL returns “C” as the locale name.
- With POSIX(ON), the POSIX C locale is chosen, and querying the locale with CEEQRYL returns “POSIX” as the locale name.

The SAA C locale provides compatibility with previous releases of C/370. The POSIX C locale provides consistency with POSIX requirements and supports the z/OS UNIX System Services environment.

For more information

- See “CEESETL—Set locale operating environment” on page 413 for more information about the current locale.
- For more information about LC_TIME, see “CEEQDTC—Query locale date and time conventions” on page 387.
- For information about the definition of the SAA C and POSIX C locales and the differences between them, see z/OS XL C/C++ Programming Guide.

Examples

For examples of how to use CEEQRYL with other Language Environment locale callable services, see “CEESETL—Set locale operating environment” on page 413.

CEERAN0—Calculate uniform random numbers

CEERAN0 generates a sequence of uniform pseudo-random numbers between 0.0 and 1.0 using the multiplicative congruential method with a user-specified seed. The uniform (0,1) pseudo-random numbers are generated using the multiplicative congruential method:

\[
\begin{align*}
\text{seed}(i) &= (950706376 \times \text{seed}(i-1)) \mod 2147483647; \\
\text{randomno}(i) &= \text{seed}(i) / 2147483647;
\end{align*}
\]

Syntax

```
CEERAN0(--seed--,--random_no--,--fc--)
```

**seed (input/output)**

A fullword binary signed integer representing an initial value used to generate random numbers. seed must be a variable; it cannot be an input-only parameter. The valid range is 0 to +2,147,483,646. If seed equals 0, the seed is generated from the current Greenwich Mean Time. On return to the calling routine, CEERAN0 changes the value of seed so that it can be used as the new seed in the next call.

**random_no (output)**

An 8-byte double precision floating-point number with a value between 0 and 1, exclusive. If seed is invalid, random_no is set to -1 and CEERAN0 terminates with a non-CEE000 symbolic feedback code.
CEERAN0

fc (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2ER</td>
<td>1</td>
<td>2523</td>
<td>The system time was not available when CEERAN0 was called. A seed value of 1 was used to generate a random number and a new seed value.</td>
</tr>
<tr>
<td>CEE2ES</td>
<td>3</td>
<td>2524</td>
<td>An invalid seed value was passed to CEERAN0. The random number was set to -1.</td>
</tr>
</tbody>
</table>

Usage notes

- z/OS UNIX considerations—In multithread applications, CEERAN0 affects only the calling thread. The seed is unique to the thread.

Examples

1. Following is an example of CEERAN0 called by C/C++.

```c
#include <string.h>
#include <stdio.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceeedcct.h>

int main (void) {
    _INT4 seed;
    _FLOAT8 random;
    _FEEDBACK fc;
    int number;

    seed = 0;
    CEERAN0(&seed,&random,&fc);
    if (_FBCHECK ( fc , CEE000 ) != 0 ) {
        printf("CEERAN0 failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    number = random * 1000;
    printf("The 3 digit random number is %d\n",number);
}
```

2. Following is an example of CEERAN0 called by COBOL.

CEESCEN—Set the century window

CEESCEN sets the century in which Language Environment contains the 2-digit year value. Use it in conjunction with CEEDAYS or CEESecs when:
- You process date values containing 2-digit years (for example, in the YYMMDD format).
- The Language Environment default century interval does not meet the requirements of a particular application.

Century intervals are kept as thread-level data, so changing the interval in one thread does not affect the interval in another thread. To query the century window, use CEEQCEN.

CEEQCEN affects and is affected by only the Language Environment NLS and date and time services, not the Language Environment locale callable services or the C locale-sensitive functions.

Syntax

CEERAN0—(—century_start—,—fc—)

century_start
An integer between 0 and 100, setting the century window. A value of 80, for example, places all two-digit years within the 100-year window starting 80 years before the system date. In 1995, therefore, all two-digit years are assumed to represent dates between 1915 and 2014, inclusive.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:
Usage notes

- z/OS UNIX considerations—CEESCEN applies to the enclave. The century window applies to the enclave.

For more information

- See “CEEDAYS—Convert date to Lilian format” on page 243 for more information about the CEDAYS callable service.
- See “CEESECS—Convert timestamp to seconds” on page 407 for more information about the CEESECS callable service.
- See “CEEQCEN—Query the century window” on page 384 for more information about the CEEQCEN callable service.

Examples

1. Following is an example of CEESCEN called by C/C++.

```c
/*Module/File Name: EDSCEN */

#include <string.h>

   DCL STARTCW REAL FIXED BINARY(31,0);
CEESCOL—Compare collation weight of two strings

CEESCOL, which is analogous to the C language function `strcoll()`, compares two character strings based on the collating sequence specified in the `LC_COLLATE` category of the current locale. CEESCOL associates a collation weight with every character in the code set for the locale. The characters in the input strings are converted to their collation weights and then compared on the basis of these weights. CEESCOL is sensitive to the locales set by `setlocale()` or `CEESETL`, not to the Language Environment settings from `COUNTRY` or `CEE3CTY`.

### Syntax

```
CEESCOL(omitted_parm,string1,string2,result,fc)
```

**omitted_parm**

This parameter is reserved for future expansion and must be omitted. For information about how to code an omitted parameter, see "Invoking callable services" on page 316.

**string1** (input)

A halfword length-prefixed character string (VSTRING) with a maximum length of 4K bytes. `string1` points to a string of characters that are to be compared against `string2`.

**string2** (input)

A halfword length-prefixed character string (VSTRING) with a maximum length of 4K bytes. `string2` points to a string of characters that `string1` is compared against.
result (output)

Specifies the result of the string comparison. If successful, the following values are returned:

- Less than 0, if string1 is less than string2
- Equal to 0, if string1 is equal to string2
- Greater than 0, if string1 is greater than string2

fc (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>

### CEESECI—Convert seconds to integers

CEESECI converts a number representing the number of seconds since 00:00:00 14 October 1582 to seven separate binary integers representing year, month, day, hour, minute, second, and millisecond. Use CEESECI instead of CEEDATM when the output is needed in numeric format rather than in character format.

The inverse of CEESECI is CEEISEC, which converts integer year, month, day, hour, second, and millisecond to number of seconds. If the input value is a Lilian date instead of seconds, multiply the Lilian date by 86,400 (number of seconds in a day), and pass the new value to CEESECI.

---

402  z/OS Language Environment Programming Reference
input_seconds
A 64-bit double floating-point number representing the number of seconds since 00:00:00 on 14 October 1582, not counting leap seconds. For example, 00:00:01 on 15 October 1582 is second number 86,401 (24*60*60 + 01). The valid range for input_seconds is 86,400 to 265,621,679,999.999 (23:59:59.999 31 December 9999). If input_seconds is invalid, all output parameters except the feedback code are set to 0.

output_year (output)
A 32-bit binary integer representing the year. The range of valid output_years is 1582 to 9999, inclusive.

output_month (output)
A 32-bit binary integer representing the month. The range of valid output_months is 1 to 12.

output_day (output)
A 32-bit binary integer representing the day. The range of valid output_days is 1 to 31.

output_hours (output)
A 32-bit binary integer representing the hour. The range of valid output_hours is 0 to 23.

output_minutes (output)
A 32-bit binary integer representing the minutes. The range of valid output_minutes is 0 to 59.

output_seconds (output)
A 32-bit binary integer representing the seconds. The range of valid output_seconds is 0 to 59.

output_milliseconds (output)
A 32-bit binary integer representing milliseconds. The range of valid output_milliseconds is 0 to 999.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2E9</td>
<td>3</td>
<td>2505</td>
<td>The input_seconds value in a call to CEEDATM or CEESECI was not within the supported range.</td>
</tr>
</tbody>
</table>
Usage notes

- z/OS UNIX consideration—In multithread applications, CEESECI affects only the calling thread.

For more information

- For more information about the CEEISEC callable service, see "CEEISEC—Convert integers to seconds" on page 332.

Examples

1. Following is an example of CEESECI called by C/C++.

```c
/*Module/File Name: EDCSECI */

#include <string.h>
#include <stdio.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void)
{
    _INT4 year, month, day, hours, minutes, seconds,
    millisecs;
    _FLOAT8 input;

CEESECS—Convert timestamp to seconds

CEESECS converts a string representing a timestamp into the number of Lilian seconds (number of seconds since 00:00:00 14 October 1582). This service makes it easier to perform time arithmetic, such as calculating the elapsed time between two timestamps.

CEESECS is affected only by the country code setting of the COUNTRY runtime option or CEE3CTY callable service, not the CEESETL callable service or the setlocale() function.

The inverse of CEESECS is CEEDA TM, which converts output_seconds to character format. By default, 2-digit years lie within the 100 year range starting 80 years prior to the system date. Thus, in 1995, all 2-digit years represent dates between 1915 and 2014, inclusive. You can change this range by using the callable service CEESCEN.

Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEESECS(input_timestamp, picture_string, output_seconds, fc)</td>
<td></td>
</tr>
</tbody>
</table>

**input_timestamp (input)**

A length-prefixed character string representing a date or timestamp in a format matching that specified by picture_string. The character string must contain between 5 and 80 picture characters, inclusive. input_timestamp can contain leading or trailing blanks. Parsing begins with the first nonblank character (unless the picture string itself contains leading blanks; in this case, CEESECS skips exactly that many positions before parsing begins).

After a valid date is parsed, as determined by the format of the date you specify in picture_string, all remaining characters are ignored by CEESECS. Valid dates range between and including the dates 15 October 1582 to 31 December 9999. A full date must be specified. Valid times range from 00:00:00.000 to 23:59:59.999.

As the following example shows, if any part or all of the time value is omitted, zeros are substituted for the remaining values.

<table>
<thead>
<tr>
<th>Date</th>
<th>Equivalent Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>1992-05-17-19:02:00</td>
<td>1992-05-17-19:02:00</td>
</tr>
<tr>
<td>1992-05-17</td>
<td>1992-05-17-00:00:00</td>
</tr>
</tbody>
</table>

**picture_string (input)**

A halfword length-prefixed character string (VSTRING), indicating the format of the date or timestamp value specified in input_timestamp. Each character in the picture_string represents a character in input_timestamp. For example, if you specify MMDDYY HH.MI.SS as the picture_string, CEESECS reads an
input_char_date of 060288 15.35.02 as 3:35:02 PM on 02 June 1988. If delimiters such as the slash (/) appear in the picture string, leading zeros can be omitted. For example, the following calls to CEESECS all assign the same value to variable secs:

```
CALL CEESECS('92/06/03 15.35.03', 'YY/MM/DD HH.MM.SS', secs, fc);
CALL CEESECS('92/6/3 15.35.03', 'YY/MM/DD HH.MM.SS', secs, fc);
CALL CEESECS('92/6/3 3.35.03 PM', 'YY/MM/DD HH.MM.SS AP', secs, fc);
CALL CEESECS('92.155 3.35.03 pm', 'YY.DDD HH.MM.SS AP', secs, fc);
```

If picture string is left null or blank, CEESECS gets picture_string based on the current value of the COUNTRY runtime option. For example, if the current value of the COUNTRY runtime option is FR (France), the date format would be DD.MM.YYYY.

If picture_string includes a Japanese era symbol <JJJJ>, the YY position in input_timestamp represents the year number within the Japanese era. For example, the year 1988 equals the Japanese year 63 in the Showa era. See Table 35 on page 490 for a list of Japanese eras supported by CEESECS.

If picture_string includes era symbol <CCCC> or <CCCCCCCC>, the YY position in input_timestamp represents the year number within the era. See Table 33 on page 489 for a list of valid picture characters, and Table 34 on page 490 for examples of valid picture strings.

output_seconds (output)
A 64-bit double floating-point number representing the number of seconds since 00:00:00 on 14 October 1582, not counting leap seconds. For example, 00:00:01 on 15 October 1582 is second 86,401 (24*60*60 + 01) in the Lilian format. 19:00:12.12 on 16 May 1988 is second 12,799,191,601.12.

The largest value represented is 23:59:59.999 on 31 December 9999, which is second 265,621,679,999.999 in the Lilian format.

A 64-bit double floating-point value can accurately represent approximately 16 significant decimal digits without loss of precision. Therefore, accuracy is available to the nearest millisecond (15 decimal digits).

If input_timestamp does not contain a valid date or timestamp, output_seconds is set to 0 and CEESECS terminates with a non-CEE000 symbolic feedback code.

Elapsed time calculations are performed easily on the output_seconds, because it represents elapsed time. Leap year and end-of-year anomalies do not affect the calculations.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>

<td>2521</td>
<td>The year-within-era value passed to CEEDAYS or CEESECS was zero.</td>
</tr>
<tr>
<td>CEE2ET</td>
<td>3</td>
<td>2525</td>
<td>CEESECS detected non-numeric data in a numeric field, or the timestamp string did not match the picture string.</td>
</tr>
</tbody>
</table>

**Usage notes**

- The probable cause for receiving message number 2518 is a picture string that contains an invalid DBCS string. You should verify that the data in the picture string is correct.
- z/OS UNIX consideration—In multithread applications, CEESECS affects only the calling thread.

**For more information**

- See [“CEESCEN—Set the century window” on page 396](#) for more information about the CEESCEN callable service.
- See [“COUNTRY” on page 24](#) for more information about the COUNTRY runtime option.

**Examples**

1. Following is an example of CEESECS called by C/C++.

```c
/*Module/File Name: EDCSECS */

#include <stdio.h>
#include <string.h>
#include <leawi.h>
#include <stdlib.h>
#include <ceeedcct.h>

int main(void) {
    _FEEDBACK fc;
    _FLOAT8 seconds1, seconds2;
    _VSTRING date,date_pic;

    /* use CEESECS to convert to seconds timestamp */
    strcpy(date.string,"09/13/91 23:23:23");
```
date.length = strlen(date.string);
strcpy(date_pic.string,"MM/DD/YY HH:MI:SS");
date_pic.length = strlen(date_pic.string);
CEESECS(&date,&date_pic,&seconds1,&fc);
if (_FBCHECK (fc, CEE000) != 0) {
    printf("CEESECS failed with message number %d\n", fc.tok_msgno);
    exit(2999);
}
strcpy(date.string,
   "December 15, 1992 at 8:23:45 AM");
date.length = strlen(date.string);
strcpy(date_pic.string,
   "Mmmm DD, YYYY at HH:MI:SS AM");
date_pic.length = strlen(date_pic.string);
CEESECS(&date,&date_pic,&seconds2,&fc);
if (_FBCHECK (fc, CEE000) != 0) {
    printf("CEESECS failed with message number %d\n", fc.tok_msgno);
    exit(2999);
}
printf("The number of seconds between:\n");
printf(" September 13, 1991 at 11:23:23 PM\n");
printf(" and December 15, 1992 at 8:23:45 AM is:\n");
seconds2 - seconds1);
}

CEESETL—Set locale operating environment

CEESETL, analogous to the C language function `setlocale()`, establishes a global locale operating environment, which determines the behavior of character collation, character classification, date and time formatting, numeric punctuation, and positive/negative response patterns. CEESETL is sensitive to the locales set by `setlocale()` or CEESETL, not to the Language Environment settings from COUNTRY or CEE3CTY.

Syntax

```
CEESETL(localename, category, fc)
```

**localename (input)**

A halfword length-prefixed character string (VSTRING) with a maximum of 256 bytes. `localename` is a valid locale name known to the locale model. The category named in the call is set according to the named locale. If `localename` is null or blank, CEESETL sets the locale environment according to the environment variables. This is the equivalent to specifying `setlocale(LC_ALL,"")`. If these environment variables are defined, you can locate them in the following order:

- LC_ALL if it is defined and not null
- LANG if it is defined and not null
- The default C locale

**category (input)**

A symbolic integer number that represents all or part of the locale for a program. Depending on the value of the `localename`, these categories can be initiated by the values of global categories of corresponding names. The following values for the `category` parameter are valid:

- **LC_ALL**
  A 4-byte integer (with a value of -1) that affects all locale categories associated with a program’s locale.

- **LC_COLLATE**
  A 4-byte integer (with a value of 0) that affects the behavior of regular expression and collation subroutines.

- **LC_CTYPE**
  A 4-byte integer (with a value of 1) that affects the behavior of regular expression, character classification, case conversion, and wide character subroutines.

- **LC_MESSAGES**
  A 4-byte integer (with a value of 6) that affects the format and values for positive and negative responses.

- **LC_MONETARY**
  A 4-byte integer (with a value of 3) that affects the behavior of subroutines that format monetary values.

- **LC_NUMERIC**
  A 4-byte integer (with a value of 2) that affects the behavior of subroutines that format non-monetary numeric values.
**LC_TIME**
A 4-byte integer (with a value of 4) that affects the behavior of time conversion subroutines.

Language Environment locale callable services do not support the LC_TOD and LC_SYNTAX categories.

**fc (output)**
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2KD</td>
<td>3</td>
<td>2701</td>
<td>An invalid category parameter was passed to a locale function.</td>
</tr>
<tr>
<td>CEE2KE</td>
<td>3</td>
<td>2702</td>
<td>An invalid locale name parameter was passed to a locale function.</td>
</tr>
<tr>
<td>CEE3T1</td>
<td>3</td>
<td>4001</td>
<td>General Failure: Service could not be completed.</td>
</tr>
</tbody>
</table>

**Usage notes**
- PL/I MTF consideration—CEESETL is not supported in PL/I MTF applications.
- This callable service uses the C/C++ runtime library. The C/C++ library must be installed and accessible even when this service is called from a non-C program.
- The LC_ALL category indicates that all categories are to be changed with regard to the specific locale. The LC_ALL value, when set by CEESETL, becomes the current values for all six LC_* categories.
- If the active locale is not explicitly set with CEESETL or setlocale(*category, *localename), then the locale chosen is as follows:
  - With POSIX(OFF), the SAA C locale is chosen, and querying the locale with CEEQRL returns “C” as the locale name.
  - With POSIX(ON), the POSIX C locale is chosen, and querying the locale with CEEQRL returns “POSIX” as the locale name.

The SAA C locale provides compatibility with previous releases of C/370. The POSIX C locale provides consistency with POSIX requirements and supports the z/OS UNIX environment.

**For more information**
- See [z/OS XL C/C++ Runtime Library Reference](#) for details of how various locale categories affect C/C++ language functions.
- For more information about specifying environment variables to set the locale, see [z/OS XL C/C++ Programming Guide](#).
- For information about the definition of the SAA C and POSIX C locales and the differences between them, see [z/OS XL C/C++ Programming Guide](#).
- For more information about LC_TIME, see “CEEQDTC—Query locale date and time conventions” on page 387.

*/

CEESGL—Signal a condition

CEESGL raises, or signals, a condition to the Language Environment condition manager. It also provides qualifying data and creates an ISI for a particular instance of the condition. The ISI contains information used by the Language Environment condition manager to identify and react to conditions.

CEESGL is typically used to generate application-specific conditions that are recognized by condition handlers registered using CEEHDLR. Conditions can also be selected to simulate a Language Environment or system condition. If you plan on using a routine that signals a new condition with a call to CEESGL, you should first call the CEECMI callable service to copy any insert information into the ISI associated with the condition.

CEESGL generates a Language Environment condition. You can map some of the Language Environment condition tokens to POSIX signals. Unique conditions signaled by CEESGL are considered to be enabled under Language Environment. Therefore, they undergo Language Environment condition handling.

CEESGL can signal a POSIX condition. If CEESGL signals a POSIX condition and the signal is blocked at the time of the generation but later unblocked and delivered, the POSIX signal processing semantics are applied. The Language Environment synchronous condition manager semantics do not apply.

Severity 0 and 1 conditions are considered safe conditions. They can be ignored if they are not handled and if no feedback token is passed when the condition is raised.

Each signaled condition (of severity 2 or above) increments the error count by one. If the error count exceeds the error count limit (as specified by the ERRCOUNT runtime option—see “ERRCOUNT” on page 32), the condition manager terminates the enclave with abend code 4091, reason code 11. T_I_U (Termination Imminent due to an Unhandled Condition) is not issued. Promoted conditions do not increment the error count. A program established using the CEEHDLR callable service or one of the HLL condition handlers, can then process the raised condition.

ERRCOUNT applies to CEESGL only if the condition generated by CEESGL is delivered synchronously. POSIX signal handling semantics are then applied to the condition.
Table 24 on page 205 contains a list of the S/370 program interrupt codes and their corresponding Language Environment condition token names and message numbers.

**Syntax**

```
CEESGL(—cond_rep—, [q_data_token—,] fc—)
```

*cond_rep* (input)

A 12-byte condition token representing the condition to be signaled. You can either construct your own condition token or use one that Language Environment has already defined. Conditions signaled by CEESGL are not necessarily handled by Language Environment. If you call CEESGL with a *cond_rep*, Language Environment passes control to the language in which the routine is written. The condition manager then determines if it should handle the condition. If so, the HLL handles the condition. If not, control returns to Language Environment. The condition might also be ignored or blocked, or might result in enclave termination.

*q_data_token* (input/output)

An optional 32-bit data object placed in the ISI to access the qualifying data (q_data) associated with the given instance of the condition. The *q_data_token* is a list of information addresses a user condition handler uses to specifically identify and, if necessary, react to, a given condition. The information in the *q_data_token* provides a mechanism by which user-written condition handlers can provide a complete fix-up of some conditions. The *q_data token* associated with a condition using CEESGL can be extracted later using the CEEGQDT callable service.

*fc* (output / optional)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE069</td>
<td>0</td>
<td>0201</td>
<td>An unhandled condition was returned in a feedback code.</td>
</tr>
<tr>
<td>CEE0CE</td>
<td>1</td>
<td>0398</td>
<td>Resume with new input.</td>
</tr>
<tr>
<td>CEE0CF</td>
<td>1</td>
<td>0399</td>
<td>Resume with new output.</td>
</tr>
<tr>
<td>CEE0EB</td>
<td>3</td>
<td>0459</td>
<td>Not enough storage was available to create a new instance specific information block.</td>
</tr>
<tr>
<td>CEE0EE</td>
<td>3</td>
<td>0462</td>
<td>Instance specific information for the condition token with message number message-number and facility ID facility-id could not be found.</td>
</tr>
</tbody>
</table>

**Usage notes**

- PL/1 consideration: Conditions with a facility_ID of IBM cannot be used in CEESGL.
z/OS UNIX consideration: In multithread applications, CEESGL affects only the calling thread. Delivery of a CEESGL generated condition is limited to the thread that generated the condition. However, if the condition is a severity 2 or higher, and is not handled by the application, the default action of terminate applies to the enclave, not just the calling thread.

COBOL consideration: When a resume occurs and control resumes to the next instruction that follows the call to CEE3SRP, the COBOL RETURN-CODE special register contains an unpredictable value.

For more information

- See “CEECEMI—Store and load message insert data” on page 218 for more information about the CEECEMI callable service.
- See z/OS Language Environment Programming Guide for more information about mapping Language Environment condition tokens to POSIX signals.
- See “ERRCOUNT” on page 32 for more information about the ERRCOUNT runtime option.
- To construct your own condition token, see “CEENCOD—Construct a condition token” on page 379.
- For more information about condition handling, see z/OS Language Environment Programming Guide.
- See “CEEQDT—Retrieve q_data_token” on page 305 for more information about the CEEQDT callable service.

Examples

1. Following is an example of CEESGL called by C/C++.

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {
  _FEEDBACK fc, condtok;
  _ENTRY routine;
  _INT4 token, qdata;
  _INT2 c_1, c_2, cond_case, sev, control;
  _CHAR3 facid;
  _INT4 isi;

  /* build the condition token */
  c_1 = 1;
  c_2 = 99;
  cond_case = 1;
  sev = 1;
  control = 0;
  memcpy(facid, "ZZZ", 3);
  isi = 0;

  CEENCOD(&c_1, &c_2, &cond_case, &sev, &control,
          facid, &isi, &condtok, &fc);
  if ( _FBCHECK ( fc, CEE000 ) != 0 ) {
    printf("CEENCOD failed with message number %d\n", fc.tok_msgno);
  }
```
exit(2999);

} /* signal the condition */
CEESGL(&condtok,&qdata,&fc);
if (_FBCHECK ( fc , CEE000 ) != 0 ) {
  printf("CEESGL failed with message number %d\n", fc.tok_msgno);
  exit(2999);
} /* */

2. Following is an example of CEESGL called by COBOL.

CEESTXF—Transform string characters into collation weights

CEESTXF, which is analogous to the C language function strcfrm(), transforms
every character in a character string to its unique collation weight. The collation
weights are established from the LC_COLLATE category for the locale. CEESTFX
also returns the length of the transformed string. CEESTXF is sensitive to the
locales set by setlocale() or CEESETL, not to the Language Environment settings
from COUNTRY or CEE3CTY.

Syntax

| CEESTXF—(omitted_parm, mbstring, number, txfstring, length, fc) |

omitted_parm
This parameter is reserved for future expansion and must be omitted. For
information about how to code an omitted parm, see "Invoking callable
services" on page 116.

mbstring (input)
A halfword length-prefixed character string (VSTRING) that is to be
transformed.

number (input)
A 4-byte integer that specifies the number of bytes of mbstring to be
transformed. The value of this parameter must be greater than zero; otherwise,
an error is reported, and no transformation is attempted.

txfstring (output)
A halfword length-prefixed character string (VSTRING) where the
transformation of mbstring is to be placed.

length (output)
A 4-byte integer that specifies the length of the transformed string, if
successful.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result
The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td></td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE3T1</td>
<td>3</td>
<td>4001</td>
<td>General Failure: Service could not be completed.</td>
</tr>
<tr>
<td>CEE3TF</td>
<td>3</td>
<td>4015</td>
<td>Input Error: The number of characters to be transformed must be greater than zero.</td>
</tr>
</tbody>
</table>

**Usage notes**

- PL/I MTF consideration—CEESETL is not supported in PL/I MTF applications.
- This callable service uses the C/C++ runtime library. The C/C++ library must be installed and accessible even when this service is called from a non-C program.

**For more information**

- For more information about the `setlocale()` function, see "COUNTRY" on page 24, "CEE3CTY—Set default country" on page 135, and "CEE3LNG—Set national language" on page 174.
- For more information about the CEESETL callable service, see "CEESETL—Set locale operating environment" on page 413.

CEETDLI—Invoke IMS

CEETDLI provides an interface to PL/I facilities that operates in IMS. In assembler, COBOL, PL/I, and C/C++, you can also invoke IMS by using the following interfaces:

- In assembler, the ASMTDLI interface
CEETDLI

- In COBOL, the CBLTDLI interface
- In PL/I, the PLITDLI interface
- In C/C++, the CTDLI interface, a ctdli() function call

CEETDLI performs essentially the same functions as these interfaces, but it offers some advantages, particularly if you plan to run an ILC application in IMS.

The names CEETDLI, AIBTDLI, ASMTDLI, CBLTDLI, CTDLI, and PLITDLI are all interpreted as IMS interfaces. If you are currently using them in any other way in your application, you must change them. The CEETDLI interface supports calls to IMS that use an application interface block (AIB) or a program communication block (PCB).

**Syntax**

```
CEETDLI parmcount, function, args
```

**parmcount**

A fullword integer specifying the total number of arguments for the CEETDLI call. This option usually is not needed and can be omitted; it is supported for compatibility with earlier interface modules.

**function**

The IMS function that you want to perform. The possible values for this field are defined by IMS, not Language Environment.

**args**

Arguments that you pass to IMS. You cannot pass runtime options as CEETDLI arguments. You cannot alter the settings of runtime options when invoking IMS facilities. The order and meaning of the arguments is defined by IMS, not Language Environment.

**Usage notes**

- CEETDLI is not supported with CICS.
- z/OS UNIX considerations—IMS supports only applications that use the POSIX(ON) runtime option from a single thread. Calls to z/OS UNIX threading functions are restricted under IMS. See z/OS XL C/C++ Programming Guide for a list of restrictions on running IMS and z/OS UNIX.

**For more information**

- For more information about AIB and a complete description of all available IMS functions and argument parameters you can specify in CEETDLI, see IMS Application Programming Guide.
- For more information about CEETDLI in the context of other DLI interfaces, and in the context of IMS condition handling, see z/OS Language Environment Programming Guide.

**Examples**

1. Following is an example of CEETDLI called by C.

   ```c
   /*Module/File Name: EDCMCR */
   #pragma runopts(env(IMS),plist(IMS))
   ```
#include <ims.h>
#include <leawi.h>
#define io_pcb ((IO_PCB_TYPE *)__pcblist??(0??))

/*------------------------------------------------
*/
/* Function: Use CEETDLI - interface to IMS */
/* from C. */
/* In this example, a call is made to CEETDLI */
/* to interface to IMS for an IMS service. */
/* ENTRY POINT */
/* ------------------------------------------------
*/

main() {
    static char func_GU??(4??) = "GU ",
    char msg_seg_io_area??(32??);
    CEETDLI(func_GU,io_pcb,msg_seg_io_area);
}

PLIZIMS: PROCEDURE(IO_PTR) OPTIONS(MAIN NOEXECOPS);
%INCLUDE CEEIBMMAW;
DCL FUNC_GU CHAR(4) INIT('GU ');
CEETEST—Invoke Debug Tool

CEETEST invokes a debug service such as Debug Tool, which is supplied with z/OS.

Debug Tool supports debugging of Language Environment, except for some noted restrictions. For more information about Debug Tool for z/OS, see Debug Tool Utilities and Advanced Functions (http://www.ibm.com/software/awdtools/debugtool/) If you want to invoke another interactive debug service, refer to the appropriate user's guide.

Syntax

```
►► CEETEST((string_of_commands), fc)
```

string_of_commands (input)
A halfword-prefixed string containing a debug tool command list. string_of_commands is optional. If a debug tool is available, the commands in the list are passed to the debug tool and carried out. If this parameter is omitted, your debug service defines the action taken. For more information, refer to the appropriate user's guide for your debug service.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE2F2</td>
<td>3</td>
<td>2530</td>
<td>A debug tool was not available.</td>
</tr>
<tr>
<td>CEE2F7</td>
<td>3</td>
<td>2535</td>
<td>Profiler loaded; a debug tool was not available.</td>
</tr>
</tbody>
</table>

Usage notes

- z/OS UNIX considerations—CEETEST applies to the enclave. All threads in the enclave can access debugger information.
For more information

- If you are using CEETEST to invoke Debug Tool and need more information about how to create a Debug Tool command list, refer to [Debug Tool Utilities and Advanced Functions](http://www.ibm.com/software/awdtools/debugtool/).

Examples

1. Following is an example of CEETEST called by C/C++.

   /*Module/File Name: EDCTEST */

   #include <string.h>
   #include <stdio.h>
   #include <leawi.h>
   #include <stdlib.h>
   #include <ceeedcct.h>

   int main (void)
   {
      int x,y,z;
      _VSTRING commands;
      _FEEDBACK fc;

      strcpy(commands.string,
             "AT LINE 30 { LIST(x); LIST(y); GO; }");
      commands.length = strlen(commands.string);

      CEETEST(&commands,&fc);

      if ( _FBCHECK ( fc , CEE000 ) != 0 ) {
         printf("CEETEST failed with message number %d\n", fc.tok_msgno);
         exit(2999);
      }
      x = y = 12;
      /*
      .
      . */

CEEUTC—Get coordinated universal time

CEEUTC is an alias of CEEGMT. See “CEEGMT—Get current Greenwich Mean Time” on page 294 for more information.
Chapter 6. Bit manipulation routines

This topic lists the Language Environment bit manipulation routines. Bits are numbered from right to left, starting from 0.

CEESICLR—Bit clear

Purpose

CEESICLR returns a copy of its parm1 input, but with one bit selectively set to 0.

Syntax

```
CEESICLR((parm1, parm2, fc, result))
```

parm1 (input)
The first input to the Bit Clear routine. The input can be any 32-bit integer.

parm2 (input)
The second input to the Bit Clear routine. The parm2 value is a 32-bit integer in the range between 0 and 31, inclusive.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>Message number</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1VC</td>
<td>2</td>
<td>2028</td>
<td>The value of the second argument was outside the valid range in math routine routine-name.</td>
</tr>
</tbody>
</table>

result (output)
The result of the Bit Clear routine. The output is a copy of parm1, but with the bit numbered parm2 (counting from the right) set to 0.

CEESISET—Bit set

Purpose

CEESISET returns a copy of its parm1 input, but with one bit selectively set to 1.
Syntax

```plaintext
>>> CEESISET(|parm1|,|parm2|,fc,result)<<<
```

parm1 (input)
The first input to the Bit Set routine. The input can be any 32-bit integer.

parm2 (input)
The second input to the Bit Set routine. The parm2 value is a 32-bit integer in the range between 0 and 31, inclusive.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td></td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1VC</td>
<td>2</td>
<td>2028</td>
<td>The value of the second argument was outside the valid range in math routine routine-name.</td>
</tr>
</tbody>
</table>

result (output)
The result of the Bit Set routine. The output is a copy of parm1, but with the bit numbered parm2 (counting from the right) set to 1.

---

**CEESISHF—Bit Shift**

**Purpose**

CEESISHF returns a copy of its parm1 input right- or left-shifted by the number of bits indicated by parm2.

**Syntax**

```plaintext
>>> CEESISHF(|parm1|,|parm2|,fc,result)<<<
```

parm1 (input)
The first input to the Bit Shift routine. The input can be any 32-bit integer.

parm2 (input)
The second input to the Bit Shift routine. The parm2 value is a 32-bit integer in the range between -32 and 32, inclusive.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.
The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td></td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1VC</td>
<td>2</td>
<td>2028</td>
<td>The value of the second argument was outside the valid range in math routine.</td>
</tr>
</tbody>
</table>

**result (output)**
The result of the Bit Shift routine. The output is a 32-bit integer whose value depends upon the value of parm2; in either case, vacated bits are set to 0:
- If parm2 is greater than or equal to 0, result is a copy of parm1 shifted left by parm2 bits.
- If parm2 is less than 0, result is a copy of parm1 shifted right by |parm2| bits.

**CEESITST—Bit test**

**Purpose**
CEESITST selectively tests a bit in its parm1 input to determine if the bit is on.

**Syntax**

```
►► CEESITST(—parm1—,—parm2—,—fc—,—result—)◄◄
```

**parm1 (input)**
The first input to the Bit Test routine. The input can be any 32-bit integer.

**parm2 (input)**
The second input to the Bit Test routine. The parm2 value is a 32-bit integer in the range between 0 and 31, inclusive.

**fc (output)**
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td></td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1VC</td>
<td>2</td>
<td>2028</td>
<td>The value of the second argument was outside the valid range in math routine.</td>
</tr>
</tbody>
</table>

**result (output)**
The result of the Bit Test routine. The output is a 32-bit integer with one of the following values; bits are counted from the right:

1. If bit number parm2 in parm1 is 1
2. If bit number parm2 in parm1 is 0
Chapter 7. Language Environment math services

Language Environment math services provide standard math computations. You can call them from Language Environment-conforming languages or from assembler routines by using the call interface, or the syntax specific to the HLL of your application.

Math services do not depend on enclave-level resources. You can invoke them from any thread.

If your application uses extended-precision arithmetic and runs on a 370-mode machine under VM, you must specify the TRAP(ON) runtime option (the default) and add the CMSLIB TXTLIB with the GLOBAL TXTLIB command.

Call interface to math services

The syntax for math services has two forms, depending on how many input parameters the routine requires. The first four letters of the math services are always CEES. The fifth character is x, which you replace according to the parameter types listed in "Parameter types: parm1 and parm2." The last three letters name the math function performed. In the following examples, the first function performed is the absolute value (ABS), and the second function is the positive difference (DIM).

One Parameter

```
>>> CEESxABS(-----parm1-----,---fc---,---result---)
```

Two Parameters

```
>>> CEESxDIM(-----parm1-----,---parm2---,---fc---,---result---)
```

Parameter types: parm1 and parm2

The first parameter (parm1) is mandatory. The second parameter (parm2) is used only when you use a math service with two parameters. The x in the fifth space of CEESx must be replaced by a parameter type for input and output. Substitute I, S, D, Q, T, E, or R for x:

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>32-bit binary integer</td>
</tr>
<tr>
<td>S</td>
<td>32-bit single floating-point number</td>
</tr>
<tr>
<td>D</td>
<td>64-bit double floating-point number</td>
</tr>
<tr>
<td>Q</td>
<td>128-bit extended floating-point number</td>
</tr>
</tbody>
</table>
T  32-bit single floating-point complex number. This parameter type consists of a real part and an imaginary part, each of which is a 32-bit single floating-point number.

E  64-bit double floating-point complex number. This parameter type consists of a real part and an imaginary part, each of which is a 64-bit double floating-point number.

R  128-bit extended floating-point complex number. This parameter type consists of a real part and an imaginary part, each of which is a 128-bit extended floating-point number.

Language Environment math services expect normalized input.

In the described routines, the output range for complex-valued functions can be determined from the input range. For functions of complex variables, the image of the input is generally a non-rectangular shape. For this reason, the output range is not provided.

Feedback code parameter (fc)

The fc value is a feedback code that indicates the result of the math service. If you specify fc as an argument, feedback information in the form of a condition token is returned to the calling routine. The condition token indicates whether the routine completed successfully or whether a condition was encountered while the routine was running. If you do not specify fc as an argument and the requested service does not successfully complete, the condition is signaled. Math services call other services that might generate feedback codes.

Language-specific built-in math services

C/C++, COBOL, Fortran, and PL/I offer built-in math services that you can also use under Language Environment. For a description of these functions, refer to the reference documentation associated with each language.
Calls to math services from different languages

Table 28 shows sample calls to the Language Environment math service CEESLOG—logarithm base e, as made from C/C++, COBOL, and PL/I. For more examples, see “Examples of math services” on page 477.

Table 28. Examples of calls to CEESLOG

<table>
<thead>
<tr>
<th>Called from</th>
<th>Code example</th>
</tr>
</thead>
</table>
| C/C++       | #include <leawi.h>
|             | #include <string.h>
|             | #include <stdio.h>
|             | int main (void) { |
|             |     float int1, intr;
|             |     _FEEDBACK fc;
|             |     #define SUCCESS "\0\0\0\0"
|             |     int1 = 39;
|             |     CEESSLOG(&int1,&fc,&intr);
|             |     if (memcmp(&fc,SUCCESS,4) != 0) {
|             |         printf("CEESSLOG failed with message number %d\n", fc.tok_msgno);
|             |         exit(2999);
|             |     } |
|             |     printf("Log base e of %f is %f\n",int1,intr); |
| COBOL       | 77 ARG1RS COMP-1.
|             | 77 FBCODE PIC X(12).
|             | 77 RESLTRS COMP-1.
|             | CALL "CEESSLOG" USING ARG1RS , FBCODE , RESLTRS.
| PL/I        | DCL ARG1 RESULT REAL FLOAT DEC (6);
|             | DCL FC CHARACTER (12);
|             | CALL CEESSLOG (ARG1, FC, RESULT) |

Math services

This section describes the Language Environment math services. It also provides examples of how various services are called by different programming languages.

CEESxABS—Absolute value

CEESxABS returns the absolute value of the parameter by using the equation:

\[ result = |parm1| \]

The following routines are provided for the various data types supported:
CEESxABS

CEESIABS
32-bit binary integer

CEESSABS
32-bit single floating-point number

CEESDABS
64-bit double floating-point number

CEESQABS
128-bit extended floating-point number

CEESTABS
32-bit single floating-point complex number

CEESEABS
64-bit double floating-point complex number

CEESRABS
128-bit extended floating-point complex number

Syntax

►►CEESxABS—(parm1, fc, result)◄◄

parm1 (input)
The input to the absolute value routine. The input range is not restricted.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1V9</td>
<td>1</td>
<td>2025</td>
<td>An underflow occurred in math routine routine-name.</td>
</tr>
</tbody>
</table>

result (output)
The result of the absolute value routine. The output range is the non-negative numbers:

\[ \leq \Omega \]

Omega varies depending on the precision of parm1:
CEESxACS—Arccosine

CEESxACS returns the arccosine of the parameter by using the equation: \( \text{result} = \arccos(\text{parm1}) \)

The following routines are provided for the various data types supported:

- **CEESSACS**: 32-bit single floating-point number
- **CEESDACS**: 64-bit double floating-point number
- **CEESQACS**: 128-bit extended floating-point number

**Syntax**

```
CEESxACS( parm1, fc, result )
```

**parm1 (input)**

The input to the arccosine routine. The input range is:

\[ |\text{parm1}| \leq 1 \]

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1V0</td>
<td>2</td>
<td>2016</td>
<td>The absolute value of the parameter was greater than ( \text{limit} ) in math routine ( \text{routine-name} ).</td>
</tr>
</tbody>
</table>

**result (output)**

The result, in radians, of the arccosine routine.

For single-precision routines, \( \Omega = 16^{62}(1 - 16^{-6}) \)
For double-precision routines, \( \Omega = 16^{63}(1 - 16^{-14}) \)
For extended-precision routines, \( \Omega = 16^{63}(1 - 16^{-28}) \)
CEESxASN—Arccsine

CEESxASN returns the arccsine of the parameter by using the equation: \( \text{result} = \arcsin(parm1) \)

The following routines are provided for the various data types supported:

- CEESSASN
  32-bit single floating-point number
- CEESDASN
  64-bit double floating-point number
- CEESQASN
  128-bit extended floating-point number

Syntax

\[
\text{CEESxASN} (\text{parm1}, \text{fc}, \text{result})
\]

\( \text{parm1} \) (input)

The input to the arccsine routine. The input range is:

\[
|\text{parm1}| \leq 1
\]

\( \text{fc} \) (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1V0</td>
<td>2</td>
<td>2016</td>
<td>The absolute value of the parameter was greater than limit in math routine routine-name.</td>
</tr>
</tbody>
</table>

\( \text{result} \) (output)

The result, in radians, of the arccsine routine. The output range is:

\[
|\text{result}| < \pi/2
\]
CEESxATH—Hyperbolic arctangent

CEESxATH returns the hyperbolic arctangent of the parameter by using the following equation:

\[ \text{result} = \tanh^{-1}(\text{parm1}) \]

The following routines are provided for the various data types supported:

- **CEESSA**
  - 32-bit single floating-point number
- **CEESDA**
  - 64-bit double floating-point number
- **CEESQA**
  - 128-bit extended floating-point number
- **CEEST**
  - 32-bit single floating-point complex number
- **CEESEA**
  - 64-bit double floating-point complex number
- **CEESRA**
  - 128-bit extended floating-point complex number

**Syntax**

```ceesxath(parml, fc, result)
```

**parm1** *(input)*

The input to the hyperbolic arctangent routine. The input range for real variables is:

\[ |\text{parm1}| \leq 1 \]

For complex variables, \(\text{parm1}\) cannot be equal to 1 or -1.

**fc** *(output)*

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>
CEE1V1 2  2017  The absolute value of the argument was greater than or equal to limit in math routine routine-name.

CEE1V6 2  2022  The value of the argument was plus or minus limit in math routine routine-name.

result (output)
The result of the hyperbolic arctangent routine. The output range for functions of real variables is:

$|\text{result}| \leq \Omega$

Omega varies, depending on the precision of parm1:

For single-precision routines, $\Omega = 16^{63}(1-16^{-6})$
For double-precision routines, $\Omega = 16^{63}(1-16^{-14})$
For extended-precision routines, $\Omega = 16^{63}(1-16^{-28})$

CEESxATN—Arctangent
CEESxATN returns the arctangent of the parameter by using the equation: \( \text{result} = \arctan(parm1) \)

The following routines are provided for the various data types supported:

- **CEESSATN**
  32-bit single floating-point number

- **CEESDATN**
  64-bit double floating-point number

- **CEESQATN**
  128-bit extended floating-point number

- **CEESTATN**
  32-bit single floating-point complex number

- **CEESEATN**
  64-bit double floating-point complex number

- **CEESRATN**
  128-bit extended floating-point complex number

**Syntax**

```
>>>CEESxATN(---parm1---,---fc---,---result---)
```
restricted. The input range of complex variables in parm1 is not equal to i or -i, where:

\[ i = \sqrt{-1} \]

\( fc \)  \( (\text{output}) \)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1V6</td>
<td>2</td>
<td>2022</td>
<td>The value of the parameter was plus or minus limit in math routine routine-name.</td>
</tr>
<tr>
<td>CEE1V9</td>
<td>1</td>
<td>2025</td>
<td>An underflow occurred in math routine routine-name.</td>
</tr>
</tbody>
</table>

\( \text{result} \)  \( (\text{output}) \)
The result, in radians, of the arctangent routine. The output range for functions of real variables is:

\[ |\text{result}| < \frac{\pi}{2} \]

**CEESxAT2—Arctangent2**
CEESxAT2 calculates a result by using the equation: \( \text{result} = \) the angle (in radians) between the positive X axis and a vector defined by \( (\text{parm2}, \text{parm1}) \) with a range from:

\[-\pi \text{ to } \pi, \text{ with } \pi,\]

For example, if \( \text{parm1} \) and \( \text{parm2} \) are positive, then \( \text{result} = \arctan (\text{parm1}/\text{parm2}) \).

The following routines are provided for the various data types supported:

**CEESSAT2**
32-bit single floating-point number

**CEESDAT2**
64-bit double floating-point number

**CEESQAT2**
128-bit extended floating-point number
CEESxAT2

Syntax

\[ \text{CEESxAT2} = (\text{parm1}, \text{parm2}, \text{fc}, \text{result}) \]

parm1 (input)
The first input to the arctangent2 routine. The input range of \( \text{parm1} \) cannot equal 0 if \( \text{parm2} \) equals 0.

parm2 (input)
The second parameter to the arctangent2 routine. The input range of \( \text{parm2} \) cannot equal 0 if \( \text{parm1} \) equals 0.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>

result (output)
The result, in radians, of the arctangent2 routine. The output range is:

\[ |\text{result}| \leq \pi \]

CEESxCJG—Conjugate of complex

CEESxCJG returns the conjugate of the complex number by using the equation:

\[ \text{result} = u - vi, \text{ where } \text{parm1} = u + vi. \]

The following routines are provided for the various data types supported:

**CEESTCJG**
32-bit single floating-point complex number

**CEESECJG**
64-bit double floating-point complex number

**CEESRCJG**
128-bit extended floating-point complex number
Syntax

\[
\text{CEEESxCJG}-(\text{parm1, fc, result})
\]

**parm1 (input)**
The input to the math service. Any representable complex number can be used as input.

**fc (output)**
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

**result (output)**
The result of the conjugate of complex routine.

**CEESxCOS—Cosine**
CEEESxCOS returns the cosine of the parameter by using the equation: \( \text{result} = \cos(\text{parm1}) \)

The following routines are provided for the various data types supported:

- **CEESSCOS**
  32-bit single floating-point number

- **CEESDCOS**
  64-bit double floating-point number

- **CEESQCOS**
  128-bit extended floating-point number

- **CEESTCOS**
  32-bit single floating-point complex number

- **CEESECOS**
  64-bit double floating-point complex number

- **CEESRCOS**
  128-bit extended floating-point complex number
### For... Input range

<td>2019</td>
<td>The absolute value of the real part of the parameter was greater than or equal to (\text{limit}) in math routine (\text{routine-name}).</td>
</tr>
</tbody>
</table>

### result (output)

The result of the cosine routine. The output range for functions of real variables is:

\[|\text{result}| \leq 1\]

### CEESxCOSH—Hyperbolic cosine

CEESxCOSH returns the hyperbolic cosine of the parameter by using the equation:

\[\text{result} = \cosh(\text{parm1})\]
The following routines are provided for the various data types supported:

**CEECSH**
32-bit single floating-point number

**CEESDCSH**
64-bit double floating-point number

**CEESQCSH**
128-bit extended floating-point number

**CEESTCSH**
32-bit single floating-point complex number

**CEESECSH**
64-bit double floating-point complex number

**CEESRCSH**
128-bit extended floating-point complex number

### Syntax

```
CEESxCSH(parm1, fc, result)
```

**parm1 (input)**
The input to the hyperbolic cosine routine. The input range varies, depending on the function and type of number:

<table>
<thead>
<tr>
<th>For ...</th>
<th>Input range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions of real variables:</td>
<td>(</td>
</tr>
<tr>
<td>The real part of complex numbers:</td>
<td>(</td>
</tr>
<tr>
<td>The imaginary part of complex numbers:</td>
<td>(</td>
</tr>
</tbody>
</table>

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1V0</td>
<td>2</td>
<td>2016</td>
<td>The absolute value of the parameter was greater than limit in math routine routine-name.</td>
</tr>
</tbody>
</table>

**result (output)**
The result of the hyperbolic cosine routine. The output range for functions of real variables varies:
For ...

<table>
<thead>
<tr>
<th>Output range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single-precision routines: $1 \leq \text{result} \leq \Omega$</td>
</tr>
<tr>
<td>Double-precision routines: $\Omega = 16^{63}(1 - 16^{6})$</td>
</tr>
<tr>
<td>$16^{63}(1 - 16^{-14})$</td>
</tr>
<tr>
<td>Extended-precision routines: $16^{63}(1 - 16^{-28})$</td>
</tr>
</tbody>
</table>

**CEEExCTN—Cotangent**

CEEExCTN returns the cotangent of the parameter by using the equation: \( \text{result} = \cot(\text{parm1}) \)

The following routines are provided for the various data types supported:

**CEEExCTN**
- 32-bit single floating-point number

**CEEExDCTN**
- 64-bit double floating-point number

**CEEExQCTN**
- 128-bit extended floating-point number

**Syntax**

\[ \text{CEEExCTN}(-\text{parm1},-\text{fc},-\text{result}) \]

**parm1 (input)**

The input, in radians, into the cotangent routine. The input range varies, depending on the value of \( \text{parm1} \):

<table>
<thead>
<tr>
<th>If ( \text{parm1} ) is a 32-bit single floating-point number:</th>
</tr>
</thead>
<tbody>
<tr>
<td>(</td>
</tr>
<tr>
<td>If ( \text{parm1} ) is a 64-bit double floating-point number:</td>
</tr>
<tr>
<td>(</td>
</tr>
<tr>
<td>If ( \text{parm1} ) is a 128-bit extended floating-point number:</td>
</tr>
<tr>
<td>(</td>
</tr>
</tbody>
</table>

If this is an extended floating-point number, this argument cannot approach a multiple of pi. Single floating-point numbers and double floating-point numbers cannot approach zero.

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:
<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1UI</td>
<td>2</td>
<td>2002</td>
<td>The parameter value was too close to one of the singularities (plus or minus pi/2, plus or minus 3pi/2, for the tangent; or plus or minus pi, plus or minus 2pi, for the cotangent) in math routine routine-name.</td>
</tr>
<tr>
<td>CEE1V1</td>
<td>2</td>
<td>2017</td>
<td>The absolute value of the parameter was greater than or equal to limit in math routine routine-name.</td>
</tr>
</tbody>
</table>

result (output)
The result of the cotangent routine. The output range is:

|result| ≤ Ω
For single-precision routines, Ω = 16^{63}(1 - 16^{-6})
For double-precision routines, Ω = 16^{63}(1 - 16^{-14})
For extended-precision routines, Ω = 16^{63}(1 - 16^{-28})

The output range is:

result ≤ Ω

CEESxDIM—Positive difference
CEESxDIM returns the positive difference between two numbers by using one of the following equations:

<table>
<thead>
<tr>
<th>If</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>parm1 &gt; parm2</td>
<td>Then, result = parm1 - parm2</td>
</tr>
<tr>
<td>parm1 ≤ parm2</td>
<td>Then, result = 0</td>
</tr>
</tbody>
</table>

The following routines are provided for the various data types supported:

CEESIDIM
32-bit binary integer

CEESSDIM
32-bit single floating-point number

CEESDDIM
64-bit double floating-point number

CEESQDIM
128-bit extended floating-point number
Syntax

```
CEESxDIM—(parm1—, parm2—, fc—, result—)
```

**parm1 (input)**
The first input to the positive difference routine. The input range is not restricted.

**parm2 (input)**
The second parameter to the positive difference routine. The input range is not restricted.

**fc (output)**
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

**result (output)**
The result of the positive difference routine. The output range is the non-negative numbers.

\[ \leq \Omega \]

For single-precision routines, \( \Omega = 16^{63}(1 - 16^{-6}) \)
For double-precision routines, \( \Omega = 16^{63}(1 - 16^{-16}) \)
For extended-precision routines, \( \Omega = 16^{63}(1 - 16^{-28}) \)

**CEESxDVD—Floating-point complex divide**

CEESxDVD performs the mathematical function of floating-point complex divide by using the equation:

\[
result = \frac{parm1}{parm2}
\]

The following routines are provided for the various data types supported:

**CEESTDVD**
32-bit single floating-point complex number

**CEESEDVD**
64-bit double floating-point complex number

**CEESRDVD**
128-bit extended floating-point complex number
 syntax

Ceexvd — (parm1, —parm2, —fc, —result)

parm1 (input)
The first input to the math service. Any representable complex number can be used as input.

parm2 (input)
The second parameter to the math service. Do not set parm2 to 0.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

result (output)
The result of the floating-point complex divide routine.

Ceexerc — Error function complement

Ceexerc calculates the error function complement by using the equation:

\[
result = \left( 1 - \left( \sqrt{\frac{2}{\pi}} \int_{-\infty}^{\infty} \frac{e^{-u^2}}{u} du \right) \right)
\]

The following routines are provided for the various data types supported:

Ceesserc
32-bit single floating-point number

Ceesderc
64-bit double floating-point number

Ceesqerc
128-bit extended floating-point number

parm1 (input)
The input to the error function complement routine. The input range is not restricted.
**CEESxERC**

*fc (output)*  
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

*result (output)*  
The result of the error function complement routine. The output range is: $0 < result < 2$.

**CEESxERF—Error function**

CEESxERF calculates the error function by using the equation:

$$result = \frac{2}{\sqrt{\pi}} \int_{0}^{parm1} e^{-u^2} du$$

The following routines are provided for the various data types supported:

- **CEESSERF**  
  32-bit single floating-point number

- **CEESDERF**  
  64-bit double floating-point number

- **CEESQERF**  
  128-bit extended floating-point number

**Syntax**

```
>>> CEESxERF(---parm1---,---fc---,---result---)
```

*parm1 (input)*  
The input to the error function. The input range is not restricted.

*fc (output)*  
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>
result (output)
The result of the error function. The output range is:

|result| ≤ 1

CEESxEXP—Exponential base e
CEESxEXP calculates the mathematical function of e raised to a power by using the equation:

\[ \text{result} = e^{\text{parm1}} \]

The following routines are provided for the various data types supported:

- **CEESSEXP**: 32-bit single floating-point number
- **CEESDEXP**: 64-bit double floating-point number
- **CEESQEXP**: 128-bit extended floating-point number
- **CEESTEXP**: 32-bit single floating-point complex number
- **CEEEEXP**: 64-bit double floating-point complex number
- **CEESREXP**: 128-bit extended floating-point complex number

**Syntax**

```
 CEESxEXP(parml, fc, result)
```

**parml (input)**
The input to the exponential base e routine. The input range varies, depending on the type of function and number:

<table>
<thead>
<tr>
<th>For</th>
<th>Input range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions of real variables:</td>
<td></td>
</tr>
<tr>
<td>The real part of complex numbers:</td>
<td></td>
</tr>
<tr>
<td>The imaginary part: single floating-point complex numbers:</td>
<td></td>
</tr>
<tr>
<td>The imaginary part: double floating-point complex numbers:</td>
<td></td>
</tr>
</tbody>
</table>
For Input range

| The imaginary part: extended floating-point complex numbers: | \( |\text{Im} (\text{parm1})| < 2^{100} \) |

\( fc \) (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>

<td>The absolute value of the imaginary part of the parameter was greater than or equal to limit in math routine routine-name.</td>
</tr>
<tr>
<td>CEE1V9</td>
<td>1</td>
<td>2025</td>
<td>An underflow occurred in math routine routine-name.</td>
</tr>
</tbody>
</table>

\( result \) (output)

The result of the exponential base e routine. The output range for functions of real variables is:

\[
0 < \text{result} \leq \Omega
\]

For single-precision routines, \( \Omega = 16^{63}(1-16^{-6}) \)

For double-precision routines, \( \Omega = 16^{63}(1-16^{-14}) \)

For extended-precision routines, \( \Omega = 16^{63}(1-16^{-28}) \)

**CEESxGMA—Gamma function**

CEESxGMA performs the mathematical gamma function by using the equation:

\[
\text{result} = \int_{0}^{\infty} u^{\text{parm1}-1} e^{-u} du
\]

The following routines are provided for the various data types supported:

**CEESSGMA**

32-bit single floating-point number
CEESDGMA
64-bit double floating-point number

Syntax

```
►► CEESDGMA(—parm1—,—fc—,—result—)◄◄
```

parm1 (input)
The input to the gamma function. The input range is:

\[2^{252} < \text{parm1} < 57.5744\]

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>

</tr>
<tr>
<td>CEE1UL</td>
<td>2</td>
<td>2005</td>
<td>The value of the parameter was outside the valid range range in math routine routine-name.</td>
</tr>
</tbody>
</table>

result (output)
The result of the gamma function. The output range varies, depending on the type of routine:

<table>
<thead>
<tr>
<th>For</th>
<th>Output range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single-precision routines:</td>
<td>[0.88560 \leq \text{result} \leq \Omega]</td>
</tr>
<tr>
<td></td>
<td>[\Omega = 16^{63} \left(1-16^{-6}\right)]</td>
</tr>
<tr>
<td>Double-precision routines:</td>
<td>[\Omega = 16^{63} \left(1-16^{-14}\right)]</td>
</tr>
</tbody>
</table>

**CEESxIMG—Imaginary part of complex**

CEESxIMG returns the imaginary part of a complex number using the equation \(\text{result} = v\), where \(\text{parm1} = u + vi\).

The following routines are provided for the various data types supported:

- **CEESTIMG**
  32-bit single floating-point complex number

- **CEESEIMG**
  64-bit double floating-point complex number

- **CEESRIMG**
  128-bit extended floating-point complex number
Syntax

```
CEESxIMG(--parm1--, --fc--, --result--)```

**parm1 (input)**
The input to the math service. Any complex number can be used as input.

**fc (output)**
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td></td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

**result (output)**
The result of the math service is:

\[ |result| \leq \Omega \]

For single-precision routines, \( \Omega = 16^{63}(1 - 16^{-d}) \)
For double-precision routines, \( \Omega = 16^{63}(1 - 16^{-16}) \)
For extended-precision routines, \( \Omega = 16^{63}(1 - 16^{-28}) \)

**CEESxINT—Truncation**
CEESxINT returns the truncated value of the parameter by using the equation, where \( m \) is the greatest integer satisfying the relationship:

\[ result = (\text{sign of parm1}) \cdot n, \text{ where } n = |\text{parm1}| \]

\[ |\text{parm1}| = m \]

The result is expressed as a floating-point number:

\[ |m| \leq |\text{parm1}| \]

The following routines are provided for the various data types supported:

**CEESSINT**
32-bit single floating-point number

**CEESDINT**
64-bit double floating-point number
CEESQINT
128-bit extended floating-point number

Syntax

►► CEESxINT—(—parm1—,—fc—,—result—)◄◄

parm1 (input)
The input to the truncation routine. The input range is not restricted.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

result (output)
The result of the truncation routine. The output range is:

\[ |result| \leq \Omega \]

For single-precision routines, \( \Omega = 16^{63}(1 - 16^{-6}) \)
For double-precision routines, \( \Omega = 16^{63}(1 - 16^{-14}) \)
For extended-precision routines, \( \Omega = 16^{63}(1 - 16^{-28}) \)

CEESxLGM—Log gamma
CEESxLGM performs the mathematical function of log gamma by using either of the following equations:

<table>
<thead>
<tr>
<th>First equation</th>
<th>Alternate equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>( result = \log_e \Gamma(parm1) )</td>
<td>( result = \log_e \int_0^{\infty} u^{parm1-1} e^{-u} , du )</td>
</tr>
</tbody>
</table>

The following routines are provided for the various data types supported:

CEESSLGM
32-bit single floating-point number

CEESDLGM
64-bit double floating-point number
Syntax

```
►►CEEESxLGM—(—parm1—,—fc—,—result—)
```

**parm1 (input)**
The input to the log gamma routine. The input range is:

```
parm1 < 4.2913 \times 10^{73}
```

**fc (output)**
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>

</tr>
<tr>
<td></td>
<td>$\Omega = 16^{63}(1-16^{-14})$</td>
</tr>
</tbody>
</table>

**CEESxLG1—Logarithm base 10**
CEEESLG1 returns the logarithm base 10 of the input parameter by using the equation:

```
\text{result} = \log_{10} \text{parm1}
```

The following routines are provided for the various data types supported:

- **CEEESLG1**
  32-bit single floating-point number

- **CEEESDLG1**
  64-bit double floating-point number

- **CEEESQLG1**
  128-bit extended floating-point number
**Syntax**

```
►► CEESxLG1—(—parm1—,—fc—,—result—)◄◄
```

*parm1 (input)*

The input to the log base 10 routine. The input range is: parm1 > 0.

*fc (output)*

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

</table>

*result (output)*

The result of the log base 10 routine. The output range is: result is greater than or equal to -78.268 and is less than or equal to 75.859.

**CEESxLG2—Logarithm base 2**

CEESxLG2 performs the mathematical function logarithm base 2 by using the equation:

```
result = \log_2\text{parm1}
```

The following routines are provided for the various data types supported:

**CEESSLG2**

32-bit single floating-point number

**CEESDLG2**

64-bit double floating-point number

**CEESQLG2**

128-bit extended floating-point number

**Syntax**

```
►► CEESxLG2—(—parm1—,—fc—,—result—)◄◄
```

*parm1 (input)*

The input to the log base 2 routine. The input range is: parm1 > 0.
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1US</td>
<td>2</td>
<td>2012</td>
<td>The parameter was less than or equal to limit in math routine routine-name.</td>
</tr>
</tbody>
</table>

The result of the log base 2 routine. The output range is: result is greater than or equal to -260 and is less than or equal to 252.

**CEESxLOG—Logarithm base e**

CEESxLOG performs the mathematical function logarithm base e by using the equation:

\[
\text{result} = \ln \text{parm1} \quad (\text{result} = \ln \text{parm1})
\]

The following routines are provided for the various data types supported:

- **CEESSLOG**
  32-bit single floating-point number

- **CEESDLOG**
  64-bit double floating-point number

- **CEESQLOG**
  128-bit extended floating-point number

- **CEESTLOG**
  32-bit single floating-point complex number

- **CEESELOG**
  64-bit double floating-point complex number

- **CEESRLOG**
  128-bit extended floating-point complex number

**Syntax**

```
►►CEESxLOG—(parm1__, fc__, result__)
```

**parm1 (input)**

The input to the log base e routine. The input range varies:

<table>
<thead>
<tr>
<th>For</th>
<th>Input range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Real numbers:</td>
<td>parm1 &gt; 0</td>
</tr>
</tbody>
</table>
For

Complex numbers: parm1 is not equal to 0

fc (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1US</td>
<td>2</td>
<td>2012</td>
<td>The parameter was less than or equal to limit in math routine routine-name.</td>
</tr>
<tr>
<td>CEE1V2</td>
<td>2</td>
<td>2018</td>
<td>The real and imaginary parts of the parameter were equal to limit in math routine routine-name.</td>
</tr>
</tbody>
</table>

result (output)

The result of the log base e routine. The output range for functions of real variables is: result is greater than or equal to -180.218 and is less than or equal to \( \leq 174.673 \).

CEEDxLOG—Floating-point complex multiply

CEEDxMLT performs the mathematical function floating-point complex multiply by using the equation:

\[
\text{result} = \text{parm1} \cdot \text{parm2}
\]

The following routines are provided for the various data types supported:

CEEDMLT 32-bit single floating-point complex number

CEEDMLT 64-bit double floating-point complex number

CEEDMLT 128-bit extended floating-point complex number

Syntax

\[
\text{CEEDMLT}(-\text{parm1}-,-\text{parm2}-,-fc-,result-)
\]

parm1 (input)

The first input to the math service. Any representable complex number can be used as input.
parm2 (input)
The second parameter to the math service. Any representable complex number can be used as input.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

result (output)
The result of the floating-point complex multiply routine.

**CEESxMOD—Modular arithmetic**

CEESxMOD performs the mathematical function modular arithmetic by using the equation:

\[ \text{result} = \text{parm1} \text{(modulo} \ \text{parm2)} \]

The expression \(\text{parm1}\) (modulo \(\text{parm2}\)) is defined as follows, with the brackets indicating an integer part:

\[\text{parm1} - [(\text{parm1}/\text{parm2}) \times \text{parm2}]\]

That is, the largest integer whose magnitude does not exceed the magnitude of \(\text{parm1}/\text{parm2}\) is used.

The sign of the integer is the same as the sign of \(\text{parm1}\times\text{parm2}\).

The following routines are provided for the various data types supported:

- **CEESIMOD**
  32-bit binary integer

- **CEESSMOD**
  32-bit single floating-point number

- **CEESDMOD**
  64-bit double floating-point number

- **CEESQMOD**
  128-bit extended floating-point number
Syntax

```
►►CEESxMOD—(—parm1—,—parm2—,—fc—,—result—)◄◄
```

parm1 (input)
The first parameter to the modular arithmetic routine. The input range is not restricted.

parm2 (input)
The second parameter to the modular arithmetic routine. The input range is:
parm2 is not equal to 0.
If parm2 = 0, the modulus routine is undefined. In addition, a divide exception is recognized and an interrupt occurs.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

result (output)
The result of the mod routine. The output range is:

```
|result| ≤ Ω
```

For single-precision routines, Ω = 16^{63}(1 - 16^{-6})
For double-precision routines, Ω = 16^{63}(1 - 16^{-14})
For extended-precision routines, Ω = 16^{63}(1 - 16^{-28})

---

**CEESxNIN—Nearest integer**

CEESxNIN performs the mathematical function nearest integer by using the equation:

```
result = (sign of parm1) • n
```

If parm1 m 0, then n = |parm1 + .5i|
If parm1 < 0, then n = |parm1 - .5i|

n = lml, where m is the greatest integer satisfying the relationship lml [ |parm1 + .5i|, or lml [ |parm1 - .5i|, respectively.

The following routines are provided for the various data types supported:

**CEESSNIN**

32-bit single floating-point number
CEESxNIN

**CEESDNIN**

64-bit double floating-point number

### Syntax

```
CEESxNIN杷parm1杷fc杷result
```

**parm1 (input)**

The input to the nearest integer routine. The input range is not restricted.

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

**result (output)**

The result of the nearest integer routine. The output parameter is an unrestricted type I, a 32-bit binary integer.

### CEESxNWN—Nearest whole number

CEESxNWN performs the mathematical function nearest whole number by using the equation:

\[ \text{result} = (\text{sign of parm1}) \cdot v \]

If \( \text{parm1} \geq 0 \), then \( v = |\text{parm1} + .5| \). If \( \text{parm1} < 0 \), then \( v = |\text{parm1} - .5| \).

\[ v = |m|, \text{ where } m \text{ is the greatest integer satisfying the relationship } |m| \leq |\text{parm1} + .5|, \]

or \( |m| \leq |\text{parm1} - .5| \), respectively.

and the resulting \( v \) is expressed as a floating-point number.

The following routines are provided for the various data types supported:

**CEESSNWN**

32-bit single floating-point number

**CEESDNWN**

64-bit double floating-point number
Syntax

```plaintext
►►CEESxNWN—(—parm1—,—fc—,—result—)◄◄
```

`parm1 (input)`
The input to the nearest whole number routine. The input range is not restricted.

`fc (output)`
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

`result (output)`
The result of the nearest whole number routine. The output range varies:

<table>
<thead>
<tr>
<th>For</th>
<th>Output range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single-precision routines:</td>
<td>(</td>
</tr>
<tr>
<td></td>
<td>(\Omega = 16^{63} (1-16^6))</td>
</tr>
<tr>
<td>Double-precision routines:</td>
<td>(\Omega = 16^{63} (1-16^{-14}))</td>
</tr>
</tbody>
</table>

**CEESxSGN—Transfer of sign**

CEESxSGN performs the mathematical function transfer of sign by using *either* of the two equations:

```
result = |parm1| if parm2 \geq 0 or result = -|parm1| if parm2 < 0.
```

The following routines are provided for the various data types supported:

**CEESISGN**
32-bit binary integer

**CEESSSGN**
32-bit single floating-point number

**CEESDSGN**
64-bit double floating-point number

**CEESQSGN**
128-bit extended floating-point number
CEESxSGN

Syntax

```plaintext
>>>CEESxSGN—(—parm1—,—parm2—,—fc—,—result—)<<<
```

parm1 (input)
The first input to the transfer of sign routine. The input range is not restricted.

parm2 (input)
The second parameter to the transfer of sign routine. The input range is not restricted.

fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>

result (output)
The result of the transfer of sign routine. The output range is:

```
|result| ≤ Ω
```

For single-precision routines, Ω = 16^63(1 - 16^-6)
For double-precision routines, Ω = 16^63(1 - 16^-14)
For extended-precision routines, Ω = 16^63(1 - 16^-28)

CEESxSIN—Sine

CEESxSIN returns the sine of the parameter by using the equation: result = sin(parm1)

The following routines are provided for the various data types supported:

CEESSIN
32-bit single floating-point number

CEESDSIN
64-bit double floating-point number

CEESQSIN
128-bit extended floating-point number

CEESTSIN
32-bit single floating-point complex number

CEESESIN
64-bit double floating-point complex number

CEESRSIN
128-bit extended floating-point complex number
**Syntax**

```
►►CEESxSIN—(—parm1—,—fc—,—result—)◄◄
```

**parm1 (input)**

The input, in radians, to the sine routine. For real functions, the input range varies, depending on the value of parm1:

<table>
<thead>
<tr>
<th>If</th>
<th>Input range</th>
</tr>
</thead>
<tbody>
<tr>
<td>parm1 is a 32-bit single floating-point number:</td>
<td>(</td>
</tr>
<tr>
<td>parm1 is a 64-bit double floating-point number:</td>
<td>(</td>
</tr>
<tr>
<td>parm1 is an extended floating-point number:</td>
<td>(</td>
</tr>
</tbody>
</table>

For complex functions, the input range differs for the imaginary and real parts of the input:

<table>
<thead>
<tr>
<th>Part</th>
<th>Input range</th>
</tr>
</thead>
<tbody>
<tr>
<td>For the imaginary part:</td>
<td>(</td>
</tr>
<tr>
<td>For the real part: single floating-point complex numbers</td>
<td>(</td>
</tr>
<tr>
<td>For the real part: double floating-point complex numbers</td>
<td>(</td>
</tr>
<tr>
<td>For the real part: extended floating-point complex numbers</td>
<td>(</td>
</tr>
</tbody>
</table>

**fc (output)**

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 416 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1UT</td>
<td>2</td>
<td>2013</td>
<td>The absolute value of the imaginary part of the parameter was greater than limit in math routine routine-name.</td>
</tr>
<tr>
<td>CEE1V1</td>
<td>2</td>
<td>2017</td>
<td>The absolute value of the parameter was greater than or equal to limit in math routine routine-name.</td>
</tr>
<tr>
<td>CEE1V3</td>
<td>2</td>
<td>2019</td>
<td>The absolute value of the real part of the parameter was greater than or equal to limit in math routine routine-name.</td>
</tr>
</tbody>
</table>
result (output)
The result of the sine routine. The output range for functions of real variables is: result is greater than or equal to -1 and is less than or equal to 1.

CEESxSNH—Hyperbolic sine
CEESxSNH performs the mathematical function hyperbolic sine by using the equation: result = sinh (parm1)

The following routines are provided for the various data types supported:

- CEESSSNH
  32-bit single floating-point number
- CEESDSNH
  64-bit double floating-point number
- CEEQSNSH
  128-bit extended floating-point number
- CEEESTSNH
  32-bit single floating-point complex number
- CEEESNSH
  64-bit double floating-point complex number
- CEESRNSH
  128-bit extended floating-point complex number

Syntax

```c
►►CEESxSNH dü—parm1—,—fc—,—result—◄◄
```

parm1 (input)
The input to the hyperbolic sine routine. The input range varies.

<table>
<thead>
<tr>
<th>For</th>
<th>Input range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input range for reals:</td>
<td></td>
</tr>
</tbody>
</table>

For complex functions, the input range differs for the imaginary and real parts of the input. The input range of the imaginary part also differs depending on the precision of parm1.

<table>
<thead>
<tr>
<th>For</th>
<th>Input range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Complex functions: real part</td>
<td></td>
</tr>
<tr>
<td>Imaginary part: single floating-point complex numbers</td>
<td></td>
</tr>
<tr>
<td>Imaginary part: double floating-point complex numbers</td>
<td></td>
</tr>
<tr>
<td>Imaginary part: extended floating-point complex numbers</td>
<td></td>
</tr>
</tbody>
</table>
fc (output)
A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1V0</td>
<td>2</td>
<td>2016</td>
<td>The absolute value of the parameter was greater than limit in math routine routine-name.</td>
</tr>
</tbody>
</table>

result (output)
The result of the hyperbolic sine routine. The output range for functions of real variables is:

\[ |\text{result}| \leq \Omega \]

**CEESxSQT—Square root**
CEESxSQT returns the square root of parm1 by using the equation:

\[ \text{result} = \sqrt{\text{parm1}} \]

The following routines are provided for the various data types supported:

**CEESSSQT**
32-bit single floating-point number

**CEESDSQT**
64-bit double floating-point number

**CEESQSQT**
128-bit extended floating-point number

**CEESTSQT**
32-bit single floating-point complex number

**CEESESQT**
64-bit double floating-point complex number

**CEESRSQT**
128-bit extended floating-point complex number

**Syntax**

\[ \text{CEESxSQT}((\text{parm1}), \text{fc}, \text{result}) \]
The input to the square root routine. The input range for real number functions is: \( \text{parm1} \) is greater than, or equal to, 0.

For complex numbers, the input range is not restricted.

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to “Invoking callable services” on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1UQ</td>
<td>2</td>
<td>2010</td>
<td>The parameter was less than ( \text{limit} ) in math routine ( \text{routine-name} ).</td>
</tr>
</tbody>
</table>

The result of the square root routine. The output range for functions of real variables is:

\[
0 \leq \text{result} \leq \Omega^{1/2}
\]

For single-precision routines, \( \Omega = 16^{63}(1 - 16^{-6}) \)

For double-precision routines, \( \Omega = 16^{63}(1 - 16^{-14}) \)

For extended-precision routines, \( \Omega = 16^{63}(1 - 16^{-28}) \)

**CEESxTAN—Tangent**

CEESxTAN returns the tangent of the parameter by using the equation: \( \text{result} = \tan (\text{parm1}) \)

The following routines are provided for the various data types supported:

- **CEESSTAN**
  32-bit single floating-point number
- **CEESDTAN**
  64-bit double floating-point number
- **CEESQTAN**
  128-bit extended floating-point number
- **CEESSTTAN**
  32-bit single floating-point complex number
- **CEESETAN**
  64-bit double floating-point complex number
- **CEESRTAN**
  128-bit extended floating-point complex number
### Syntax

```ceesxtan(, parm1, fc, result)```

### parm1 (input)

The input, in radians, to the tangent routine. The input range varies, depending on the value of `parm1`:

<table>
<thead>
<tr>
<th>For</th>
<th>Input range</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>parm1</code> is a single floating-point number:</td>
<td>$</td>
</tr>
<tr>
<td><code>parm1</code> is a double floating-point number:</td>
<td>$</td>
</tr>
<tr>
<td><code>parm1</code> is an extended floating-point number:</td>
<td>$&lt;</td>
</tr>
</tbody>
</table>

Also, for extended and as complex functions, this argument cannot approach odd multiples of:

\[ \pi/2 \]

### fc (output)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1UI</td>
<td>2</td>
<td>2002</td>
<td>The parameter value was too close to one of the singularities (plus or minus pi/2, plus or minus 3pi/2, for the tangent; or plus or minus pi, plus or minus 2pi, for the cotangent) in math routine <code>routine-name</code>.</td>
</tr>
<tr>
<td>CEE1V1</td>
<td>2</td>
<td>2017</td>
<td>The absolute value of the parameter was greater than or equal to <code>limit</code> in math routine <code>routine-name</code>.</td>
</tr>
<tr>
<td>CEE1V9</td>
<td>1</td>
<td>2025</td>
<td>An underflow occurred in math routine <code>routine-name</code>.</td>
</tr>
</tbody>
</table>

### result (output)

The result of the tangent routine. The output range for functions of real variables is:
CEESxTNH—Hyperbolic tangent

CEESxTNH performs the mathematical function hyperbolic tangent by using the equation: \( \text{result} = \tanh (\text{parm1}) \)

The following routines are provided for the various data types supported:

- **CEESSTNH**
  - 32-bit single floating-point number

- **CEESDTNH**
  - 64-bit double floating-point number

- **CEESQTNH**
  - 128-bit extended floating-point number

- **CEESTTNH**
  - 32-bit single floating-point complex number

- **CEESETNH**
  - 64-bit double floating-point complex number

- **CEESRTNH**
  - 128-bit extended floating-point complex number

**Syntax**

```plaintext
>>> CEESxTNH(parm1, fc, result)
```

*parm1 (input)*

The input to the hyperbolic tangent routine. The input range is not restricted for real functions. For complex functions, \( \text{parm1} \) must not approach odd multiples of:

\[ \pi/2 \times i \text{, where } i = \sqrt{-1} \]

*fc (output)*

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to "Invoking callable services" on page 116 for the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td></td>
<td>The service completed successfully.</td>
</tr>
</tbody>
</table>
result (output)
The result of the hyperbolic tangent routine. The output range for functions of
real variables is:

\[ |\text{result}| < 1 \]

CEESxXPx—Exponentiation
CEESxXPx performs the mathematical function exponentiation by using the
equation:

\[ \text{result} = \text{parm}1^{\text{parm}2} \]

The following routines are provided for the various data types supported:

- CEESIXPI: 32-bit binary integer raised to a 32-bit binary integer
- CEESSXPI: 32-bit single floating-point number raised to a 32-bit binary integer
- CEESDXPI: 64-bit double floating-point number raised to a 32-bit binary integer
- CEESQXPI: 128-bit extended floating-point number raised to a 32-bit binary integer
- CEESTXPI: 32-bit single floating-point complex number raised to a 32-bit binary integer
- CESEEXPI: 64-bit double floating-point complex number raised to a 32-bit binary integer
- CEESRXPI: 128-bit extended floating-point complex number raised to a 32-bit binary integer
- CEESSXPS: 32-bit single floating-pointing point raised to a 32-bit single floating-point
- CEESDXPD: 64-bit double floating-point raised to a 64-bit double floating-point
- CEESQXPO: 128-bit extended floating-point raised to a 128-bit extended floating-point
- CEESTXPT: 32-bit single floating-point complex raised to a 32-bit single floating-point complex
- CEESEXPE: 64-bit double floating-point complex raised to a 64-bit double floating-point complex
- CEESRXPR: 128-bit extended floating-point complex raised to a 128-bit extended floating-point complex
Syntax

```
CEEsxXPx---(parm1, parm2, fc, result)
```

**parm1** (*input*)

The input for the base of the exponentiation routine. The input range varies.

For functions of real variables:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Expression</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>parm1 is a 32-bit number and parm1 &lt; 0:</td>
<td></td>
<td>(</td>
</tr>
<tr>
<td>parm1 is a 64-bit number and parm1 &lt; 0:</td>
<td></td>
<td>(</td>
</tr>
<tr>
<td>parm1 is a 128-bit number and parm1 &lt; 0:</td>
<td></td>
<td>(</td>
</tr>
</tbody>
</table>

The input range for functions of complex variables: If Re(parm1) = 0 and Im(parm1) = 0, then Re(parm2) must be positive.

**parm2** (*input*)

The input for the power of the exponentiation routine. The type is determined by the eighth character of the service name.

**fc** (*output*)

A 12-byte feedback code, optional in some languages, that indicates the result of this service. If you choose to omit this parameter, refer to the appropriate syntax to indicate that the feedback code was omitted.

The following symbolic conditions can result from this service:

<table>
<thead>
<tr>
<th>Code</th>
<th>Severity</th>
<th>Message number</th>
<th>Message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE1UJ</td>

</tbody>
</table>

**result (output)**

The result of the exponentiation routine. The output range for functions of real variables is:

\[|result| \leq \Omega\]

**Examples of math services**

The following sections contain examples of calls to various math services made from supported languages.

**C/C++ math service examples**

Table 29 on page 478 shows code examples of calling various math services from C/C++.

Part 3. Appendixes
Appendix A. IBM-supplied country code defaults

Table 32 contains the currency symbols and default picture strings for the `country_code` parameters of the COUNTRY runtime option and the national language support callable services. See “COUNTRY” on page 24 and the services listed in Table 17 on page 114 for more information.

Note: In the table, some currency symbols are shown as hexadecimal strings. How these are displayed depends on the codeset in use by the terminal device. For example, when using code page 01140, 'X'9F404040' is displayed as the Euro symbol followed by three blanks.

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:**

1. The Czechoslovakia country code CS is obsolete. Use either the Czech Republic country code CZ, or the Slovakia country code SK.
2. Country code DE was used for the former Federal Republic of Germany and now represents the settings for Germany. The DD country code, used in the past for the German Democratic Republic, is obsolete and should be replaced by DE.
3. The SU country code is obsolete. Use the following country codes for the appropriate country: Estonia, EE; Latvia, LV; Lithuania, LT; Russian Federation, RU.
Appendix B. Date and time services tables

This appendix contains information to help you use Language Environment date and time callable services. Included are tables for picture term and national language era usage.

Table 33. Picture character terms used in picture strings for date and time services

<table>
<thead>
<tr>
<th>Picture terms</th>
<th>Explanations</th>
<th>Valid values</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y, YY, YYY, ZY, ZYY</td>
<td>1-digit year, 2-digit year, 3-digit year, 3-digit year within era, 4-digit year</td>
<td>0-9, 00-99, 000-999, 1-999, 1582-9999</td>
<td>Y valid for output only. YY assumes range set by CEESCN. YYY and ZYY valid only if used with &amp;&lt;jjjj&gt;, &amp;&lt;cccc&gt;, or &amp;&lt;ccccccc&gt;.</td>
</tr>
<tr>
<td>&lt;jjjj&gt;</td>
<td>Japanese era name in DBCS characters</td>
<td>Heisei (X'0E45A645840F'), Showa (X'0E45B3457A0F'), Taisho (X'0E455A45770F'), Meiji (X'0E45A645840F')</td>
<td>Affects YY field: if &amp;&lt;jjjj&gt; specified, YY means the year within Japanese era, for example, 1988 equals Showa 63. See example in Table 34 on page 490.</td>
</tr>
<tr>
<td>&amp;&lt;cccc&gt; &amp;&lt;cccccccc&gt;</td>
<td>Era name in DBCS characters (X'0E4D8256CE0F'), (X'0E4C845ADD4D8256CE0F')</td>
<td>Affects YY field: if &amp;&lt;cccc&gt; specified, YY means the year within the era. See example in Table 34 on page 490.</td>
<td></td>
</tr>
<tr>
<td>MM ZZ</td>
<td>2-digit month 1- or 2-digit month</td>
<td>01-12, 1-12</td>
<td>For output, leading zero suppressed. For input, ZZ treated as MM.</td>
</tr>
<tr>
<td>RRRR RRRZ</td>
<td>Roman numeral month</td>
<td>Iibb-Xibb (left-aligned)</td>
<td>For input, source string is folded to uppercase. For output, uppercase only. I=Jan, II=Feb, ..., XII=Dec.</td>
</tr>
<tr>
<td>MMM, Mmm, MMMM...m, MMMM...M, MMMMMMMMMZ, MMMMMMMMMmMz</td>
<td>3-char month, upper case, 3-char month, mixed case, 3-20 char mo., mixed case, 3-20 char mo., upper case, trailing blanks suppressed, trailing blanks suppressed</td>
<td>JAN-DEC, Jan-Dec, JJanuary-December, JANUARY-DECEMBER, JANUARYy-My-DECEMBERy, Januaryy-Mby-Decembery</td>
<td>For input, source string always folded to uppercase. For output, uppercase only. M generates upper case and m generates lowercase. Output is padded with blanks (b) (unless Z specified) or truncated to match the number of Ms, up to 20.</td>
</tr>
<tr>
<td>DD DD DD</td>
<td>2-digit day of month 1- or 2-digit day of year (Julian day)</td>
<td>01-31, 1-31, 001-366</td>
<td>For output, leading zero is always suppressed. For input, DD treated as DD.</td>
</tr>
<tr>
<td>HH ZZ</td>
<td>2-digit hour 1- or 2-digit hour</td>
<td>00-23, 0-23</td>
<td>For output, leading zero is always suppressed. For input, ZZ treated as HH. If AP specified, valid values are 01-12.</td>
</tr>
<tr>
<td>M, S</td>
<td>minute, second</td>
<td>00-59, 00-59</td>
<td></td>
</tr>
<tr>
<td>9 99 999</td>
<td>tenths of a second, hundredths of a second, thousandths of a second</td>
<td>0-9, 00-99, 000-999</td>
<td>No rounding.</td>
</tr>
<tr>
<td>AP ap A.P., a.p.</td>
<td>AM/PM indicator</td>
<td>AM or PM am or pm A.M. or P.M. a.m. or p.m.</td>
<td>AP affects HH/ZZ field. For input, source string always folded to uppercase. For output, AP generates uppercase and ap generates lowercase.</td>
</tr>
<tr>
<td>W, WWW, Www, <a href="http://WWW...W">WWW...W</a>, <a href="http://WWW...w">WWW...w</a>, WWWWWW, WWWWWWZ, WWWwwwwwwzz</td>
<td>1-char day-of-week, 3-char day, upper case, 3-char day, mixed case, 3-20 char day, upper case, 3-20 char day, mixed case, trailing blanks suppressed, trailing blanks suppressed</td>
<td>S, M, T, W, T, F, S, SUN-SAT, Sunday-Saturday, SUNDAY-SATURDAY, Sundayyyyy-Saturdayyyyy</td>
<td>For input, ws are ignored. For output, W generates uppercase and w generates lowercase. Output padded with blanks (unless Z specified) or truncated to match the number of ws, up to 20.</td>
</tr>
</tbody>
</table>
### Table 33. Picture character terms used in picture strings for date and time services (continued)

<table>
<thead>
<tr>
<th>Picture terms</th>
<th>Explanations</th>
<th>Valid values</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>All others</td>
<td>Delimiters Constants</td>
<td>X’01’-X’FF’ (X’00’ reserved for Language Environment use)</td>
<td>For input, treated as delimiters between the month, day, year, hour, minute, second, and fraction of a second. For output, copied exactly as is to the target string. Constant designating year in Russia, Estonia, Latvia, Lithuania, and the Russian Federation. Constant designating time in Sweden.</td>
</tr>
</tbody>
</table>

**Note:** If a Z/z could be interpreted as belonging to the preceding character string and to the following string, then it is always considered part of the following string, even if it would be legal with the preceding string but illegal with the following string. For clarity, you should always use a delimiter to define which string the Z/z belongs with. See Table 34 for an example.

### Table 34. Examples of picture strings recognized by date and time services

<table>
<thead>

Appendix C. Controlling storage allocation

To generate a report of the storage a routine (or more specifically, an enclave) used during its run, specify the RPTSTG(ON) runtime option. The storage report, generated during enclave termination, provides statistics that can help you understand how space is being consumed as the enclave runs. If storage management tuning is desired, the statistics can help you set the corresponding storage-related runtime options for future runs.

Neither the storage report nor the corresponding runtime options include the storage that Language Environment acquires during early initialization, before runtime options processing, and before the start of space management monitoring.

Storage statistics

Attention: This section does not apply to AMODE 64 applications. For information about AMODE 64 statistics, see “Storage statistics for AMODE 64 applications.”

The following runtime options control storage allocation:
- ANYHEAP
- BELOWHEAP
- HEAP
- HEAPPOOLS
- LIBSTACK
- STORAGE
- STACK
- THREADHEAP
- THREADSTACK

Ensure that these options are tuned appropriately to avoid performance problems. Tuning tips are provided in the z/OS Language Environment Programming Guide. For an example and complete description of the storage report, see z/OS Language Environment Debugging Guide.

Storage statistics for AMODE 64 applications

The following runtime options control storage allocation:
- HEAP64
- HEAPPOOLS
- HEAPPOOLS64
- IOHEAP64
- LIBHEAP64
- STACK64
- THREADSTACK64

Ensure that these options are tuned appropriately to avoid performance problems. Tuning tips are provided in the z/OS V2R1.0 Language Environment Programming Guide for 64-bit Virtual Addressing Mode. For an example and complete description of the storage report, see z/OS Language Environment Debugging Guide.
Appendix D. Accessibility

Accessible publications for this product are offered through IBM Knowledge Center (http://www.ibm.com/support/knowledgecenter/SSLTBW/welcome).

If you experience difficulty with the accessibility of any z/OS information, send a detailed message to the "Contact us" web page for z/OS (http://www.ibm.com/systems/z/os/zos/webqs.html) or use the following mailing address.

IBM Corporation
Attention: MHVRCFS Reader Comments
Department H6MA, Building 707
2455 South Road
Poughkeepsie, NY 12601-5400
United States

Accessibility features

Accessibility features help users who have physical disabilities such as restricted mobility or limited vision use software products successfully. The accessibility features in z/OS can help users do the following tasks:

• Run assistive technology such as screen readers and screen magnifier software.
• Operate specific or equivalent features by using the keyboard.
• Customize display attributes such as color, contrast, and font size.

Consult assistive technologies

Assistive technology products such as screen readers function with the user interfaces found in z/OS. Consult the product information for the specific assistive technology product that is used to access z/OS interfaces.

Keyboard navigation of the user interface

You can access z/OS user interfaces with TSO/E or ISPF. The following information describes how to use TSO/E and ISPF, including the use of keyboard shortcuts and function keys (PF keys). Each guide includes the default settings for the PF keys.

• z/OS TSO/E Primer
• z/OS TSO/E User’s Guide
• z/OS V2R2 ISPF User’s Guide Vol 1

Dotted decimal syntax diagrams

Syntax diagrams are provided in dotted decimal format for users who access IBM Knowledge Center with a screen reader. In dotted decimal format, each syntax element is written on a separate line. If two or more syntax elements are always present together (or always absent together), they can appear on the same line because they are considered a single compound syntax element.

Each line starts with a dotted decimal number; for example, 3 or 3.1 or 3.1.1. To hear these numbers correctly, make sure that the screen reader is set to read out
punctuation. All the syntax elements that have the same dotted decimal number (for example, all the syntax elements that have the number 3.1) are mutually exclusive alternatives. If you hear the lines 3.1 USERID and 3.1 SYSTEMID, your syntax can include either USERID or SYSTEMID, but not both.

The dotted decimal numbering level denotes the level of nesting. For example, if a syntax element with dotted decimal number 3 is followed by a series of syntax elements with dotted decimal number 3.1, all the syntax elements numbered 3.1 are subordinate to the syntax element numbered 3.

Certain words and symbols are used next to the dotted decimal numbers to add information about the syntax elements. Occasionally, these words and symbols might occur at the beginning of the element itself. For ease of identification, if the word or symbol is a part of the syntax element, it is preceded by the backslash (\) character. The * symbol is placed next to a dotted decimal number to indicate that the syntax element repeats. For example, syntax element *FILE with dotted decimal number 3 is given the format 3 \* FILE. Format 3* FILE indicates that syntax element FILE repeats. Format 3* \* FILE indicates that syntax element * FILE repeats.

Characters such as commas, which are used to separate a string of syntax elements, are shown in the syntax just before the items they separate. These characters can appear on the same line as each item, or on a separate line with the same dotted decimal number as the relevant items. The line can also show another symbol to provide information about the syntax elements. For example, the lines 5.1*, 5.1 LASTRUN, and 5.1 DELETE mean that if you use more than one of the LASTRUN and DELETE syntax elements, the elements must be separated by a comma. If no separator is given, assume that you use a blank to separate each syntax element.

If a syntax element is preceded by the % symbol, it indicates a reference that is defined elsewhere. The string that follows the % symbol is the name of a syntax fragment rather than a literal. For example, the line 2.1 %OP1 means that you must refer to separate syntax fragment OP1.

The following symbols are used next to the dotted decimal numbers.

? indicates an optional syntax element
The question mark (?) symbol indicates an optional syntax element. A dotted decimal number followed by the question mark symbol (?) indicates that all the syntax elements with a corresponding dotted decimal number, and any subordinate syntax elements, are optional. If there is only one syntax element with a dotted decimal number, the ? symbol is displayed on the same line as the syntax element, (for example 5? NOTIFY). If there is more than one syntax element with a dotted decimal number, the ? symbol is displayed on a line by itself, followed by the syntax elements that are optional. For example, if you hear the lines 5 ?, 5 NOTIFY, and 5 UPDATE, you know that the syntax elements NOTIFY and UPDATE are optional. That is, you can choose one or none of them. The ? symbol is equivalent to a bypass line in a railroad diagram.

! indicates a default syntax element
The exclamation mark (!) symbol indicates a default syntax element. A dotted decimal number followed by the ! symbol and a syntax element indicate that the syntax element is the default option for all syntax elements that share the same dotted decimal number. Only one of the syntax elements that share the dotted decimal number can specify the ! symbol. For example, if you hear the lines 2? FILE, 2.1! (KEEP), and 2.1 (DELETE), you know that (KEEP) is the
default option for the FILE keyword. In the example, if you include the FILE keyword, but do not specify an option, the default option KEEP is applied. A default option also applies to the next higher dotted decimal number. In this example, if the FILE keyword is omitted, the default FILE(KEEP) is used. However, if you hear the lines 2? FILE, 2.1, 2.1.1! (KEEP), and 2.1.1 (DELETE), the default option KEEP applies only to the next higher dotted decimal number, 2.1 (which does not have an associated keyword), and does not apply to 2? FILE. Nothing is used if the keyword FILE is omitted.

* indicates an optional syntax element that is repeatable
The asterisk or glyph (*) symbol indicates a syntax element that can be repeated zero or more times. A dotted decimal number followed by the * symbol indicates that this syntax element can be used zero or more times; that is, it is optional and can be repeated. For example, if you hear the line 5.1* data area, you know that you can include one data area, more than one data area, or no data area. If you hear the lines 3*, 3 HOST, 3 STATE, you know that you can include HOST, STATE, both together, or nothing.

Notes:
1. If a dotted decimal number has an asterisk (*) next to it and there is only one item with that dotted decimal number, you can repeat that same item more than once.
2. If a dotted decimal number has an asterisk next to it and several items have that dotted decimal number, you can use more than one item from the list, but you cannot use the items more than once each. In the previous example, you can write HOST STATE, but you cannot write HOST HOST.
3. The * symbol is equivalent to a loopback line in a railroad syntax diagram.

+ indicates a syntax element that must be included
The plus (+) symbol indicates a syntax element that must be included at least once. A dotted decimal number followed by the + symbol indicates that the syntax element must be included one or more times. That is, it must be included at least once and can be repeated. For example, if you hear the line 6.1+ data area, you must include at least one data area. If you hear the lines 2+, 2 HOST, and 2 STATE, you know that you must include HOST, STATE, or both. Similar to the * symbol, the + symbol can repeat a particular item if it is the only item with that dotted decimal number. The + symbol, like the * symbol, is equivalent to a loopback line in a railroad syntax diagram.

Policy for unsupported hardware

Various z/OS elements, such as DFSMS, HCD, JES2, JES3, and MVS, contain code that supports specific hardware servers or devices. In some cases, this device-related element support remains in the product even after the hardware devices pass their announced End of Service date. z/OS may continue to service element code; however, it will not provide service related to unsupported hardware devices. Software problems related to these devices will not be accepted
for service, and current service activity will cease if a problem is determined to be associated with out-of-support devices. In such cases, fixes will not be issued.

Minimum supported hardware

The minimum supported hardware for z/OS releases identified in z/OS announcements can subsequently change when service for particular servers or devices is withdrawn. Likewise, the levels of other software products supported on a particular release of z/OS are subject to the service support lifecycle of those products. Therefore, z/OS and its product publications (for example, panels, samples, messages, and product documentation) can include references to hardware and software that is no longer supported.

- For information about software support lifecycle, see: IBM Lifecycle Support for z/OS (http://www.ibm.com/software/support/systemsz/lifecycle/)
- For information about currently-supported IBM hardware, contact your IBM representative.

Programming Interface information

This book documents intended Programming Interfaces that allow the customer to write programs to obtain the services of Language Environment in z/OS.

reason code

CEE3DMP callable service and 147

dumps and 147

RECPAD runtime option
syntax 70

REDIR runtime option
syntax description 71

directions

of stderr, stdout and stdin output 57, 71

REDIR runtime option and 71

register

save area, as component of
dsa_alloc_value 82

report

generating options report (RPTOPTS runtime option) 71

runtime options (continued)

HEAPPOOLS64 — controls optional
user heap storage management
algorithm 46, 48

HEAVZONES 48

INQPCOPN—control value in
OPENED specifier of INQUIRE by
unit statement 50

INTERRUPT—cause attentions to be
recognized by Language
Environment 50

IOHEAP64 — controls allocation of
I/O heap storage 51

LIBSTACK—control library stack
storage 54

MSGQ—specify number of ISI blocks
allocated 58

NATLANG—specify national
language 59

OCSTATUS—control checking of file
existence and whether file deletion
occurs 60

PC—control whether Fortran status
common blocks are shared among
load modules 65

PLIST—specify format of C
arguments 66

PLITASKCOUNT—control the
maximum number of active
tasks 67

PRUNIT—specifies unit number
used for PRINT and WRITE
statements 69

PUNUNIT—specifies unit number
used for PUNCH statements 69

Quick Reference Tables 3, 6

RDRUNIT—specifies unit number
used for READ statements 70

RECPAD—specifies whether a
formatted input record is padded
with blanks 70

REDIR—specify redirections for C
output 71

report of options specified

generating heading for 199

language report is written in
59, 71, 73

not generated if application
abends 72

sample of 72

RPTOPTS—generate a report of
runtime options used 71

RTEREUS—initialize a reusable
COBOL environment 74

SIMVRD—specify VSAM KSDS for
COBOL 76

STACK—allocate stack storage
76, 79

STORAGE—control storage 81

TERMTHDACT—specify type of
information generated with
unhandled error 83

TEST—indicate debug tool to gain
control 89

TRACE—activate Language
Environment runtime library
tracing 96

RESUME cursor

moving (CEEMRCSR) 365

reset summary point (CEE3SRP) 209

reusability of an environment 74

routine that incurred condition, getting
(CEE3GRN) 160, 161, 164

RPTOPTS runtime option

relationship to MSGFILE runtime
option 71

sample options report generated
by 72

syntax 72

RPTSTG runtime option

CEE3TST and 315

storage report generated by
setting heading for 199

RTEREUS runtime option

CICS ignores this option 75

syntax 74

runtime options

ABPERC—percolate an abend 9

AIXBLD—invoke AMS for
COBOL 11

ALL31—indicate whether application
runs in AMODE(31) 12

ARGPARSE—specify whether
arguments are parsed 15

AUTOTASK—specify whether Fortran
MTF is to be used 16

BELOWHEAP—control library heap
storage below 16M 17

CBLOPTS—specify format of COBOL
argument 18

CBLPUSHPOP—control CICS
commands 18

CBQPDA—control COBOL
QSAM 19

CHECK—detect checking errors 24

COUNTRY—specify default date/time
formats 24

DEBUG—activate COBOL batch
debugging 26

DEPTHCONDLM—limit extent of
nested conditions 26

ENV—specify operating environment
for C application 31

ERRCOUNT—specify number of
errors allowed 32

ERRUNIT—specify unit number to
which error information is
directed 33

EXECOPS—let runtime options be
specified on command line 34

FILEHIST—specify whether to allow a
file definition to be changed at run
time 35

FILETAG—specify whether to allow
AUTO TAG / AUTO CVT. 35

FLOW—control FLOW output for
OS/VS COBOL 37

HEAP—control allocation of
heaps 38, 51

HEAP64—controls allocation of user
heap storage 40

HEAP64 — performs diagnostic tests
against the user heap 41

HEAPPOOLS64 — controls optional
user heap storage management
algorithm 46, 48

HEAVZONES 48

INQPCOPN—control value in
OPENED specifier of INQUIRE by
unit statement 50

INTERRUPT—cause attentions to be
recognized by Language
Environment 50

IOHEAP64 — controls allocation of
I/O heap storage 51

LIBSTACK—control library stack
storage 54

MSGQ—specify number of ISI blocks
allocated 58

NATLANG—specify national
language 59

OCSTATUS—control checking of file
existence and whether file deletion
occurs 60

PC—control whether Fortran status
common blocks are shared among
load modules 65

PLIST—specify format of C
arguments 66

PLITASKCOUNT—control the
maximum number of active
tasks 67

PRUNIT—specifies unit number
used for PRINT and WRITE
statements 69

PUNUNIT—specifies unit number
used for PUNCH statements 69

Quick Reference Tables 3, 6

RDRUNIT—specifies unit number
used for READ statements 70

RECPAD—specifies whether a
formatted input record is padded
with blanks 70

REDIR—specify redirections for C
output 71

report of options specified

generating heading for 199

language report is written in
59, 71, 73

not generated if application
abends 72

sample of 72

RPTOPTS—generate a report of
runtime options used 71

RTEREUS—initialize a reusable
COBOL environment 74

SIMVRD—specify VSAM KSDS for
COBOL 76

STACK—allocate stack storage
76, 79

STORAGE—control storage 81

TERMTHDACT—specify type of
information generated with
unhandled error 83

TEST—indicate debug tool to gain
control 89

TRACE—activate Language
Environment runtime library
tracing 96

Index 513
runtime options (continued)
TRAP—handle abends and program interrupts 98
UPI—set UPI switches 100
USRHDLR—register a user condition handler at stack frame 0 101
VCTRSAVE—use vector facility 102
XUFLLOW—specify program interrupt due to exponent underflow 105

S
safe condition 417
sample programs 118
SCEESAMP sample library
declaration files in 117
sending comments to IBM xvi
sending product messages to a file (CEEMSG) 375
examples of 376, 377
sending user-defined message string to file (CEEMOUT) 357
examples of 358, 359
SET function
changing the COUNTRY setting with 136
changing the enablement of hardware conditions with 203
changing the national language with 174, 175
setlocale () function
COUNTRY runtime option and 25
setlocale() function
CEE3CTY callable service and 137
severity of a condition
CEE3GL and 417
ERRCOUNT runtime option and 32
severity levels that cause the debug tool to gain control 89
shortcut keys 493
Showa era 490
SIGNIFICANCE condition 203, 204
SIMVRD runtime option
syntx 76
sine math service (CEESxSIN) 469
slash (/)
NOEXECOPS alters behavior of 34
specifying in parameters of TEST runtime option 90
SPIE runtime option 98
square root math service
(CEExsSQRT) 471
SSRANGE option for COBOL 24
stack frame
CEE3DMP callable service and 147
library, allocating (LIBSTACK runtime option) 54
storage
ALL31 runtime option and 12
allocating (STACK runtime option) 76, 79
initializing (STACK runtime option) 81
stack (continued)
storage (continued)
RPTSTG runtime option and 74
setting initial stack segment (STACK runtime option) 76, 79
threads and 74
user, allocating (STACK runtime option) 76, 79
STACK runtime option
syntax 76, 79
using with RPTSTG to tune the stack 74
stack storage
allocating
stack storage (THREADSTACK runtime option) 93
stack storage (THREADSTACK64 runtime option) 95
STAE
Coptions 98
VS COBOL Ioptions 98
stderr
MSGFILE runtime option and 57
REDIR runtime option and 71
redirecting output from 71
stdin 71
MSGFILE runtime option and 71
REDIR runtime option and 71
redirecting output from 71
stdout 71
MSGFILE runtime option and 71
REDIR runtime option and 71
redirecting output from 71
storage
additional heaps, creating new (CEECRHP) 223
discarding an entire heap (CEEDSHP) 258
freeing
discarding an entire heap (CEEDSHP) 258, 261
freeing additional heap (CEEFRST) 284, 287
getting
heap storage (CEEGTST) 315
initializing (STORAGE runtime option) 81
options for 81
BELOWHEAP—control library heap below 16M 17
HEAP—control initial heap 38, 51
LIBSTACK—control library stack storage 54
STACK—control thread stack storage 76, 79
report
language written in 59, 71, 73
not generated if application abends 73
setting heading for 199
STACK runtime option and 74
services
CEE3RPH—set report heading 199
CEECRHP—create new additional heap 223
storage (continued)
services (continued)
CEECZST—reallocate (change size of) storage 227
CEEEDSHP—discard heap 258
CEEFRST—free heap storage 285
CEEGTST—get heap storage 315
stack storage, controlling (THREADSTACK runtime option) 93
stack storage, controlling (THREADSTACK64 runtime option) 95
thread, level heap, controlling (THREADHEAP runtime option) 91

T
Taiho era 490
Taiwan era 490
tangent math service (CEESxTAN) 472
task
controlling number of tasks under MTF (PLITASKCOUNT option) 88
termination
ecluve
CEE3ABD and 125, 128, 170
termination imminent step
TERMTHDACT runtime option and 88
TERMTHDACT runtime option
CEE3DMP and 88
CESE transient data queue and different treatment under CICS 88
TEST compile-time option 146
TEST runtime option
syntax 89
thousands separator
obtaining default of (CEE3CTY) 135
setting defaults for (COUNTRY) 24
thread
multiple
storage report for (RPTSTG runtime option) 74
THREADHEAP—control the allocation of thread-level heap storage
syntax 91
THREADSTACK—control the allocation of the thread’s stack storage for both the upward and downward-growing stacks
syntax 93
THREADSTACK64—control the allocation of the thread’s stack storage for for AMODE 64 applications
syntax 95
time, getting local (CEELOCT) 348
timestamp 238, 407
TRACE runtime option
syntax 96
trace, generating a 84
trademarks 499
transfer of sign math service (CEESxSGN) 467
TRAP runtime option
ABPerc runtime option and 9
syntax 98
truncation math service (CEESxINT) 459

U
UNDERFLOW condition 105, 202, 204
UPSI runtime option
syntax 100
UPSI—set UPSI switches 100
USE FOR DEBUGGING declarative 26
user
area fields 208, 210, 211
heap (initial heap)
allocating storage from 38, 51, 315
restrictions against discarding 258
stack, controlling (STACK runtime option) 74
user interface
ISPF 493
TSO/E 493
user-written condition handler
CEE3SPM callable service and 203
user-written condition handler (continued)
CEEMRCR callable service and 365
registering with CEEHDLR callable service 319
unregistering 328
VCTRSAVE runtime option and 102
USRHDLR runtime option
syntax 101
V
valid condition 417
VCTRSAVE runtime option
syntax 102
vector facility 102
VSAM
KSDES 11, 76
RRDES 11
W
WITH DEBUGGING MODE clause for COBOL 26
X
XPLINK runtime option 103
XPLink 103
XUFLOW runtime option
syntax 105
Product Number: 5650-ZOS

Printed in USA
