**Figures** ........................................ vii

**Tables** ........................................ ix

**About this information** ......................... xiii
- Who should use this information ........ xiii
- Where to find more information .......... xiii
- Information updates on the web .......... xiv
- How to read syntax diagrams ............ xiv
  - Symbols .................................... xiv
  - Syntax items .............................. xiv
  - Syntax examples ........................... xv

**How to send your comments to IBM** ......... xvii

**Summary of changes** ............................ xix
- Changes made in z/OS Version 2 Release 2 (V2R2) as updated March 2017 ........ xix
- Changes made in z/OS Version 2 Release 2 (V2R2) as updated December 2015 .... xix
- Summary of changes for z/OS Version 2 Release 2 (V2R2) .................... xix
- Changes made in z/OS Version 2 Release 1 (V2R1) as updated December 2013 .... xx
- Changes made in z/OS Version 2 Release 1 .......... xx

**Part 1. Using the workload management services** ........ 1

**Chapter 1. Introduction to the workload management services** .......... 3
- Services for subsystem work managers .......... 3
  - Why use the work manager services .......... 4
  - Why use the execution delay monitoring services ...... 5
  - Why use the enclave services ................ 6
  - Why use the queueing manager services ......... 9
  - Why use the routing manager services ......... 11
  - Why use the scheduling environment services .... 12
  - Why use the sysplex routing services .......... 12
  - Why use the query system information service ... 13
- Services for performance monitors .......... 13
  - Why use the workload reporting services .... 14
  - Getting information from SMF type 99 records ... 15
- Services for application programs ............ 16
- WLM services that support 64-bit addressing .... 16

**Chapter 2. Using the subsystem work manager services** .......... 21
- Considerations for using the services .......... 21
  - Suggested services for a single address space transaction manager ...... 22
    - Using the execution delay monitoring services .......... 24
  - Suggested services for a work manager that calls a data manager .......... 26
  - Services for multiple address space work managers .......... 27
    - Execution delay monitoring services for multiple address space work managers .......... 29
  - Services for work managers that distribute work requests ............ 31
    - Determining the subsystem name and type ................ 31
    - Using IWMWMCON when distributing work in a sysplex .......... 31

**Chapter 3. Creating and using enclaves** .......... 33
- Why would you use an enclave? .......... 33
  - SRBs in enclaves ........................... 34
  - Tasks in enclaves ........................... 35
  - Comparison of enclaves and execution delay services ............ 35
- Creating an enclave .......................... 36
  - Comparison between independent, dependent, and work-dependent enclaves ........ 36
  - Registering an enclave .................... 37
  - Multisystem enclaves ...................... 37
  - Scheduling an SRB in an independent enclave .......... 39
  - Joining tasks to an independent enclave ........ 41
  - Using dependent enclaves .................. 43
  - Using a multisystem enclave .............. 44
  - Performance management of address spaces with enclaves ............ 46
  - Using ENQ/DEQ or latch manager services with enclaves .......... 48
  - Enclave resource accounting ............... 49
  - Managing the performance of work in enclaves .......... 51
  - Using independent enclaves ............... 51
  - Using dependent enclaves ................. 52
  - Using work-dependent enclaves .......... 52
  - Querying an enclave’s classification information ........ 52
  - Querying a dispatchable unit’s enclave status .......... 53
  - Deleting an enclave ...................... 53

**Chapter 4. Participating in Enterprise Workload Management** .... 55
- Enclave Services and EWLM ................. 56
  - Modelling your business transactions ........ 56
  - Connecting with WLM as an EWLM participant .......... 57
  - Disconnecting from WLM ................... 58
  - Creating an enclave ...................... 58
  - Deleting an enclave ..................... 59
  - Classifying work requests ................ 59
  - Explicitly starting and stopping work requests .......... 60
  - Continuously a work request at another application .......... 60
  - Blocking and unblocking work requests .......... 60
  - Enclave services and the ARM API ........ 60
  - Instrumenting a C application for ARM .......... 61

### Part 3. Appendixes
Appendix A. SMF type 99 action
codes. ........................................ 775

Appendix B. Application validation
reason codes ................................. 801

Appendix C. Structure of the XML
service definition (DTD) ......... 817

Appendix D. C language interfaces for
workload management services . . 823
Interfaces for sysplex routing services .......... 824
Interface for querying a virtual server .......... 825

Appendix E. WLM services supporting
31-bit addressing only ............... 827
IWMMAEDEF — Defining Dynamic Application
Environments to Workload Management .... 828
IWMCLSFY — Classify work request ......... 837
IWMCONN — Connect to workload management 853
IWMDISC — Disconnect from workload
management .................................. 872
IWMECQRY — Query enclave classification
attributes .................................. 879
IWMCREA — Create an enclave ............. 885
IWMEDELE — Delete an enclave. .......... 896
IWMEQRY — Enclave query ............... 904
IWMMABNL — Record abnormal event ....... 911
IWMMCHST — Monitor change state of work unit 915
IWMMCREA — Create delay monitoring
environment. ................................ 922
IWMMDELE — Delete the monitoring
environment. .............................. 932
IWMMEXTR — Monitoring environment extract 936
IWMMINIT — Initialize monitoring environment 943
IWMMNTFY — Notify of work execution
completion ................................ 958
IWMMRELA — Relate monitoring environment
service .................................... 967
IWMMSTOP — Stop a work unit .......... 976
IWMMSTRT — Indicate the start of a work unit 983
IWMMSWCH — Switch monitoring environment 990
IWMMUPD — Update data for a work unit .... 995
IWMMXFER — Transfer monitoring environment 1001
IWMQDEL — Delete a request from the queue for
an execution address space ........... 1009
IWMQINS — Insert a request onto the queue for
an execution address space ................ 1016
IWMRPT — Report on work request completion 1028
IWMFAIL — Application environment limit
service .................................. 1040
IWMSEL — Select a request from a caller's work
manager queue ............................ 1047
IWMSES — WLM server select secondary
service ................................ 1055
IWMSTBN — Begin a request from a caller's
work manager queue ..................... 1062
IWMMEND — End a request from a caller's
work manager queue ..................... 1070
IWMTAFF — WLM temporal affinity service .... 1076

Appendix F. Accessibility ............... 1083
Accessibility features ...................... 1083
Consult assistive technologies .......... 1083
Keyboard navigation of the user interface . 1083
Dotted decimal syntax diagrams ......... 1083

Notices .................................... 1087
Policy for unsupported hardware .......... 1088
Minimum supported hardware .......... 1089
Programming interface information .... 1089
Trademarks ................................ 1089

Index ..................................... 1091

About this information

This document supports z/OS (5650-ZOS). This document describes the z/OS® workload management services. The services are intended for programmers who write authorized programs.

This document is divided into two main parts:
- Part 1, “Using the workload management services,” on page 1, which provides an overview of the WLM services and how to use them
- Part 2, “Reference: Workload Management Services,” on page 141, which describes each service in detail, including syntax, parameters, and usage examples

Who should use this information

Programmers using assembly language can use the macros described in this document to invoke the services they need. This document includes some guidance information and detailed information, such as the function, the syntax, and the parameters needed to code the macros. To understand the information in this document, programmers should have read z/OS MVS Planning: Workload Management.

Where to find more information

Where necessary, this document references information in other documents, using shortened versions of the document title. For complete titles and order numbers of the documents for all products that are part of z/OS, see z/OS V2R2 Information Roadmap:

How to read syntax diagrams

This section describes how to read syntax diagrams. It defines syntax diagram symbols, items that may be contained within the diagrams (keywords, variables, delimiters, operators, fragment references, operands) and provides syntax examples that contain these items.

Syntax diagrams pictorially display the order and parts (options and arguments) that comprise a command statement. They are read from left to right and from top to bottom, following the main path of the horizontal line.

For users accessing the Information Center using a screen reader, syntax diagrams are provided in dotted decimal format.

Symbols

The following symbols may be displayed in syntax diagrams:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>➯</td>
<td>Indicates the beginning of the syntax diagram.</td>
</tr>
<tr>
<td>➯PTY</td>
<td>Indicates that the syntax diagram is continued to the next line.</td>
</tr>
<tr>
<td>➯PTY</td>
<td>Indicates that the syntax is continued from the previous line.</td>
</tr>
<tr>
<td>➯PTY</td>
<td>Indicates the end of the syntax diagram.</td>
</tr>
</tbody>
</table>

Syntax items

Syntax diagrams contain many different items. Syntax items include:

- Keywords - a command name or any other literal information.
- Variables - variables are italicized, appear in lowercase, and represent the name of values you can supply.
- Delimiters - delimiters indicate the start or end of keywords, variables, or operators. For example, a left parenthesis is a delimiter.
- Operators - operators include add (+), subtract (-), multiply (*), divide (/), equal (=), and other mathematical operations that may need to be performed.
- Fragment references - a part of a syntax diagram, separated from the diagram to show greater detail.
- Separators - a separator separates keywords, variables or operators. For example, a comma (,) is a separator.

Note: If a syntax diagram shows a character that is not alphanumeric (for example, parentheses, periods, commas, equal signs, a blank space), enter the character as part of the syntax.

Keywords, variables, and operators may be displayed as required, optional, or default. Fragments, separators, and delimiters may be displayed as required or optional.
**Item type**

**Definition**

**Required**
Required items are displayed on the main path of the horizontal line.

**Optional**
Optional items are displayed below the main path of the horizontal line.

**Default**
Default items are displayed above the main path of the horizontal line.

**Syntax examples**
The following table provides syntax examples.

<table>
<thead>
<tr>

How to send your comments to IBM

We appreciate your input on this documentation. Please provide us with any feedback that you have, including comments on the clarity, accuracy, or completeness of the information.

Use one of the following methods to send your comments:

**Important:** If your comment regards a technical problem, see instead “If you have a technical problem.”

- Send an email to mhvrdfs@us.ibm.com.
- Send an email from the [Contact us" web page for z/OS](http://www.ibm.com/systems/z/os/zos/webqs.html).

Include the following information:
- Your name and address
- Your email address
- Your phone or fax number
- The publication title and order number:
  - z/OS V2R2 MVS Programming: Workload Management Services
  - SC34-2663-04
- The topic and page number or URL of the specific information to which your comment relates
- The text of your comment.

When you send comments to IBM®, you grant IBM a nonexclusive right to use or distribute the comments in any way appropriate without incurring any obligation to you.

IBM or any other organizations use the personal information that you supply to contact you only about the issues that you submit.

If you have a technical problem

Do not use the feedback methods that are listed for sending comments. Instead, take one or more of the following actions:

- Contact your IBM service representative.
- Call IBM technical support.
Summary of changes

This information includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations for the current edition are indicated by a vertical line to the left of the change.

Changes made in z/OS Version 2 Release 2 (V2R2) as updated March 2017

Changed

“IWMPACT — Activate service policy” on page 292 is updated to reflect the new CHECKHISTORY parameter, which specifies the criteria that WLM applies to decide whether or not to discard historical data for service class periods, due to changes that come into effect with a reactivated WLM policy.

Appendix C, “Structure of the XML service definition (DTD),” on page 817 is updated to reflect HonorPriority and MemoryLimit, which support new function that allows WLM administrators to prevent the overflow of specialty-engine-intensive work, in individual service classes, to standard processors.

Changes made in z/OS Version 2 Release 2 (V2R2) as updated December 2015

Changed

Several topics are updated for WLM support of mobile pricing. This support allows WLM administrators to classify transactions in the WLM service definition so that they can benefit from mobile application pricing. The updated topics include the following:

• “Suggested services for a single address space transaction manager” on page 22
• “Suggested services for a work manager that calls a data manager” on page 26
• “Services for multiple address space work managers” on page 27
• “Execution delay monitoring services for multiple address space work managers” on page 29
• “Using the information in IWMWRCAA” on page 103
• “Using the response time information” on page 109
• Appendix C, “Structure of the XML service definition (DTD),” on page 817

Summary of changes for z/OS Version 2 Release 2 (V2R2)

The following changes are made for z/OS Version 2 Release 2 (V2R2). All technical changes for z/OS V2R2 are indicated by a vertical line to the left of the change.

New

The following new information is added in this publication:

• Service “IWMP4OPTQ — Query IEAOPTxx parameters” on page 677
• Service “IWMP4QHLT — Query server health indicators” on page 689
Changes made in z/OS Version 2 Release 1 (V2R1) as updated
December 2013

Changed

- The order number for z/OS Version 2 Release 1 (5650-ZOS) has been corrected.
- New SMF type 99 action codes 111-123 and 125-127 have been added in Appendix A, “SMF type 99 action codes,” on page 775.

Changes made in z/OS Version 2 Release 1

See the following publications for specific enhancements for z/OS Version 2 Release 1:

- z/OS Summary of Message and Interface Changes, SA23-2300
- z/OS Introduction and Release Guide, GA32-0887
- z/OS Planning for Installation, GA32-0890
- z/OS Migration, GA32-0889

This document contains information previously presented in z/OS MVS™ Programming: Workload Management Services, SA22-7619-21 which supports z/OS Version 1 Release 13.

New information

The descriptions of the following new macros supporting 64-bit addressing were added.

- IWM4CLSY (see “IWM4CLSY — Classify work” on page 464)
- IWM4EQRY (see “IWM4EQRY — Query an enclave” on page 528)
- IWM4MABN (see “IWM4MABN — Monitor environment abnormal event” on page 543)
- IWM4MDEL (see “IWM4MDEL — Delete delay monitoring environment” on page 571)
- IWM4MXTR (see “IWM4MXTR — Monitoring environment extract service” on page 670)
- IWM4MNTF (see “IWM4MNTF — Notify of work execution completion” on page 606)
- IWM4MRLT (see “IWM4MRLT — Relate monitoring environments (PBs)” on page 623)
- IWM4MSTO (see “IWM4MSTO — Stops a work unit” on page 633)
- IWM4MSTR (see “IWM4MSTR — Indicate the start of a work unit” on page 640)
- IWM4MSWC (see “IWM4MSWC — Monitoring environment switch” on page 648)
- IWM4MUPD (see “IWM4MUPD — Update data for a work unit” on page 655)
- IWM4MXFR (see “IWM4MXFR — Monitoring environment transfer” on page 662)
- IWM4RPT (see “IWM4RPT — Report response time” on page 708)

Updated information

- The descriptions of the IWMDEXTR, IWMESTRT, IWMPACT, and IWM4ECRE macros are updated.
Moved information

The descriptions of the following macros were moved to Appendix E, “WLM services supporting 31-bit addressing only,” on page 827.

- IWMCLSFY (see “IWMCLSFY — Classify work request” on page 837).
- IWMECQRY (see “IWMECQRY — Query enclave classification attributes” on page 879).
- IWMRPT (see “IWMRPT — Report on work request completion” on page 1028).
- IWMABNL (see “IWMABNL — Record abnormal event” on page 911).
- IWMDELE (see “IWMDELE — Delete the monitoring environment” on page 932).
- IWMEXTR (see “IWMEXTR — Monitoring environment extract” on page 936).
- IWMNTFY (see “IWMNTFY — Notify of work execution completion” on page 958).
- IWMRELA (see “IWMRELA — Relate monitoring environment service” on page 967).
- IWMWSWCH (see “IWMWSWCH — Switch monitoring environment” on page 990).
- IWMMXFER (see “IWMMXFER — Transfer monitoring environment” on page 1001).
- IWMMSTOP (see “IWMMSTOP — Stop a work unit” on page 976).
- IWMMSTRT (see “IWMMSTRT — Indicate the start of a work unit” on page 983).
- IWMMXFER (see “IWMMXFER — Transfer monitoring environment” on page 1001).
Part 1. Using the workload management services

These topics provide an overview of the workload management services.
Chapter 1. Introduction to the workload management services

The workload management services enable MVS to cooperate with subsystem work managers to achieve installation-defined goals for work, to distribute work across a sysplex, to manage servers and to provide meaningful feedback on how well workload management has achieved those goals. They also allow programs to create an interface to define a service definition.

To change from resource-based performance management to goal-oriented workload management, many transaction managers, data managers, and performance monitors and reporters need to take advantage of the services MVS workload management provides.

This introduction describes the services available for subsystem work managers, performance monitors, and administrative application programs.

Services for subsystem work managers

The workload management services for subsystem work managers allow an installation to process work towards performance goals defined in a service policy. Workload management uses the information provided by the subsystem work managers through the services to match system resources to work to meet goals.

A service policy contains performance goals for all kinds of MVS-managed work expressed in the same terms. A service level administrator identifies and categorizes all of an installation’s work and assigns the work performance goals in the workload management service policy. For information about how to set up and use a service policy, see z/OS MVS Planning: Workload Management.

The services provide workload management with the information it needs to dynamically adapt to match resources to work to meet the performance goals.

Workload management matches system resources to meet the performance goal assigned to a service class. This management involves handling address space-related resources, such as processor storage, multiprogramming level (MPL), dispatching, and I/O queueing.

The services for subsystem work managers can be grouped into the following categories:

- Work manager services
- Execution delay services
- Enclave services
- Queueing manager services
- Routing manager services
- Scheduling environment services
- Sysplex routing services
- Query system information service
Why use the work manager services

Work manager services allow MVS to recognize:
• A subsystem work manager and the transactions it processes.
• The service class goals associated with the transactions.
• The address spaces that are processing the transactions.

Based on this information, workload management can determine whether goals are being met, and which work needs resources to meet the goals.

The work manager services allow:
• Your customers to define performance goals to your subsystem work manager’s transactions.
• MVS to recognize the goals, and match resources to the work to meet the goals.
• Your customers to get reports from performance monitors like RMF™ on how well work is executing and whether the goals are being met.

Using the work manager services in your product allows your customers to specify goals for your work the same way they specify them for MVS-managed work.

The work manager services allow workload management to associate incoming work with a service class. When the work is associated with a service class, MVS knows the performance goal and importance level associated with the work, as well as understanding which address spaces are involved in processing the work request.

If your work manager has a client-server structure and has any of the following objectives, consider using either the queueing manager, the routing manager, or enclave services instead of the work manager services:
• Dynamic management of server address spaces, or
• Management of server work requests as part of the originating unit of work,
• Resource management and/or reporting of individual requests, or
• Balancing workload among servers across a sysplex,

Table 2 summarizes the work manager services.

</tbody>
</table>
Why use the execution delay monitoring services

From the execution delay monitoring services, workload management knows how well work is executing, and where any delays are occurring. The execution delay monitoring services are for complex work manager configurations that process across systems in a sysplex, but do not allow MVS to individually manage resource consumption of the transactions. The services allow MVS to recognize additional address spaces that are processing transactions.

When the execution delay monitoring services are used, MVS can allocate resources for address spaces based on the behavior of the transactions being serviced by them. The services also provide execution delay information, so that your customers can determine where work is being delayed. They can then adjust the work manager configuration to consistently meet the goals. Only response time goals can be used with execution delay services. If you need to use velocity goals, discretionary goals, or period switch, consider using enclave services instead.

Execution delay monitoring is mutually exclusive with enclaves in the same address space so you must choose whichever function best suits your needs. Enclave services provide more granular resource control and reporting than execution delay monitoring services, but do not provide the capability for the work manager to report its own view of transaction states.

The subsystem work manager uses the execution delay monitoring services to tell workload management about their view of the current state of a work request, such as ready state, idle state, or waiting state. The actual state may be different. For example, a work request may be active from the subsystem’s view, but might be delayed by a page fault, or for CPU access. The information is kept in performance blocks, also called monitoring environments.

The monitoring environments represent work wherever it executes: across multiple dispatchable units, address spaces, and systems.

Table 3 summarizes the execution delay monitoring services.

### Why use the enclave services

An enclave is an anchor for a transaction that can be spread across multiple dispatchable units in multiple address spaces. These multiple address spaces can even span across multiple systems in a parallel sysplex. The value of using an enclave to represent a transaction is that the resources used to process the transaction can be accounted to the transaction itself, rather than to the address...
space or spaces that the transaction runs in. In addition, you can assign a performance goal to the enclave, which means that as a transaction consumes system resources, it can switch periods to run with a new goal.

Any number of tasks and SRBs can be grouped together in an enclave:

- Enclave SRBs offer the advantage that they are preemptable and will not tie up the system.
  
  SRBs in enclaves work well for higher volume, small requests, as SRBs have very little overhead compared to tasks. The subsystem can create an enclave using the IWM4ECRE macro, and then schedule SRBs to run in the enclave using the IEAMSCHD macro.

- Tasks in enclaves automatically associate the enclave with the address spaces where they are dispatched, so workload management can manage the storage of those address spaces to meet the goal of the enclave. The enclave can perform functions that require a task environment, such as supervisor calls. Tasks can dynamically leave and join an enclave as they finish one piece of work and begin another. The subsystem creates an enclave using the IWM4ECRE macro, and then the task joins the enclave using the IWMEJOIN macro.

**Comparison to other services**

Enclaves should not be run in the same address space with execution delay monitoring environments. Unpredictable workload management actions could result.

Although enclaves have some characteristics that are similar to those of execution delay monitoring, there are some important differences. These differences should be considered before choosing which set of services to use. Enclaves support all types of performance goals; delay monitoring supports only response time goals. Enclaves allow period switching; delay monitoring does not. Enclaves can span address spaces in multiple systems in a parallel sysplex; delay monitoring cannot. Enclaves allow the separate management of work units that run in the same address space but have different performance goals; a delay monitoring environment can only be managed at the address space level. One advantage of delay monitoring is that it does enable a work manager to report its own view of transaction states.

Enclaves are required to be used with queueing manager services. For more information, see “Why use the queueing manager services” on page 9.

**Enterprise Workload Manager (EWLM)**

With enclave services, work managers that use enclaves to manage and report individual business transactions can become Enterprise Workload Manager™ (EWLM) participants. EWLM allows you to define business-oriented performance goals for an entire domain of servers across a variety of platforms (z/OS, AIX®, i5/OS™, Windows, Solaris and Linux), and then get an end-to-end view of actual performance relative to those goals. You can use enclave services to:

- Connect a calling address space to WLM as an EWLM participant
- Classify work requests in order to assign an EWLM transaction class
- Indicate the start and end of an EWLM work request
- Block work requests while waiting for the completion of a work request in another application.

**Why use the queueing manager services**

A queueing manager is a subsystem or application that queues work requests to workload management for execution by one or more server address spaces.

Queueing manager services allow MVS to:

- Dynamically start and stop server address spaces based on workload.
- Control the number of server instances per server address space.
- Manage the work queues associated with the server address spaces to meet the performance goals set by the customer.

With the dynamic management of server address spaces, an installation does not need to calculate the proper number of address spaces to process work, nor do they have to monitor workload fluctuations that change the number of address spaces needed. Customers can segregate work requests into different server address spaces if this is important for security or integrity.

Enclaves are required to be used with the queueing manager services. This means that customers can define velocity and discretionary goals for work as well as response time goals. Multiple period control is also available for work running in enclaves.

Queueing manager services may provide incentive to subsystems who run with multiple tasks in one address space to switch to multiple address spaces. The queueing manager services make it easier for installations to isolate individual work requests from each other, by running only one in each execution address space, with workload management managing the number of execution address spaces.

Table 5 summarizes the queueing manager services.

Why use the routing manager services

A routing manager is a subsystem that establishes and manages connections between a client and a server address space.

Routing manager services perform two main functions:

- Automatically starting and maintaining server address spaces as needed by the workload across the sysplex.
- Balancing the workload among the servers in the sysplex by deciding on the best server and providing the server routing information when a server is requested by the routing manager.

Table 6 summarizes the routing manager services.

Why use the scheduling environment services

A scheduling environment is a list of resource requirements, allowing you to ensure that units of work are sent to systems that have the appropriate resources to handle them. Resources can represent actual physical entities, such as a database or a peripheral device, or they can represent intangible qualities such as a certain period of time (like second shift or weekend).

These resources are listed in the scheduling environment according to whether they must be set to ON or set to OFF. A unit of work can be assigned to a specific system only when all of the required resource states are satisfied.

Table 7 shows a summary of the scheduling environment services.

Table 7. Scheduling environment services

</tr>
</tbody>
</table>

Why use the sysplex routing services

The sysplex routing services allow work associated with a server to be distributed across a sysplex. They are intended for use by clients and servers when the incoming work requests have not been classified by workload management at the time the routing decision is being made.

The sysplex routing services enable distributed client/server environments to balance work among multiple servers. These services help distributed programs make the routing decisions, rather than having each installation make these decisions. Unlike the routing manager services described earlier, sysplex routing services do not automatically start server address spaces as needed.

A client is any subsystem work manager, application or product, in the network that requests a service. The service could be a request for data, a program to be run, or access to a database or application. In terms of the sysplex routing services,
a client is any program routing work to a server. A server is any subsystem address space that provides a service on an MVS image.

The sysplex routing services provide information for more intelligent routing. They do not route or distribute work requests. The server must use its existing routing mechanisms.

Table 8 summarizes the sysplex workload balancing services.

Why use the query system information service

The query system information service, IWMSYSQ, returns a list of systems running in goal mode and information related to available CPU capacity and resource constraints. Applications that schedule work across multiple systems in an MVS sysplex can use this service to:

- Locate the “best” (fastest or most idle) system in a sysplex for scheduling specific work
- Avoid scheduling additional work to systems already critically overloaded
- Factor workload management business importance level information into scheduling decisions.

The output of this service is a data area mapped by the IWMWSYSI macro, that provides a point-in-time snapshot of each system workload management is managing in the sysplex. A scheduling application can interpret and use this information to schedule one or more types of work to systems with specific operating characteristics.

See “IWMSYSQ — Query system information” on page 446 for more information about this service.

Services for performance monitors

The workload reporting services are intended for use by monitoring or reporting products to collect performance data. These services replace some of the existing methods of collecting data, and provide as complete a picture of performance information as possible.
A workload management ISPF application contains an installation's goals for work in a service policy. The reporting services access the service policy information, and report on how well the installation is doing in processing towards the goals in the policy. The services report information based on the service classes defined in the service policy. They also provide delay information on work managed by subsystems using the execution delay monitoring services.

Because the system collects performance data continually, there is no set reporting interval. So, unlike earlier releases of MVS, multiple performance monitors can request the services at the same time. And, performance monitors can collect the data based on their own reporting intervals. When the performance monitor invokes a service to collect performance data, the data is provided in a cumulative fashion.

When a significant change occurs in workload management, such as a policy activation, the data collection is stopped and restarted. At such times, performance monitors should also stop and restart their reporting intervals. For each time that data collection is stopped and restarted in workload management, an event notification facility (ENF) signal notifies listeners of the change.

Why use the workload reporting services

The workload reporting services provide information for performance monitors to report on how well an installation is doing in meeting performance goals.

Prior to z/OS V1R3, workload reporting services were available to systems running in either goal or compatibility mode. Some of the collected data was different for each mode. The performance monitor should realize the system will now be running exclusively in goal mode, and be able to locate and use the collected performance data appropriately.

For goal mode, with the cooperation of subsystem work managers, the service can provide more performance data than previously reported. They provide information about work that is processed by many address spaces, and allow for a view of subsystem transactions, not just address spaces and enclaves. The data includes:

- Response time information
- Response time distributions
- Execution delay state information for transactions
- Information about service classes that different address spaces are serving.

The services allow a performance monitor to show the goal for a service class period, how well the system is doing to meet the goal, and if it is not meeting the goal, why it is delayed. The performance monitor can show this goal vs. actual data in terms that are consistent for all MVS-managed work.

Table 9 summarizes the workload reporting services, and where the information about them is documented.

Getting information from SMF type 99 records

SMF record type 99 provides detailed audit information. You can use the type 99 records for analyzing performance characteristics of work. The records contain performance data for each service class period, a trace of SRM actions, the data SRM used to decide which actions to take, and the internal controls SRM uses to manage work.

This can help you determine in detail what SRM is doing to meet your work’s goals with respect to other work, and the types of delays the work is experiencing.

Attention: Be aware that the SMF type 99 records are written frequently. The SMF type 99 records are for detailed audit information only. You should make sure you do not write SMF type 99 records unless you want them.

Chapter 11, “Using SMF record type 99,” on page 123 explains how to use the information provided in SMF type 99 records. For a mapping of the records, see /OS MVS System Management Facilities (SMF)
Services for application programs

The administrative application services are intended for programs which provide a user interface to define and edit a workload management service definition.

Table 10 summarizes the administrative application services.

WLM services that support 64-bit addressing

Several WLM services support 64-bit environments. These services run in both 31-bit and 64-bit address mode.

To use 64-bit services, change the names of the services in your application program to invoke the 64-bit versions of the services. For example, change IWMCQNN to IWM4CONN. The prefix of all 64-bit services names is IWM4.

Generally, the services that run in 64-bit address mode support the same parameters as their equivalents in 31-bit address mode. Note that the only exception is the PLISTVER parameter, which has slightly changed. The 64-bit services only support PLISTVER=0, in case a PLIST version is explicitly used. The following example shows how to use the PLISTVER keyword for 31-bit services:

```
12345678 SPACE 1 DS 0H
   IWMxxxxx ETOKEN=ETOKEN
   RSNCODE=RSNCODE,
   PLISTVER=2
```

```
ETOKEN   DS   F
RSNCODE  DS   F
```

where xxxx is the name of the 31-bit service.

The following example shows how to use the PLISTVER keyword for 64-bit services:

```
12345678 SPACE 1 DS 0H
   IWM4xxxx ETOKEN=ETOKEN
   RSNCODE=RSNCODE,
   PLISTVER=0
```

```
ETOKEN   DS   F
RSNCODE  DS   F
```

where xxxx is the name of the 64-bit service.
Table 11 lists the WLM services that support 64-bit addressing and their equivalents for 31-bit addressing only:

<table>

Chapter 2. Using the subsystem work manager services

You can use many different combinations of the workload management services. Which ones and which combination you choose to use depends on the benefit you expect from using them, whether your programming environment allows you to use them, and the structure of the subsystem work manager using the services. The following section describes some suggested uses of the MVS workload management services.

If you need to manage a transaction separately from the address space in which it runs, or you want to use velocity goals, discretionary goals, or period control, use enclaves. For more information about using enclave services, see Chapter 3, “Creating and using enclaves,” on page 33.

Considerations for using the services

Before you use the subsystem work manager and the execution delay monitoring services, consider the following questions:

- What “type” of subsystem work manager do you need?
  - Transaction processing system
  - Data or resource manager
- What benefits do you expect to reap from using the WLM services?
  - Do you want your customers to be able to specify goals for transactions?
  - Do you plan to get reporting information for goals defined in the MVS workload management service definition?
- What kinds of address spaces does the subsystem work manager consist of?
- What is the definition of a transaction or work request, from your customer’s perspective?
- What kind of functions do the address spaces provide?
  - Control address spaces
  - Transaction level dispatching
  - Other execution regions
  - Other supporting address spaces
- What environments does the subsystem work manager run in?
  - Authorization, including PSW key
  - Dispatchable unit mode
  - Cross memory mode
  - AMODE
  - ASC mode
  - Interrupt status
  - Locks
- Does the subsystem work manager use other products, such as a data manager?
- Does the work cross MVS system (MVS image) boundaries?
- Does the work cross MVS sysplex boundaries?
Suggested services for a single address space transaction manager

A single address space subsystem work manager performs functions similar to those functions shown in Figure 1. It goes through address space initialization and startup routines. It receives a work request, processes the work request, receives another work request, and so on. At some point, it processes some address space cleanup and termination routines.

If you have a single address space transaction manager, consider using the services that are shown in Figure 2 on page 23 for the following functions in workload management:

- Associate work that is coming into the subsystem with a service class
- Have MVS match resources to the work to meet the service class goal
- Provide goal versus actual information for reporting
- Provide response time information and, optionally, processor consumption data for work requests

The services that are shown in Figure 2 on page 23 show when a single address space manager could invoke the appropriate workload management services. They are the minimum set of services a work manager can use to achieve the listed objectives.

Note: You can instead use enclave services for a single address space transaction manager. For more information about using enclave services, see Chapter 3.
You issue the IWM4CON service at address space initialization time. This connect service returns a token that is required by the IWM4CLSY and IWM4RPT services. When the address space receives a work request, it should issue the classify (IWM4CLSY) macro to associate arriving work with a service class. The subsystem work manager can issue IWM4CLSY in either problem state or supervisor state, in any PSW key. The PSW key, however, must be compatible with the key specified when IWM4CON was issued.

IWM4CLSY passes WLM information that identifies the work request. This information includes, among other things, the following:

- Subsystem environment and name (used on IWM4CON)
- Transaction/job name
- Transaction/job class
- User ID
- Accounting information
- LU name
- Network ID

These are called work qualifiers. For a complete list of work qualifiers, see the topic about defining classification rules in [z/OS MVS Planning: Workload Management](#).

IWM4CLSY also supports a product-specific parameter, called the subsystem parameter. If none of the available qualifier types defines your subsystem work manager's work requests, you can use the subsystem parameter.

The transaction manager should document which work qualifiers they use on the IWM4CLSY service, so that a customer knows how to define the classification rules that are defined in the workload management ISPF application. Also, because your
transaction manager might not support all of the qualifier types, you should recommend that your customers customize the list of qualifiers for your subsystem type in the WLM ISPF application.

After receiving the work request and classifying it, the transaction manager then processes the work request. When it completes the request, it should issue IWM4RPT. The report service provides the arrival time and, optionally, completion information about the work request and processor consumption data. Only normal completions are included in the response time information, so the information is not skewed by abnormal completions. The transaction manager should issue IWM4RPT only once per work request.

Then, at address space cleanup and termination time, the transaction manager should issue a IWM4DIS, to disconnect from workload management services.

Using the execution delay monitoring services

If you have a single address space subsystem work manager and would like the following functions from workload management, consider using the services shown in Figure 3 on page 25:

- Associate work coming into the subsystem with a service class
- Goals vs. actual information for reporting
- Response time information and, optionally, processor consumption data for work requests
- Execution delay information about work for reporting and for MVS management purposes

The execution delay monitoring services support response time goals only. If you want your customers to assign velocity or discretionary goals, or if you want to support period switching, consider using enclaves instead. For information about using enclave services, see Chapter 3, “Creating and using enclaves,” on page 33.

It is important to use the IWM4CHST service together with the IWM4RPT service, otherwise the delay information is not meaningful.
At address space initialization, the address space issues the IWM4CON service to establish authorization for subsequent services. It then issues the IWM4MCRE service. Create establishes a monitoring environment to keep track of the execution delays encountered by a work request. If the transaction manager sets up multiple tasks to process work, you should create one monitoring environment per task, assuming each task is dedicated to one work request. Similarly, if the task processes multiple work requests at the same time, then it should issue one IWM4MCRE for each work request that may be running under that task at one time. You can use the REQUEST=MULTIPLE parameter on the IWM4MCRE service to create a pool of monitoring environments at initialization time. This saves the repeated system overhead of issuing a single IWM4MCRE service for each monitoring environment needed.

The IWM4MCRE service also defines the PSW key in which the transaction manager is to run. Because monitoring environments are not initially associated with a work request, the IWM4MCRE sets the state of the monitoring environment to “free”.

When you create a monitoring environment, workload management establishes recovery at both the task and address space level. If the address space or the task that created the monitoring environment fails, workload management cleans up the resources associated with the monitoring environment.

When the transaction manager receives a work request, it should issue the IWM4CLSY service to associate an incoming work request with a service class. At that time, the transaction manager should issue an IWM4MINI to initialize the monitoring environment. The IWM4MINI service with the MODE=RESET parameter sets the state of the monitoring environment to “active”, and associates the monitoring environment with the work request.
Whenever that work request encounters a different state, such as waiting on a conversation, waiting on a lock, or for I/O, the transaction manager should issue the IWM4MCHS (change state of work request) service. Since IWM4MCHS is an inline expansion, there is very little overhead, and you can issue it frequently. Workload management can then update the monitoring environment to reflect these changes, and represent the execution delays the work request encountered.

When the transaction manager has completed processing the work request, it should issue the IWM4RPT service. The transaction manager should delete all created monitoring environments at address space cleanup and termination, and disconnect from workload management services.

**Suggested services for a work manager that calls a data manager**

If you have a work manager that calls a data manager on the same MVS image, you can use the combination of services that are described in this topic. If you want to do any of the following, consider using the services that are shown in Figure 4:

- Associate work that is coming into the subsystem with a service class
- Goals versus actual information for reporting
- Response time information and, optionally, processor consumption data for work requests
- Execution delay information about work
- Track work from a work manager to a data manager

---

Figure 4. Services for a work manager that uses a database manager.
Because the transaction manager is using the work manager services, it must issue the IWM4CON at address space initialization. In this example, the transaction manager is using monitoring environments, so it issues an IWM4MCRE at address space initialization time to create the monitoring environment. Similarly, the database manager is also using monitoring environments, so it issues IWM4MCRE at its address space initialization.

Assuming that the database manager uses a dedicated dispatchable unit, it should also create one monitoring environment per task or SRB that it uses. The transaction manager and the database manager might be running in different tasks, or in the same tasks. The tasks in the figure (one in the work manager, and one in the database manager) might be the same one.

However, the database manager, instead of using IWM4MINI, issues IWM4MRLT (relate monitoring environment) when it is called by the transaction manager task. The relate monitoring environment service associates the database manager’s monitoring environment for the work request to the transaction manager’s monitoring environment for the same work request. Because the relate service requires the token and key that identifies the transaction manager’s monitoring environment, the transaction manager should pass the token and key to the database manager. In this example, the transaction manager monitoring environment is called the parent environment, and the database manager that issues the relate service is called the dependent environment.

After the database manager has related to the work manager, it can be called to process a specific database request. Each such call should begin with a transfer (IWM4MXFR) service with a FUNCTION=CONTINUE parameter, and end with a transfer (IWM4MXFR) with a FUNCTION=RETURN parameter.

When the work manager issues a call to the database manager, the database manager issues an IWMMXFER. The work manager state can be either active, or waiting throughout the transfer. The IWM4MXFR FUNCTION=CONTINUE parameter indicates that the real state for the work request now resides in the data manager monitoring environment. From that point on, the database manager should use change state (IWM4MCHS) as its view of the work request changes. You should issue IWM4MRLT and IWM4MXFR in pairs for each database call or return.

The transfer with the FUNCTION=RETURN parameter resets the dependent monitoring environment state to free. At this point, workload management recognizes that the dependent monitoring environment no longer represents the work request. The parent and dependent monitoring environments are still related, for any future transfers, such as with a second call to the database manager. When the database manager is done with any work requests that require related monitoring environments between the parent and the dependent, it should issue the IWM4MRLT with the FUNCTION=DELETE parameter. This disassociates the parent and dependent monitoring environments.

---

**Services for multiple address space work managers**

The structure of the subsystem work manager dictates which workload management services can be used. A multiple address space work manager normally consists of three kinds of address spaces: router, execution, and supporting. The router address space receives incoming work requests, and passes them off to execution address spaces, which might use the services of supporting address spaces. Figure 5 on page 28 shows the sequence of functions in a multiple
address space work manager.

Several groups of services are useful to a multiple address space work manager. They are described in the following topics:

- **Chapter 3, “Creating and using enclaves,” on page 33**
  The enclave services let you manage transactions across multiple address spaces in the same service class as the original request. The customer can assign a response time, discretionary, or a velocity goal to work, and can define period switching.

- **Chapter 5, “Using the queueing manager services,” on page 69**
  The queuing manager services make it possible for the system to dynamically start and stop server address spaces based on the workload, and manage the work queues associated with the server address spaces to meet service class goals. The customer can assign a response time, discretionary, or a velocity goal to work, and can define period switching.

- **“Execution delay monitoring services for multiple address space work managers” on page 29**
  The execution delay monitoring services let you associate a service class with work, and the customer can assign a response time goal. You can also get

![Multiple Address Space Work Manager](image-url)
response time and delay information about how well the work did to meet the goal. Optionally, processor consumption data can be provided. However, if you want to have the advantages of enclaves (such as having a single transaction that spans multiple address spaces and is managed to the goal of the originating address space), use enclave services rather than execution delay monitoring services.

**Execution delay monitoring services for multiple address space work managers**

The structure of the multiple address space subsystem work manager determines which workload management services you can use to monitor work in multiple address spaces across a sysplex. The relate (IWM4MRLT), transfer (IWM4MXFR), and switch (IWM4MSWC) services provide a way for the work manager to indicate that a transaction is continuing execution somewhere else.

Some questions to help determine which services are appropriate include the following:

- **Are the router, execution, and support address spaces all on one MVS image, or can they be distributed across MVS images?**
  
  How many MVS images are involved influences the choice of the relate/transfer pair or switch service. IWM4MXFR requires both monitor environments to be on the same image, and knowledge of the parent monitoring environment. IWM4MSWC indicates that the continuation of this work is “somewhere else,” either waiting within the MVS image, or in the sysplex, or the network. In addition, it indicates that the work request is waiting for the continuation to return.

- **What are the addressability requirements?**
  
  Connect (IWM4CON) and create (IWM4MCRE) identify the key in which future services are issued, and IWM4MRLT requires addressability to the parent monitoring environment. IWM4MXFR requires updating the dependent monitoring environment, and requires addressability and key update access to the parent monitoring environment.

- **What are the dispatchable units in the servers and support address spaces?**
  
  You must specify the dispatchable unit type on the INIT and RELATE services.

- **When are the “arrival time” and the work qualifiers (name, user ID, and so on) known?**
  
  The arrival time for the work request is required for INIT, and the work qualifiers are required for CLASSIFY.

- **What is the current communication between the router, servers, and the support address spaces, so that new data can be passed?**
  
  The participating subsystem work managers might want to pass the service class token that is returned from the IWM4CLS service, together with the work request using their own communication methods.

Figure 6 on page 30 shows some suggested services for a multiple address space work manager that take into account the considerations that were discussed previously.
In the figure, the router might be like a CICS® TOR that routes off the work to an AOR, the execution address space, for processing. There might be some supporting address space involved that help process the work requests. The router would issue the IWM4CON macro to connect to workload management. It would also issue the IWM4CLSY service to associate the arriving work with a service class. Because it also receives the work request back once it has been processed, it also issues the IWM4RPT service to report the completion, and the IWM4DIS at address space termination.

The execution address spaces would issue the IWM4MCRE to create the monitoring environments and record information about the work with the IWM4MCHS service. It would issue the IWM4MNTF to signify that the execution phase of work request execution is complete and, optionally, to provide processor consumption data. Then, at address space termination, it would issue the IWM4MDEL service to delete the monitoring environments.

The supporting address spaces would also use monitoring environments, so they would issue IWM4MCRE and IWM4MDEL. To show that the information they are keeping in the performance block reflects the same work request as the monitoring environment created by the execution address spaces, they issue the IWM4MRLT and IWM4MXFR services.

IWM4MRLT and IWM4MXFR require the supporting address space to be on the same MVS image, and that the monitoring token is passed from the execution address space to the supporting address space.
Some work managers distribute work across systems in a sysplex. Distributed work may originate from one subsystem work manager, and be processed by another. For example, a work manager may send work to a data base manager for processing. Other work managers may split up complex work into smaller pieces and distribute the pieces to other systems in the sysplex for processing.

Whether the work is distributed, or split and distributed, you may still want to keep the work classified according to the subsystem originating the work request. Not all classification information may be available to the receiving subsystem. For example, suppose JES has distributed a batch job to a data base system. The data base system issues IWM4CLSY when it receives the batch job. Because it is not the same subsystem environment, the batch job is now classified into a service class representing the data base work, and not to a service class representing batch jobs.

A work manager can use the IWMWMCON macro when it receives work and wants it to be classified using the originator's subsystem environment, and not its own. The IWMWMCON macro lets a caller modify the subsystem type and subsystem name previously provided on the IWM4CON macro.

Once the receiving subsystem has issued the IWMWMCON macro, the subsystem can issue the IWM4CLSY macro. The work is then classified according to the modified environment. Note that any other macro that requires subsystem name, subsystem type, or service class name is affected by the change. Those macros are:

- IWM4CLSY, which returns a service class based on the modified subsystem environment attributes. See “IWM4CLSY — Classify work” on page 464 for a complete description.
- IWM4ECRE, which creates an enclave based on the parameter list from IWM4CLSY. See Chapter 3, “Creating and using enclaves,” on page 33.
- IWM4RPT, which reports on the completion of the work associated with the service class received from IWM4CLSY. See “IWM4RPT — Report response time” on page 708 for a complete description.

For details about the IWMWMCON macro, see “IWMWMCON — WLM modify connect” on page 428.

Determining the subsystem name and type

A caller must provide a subsystem name and type on the IWMWMCON macro. To determine the subsystem name or type, a caller can use the REQASCL SYSEVENT. The REQASCL SYSEVENT provides information about an address space’s classification information. The originating subsystem should issue REQASCL, and pass the information with the work request.

For information about how to use the REQASCL SYSEVENT, see z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO.

Using IWMWMCON when distributing work in a sysplex

The expected use of the IWMWMCON service is in a multiple system work environment, where work is received by a work router and distributed to other systems in the sysplex. In this case, the enclave or address space transaction of the originator cannot be used to manage the work request, because a transaction has a single system scope. When a request or a part of a request is distributed to a different system, it must run under a new transaction. The example below shows
how IWMWMCON can be used in conjunction with the IWM4ECRE service to create an independent enclave on the system receiving the work request. For details on using enclaves, see Chapter 3, “Creating and using enclaves,” on page 33.

**Example of using IWMWMCON**

Suppose a subsystem work manager called DISS splits complex work requests into pieces and distributes the split work to six data base manager address spaces, called DB1 through DB6, each running on a separate system in the sysplex. DISS might communicate with the data base address spaces through a shared queue on DASD or a coupling facility, or through sysplex services. The DISS subsystem does the following:

1. Receives a work request
2. Determines the work requestor’s classification attributes using the SYSEVENT REQASCL macro
3. Splits the request and distributes pieces to DB1 through DB6, passing the information returned by REQASCL

Each data base subsystem, DB1 through DB6, does the following:

1. Receives the split work request along with its classification attributes
2. Obtains a latch or lock prior to issuing IWMWMCON to serialize the use of the work manager connect environment
3. Modifies the connect environment by issuing IWMWMCON with the subsystem name and type passed by DISS
4. Builds a classification parameter list with the attributes passed by DISS using the modify form of the IWM4CLSY macro
5. Creates an independent enclave using the IWM4ECRE macro to manage the split work request
6. Restores the previous connect environment using the IWMWMCON macro with the previous subsystem type and name
7. Releases the latch or lock being used to serialize the connect environment
8. Processes the work by joining tasks to the enclave and/or scheduling SRBs into it
9. When the work is finished, deletes the enclave using the IWM4EDEL macro
Chapter 3. Creating and using enclaves

An enclave is a transaction that can span multiple dispatchable units (SRBs and tasks) in one or more address spaces and is reported on and managed as a unit. The enclave is managed separately from the address spaces it runs in. CPU and I/O resources associated with processing the transaction are managed by the transaction's performance goal, accounted to the transactions, and reported to the transaction. A program can create an enclave, schedule SRBs into it, or join tasks to it. A multisystem work manager can process a transaction on multiple systems by using a multisystem enclave.

Use the following services to work with enclaves:

- The IWM4ECRE macro allows you to create an enclave.
- The IWMEREG macro allows you to register an enclave to prevent it from premature deletion.
- The IWMDREG macro allows you to deregister an enclave.
- The IEAMSCHD macro allows you to schedule an SRB into the enclave.
  
  For information about using the IEAMSCHD macro, see z/OS MVS Programming: Authorized Assembler Services Guide.
- The SYSEVENT ENCASSOC macro allows an enclave running SRBs to be associated with an address space. This way the storage-related resources of the server address space can be managed to the performance goal of the enclave.
  
  For information about using the SYSEVENT ENCASSOC macro, see z/OS MVS Programming: Authorized Assembler Services Reference SET-WTC.
- The SYSEVENT ENCSTATE macro allows the creator of an enclave to notify SRM when the enclave is idle, so that its state is sampled correctly.
  
  For information about using the SYSEVENT ENCSTATE macro, see z/OS MVS Programming: Authorized Assembler Services Guide.
- The IWMEJOIN macro allows a task to join an enclave.
- The IWMELEAV macro allows a task to leave an enclave.
- The IWMEXPT macro allows you to export an enclave to all systems in a parallel sysplex.
- The IWMUEXPT macro allows you to undo an export.
- The IWMUIIMPT macro allows you to import an enclave that has been exported.
- The IWMUIMPT macro allows you to undo an import.
- The IWM4EQRY macro allows a program to query the classification information associated with an enclave.
- The IWMESQRY macro provides a program with information about whether the current dispatchable unit is associated with an enclave.
- The IWM4EDEL macro allows a program to delete a previously created enclave.

Why would you use an enclave?

Use an enclave when you have a transaction that spans multiple tasks or SRBs in one or more address spaces, and you want to manage it as a unit. An enclave allows you to manage and report on resource consumption in the enclave based on a performance goal unrelated to the performance goal(s) of the address space(s) in which the enclave’s dispatchable units execute.
An independent enclave represents a complete transaction. Its performance goal is assigned based on the service class to which it is classified when the enclave is created. Each independent enclave starts in period 1 of its service class and switches periods based on the service consumed by the dispatchable units belonging to the enclave.

A work-dependent enclave represents a continuation of an existing independent enclave's transaction. It inherits its classification and performance goals from the independent enclave. Service consumed by a work-dependent enclave is treated as if it was consumed by the independent enclave, and can cause the independent enclave (including all associated work-dependent enclaves) to switch into later periods.

A dependent enclave represents the continuation of an existing address space transaction under a new set of dispatchable units. Its performance goal is inherited from the existing address space transaction based on the service class (or PGN) and period being used to manage the address space at the instant the dependent enclave is created. CPU service consumed by a dependent enclave is treated as if it were consumed by the address space transaction, and can cause the address space along with the dependent enclave to switch into later periods.

If your work manager does not use enclaves, work can only be managed on an address space basis, tied to the address space the work runs in. If you have a transaction that spans multiple address spaces, use an enclave to manage the transaction as a unit.

If you have an address space that executes multiple transactions, use enclaves to isolate the transactions so they can be reported on and managed individually.

**SRBs in enclaves**

Enclave SRBs offer advantages over local and global SRBs in that they are preemptable and can be run at a lower major dispatching priority than tasks in the same address space.

SRBs in enclaves work well for transactions having short durations, not issuing supervisor calls, and not otherwise requiring a task environment. SRBs have very little startup overhead compared to tasks. The subsystem can create an enclave using the IWM4ECRE macro, and then schedule SRBs to run in the enclave using the IEAMSCHD macro.

The SYSEVENT ENCASSOC macro is used to indicate that an enclave and an address space are related for storage management purposes. The ENCASSOC sysevent is necessary only when SRBs are used. A task that joins an enclave automatically associates the home address space with the enclave.

**Note:** It is not required to use SYSEVENT ENCASSOC when you run SRBs in enclaves. It is an improvement for storage management but it is not recommended when the address space into which the SRB is scheduled runs other significant work because the association may change the goal management for the target address space.

For more information about the SYSEVENT macro, see [z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO](z/OS MVS Programming).
For more information about SRBs and how to use them, see z/OS MVS Programming: Authorized Assembler Services Guide.

For more information about the IEAMSCHD macro, see z/OS MVS Programming: Authorized Assembler Services Reference EDT-IXG.

Tasks in enclaves

Using tasks in enclaves offers all the advantages of enclaves and allows the enclave to perform functions that require a task environment, such as supervisor calls. Unlike SRBs, tasks can dynamically leave and join an enclave as they finish one piece of work and begin another.

A subsystem can create an enclave using the IWM4ECRE macro, join the task to the enclave using the IWMJEJOIN macro, process the work request, and remove the task from the enclave using the IWMJELEAV macro. If a task joins an enclave and subsequently attaches subtasks, the subtasks are automatically joined to the enclave. The interactions between enclaves and attach/detach are summarized as follows:

- Subtasks attached while the mother task belongs to an enclave inherit membership in the same enclave.
- Subtasks that already exist when the mother task joins an enclave are not automatically made part of the enclave although they may explicitly join and leave the enclave using IWMJEJOIN and IWMJELEAV.
- Tasks which inherit membership in an enclave can only leave the enclave by terminating or by deleting the entire enclave.
- Mother tasks with subtasks that inherited enclave membership cannot leave the enclave until all such subtasks terminate.

Comparison of enclaves and execution delay services

You cannot use tasks in enclaves and execution delay services in the same address space. This same restriction applies to SRBs in enclaves if you use the SYSEVENT ENCASSOC to associate the enclave with an address space. When deciding which set of services to use for a work manager, you should consider the following advantages of enclaves over execution delay services:

- Isolation of transactions
  Enclaves allow separate dispatching priorities to be assigned to work running in the same address space. Therefore, workload management can manage this work to different performance goals. Without enclaves, all work in an address space runs at the same major dispatching priority.

- Period control
  Enclaves can run in a service class with multiple periods. Because resource consumption is tracked for individual enclaves, the enclave can move from one period to the next as it consumes CPU resource. The goals for the periods can be chosen to favor short transactions over long ones within a single address space.

- Full goal support
  Enclaves support response time, velocity, and discretionary goals, whereas transactions reported using execution delay services can be managed only to response time goals.

- Server address space management
  Enclaves are independent from an address space, so a transaction that moves from the originating address space to one or more server address spaces can be managed as a single transaction.
Multisystem scope

Enclaves can span address spaces on multiple systems in a parallel sysplex, whereas transactions supported using execution delay services are constrained to a single system.

Creating an enclave

A subsystem uses the IWM4ECRE service to create an enclave. You can define independent enclaves, work-dependent enclaves, or dependent enclaves.

Comparison between independent, dependent, and work-dependent enclaves

You use independent, dependent and work-dependent enclaves for different purposes, as follows:

• Independent enclaves
  Use an independent enclave to represent a new transaction. The TYPE=INDEPENDENT parameter on IWM4ECRE is the default. An independent enclave must be classified into a service class or performance group when it is created, so the caller must provide classification qualifiers as input to IWM4ECRE. The home address space when IWM4ECRE is issued is the owner of an independent enclave. CPU service consumed by the enclave is accumulated in the SMF type 30 record of the owning address space and the SMF type 72 record of the enclave's service class or performance group period.
  For an independent enclave, the connect token provided with the CLSFY keyword of macro IWM4ECRE must not be associated with a user key (as specified with the CONNTKNKEY parameter of IWM4CON, or IWMCONN).
  For examples showing how to use independent enclaves, see “Scheduling an SRB in an independent enclave” on page 39 and “Joining tasks to an independent enclave” on page 41.

• Dependent enclaves
  Use a dependent enclave when you have an existing address space defined with its own performance goal that you wish to extend to programs running under dispatchable units in other address spaces. For a dependent enclave that is created with TYPE=DEPENDENT specified on IWM4ECRE, the owner will become the home address space at the time the service is invoked. The owner address space of a dependent enclave, resulting from IWM4ECRE with TYPE=WORKDEPENDENT specified, will be the creating enclave’s (that is, the enclave the TCB/SRB was running in when it called IWM4ECRE) owner. A dependent enclave derives its performance goal from the owning address space, and all CPU service consumed by the enclave is accumulated in the SMF type 30 record of the owning address space and the SMF type 72 record of the owning address space's service class or performance group period.
  The TYPE=M0NENV parameter creates a dependent enclave owned by the address space of a specified monitoring environment. Note that this dependent enclave is managed to the goal established for the owning address space, not the response time goal that might have been established for the monitoring environment.
  For an example showing how to use dependent enclaves, see “Using dependent enclaves” on page 43.

• Work-dependent enclaves
  Use a work-dependent enclave to extend an existing independent enclave's transaction. A work-dependent enclave inherits its classification and its owner
address space from the independent enclave it extends. CPU service consumed by the enclave is accumulated in the SMF type 30 record of the owning address space and the SMF type 72 record of the enclave's service class.

For more specific differences between independent, work-dependent, and dependent enclaves, see Table 13 on page 49.

Registering an enclave

Enclave transactions do not only exist within a subsystem, but also across subsystems. Enclaves can be deleted by any subsystem at any time. So, it might happen that a subsystem deletes an enclave that is still used by another subsystem. To avoid premature deletion, you can register an enclave. The registration indicates to the system that an enclave must not be deleted until the registering subsystem deregisters it.

The new service, IWMEREG, allows an enclave to be registered in order to prevent it from premature deletion until the enclave is deregistered. The new service, IWMEDREG, allows the registration for an enclave to be undone and deleted.

The registration is owned by the job step task of the home address space at the time IWMEREG is invoked. If the job step task or the address space terminates, the system implicitly deregisters the enclave.

Only subsystems which utilize enclaves created by other subsystems need to register interest in an enclave while using it. If a subsystem only uses enclaves that it created itself, there is no need to register interest in the enclave.

Multisystem enclaves

Some work managers split large transactions across multiple systems in a Parallel Sysplex, improving the transaction's overall response time. These work managers can use multisystem enclaves to provide consistent management and reporting for these types of transactions.

Note: The use of multisystem enclaves requires the definition of a coupling facility structure named SYSZWLM_WORKUNIT in the CFRM policy. Once the CFRM policy with this structure definition is activated, then WLM will automatically connect to the structure, enabling the use of multisystem enclaves. See z/OS MVS Planning: Workload Management for more information.

Among the benefits of using multisystem enclaves:

- All parts of a split transaction are managed using the same service class. If the service class has multiple periods, the CPU usage of the entire transaction is used to switch periods.
- The enclave owner's SMF type 30 record includes CPU time accumulated by all of the multisystem enclaves it owns, for all systems on which they executed. Remote system service is reported by individual system within the SMF type 30 record.

A multisystem enclave begins as either an independent or dependent enclave on a single system. This enclave is called the original enclave. Note that WLM does not allow you to export work-dependent enclaves. If the work manager decides to involve other systems in the processing of the work unit, it issues IWMEXPT to export the enclave to other systems in the parallel sysplex. The export token it receives back from IWMEXPT is a sysplex-wide unique name that it must now pass along with the work request to other systems.
Each work manager in the supporting address spaces on other systems can now issue IWMIMPT to import the enclave onto its system. It passes the export token and receives a special enclave token that is valid for its system only. This new, supporting enclave is called a foreign enclave. The original enclave and the foreign enclaves are all referred to as one unit called a multisystem enclave.

When work has completed in a foreign enclave, the supporting work manager issues IWMUIMPT to unimport the enclave, and then signals its completion to the original work manager. When all of the supporting work managers have unimported their enclave, the original work manager issues IWMUEXPT to unexport the original enclave. When all work is finished, the original work manager that created the original enclave deletes it.

If your subsystem uses an enclave that it did not create for its processing, then you should use the registration services (IWMEREG, IWMEDREG) to protect the enclave against deletion by its owner while your subsystem is using it. The IWMUIMPT service delays the physical deletion of an enclave as long as the enclave is registered by any subsystem.

Each work manager must first connect to WLM using the IWM4CON service, specifying EXPTIMPT=YES to enable exporting and importing. IWMEXPT, IWMIMPT, IWMUIMPT, and IWMUEXPT must all be invoked from the address space that connected.

WLM will automatically undo a work manager’s export and import requests when:
- The work manager disconnects from WLM
- The work manager’s connecting task or address space ends
- The work manager’s system fails

If an export is undone, whether by the original work manager’s request or due to WLM’s recovery action, before all of the supporting work managers have completed their work in the foreign enclaves, the outstanding imports are handled as follows:
- An outstanding import on the same system as the original enclave is automatically undone. (When a work manager on the same system as the original work manager attempts to import the original enclave, it receives the original enclave token. It is not really exported at all.) The only effect will be a warning return code when the work manager attempts to unimport the enclave.
- An outstanding import on a foreign system will remain in effect. WLM provides no notification to the supporting work manager that the export has ended. The supporting work manager must learn of the failure through its own mechanisms and then terminate the work on its own.
- New import requests are rejected. The supporting work manager should terminate any work being done on behalf of the original work manager.

As a transaction flows from one work manager to another, it is possible that more than one work manager will split its processing across multiple systems. In this way, an original enclave can be exported multiple times, both by the original work manager and by other work managers. Each export request is tracked separately, and requires a corresponding unexport request. Multiple concurrent exports all share the same export token.
If a work manager on the original system attempts to import the original enclave, it will receive the enclave token of the original enclave. The work manager can schedule SRBs into or join tasks to the original enclave just as it would any other enclave on the same system.

Just as an enclave can be exported multiple times, it can also be imported multiple times by one or more supporting work managers. Each import request is tracked separately, and requires a corresponding unimport request. Multiple concurrent imports on a single system all share a single foreign enclave.

A foreign enclave cannot be exported—in other words, once an enclave has been imported onto a foreign system, it cannot be exported again from that system. If a work manager invokes IWMEXPT for a foreign enclave, it will receive a warning code along with the existing export token for that enclave.

For an example showing how to use multisystem enclaves, see “Using a multisystem enclave” on page 44.

**Scheduling an SRB in an independent enclave**

Suppose an address space representing a subsystem uses the specialized processing services of a supporting address space to satisfy a work request. The subsystem creates an independent enclave that is used by an SRB executing in the supporting address space on behalf of the work request. Part of the work request executes under an SRB in the subsystem address space, so that SRB uses the same enclave.

Figure 7 on page 40 shows the two address spaces.
Figure 7 illustrates the following sequence:

1. Connect as a work manager
   Subsystem address space A issues IWM4CON to connect to workload management with WORK_MANAGER=YES specified or defaulted. This makes work management services, including enclave services, available to the connecting address space.

2. Create enclave Z
   Subsystem address space A wants to manage multiple SRBs (SRBs 1 and 2) as a unit, so address space A creates an independent enclave Z by issuing IWM4ECRE. Subsystem address space A is the home address space, and is the owner of enclave Z. Any work that the subsystem and its supporting address space B process can be managed as an enclave. Classification information is passed in with IWM4ECRE so workload management can assign the enclave to a service class or performance group and manage to those goals.
   For more information, refer to "Performance management of address spaces with enclaves" on page 46.

3. Schedule SRB 1 into enclave Z
   The subsystem address space then schedules an SRB, SRB 1, to execute in its own address space and to be managed as part of enclave Z, using the IEAMSCCHD macro:

   IEAMSCCHD ENV=PRIMARY,
   EPADDR=entry_point_address,
   PRIORITY=ENCLAVE,
   ENCLAVETOKEN=tokenZ

   ***

   IEAMSCCHD ENV=STOKEN
   TARGETSTOKEN=tokenB
   PRIORITY=ENCLAVE
   ENCLAVETOKEN=tokenZ

   ***
Where the subsystem address space has defined:

\[ \text{tokenZ FL4 The enclave token for enclave Z} \]

4. Schedule SRB 2 into enclave Z

The subsystem address space then schedules an SRB (SRB 2) to execute in supporting address space B and to be managed as part of enclave Z, using the IEAMSCHD macro:

\[
\text{IEAMSCHD ENV=} \text{STOKEN}, \\
\text{TARGETSTOKEN=} \text{tokenB}, \\
\text{EPADDR=} \text{entry_point_address}, \\
\text{PRIORITY=} \text{ENCLAVE}, \\
\text{ENCLAVENTOKEN=} \text{tokenZ}
\]

5. Wait for the SRBs to complete and delete enclave Z

The subsystem waits for the SRBs to complete the request, then deletes the enclave using the IWM4EDEL macro and returns to the caller.

**Joining tasks to an independent enclave**

An address space representing a subsystem is using a supporting address space for part of the processing for a unit of work. The subsystem address space creates an independent enclave, and a task in the supporting address space joins the enclave. A task in subsystem address space can also join the enclave when it is processing on behalf of the unit of work.

*Figure 8* shows how this works.

---

*Figure 8. Creating an enclave and joining tasks to it*

*Figure 8* illustrates the following sequence:
1. Connect as work manager.
   Subsystem address space A issues IWM4CON to connect to workload management with WORK_MANAGER=YES specified or defaulted. This makes work management services, including enclave services, available to the connecting address space.

2. Create enclave X.
   Subsystem address space A wants to manage work in multiple address spaces as a unit, so address space A creates independent enclave X by issuing IWM4ECRE. Subsystem address space A is the home address space, and is the owner of the enclave. IWM4ECRE passes back the enclave token tokenX to the subsystem. Any work that the subsystem and its supporting address space B process can be managed together as an enclave. Classification information is passed in with IWM4ECRE so workload management can assign the enclave to a service class or performance group and manage to those goals.

   For further information, refer to "Performance management of address spaces with enclaves" on page 46.

3. Task 1: Join enclave X.
   The subsystem passes the work to its supporting address space B along with the enclave token tokenX from IWM4ECRE. Before Task 1 in address space B runs the work passed in by the subsystem, it joins the enclave by issuing the IWMEJOIN service with enclave token tokenX. Now the work running under Task 1 is managed to the goal of the enclave.

   Although this example shows only one enclave, the subsystem can create an enclave for each new unit of work that arrives. These enclaves can be running work simultaneously in the subsystem and the supporting address space, with each unit of work being managed to its own unique goal.

4. Task 1: Attach subtask; detach subtask.
   In address space B, Task 1, which now belongs to enclave X, issues the ATTACH macro to create a subtask. This subtask will also, automatically, be part of enclave X and be managed to the enclave's goal. When the subtask is detached, it automatically leaves the enclave. The subtask cannot use IWMELEAV to do this. Each subtask attached by Task 1 after it joins the enclave must be detached before Task 1 leaves the enclave.

5. Task 1: Leave enclave X.
   Task 1 finishes its processing and leaves the enclave by issuing the IWMELEAV service with the enclave token tokenX specified. Any processing in Task 1 after it leaves the enclave is managed to the goal of the address space, not of the enclave.

6. Task 2: Join enclave X.
   If the subsystem itself has work to do on behalf of the unit of work, it can join a task, Task 2, to the same enclave as the supporting address space used. It uses the same enclave token, tokenX, on IWMEJOIN. The work in Task 2 is now managed to the enclave's goal. Task 1 and 2 can be run concurrently or in sequence. At any point in time, an enclave can have multiple tasks and/or SRBs running in it across multiple address spaces, and they are all managed to the same enclave goal.

7. Task 2: Leave enclave X.
   Task 2 finishes its processing for the transaction and leaves the enclave. The task is now managed to the address space goal.

8. Delete enclave X.
The transaction is now complete, so the subsystem deletes the enclave using IWM4EDEL with enclave token `tokenX`. Note that the address space that deletes the enclave need not be the same one that created it.

**Using dependent enclaves**

When a unit of work is processed in multiple address spaces, you can use dependent enclaves to tie the work done in a supporting (server) address space back to the originating client address space. The dependent enclave represents the continuation of an existing address space transaction under a new set of dispatchable units in another address space.

Figure 9 shows how this works.

---

1. Request subsystem function.

   The originating address space, address space A, sends a work request to subsystem address space B, for example, by issuing a space-switching PC. A space-switching PC isn't required—it is used here only as an example. A nonspace-switching PC or other linkage can be used so long as the originating space remains the home space.

2. Determine if an enclave exists.

   Address space A could be a TSO, batch job, or started task. The address space's performance goal is used to manage the transaction while running in address space A and also when running in the dependent enclave.

---

1. A space-switching PC isn't required—it is used here only as an example. A nonspace-switching PC or other linkage can be used so long as the originating space remains the home space.
Subsystem address space B uses IWMESQRY to determine whether the caller is already in an enclave. If it is in an enclave, it would use that enclave and schedule SRBs to the enclave, or join tasks to the enclave.

3. Create dependent enclave Y.
   If the caller is not in an enclave, the subsystem creates a dependent enclave using IWM4ECRE with the TYPE=DEPENDENT parameter. The home space when IWM4ECRE is issued, in this example address space A, is the owner of the dependent enclave. No classification information is required on IWM4ECRE for a dependent enclave. The service class or performance group of the owning address space A is used to manage the work in the enclave. The subsystem does not need to connect to workload management (using IWM4CON) to create a dependent enclave.

4. Pass enclave token.
   The subsystem posts Task 1 in the supporting address space, address space C, to join the enclave, passing it the enclave token tokenY passed back by IWM4ECRE. The subsystem can also schedule SRBs into the same enclave. The work running in the dependent enclave executes in address space C but is managed to the goal of the owning address space A.

5. Join enclave Y.
   Task 1 joins enclave Y using the enclave token passed from the subsystem. The work running under Task 1 is now managed to the goal of address space A.
   For further information, see “Performance management of address spaces with enclaves” on page 46.

6. Attach subtask; detach subtask.
   Task 1 may attach one or more subtasks while it is joined to enclave Y. These subtasks are automatically joined to enclave Y and also managed to address space A’s goal.

7. Leave enclave Y.
   When Task 1 completes the work request, it leaves the enclave. It reverts back to being managed to address space C’s goal.

8. Delete the enclave.
   The subsystem waits for the tasks, and any SRBs, to complete the request, then deletes the enclave (if it created it) and returns to the caller.

Using a multisystem enclave
   In this case, a work manager will process a work request using one or more supporting address spaces on different systems in a Parallel Sysplex.

Figure 10 on page 45 shows how this works.
Figure 10 illustrates the following sequence:

1. Connect as work manager.
   The work manager issues IWM4CON, with WORK_MANAGER=YES specified or defaulted so that it can create independent enclaves, and EXPTIMPT=YES specified to allow for exporting the enclaves.

   **Note:** It is assumed here that the CFRM policy already contains the coupling facility structure SYSZWLM_WORKUNIT, which is required for the use of multisystem enclaves. If the coupling facility structure is not available, IWM4CON will succeed, but export and import requests will return errors. See z/OS MVS Planning: Workload Management for more information.

2. Create original enclave E.
   The work manager creates an independent enclave in address space A on system 1 by issuing IWM4ECRE. Address space A is the owner of the original enclave. Classification information is passed in with IWM4ECRE so workload management can assign the enclave to a service class or performance group. IWM4ECRE passes back the enclave token tokenE to the work manager.

3. Address space A on System 1: Export enclave E.
   The work manager exports enclave E to all other systems in the parallel sysplex by issuing IWMEXPT with the enclave token tokenE. IWMEXPT passes...
back the export token $tokenX$. The work manager can now pass this sysplex-wide unique export token to supporting address spaces on other systems, using its own communication mechanism.

4. **Address space B on System 2: Import enclave $E'$.**
   
   Once an enclave has been exported, a work manager in the supporting address space B can import the enclave by issuing IWMIMPT with the export token $tokenX$. A foreign enclave $E'$ is created. It receives back an enclave token $tokenE'$ that is valid on system 2 only.
   
   Although this example shows only one supporting address space on one separate system, the enclave can be imported by several address spaces on several different systems in the parallel sysplex. These foreign enclaves can all be running work simultaneously, with each unit of work being managed to the goals of the original enclave.

5. **Task J: Join foreign enclave $E'$.**
   
   Task J in address space B on system 2 joins the foreign enclave by issuing IWMEJOIN with the enclave token $tokenE'$.

6. **Task J: Leave foreign enclave $E'$.**
   
   Task J in address space B on system 2 leaves the foreign enclave by issuing IWMELEAV with the enclave token $tokenE'$. Any further processing in Task J after it leaves the enclave is now managed to the goal of the address space B, not of the enclave.

7. **Task K: Join original enclave $E$.**
   
   If work is to be done in the original enclave at the same time that work is being done in the foreign enclaves, task J in address space A on system 1 can join the original enclave by issuing IWMEJOIN with the enclave token $tokenE$. The work in Task K is now managed to the goals of the original enclave. At any point in time, a multisystem enclave can have multiple tasks and/or SRBs running in it across multiple address spaces on multiple systems, and they are all managed to the original enclave's goal.

8. **Task K: Leave original enclave $E$.**
   
   Task K in address space A on system 1 leaves the original enclave by issuing IWMELEAV with the enclave token $tokenE$. Any further processing in Task K after it leaves the enclave is now managed to the goal of the address space A, not of the enclave.

9. **Address space B on System 2: Unimport enclave $E'$.**
   
   Once the task has left the foreign enclave, the work manager in the supporting address space B unimports the enclave by issuing IWMUIMPT with the export token $tokenX$. This deletes the foreign enclave $E'$. The supporting work manager now reports its completion and any results to the original work manager using its own communication mechanism.

10. **Address space A on System 1: Unexport enclave $E'$.**
    
    After every supporting work manager has reported its completion, the original work manager unexports the enclave by issuing IWMUEXPT with the export token $tokenX$.

11. **Delete enclave X.**
    
    The transaction is now complete, so the work manager deletes the enclave using IWM4EDEL with enclave token $tokenE$.

**Performance management of address spaces with enclaves**

Table 12 on page 47 describes the performance management of address spaces with enclaves in terms of MPL level, paging, dispatching, and I/O priorities.
Address spaces with enclaves (dependent enclaves or independent enclaves) are managed either towards the performance goal of the address space or towards the performance goal of the enclave depending on how the program associates the enclave with the address space. In either case, the enclave’s dispatching priority is always managed towards the performance goal of the enclave.

### Table 12. Performance management of address spaces with enclaves

<table>
<thead>
<tr>
<th>Managing performance towards the performance goal of the address space</th>
<th>Managing performance towards the performance goal of the enclave</th>
</tr>
</thead>
</table>
| Address spaces are managed towards the performance goal of the **address space** if an enclave SRB was scheduled to run in this address space without the enclave being associated to the address space (the SRB did not issue SYSEVENT ENCASSOC). In this case, the **non-enclave work** is also managed towards the performance goal of the address space. | Address spaces are managed towards the performance goal of the **enclave**, if one of the following is true:  
  • At least one task of the address space has joined an enclave by the services IWMEJOIN or IWM4STBG having been issued, or  
  • At least one enclave SRB was scheduled to run in this address space that has issued the SYSEVENT ENCASSOC to associate the enclave with this address space. |

**Note:** An address space must be non-swappable if it has enclave SRBs dispatched and SYSEVENT ENCASSOC has not been issued.

Note that the performance management of the **non-enclave work** depends on the specification of the IEAOPT parameter **ManageNonEclaveWork**:

- **For ManageNonEnclaveWork=NO** (and for releases earlier than z/OS V1R12): It is assumed that no work consuming significant CPU service is running in the address space outside of an enclave. The CPU consumption of work running outside of enclaves is not included when Workload Management assesses the impact of CPU adjustments for the enclave work.

- **For ManageNonEnclaveWork=YES**: The non-enclave work of an address space is performance managed towards the first service class period of the address space goal. Based on this expanded performance management it is recommended to verify the performance goals for the service class of the address spaces which process enclave work. See Figure 11 on page 48 for an example.

**Note:** The non-enclave work of the address space is not performance managed if the service class of the address space is a system-provided service class other than SYSOTHER, even if the ManageNonEnclaveWork=YES IEAOPT parameter was specified.

Refer to z/OS MVS Initialization and Tuning Reference for further information about the OPT parameter.
Figure 11 shows an example of how the non-enclave work of Task F is managed towards the first period of the service class A (SC A) which is the address space goal.

Using ENQ/DEQ or latch manager services with enclaves

There are some considerations to be aware of when using enclaves for tasks or SRBs that serialize on resources using the ENQ macro or the latch manager callable services. A task cannot change its transaction status, that is, cannot join or leave an enclave, while holding a resource using ENQ or the latch manager; an SRB cannot issue SYSEVENT ENCASSOC while holding a resource using the latch manager. Otherwise, enqueue promotion processing may not work properly. The recommended sequence is:

1. Task: Join an enclave using IWMEJOIN or IWM4STBG. SRB: Associate enclave with an address space using SYSEVENT ENCASSOC.
2. Obtain resource with ENQ or latch manager.
3. Release resource.
4. Task: Leave an enclave using IWMELEAV or IWM4STEN. SRB: Disassociate enclave from the address space using SYSEVENT ENCASSOC.

In addition, to ensure correct enqueue promotion processing, a task executing in an enclave should not make the following types of ENQ requests:

- Directed enqueues, that is, issuing the ENQ macro with the TCB parameter
Matching task enqueues, that is, issuing the ENQ macro with the **MASID** and **MTCB** parameters

### Enclave resource accounting

The accounting for resources consumed by an enclave depends on whether it is an independent, work-dependent, dependent, or a foreign enclave.

A dependent enclave is a logical continuation of the transaction already active in a client’s address space. Therefore, CPU and MSO service for a dependent enclave is included in the SMF type 30 record of the owning address space, and in the SMF type 72 record for the address space’s transaction. MSO service for the enclave is calculated based on the frame count of the owning address space, not on frame usage in the address space(s) where the enclave is executing.

For an independent enclave and for work-dependent enclaves, CPU service is included in the SMF type 30 record of the owning address space, and in the SMF type 72 record for the enclave’s service class or performance group period. MSO service is not calculated for either kind of enclave.

For dependent, work-dependent and independent enclaves, IOC service is included in the SMF type 30 and 72 records associated with the address space where the enclave work is executing. SRB service for enclaves is always zero.

For a foreign enclave, CPU time is included in the SMF type 30 record of the owning address space on the originating system. It is reported separately from local CPU time. CPU service is also included in the SMF type 72 record on each system where the enclave executed.

Because CPU time used by foreign enclaves is included in the owner's SMF type 30 record, it is not included in the SMF type 30 records on the other systems where it actually executed. In order for those other systems to have some record of the CPU time used by foreign enclaves, an SMF type 97 record is written for each SMF global recording interval. This SMF type 97 record identifies the CPU time used by foreign enclaves during that interval, broken down by originating system. The installation can review the originating system's SMF type 30 records to identify the specific jobs that consumed the CPU time in the foreign enclaves. Note that because data is collected asynchronously for the SMF type 30 records, and because SMF intervals can vary from system to system, it may not be possible to exactly match the times on SMF type 30 records with those on SMF type 97 records from one global interval to another.

**Table 13** compares control characteristics and resource accounting for independent, work-dependent, dependent, and foreign enclaves.

Notes:
1. The address space associated with the monitoring environment is one of the following:
   • The address space related to the monitoring environment via the IWMMRELA service
   • If there is no related space, the home space at the time IWM4MINI was issued
2. The attributes passed to IWM4ECRE are used with the classification rules in the active service policy to assign a service class and/or report class to the enclave.
3. Connect time is used as an example here. Other measures associated with I/O in the SMF records are:
   • DASD I/O disconnect time in fields SMF30EID, SMF30AID, R723CIDT, and SMF72IDT.
   • DASD I/O wait time in fields SMF30EIIW, SMF30AIW, R723CIWT, and SMF72IWT.
4. Storage management is in effect for an enclave if either of the following is true:
   • The enclave includes one or more tasks.
   • The enclave includes at least one SRB which has issued the SYSEVENT ENCASSOC to associate itself with an address space.

Managing the performance of work in enclaves

This information describes how to classify the work running in enclaves:
• Using independent enclaves
• Using dependent enclaves
• Using work-dependent enclaves

Using independent enclaves

You define a service class and a goal for work that is processed by the subsystem using the independent enclaves. Workload management then dynamically manages resource controls based on the goal.
For more information about defining performance characteristics for enclaves, see z/OS MVS Planning: Workload Management.

Example

Suppose your installation has a subsystem called DDF that uses enclaves for its distributed work requests. Your installation is running in goal mode with an active policy. To define the performance characteristics for the work scheduled to an enclave, you do the following:

- Define a workload and a service class for DDF work using the WLM ISPF application:

  Service Class: DDF_ALL
  Goal: 5 second response time
  Importance: 3

- Using the WLM ISPF application, define a classification rule for the DDF subsystem type where all work goes into the DDF_ALL service class.

  Subsystem Type: DDF

  DEFAULTS: DDF_ALL

- Install the service definition.
- Activate the service policy.

Using dependent enclaves

Dependent enclaves are managed to the performance goal of the owning address space, so there is no need to separately classify dependent enclaves, or to define separate service classes or performance groups for them.

Using work-dependent enclaves

Work-dependent enclaves inherit their classification from the owning independent enclave and are thus managed to the independent enclave’s performance goal.

Querying an enclave’s classification information

A caller can use the IWM4EQRY macro to determine the classification information about an enclave. The classification information is that information passed on the IWM4CLSYS macro for an independent enclave or inherited from the owning address space for a dependent enclave. For details on IWM4CLSYS, see “IWM4CLSYS — Classify work” on page 464.

Example

To determine the classification attributes associated with an enclave represented by ETOKEN, first issue IWM4EQRY to determine the length of the storage required to contain the classification information. The length of the area is dependent on the MVS release. Specify the following:

IWM4EQRY ETOKEN=etoken,
ANSAREA=ansarea,
ANSLEN=anslen,
QUERYLEN=querylen

where the calling program has defined the following, and ansarea and anslen are set to zero:
etoken DS FL4 enclave token
ansarea DS A Area to contain address of classification
anslen DS A Length of the answer area
querylen DS A Length of storage required

Obtain the amount of storage passed back in querylen and set anslen equal to querylen. Set ansarea to point to the storage and issue IWM4EQRY again for the enclave classification information:

IWM4EQRY ETOKEN=etoken
ANSAREA=ansarea
ANSLEN=anslen
QUERYLEN=querylen

### Querying a dispatchable unit’s enclave status

A caller can use the IWMESQRY macro to determine whether the current dispatchable unit is associated with an enclave. If the dispatchable unit is associated with an enclave, the service returns the enclave token.

### Deleting an enclave

A caller can delete an enclave using the IWM4EDEL macro. If the enclave is registered, it is only logically deleted. That is, it remains available until it is no longer registered by any subsystem.

When the enclave is deleted, the following occurs for each remaining dispatchable unit:

- **SRBs:**
  
  Each SRB belonging to the enclave is changed to a preemptable SRB and run at the dispatching priority of the current home address space (the address space into which the SRB was scheduled). The subsystem can purge SRBs using the PURGEDQ macro when the enclave still exists in the system. In most cases, this prevents the SRB from existing beyond the life of the enclave. For information on how to use PURGEDQ, see [z/OS MVS Programming: Authorized Assembler Services Guide](https://www.ibm.com/docs/en/zos?topic=asmr).  

- **Tasks:**
  
  If an enclave ends with tasks still joined to the enclave, the tasks revert back to ordinary non-enclave tasks.

A foreign enclave is deleted using the IWMUIMPT macro. Work-dependent enclaves are implicitly deleted when the owning independent enclaves get deleted.

For information about the IWM4EDEL macro, see [“IWM4EDEL — Delete an enclave” on page 520](https://www.ibm.com/docs/en/zos?topic=asmr).

### Example

To delete an enclave, specify the following:

IWM4EDEL ETOKEN=etoken,
RETCODE=retcode,
RSNCODE=rsncode

where the calling program has defined the following:
<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>etoken</td>
<td>DS</td>
<td>FL4</td>
<td>Enclave token</td>
</tr>
<tr>
<td>retcode</td>
<td>DS</td>
<td>CL4</td>
<td>Return code</td>
</tr>
<tr>
<td>rsncode</td>
<td>DS</td>
<td>CL4</td>
<td>Reason code</td>
</tr>
</tbody>
</table>
Chapter 4. Participating in Enterprise Workload Management

Enterprise Workload Manager (EWLM) is a systems service of the IBM Virtualization Engine™. Virtualization Engine is a set of technologies and systems services that allow system administrators to access and manage resources across multiple platforms (z/OS, AIX, i5/OS, Windows, Solaris and Linux). The EWLM systems service allows you to define business-oriented performance goals for an entire domain of servers across multiple platforms, and then provides an end-to-end view of actual performance relative to those goals.

For example, a multi-platform environment might include:
- A Web server tier running Windows
- An application server tier running AIX
- A database tier running z/OS

To ensure that work requests are performing as expected in this environment, you must be able to track the performance of those requests across server and subsystem boundaries. EWLM allows you to do that.

EWLM uses middleware that has been instrumented with the Open Group’s Application Response Measurement (ARM) 4.0 standard. ARM 4.0 provides a set of interfaces that an application calls; these are then used by EWLM to calculate the response time and status of work processed by the application.

In a multi-tiered environment, what is perceived as one transaction may be implemented as many sub-transactions across several different applications. To relate the sub-transactions with one another, ARM 4.0 uses correlators. Relationships are established by passing the correlator of a parent sub-transaction to its child sub-transactions. The correlator for a parent sub-transaction, that is, a correlator that is passed from the sending application tier, is called a parent correlator. A correlator for its child sub-transaction is called a current correlator.

Ordinarily, applications that participate in EWLM use standard instrumentation based on the ARM 4.0 Java™, C or C++ language bindings. However, because applications that use the WLM enclave services are already instrumented, WLM provides support for EWLM through a set of new and enhanced enclave services.

The WLM support for EWLM is effective only if the ARM agent is enabled and an EWLM policy is installed. Operators can control the state of the ARM agent by disabling or enabling the function from an operator console at any time with the F WLM,AM command. Additionally, the current state of the ARM agent can be displayed by the operator command D WLM,AM. For more information, see z/OS MVS System Commands.

For more information on Virtualization Engine and EWLM, including using the ARM APIs to instrument an application, see the eServer Information Center on the Internet at http://publib.boulder.ibm.com/eserver/eserver/v1r1/en_US/index.htm?info/icmain.htm

For more information on enclaves, see Chapter 3, “Creating and using enclaves,” on page 33.
Enclave Services and EWLM

The enclave services related to EWLM are:

- **IWM4CON**
  This service connects a calling address space to WLM and optionally indicates that this work manager will participate in EWLM.

- **IWM4DIS**
  This service allows the caller to disconnect from WLM. If the caller is connected as an EWLM participant, participation with EWLM is terminated.

- **IWM4CLSY**
  This service associates a service class and possibly a report class with an arriving work request. With respect to EWLM, this service allows you to specify the correlator of a parent work request to start a new sub-work request, either implicitly, when creating an enclave, or explicitly, with the use of the IWMESTRT service.

- **IWM4ECRE**
  This service creates an enclave. An optional parameter indicates whether the work manager starts a new EWLM work request implicitly.

- **IWM4EDEL**
  This service stops all existing work requests that are still active and then deletes an enclave.

- **IWMESTRT**
  This service allows work managers that participate in EWLM to explicitly indicate the start of an EWLM work request.

- **IWMESTOP**
  This service allows work managers that participate in EWLM to explicitly indicate the end of an EWLM work request and all of its sub-work requests.

- **IWMEBLK**
  This service allows work managers that participate in EWLM to indicate that processing of a work request is blocked while it waits for a sub-work request in another application to complete.

- **IWMEUBLK**
  This service allows work managers that participate in EWLM to indicate that processing of a work request is no longer blocked.

- **IWMEGCOR**
  This service allows work managers that participate in EWLM to retrieve the correlator for a given work request handle or the maximum length of a correlator.

Modelling your business transactions

With the introduction of support for EWLM, there are two ways of modelling your business transactions:

- Using enclaves without EWLM participation
- Mapping EWLM work requests, either closely or loosely, to enclaves

Using enclaves without EWLM participation

With this model, a business unit of work is represented by the lifetime of the enclave under which it will be processed, that is, from the time the enclave is created until it is deleted. At the time the enclave is created, the business unit of
work is classified and assigned a WLM service class. The work manager does not further interact with EWLM to identify when such a business unit of work starts and stops, and the work manager is not an EWLM participant.

**Mapping EWLM work requests to enclaves**

With the EWLM model, a business transaction is measured by the EWLM ARM agent and may be referred to as a *work request*. A work request lasts from the time it is started until the time that it is stopped. Only EWLM participants can start and stop work requests. Work requests are mapped to an enclave, as the enclave is the MVS means to manage (with SRM) transactions directly across address space boundaries.

Work requests may be started and stopped explicitly by the EWLM-participant application. In this case, the work requests can be said to be loosely mapped to enclaves. Alternatively, work requests may be started implicitly when the enclave is created, and stopped implicitly when the enclave is deleted. In this case, the work requests can be said to be closely mapped to enclaves. Note that such work requests do not differ from the non-EWLM model, except that:

- EWLM is notified about the work request’s start and stop time.
- EWLM may optionally classify the work request based on its end-to-end policy.

It is also possible to combine the explicit and implicit starting and stopping of work requests. For example, a work request may be started explicitly but stopped implicitly. The possibilities, along with the associated WLM services, are shown in Table 14.

<table>
<thead>
<tr>
<th>Start</th>
<th>WLM service</th>
<th>Stop</th>
<th>WLM service</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implicit</td>
<td>IWM4ECRE</td>
<td>Implicit</td>
<td>Work request is stopped by IWM4EDEL</td>
</tr>
<tr>
<td>Explicit</td>
<td>IWM4ECRE with ESTRT=EXPLICIT and subsequent IWMESTRT</td>
<td>Implicit</td>
<td>Work request is stopped by IWM4EDEL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Explicit</td>
<td>IWMESTOP</td>
</tr>
<tr>
<td>Implicit</td>
<td>IWM4ECRE with ESTRT=EXPLICIT_SINGLE and subsequent IWMESTRT</td>
<td>Implicit</td>
<td>Work request is stopped by IWM4EDEL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Explicit</td>
<td>IWMESTOP</td>
</tr>
</tbody>
</table>

An EWLM participant can process multiple single work requests under the same enclave. The underlying assumption is that an enclave can only process one work request at a time. Within a work request, however, processing of sub-work requests is allowed. The ARM transaction model requires that nested sub-work requests be completed before the nesting work request completes. WLM enforces this requirement.

**Connecting with WLM as an EWLM participant**

A work manager becomes an EWLM participant when it connects to WLM through the IWM4CON service with the following options:

- WORK_MANAGER=YES
- EWLM=YES
An optional **GROUPNM** parameter specifies an application group to which the work manager belongs.

The IWM4CON service connects a subsystem to WLM so that workload manager services can be used. Note that the default for the **EWLM** parameter is **NO**, which indicates that:

- The work manager interacts only with WLM. No interaction with EWLM takes place.
- The use of the IWMESTRT and IWMESTOP services, as well as the use of the **ESTRT** parameter on the IWM4ECRE service, is not permitted.

For more information, see “IWM4CON — Connect to workload management” on page 480.

### Disconnecting from WLM

The IWM4DIS service allows the caller to disconnect from the workload management services and, thus, also terminate EWLM participation. For more information, see “IWM4DIS — Disconnect from workload management” on page 499.

### Creating an enclave

The IWM4ECRE service creates an enclave. The optional **ESTRT** parameter indicates whether the work manager implicitly starts an EWLM work request. The **ESTRT** values can be:

- **IMPLIED** specifies that a work request is started implicitly when the enclave is created.
- **EXPLICIT** specifies that the work manager explicitly indicates the start of an EWLM work request by invoking the IWMESTRT service.
- **EXPLICIT_SINGLE** specifies the same as option **ESTRT=EXPLICIT** and, in addition, the application ensures that only one work request is active. No nested calls to IWMESTRT are allowed.

If the **EXPLICIT_SINGLE** option is specified, the CPU consumption on all EWLM enclave services (IWMEGCOR, IWMESTRT, IWMESTOP, IWMEBLK, IWMEUBLK) will be reduced.

For details, see the corresponding macro descriptions.

- **NEVER** specifies that this enclave will never use any EWLM-related enclave services (IWMEGCOR, IWMESTRT, IWMESTOP, IWMEBLK, IWMEUBLK) after the enclave has been created, even if the work manager has registered (IWM4CON or IWMCONN) with EWLM=YES. Also, IWM4ECRE will not start an EWLM work request on the enclave and will not do any EWLM-related processing.

The use of the **ESTRT** parameter is allowed only when the work manager previously connected to WLM with IWM4CON **EWLM=YES**.

An optional **WORKREQ_HDL** parameter allows the caller to get the work request handle of an implicitly created work request. The handle can be used subsequently with any of the other new services (IWMEBLK, IWMEUBLK, IWMESTOP and IWMEGCOR). The **WORKREQ_HDL** parameter is valid only with **ESTRT=IMPLIED**.

For more information, see “IWM4ECRE — Create an enclave” on page 506.
Deleting an enclave

The IWM4EDEL service stops all existing work requests that are still active and then deletes an enclave.

Classifying work requests

For WLM management and reporting purposes, classification is done when an enclave is created. The resulting service class is assigned to the enclave and remains until the enclave is deleted.

For EWLM purposes, classification for an EWLM-participant work request is always done at the first hop, that is, the first application tier in a domain that accepts a request. Subsequent tiers usually do not classify the work request again unless the domain border has been crossed or different EWLM policies are installed on the sending and receiving tier. However, each time a new work request is started, a new correlator is created that must be obtained and forwarded to each subsequent application tier, if any. To obtain the correlator, you use the IWMDCOR service.

If the work manager represents the first hop, the classification structure mapped by the IWM4CLSY service is used to classify the work request. To specify the EWLM correlator associated with the parent correlator, you use the EWLM_CORR parameter on the IWM4CLSY service.

The parent correlator is the correlator that is passed from the sending application tier. It contains, among other information, the transaction class of the work request. When a sub-work request is started, the parent correlator must be used to indicate to EWLM that a sub-work request is to be started, and the current correlator can be derived from the parent correlator. Otherwise, the current correlator is generated by classifying the new work request.

z/OS passes classification attributes to ARM as property names. These attributes are used in case EWLM classification on z/OS is required, for example, because no correlator was passed into an EWLM participant, or the work manager represents the first hop. For EWLM classification it is critical that these names are in upper case in the EWLM policy. The attribute value, however, can be upper or lower case.

The classification attributes passed to ARM are:

- ACCTINFO
- COLLECTION
- CONNECTION
- CORRELATION
- LUNAME
- NETID
- PACKAGE
- PERFORM
- PLAN
- PRCNAME
- PRIORITY
- PROCESSNAME
- SCHEDENV
- SUBCOLN
- SUBSYSMP
- TRXCLASS
- TRXNAME
Explicitly starting and stopping work requests

WLM services allow work managers that are EWLM participants to explicitly indicate the start and end of an EWLM work request:

- To start: IWMESTRT
- To stop: IWMESTOP

Required parameters for each service specify the enclave under which the work request is processed and the handle that represents the work request. On IWMESTRT, you also specify classification attributes and a parent correlator when a sub-work request should be started.

For more information, see "IWMESTRT — Start a work request" on page 248 and "IWMESTOP — Stop a work request" on page 241.

Continuing a work request at another application

To continue a work request at another application, a work manager must pass the correlator of the current work request to that application. To retrieve the correlator for a given work request handle, you use the IWMEGCOR service. The service can also be used to return the maximum length of a correlator. The receiving application would in turn use this correlator as the parent correlator to start a sub-work request.

Blocking and unblocking work requests

Services are provided for the blocking and unblocking of work requests. You would block the processing of a work request when it is waiting for a work request in another application to complete.

- IWMEBLK indicates that processing of a work request is blocked.
- IWMEUBLK indicates that processing of a work request is no longer blocked.

For more information, see "IWMEBLK — Work request blocked" on page 180 and "IWMEUBLK — Work request no longer blocked" on page 256.

Enclave services and the ARM API

For a work manager that is an EWLM participant, the enclave services internally invoke the ARM services. A work manager becomes an EWLM participant when it connects to WLM through the IWM4CON service with EWLM=YES. Table 15 shows the ARM services that are invoked by the enclave services.

Instrumenting a C application for ARM

The topics in this section describe how to instrument, compile, bind and run an ARM-instrumented application on z/OS.

Using the ARM services for instrumenting applications and for managing ARM transactions on z/OS

This information describes the support for ARM transaction management and WLM management.

Supporting transaction management

The services `arm_start_transaction` and `arm_stop_transaction` indicate the beginning and the end of an ARM transaction and support the use of enclaves. Thus, ARM transactions can be managed individually on z/OS.

To allow for transaction management, you must code the `arm_bind_thread` and `arm_unbind_thread` services in their applications to indicate that the current thread (TCB) is now performing on behalf of a specified transaction. Only when you use the `arm_bind_thread` and `arm_unbind_thread` services, WLM is able to track the thread. WLM can then assign the necessary resources to that unit of work to help the transaction to reach its goals.

Note: The z/OS implementation of `arm_bind_thread` and `arm_unbind_thread` conform to the original EWLM R1 semantic specifications. For example, threads are implicitly unbound by `arm_stop_transaction` or `arm_discard_transaction`.

A sample C-program IWMSARM4 that demonstrates the usage of the services and the new sub-buffers is available in SYS1.SAMPLIB(IWMSARM4). A sample JCL to compile, bind and run this application is provided in SYS1.SAMPLIB(IWMCARM4).

To understand the management of ARM transactions on z/OS it is important to understand that a distributed transaction on a single z/OS system is managed as a whole, even if it spans several address spaces, as shown in Figure 12 on page 62.
When WLM running on a z/OS system first detects an ARM-instrumented transaction (when the first application A1 performs an arm_start_transaction in the example in the figure) a management control block (enclave) is created. Later on, when application A2 performs its arm_start_transaction call, the same control block (enclave) is used to track the transaction. Of course, it is necessary to pass the current_correlator c1 from the arm_start_transaction call in A1 to application A2 and use that correlator as the parent_correlator in the arm_start_transaction call in A2 (and equally so for additional applications A3, A4, and so on). The correlator is used by WLM to find out that A1 and A2 are working on behalf of the same transaction.

Each application in a transaction call sequence needs to indicate that it wants its transactions to be managed towards transaction goals (see next chapter). For example, if A1 has indicated transaction management, but A2 has not, and just because A1 passes a correlator to A2, A2 will not be managed towards transaction goals.

In an A1*A2*A3 scenario, where every application correlates properly but only A1 and A3 have indicated transaction management, A1 and A3 are managed together, but A2 is not.

**z/OS ARM sub-buffers to support WLM management**

Two z/OS-specific ARM sub-buffers support ARM-instrumented application on z/OS. The first one is for arm_register_application and the second is for arm_start_transaction.

---

**Figure 12. Typical synchronous application flow between applications on the same z/OS system**

When WLM running on a z/OS system first detects of an ARM-instrumented transaction (when the first application A1 performs an arm_start_transaction in the example in the figure) a management control block (enclave) is created. Later on, when application A2 performs its arm_start_transaction call, the same control block (enclave) is used to track the transaction. Of course, it is necessary to pass the current_correlator c1 from the arm_start_transaction call in A1 to application A2 and use that correlator as the parent_correlator in the arm_start_transaction call in A2 (and equally so for additional applications A3, A4, and so on). The correlator is used by WLM to find out that A1 and A2 are working on behalf of the same transaction.

Each application in a transaction call sequence needs to indicate that it wants its transactions to be managed towards transaction goals (see next chapter). For example, if A1 has indicated transaction management, but A2 has not, and just because A1 passes a correlator to A2, A2 will not be managed towards transaction goals.

In an A1*A2*A3 scenario, where every application correlates properly but only A1 and A3 have indicated transaction management, A1 and A3 are managed together, but A2 is not.

**z/OS ARM sub-buffers to support WLM management**

Two z/OS-specific ARM sub-buffers support ARM-instrumented application on z/OS. The first one is for arm_register_application and the second is for arm_start_transaction.
The sub-buffers are defined in header file <armewlm.h> and are located in data set SYS1.SIEAHDRV.H(ARM4EWLM). The sub-buffers have the following names:

- arm_subbuffer_zos_connect_t
- arm_subbuffer_zos_classify_t

These sub-buffers provide WLM with the information that it needs to connect to WLM for management purposes and to specify WLM classification attributes.

**Sub-buffer arm_subbuffer_zos_connect**: Use the arm_subbuffer_zos_connect sub-buffer to specify the attributes for the connection of the ARM-instrumented address space (application) to WLM. It can be provided as a sub-buffer with the format_id= ARM_SUBBUFFER_ZOS_CONNECT (-30400) on an arm_register_application service call. WLM needs this sub-buffer to manage individual transactions.

Figure 13 shows the layout of the sub-buffer and the parameters which can be passed to the arm_register_application service, where:

- The **subsys** and **subsysName** parameters are required
- **groupName** is an optional parameter

Specify all character parameters in the character set that the application uses (arm_charset_t). There is no restriction for an application using EBCDIC (IBM-1047) or US-ASCII encoding. For UTF8 and UTF16, the strings are restricted to characters from the US-ASCII (codepoints 0..127) subset.

The **subsys** parameter also determines the subsystem type parameter that can be specified in the WLM administrative application. For example, the sample application in SYS1.SAMPLIB(IWMSARM4) refers to a subsystem type of ST0K that could be defined in the WLM classification rules as follows:
Sub-buffer arm_subbuffer_zos_classify: ARM service arm_start_transaction can associate a starting transaction to a WLM enclave. The new enclave has to be classified to a WLM service class. This is accomplished by passing the WLM classification attributes in an optional z/OS sub-buffer arm_subbuffer_zos_classify with format_id=ARM_SUBBUFFER_ZOS_CLASSIFY (-30401). The values of the classification attributes can then be used in classification rules of the WLM administrative application to associate a specific service class with a transaction. If the sub-buffer is not present but arm_subbuffer_zos_connect has been specified on the arm_register_application call, the transaction will be assigned the default service class for the subsystem.

Figure 14 on page 65 shows the layout of this sub-buffer and the parameters which can be passed to the arm_start_transaction service. The parameters are the same as those specified on the WLM IWM4CLSY service. Specify all character parameters in the character set that the application uses (arm_charset_t). There is no restriction for an application using EBCDIC (IBM-1047) or US-ASCII encoding. For UTF8 and UTF16 the strings are restricted to characters from US-ASCII (codepoints 0..127) subset.
Compiling an ARM-instrumented application

When compiling an ARM-instrumented application, the application should use
#include "arm4.h" to include the ARM header file. As a result, the arm4.h header
file library, SYS1.SIEAHDRV.H, must be included in the SEARCH/LSEARCH path.
Using the C/C++ compiler in batch

Figure 15 shows sample JCL that illustrates the required options to compile an ARM-instrumented 31-bit XPLINK application in MVS batch.

```
/MYJOB jobcard
/**
// JCLLIB ORDER=CBC.SCCNPRC
/**
//COMPILE EXEC CBCC,
// CPARM='OPTF(DD:OPTIONS)',
// INFILE='mysource(mymember)',
// OUTFILE='myobjectdeck(mymember),DISP=SHR'
//COMPILE.OPTIONS DD *
LSEARCH('/SYS1.SIEAHDRV.+')
SEARCH('/SYS1.SIEAHDRV.+')
LANGLVL(EXTENDED)
XPLINK Non-XPLINK: omit, 64BIT: LP64
SOURCE other options
```

Figure 15. Sample JCL for compiling an ARM-instrumented application in MVS batch

For a 31-bit non-XPLINK application, omit XPLINK (third line from the bottom in the example).

For a 64-bit application, specify the LP64 option instead of XPLINK. (The LP64 option is supported by the C/C++ compiler on z/OS V1R6 or later.)

Using the C/C++ compiler under z/OS UNIX System Services

Run the `c89` or `c++` z/OS UNIX System Services shell command to compile your program and store the object. For C++ compiles add the `--` option. Table 16 shows examples of compiling under z/OS UNIX System Services in the various environments.

<table>
<thead>
<tr>
<th>Environment</th>
<th>Sample command</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-bit XPLINK</td>
<td>`c++ -c -o mymain.o -Wc,&quot;DLL,XPLINK,LANGLVL(EXTENDED)&quot; \</td>
</tr>
<tr>

Binding an ARM-instrumented application

This information describes using the binder under z/OS UNIX System Services and in MVS batch.

Using the binder in batch

Figure 16 on page 67 shows sample JCL that illustrates the required options to compile an ARM-instrumented, 31-bit XPLINK application in MVS batch.
For 31-bit non-XPLINK applications, use the procedure CBCB, rather than CBCXB (line 5 in the example), and specify SIEASID member LARM431, rather than LARM43X (third line from the bottom in the example).

For 64-bit applications (compiled with compiler option LP64) use the procedure CBCQB, rather than CBCXB (line 5 in the example), and specify SIEASID member LARM464, rather than LARM43X (third line from the bottom). In addition, specify an ENTRY point for the binder of CELQSTRT, instead of CEESTART (second line from the bottom in the example).

### Using the binder under z/OS UNIX System Services

Run the `c89` or `c++` command specifying the appropriate side-deck for the ARM DLL and the correct binder options. Table 17 shows sample commands for 31-bit and 64-bit environments.

<table>
<thead>
<tr>
<th>Environment</th>
<th>Sample command</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-bit XPLINK</td>
<td>`c++ -o mymain -Wl,&quot;DLL,XPLINK&quot; mymain.o mymem2.o \</td>
</tr>
<tr>

<td>/usr/lib/libarm4_64.x</td>
</tr>
</tbody>
</table>

### Running an ARM-instrumented application

An ARM-instrumented application can run:

- In batch or as a started task
- Under z/OS UNIX System Services

#### Running an application in batch or as a started task

To run an ARM application in batch or as a started task, you must ensure that either:

- The data set SYS1.SIEALNKE is in the system LINKLIST. This is the default, and is the recommended approach.
- The library is in the application’s STEPLIB or JOBLIB, as appropriate.
Running an application under z/OS UNIX System Services

To run an ARM application under z/OS UNIX System Services, you must ensure that the path /usr/lib is in the application’s LIBPATH.
Chapter 5. Using the queueing manager services

The queueing manager services are intended for queueing managers to use to manage server (execution) address spaces and the work requests they process to meet service class performance goals. Through queueing manager services, workload management maintains the queues for passing work requests from the queueing manager to its servers. A queueing manager is a subsystem that queues work requests to workload management for execution in server address spaces.

Workload management dynamically starts and maintains server address spaces as required to meet the queueing managers workload. Therefore, installations do not have to manage the address spaces manually, nor do they have to monitor workload fluctuations that change the number of address spaces needed for the work to meet its goals. Workload management automatically adjusts to changes in the workload.

For queue managers using the services, workload management spreads the work across multiple address spaces, providing workload isolation and greater scalability based on workload demands. For a queueing manager that queues and executes work all in the same address space, sometimes encountering storage overlay problems, the services provide an incentive to change to a multiple address space configuration.

This chapter describes how to use the queueing manager services, and suggests the information you should provide to your customers so they can properly set up the required service definitions.

*Note:* The queueing manager services uses application environments. (See "Updating a service definition with application environment information" on page 77 for a discussion of defining policy for application environments.)

**Example of using the queueing manager services**

This section describes how a queueing manager can use the services to:

- Isolate different types of requests into separate server address spaces for integrity, security, and operational reasons.
- Classify work into service classes according to business goals.
- Manage the application execution in the server address space as a continuation of the originating unit of work.
- Specify dynamic management of server address spaces, and other resources to meet the service class goals of the work requests.
- Report service class goals against actual service class performance.
- Report response time information.

*Figure 17 on page 70* shows an example of how a queueing manager can use the services. The example shows the services used to achieve the objectives listed above. The services are intended to be used with the enclave services, and must be used independently of the execution delay monitoring services.
Figure 17 shows a queueing manager address space starting up, connecting to workload management, and queueing work requests to workload management. The server address spaces are created dynamically by workload management as needed. When the server initializes, it connects to workload management, which allows it to select work from the queues. The server address space indicates to workload management when each request starts and ends, so the work request can be properly managed and its performance statistics reported. The following steps describe the flow illustrated in Figure 17.

1. Establish the queueing manager.
The queueing manager address space starts up through either a manual start or customer automation. During its initialization, it issues the IWM4CON service with the QUEUE_MANAGER=YES parameter, and provides the subsystem type (SUBSYS parameter), the subsystem name (SUBSYSNM parameter), and, optionally, the node name (NODENM parameter) to identify the type of work associated with the queueing manager. If you need to create an independent enclave, then the queueing manager should also specify WORK_MANAGER=YES (the default) on IWM4CON. If you are creating dependent enclaves, you do not need to specify WORK_MANAGER=YES.

If the queueing manager needs to take some action when workload management deletes work requests that the queueing manager previously queued, specify a connect exit routine on the QMGR_EXIT parameter. Workload management deletes all queue requests when the queue manager disconnects from workload management or the application environment is deleted. This exit gets control when workload management has deleted a work element from its queue. Input to the exit is mapped by the list form of the IWMQCXIT macro. For information about the IWMQCXIT exit, see “Using the queueing manager connect exit” on page 77. Workload management provides the exit with the information passed to workload management when a work element is queued and an indication that the work element has been removed from the queue.

2. Define the dynamic application environment.
   Optionally, you can define a dynamic application environment using the IWM4AEDF service. The scope of this newly defined DAE only applies to the queueing manager that invoked this service. For further information, refer to “IWM4AEDF — WLM define dynamic application environments” on page 454.

3. Create an enclave.
   The queueing manager receives a work request and must use an enclave to manage it. Depending on the environment, the queueing manager can use an existing enclave or create a new enclave, either dependent or independent, using the IWM4ECRE service.
   If running under the requestor's dispatchable unit, IWMESQRY can be used to determine whether the requestor belongs to an enclave and if so, which enclave. If running under a different dispatchable unit, it is the subsystem's responsibility to pass information on any existing enclave along with the work request. For example, the subsystem could pass information it obtained from IWMESQRY while running under the requestor's dispatchable unit.
   If the requestor does not belong to an enclave but has an address space transaction (for example, it is a TSO user or a batch job), the queueing manager can create a dependent enclave to represent a continuation of the requestor's transaction. This requires that the requestor be the home address space.
   If there is no existing enclave or address space transaction, such as when the requestor is on another system, the queueing manager must create an independent enclave to begin a new transaction. This requires the queueing manager to classify the work request.

4. Queue a work request.
   The queueing manager uses the IWM4QIN service to add the work request to a workload management queue. The application environment, enclave token, and optional user ID for resource access control are provided as input to workload management. The service class is determined from the enclave token, and the request is added to a queue associated with that service class within the specified application environment. You can optionally pass information to the
server address space when it selects this work request. Workload management
does not read or modify this data in any way.

Workload management stages work requests between the queueing manager
address space and the server(s), but the queueing manager is still responsible
for managing the flow of work requests and handling timeout and abnormal
conditions where servers are failing to properly process requests. Workload
management detects and reacts to certain error conditions such as JCL errors in
the procedure used to start the server and repeated, unexpected terminations
of the server address space. For more information, see “Defining Application
Environments” in \textit{z/OS MVS Planning: Workload Management}.

If the queueing manager needs to remove a work request that it previously
queued through the IWM4QIN service before it has been processed by the
server, it uses the IWM4QDE service. This service is provided for exceptional
circumstances, such as:

\begin{itemize}
  \item Timeout of the work request
  \item An external request to cancel a queued request
  \item Queueing manager recovery
\end{itemize}

A queueing manager must not insert requests for a dynamic and static
application environment with the same application environment name
concurrently.

5. \textbf{Establish a server address space.}

When the first request is queued to an application environment, workload
management detects that there are no active servers for the request, and
automatically starts one. The MVS procedure name and start parameters are
taken from the application environment definition in the service definition. As
the workload fluctuates, workload management adjusts the number of server
address spaces so the goals of the work are met.

When the server initializes, it must establish itself as a server address space
using the IWM4CON service with \texttt{SERVER\_MANAGER=YES} parameter, and indicate
which application environment it is servicing. The subsystem type and name
specified on the server connect must match the values specified on the
associated queueing manager connect.

Workload management creates as many server address spaces as are needed to
meet the goals of the work running in the servers, unless the application has
limited the number of server instances that workload management can create
using IWM4SLI.

Immediately after invoking IWM4CON, you have the option of using IWM4SLI
to control the number of server instances that WLM will create. Use the
\texttt{AE\_SERVERMAX} parameter to establish a maximum number—this is particularly
useful for applications, such as MQSeries\textsuperscript{®} Workflow, that connect to backend
applications supporting a limited number of parallel connections. Use the
\texttt{AE\_SERVERMIN} parameter to establish a minimum number—this allows an
application to keep a number of servers active, even during low utilization
periods. In addition, you can specify \texttt{AE\_SPREADMIN=YES} to ensure that the
defined minimum number of servers are distributed evenly across all of the
service classes used to execute work requests in the application environment.

There will be at least as many servers for an application environment as there
are unique service classes associated with the work requests, even if the
workload is low. This is so workload management can separately manage work
with different service class goals.

Applications can optionally give workload management the control about the
number of server instances per server address space. Directly after IWM4CON,
you can use IWMSINF to obtain recommendations from workload management
about the number of server instances to be started. WLM will pass the number of instances to be started in addition to the already running server instances to the server address space. The caller must have previously connected to WLM using the IWM4CON service specifying SERVER_MANAGER=YES, SERVER_TYPE=QUEUE, and MANAGER_TASKS=YES. See “Managing the number of server instances per server address space” on page 75 for a more detailed explanation on using IWMSINF.

Because the workload management services used by server address spaces are available to problem programs, a SAF call is made as part of the connection process to allow the installation to protect against malicious use or damage due to incorrect startup definitions. This SAF check permits the server address space to be totally unauthorized (no APF authorization required). The RACF-supported resource for this call is of the SERVER class and has the name:

sstype.subsys.applevn [.nodenm]

where:

sstype  is the subsystem type.

subsys  is the subsystem name of the queueing manager address space.

applevn  is the name of the application environment being serviced

odennm  is an optional qualifier of the queueing manager

Workload management picks up these values from the IWM4CON parameters, SUBSYS, SUBSYSNM, APPLENV, and NODENM, respectively. For more information, see “Workload management migration” in \(z/OS MVS Planning: Workload Management\).

6. Process the work request.

The server uses the IWM4SSL service to remove a work request from the queue associated with its application environment and service class. If no requests are queued, workload management suspends the task issuing the IWM4SSL until work is available. After a request is selected, the server uses the IWM4STBG service to indicate the processing of the request is beginning. At this point the task joins the enclave identified when the work was queued through IWM4QIN. When the server is finished processing the request, it uses the IWM4STEN service to cause the task to leave the enclave.

Almost all of the processing in a server address space should be on behalf of a work request and occur between the IWM4STBG and IWM4STEN calls. A server address space should not have other tasks performing unrelated processing as this could interfere with effectively managing the enclave to its goals.

If the queueing manager provided a user ID on the IWM4QIN service, IWM4STBG sets up a SAF environment for the work request to control access to resources.

Alternative task structures: This example shows a single task issuing the IWM4SSL, IWM4STBG, and IWM4STEN services: one task within the server address space selects work from the queue, processes the request, then loops back to select more work. Queueing manager services does not impose any rules limiting the ways a server can organize its tasks. The following task structures are also possible:

- Multiple tasks with single thread execution
One task selects work from the queue, selects a “worker” subtask to process the request, posts the worker task, and then waits to be posted by the worker task when the processing of the request is complete.

- Multiple tasks with parallel work selection and execution

There is a set of “worker” subtasks within the server address space, each of whom selects work from the queue, processes the request, and loops back to obtain a new request.

At the time the server connects to workload management (IWM4CON), the server must specify how many tasks will execute work in parallel (PARALLEL_EU).

7. **Delete the enclave.**

The server address space informs the queueing manager using its own interface that a work request is complete. If the queueing manager had previously created an enclave for the work request, it determines if there are other work requests active for the same enclave. If there are none, the queueing manager deletes the enclave and returns to the originator of the request.

8. **Terminate the server address space.**

Under normal circumstances, it is expected that a server address space will continue to select work until told by workload management that the space is no longer needed through a return and reason code (x'0C14') on the IWM4SSL service. The server is then expected to complete any work requests already selected, clean up, disconnect from workload management through the IWM4DIS service, and terminate. Possible reasons for this IWM4SSL return code are:

- The operator entered one of the following commands for the application environment:
  - VARY WLM,APPLENV=applenvname,QUIESCE
  - VARY WLM, DYNAPPL=applenvname,QUIESCE or
  - VARY WLM,APPLENV=applenvname,REFRESH
  - VARY WLM,DYNAPPL=applenvname,REFRESH
- A policy was activated from a new service definition which no longer includes the application environment associated with the server.
- WLM determines that the server is not needed to meet the goals of the enclave's service class.

The server should make reasonable recovery attempts when errors occur. If the server encounters a failure that forces it to terminate, it should disconnect from workload management as part of its shutdown. If the server address space terminates without explicitly disconnecting from workload management, workload management detects the termination and performs the IWM4DIS processing at that time. If workload management detects five unexpected server disconnects or address space terminations within ten minutes, it will put the application environment into a STOPPED state. This means that no new servers are created for the application environment until the VARY WLM,APPLENV=applenvname,RESUME or VARY WLM, DYNAPPL=applenvname,RESUME command is issued for it. Existing server address spaces continue to run work while the application environment is in the STOPPED state, as long as they are operating normally.

9. **Terminate the queueing manager address space.**

When the queueing manager terminates normally, it is expected to quiesce its activities, drain its queues of pending work, and disconnect from workload management using the IWM4DIS service. If the queueing manager address
space terminates without first disconnecting from workload management, workload management detects the termination and performs the IWM4DIS processing at that time.
Workload management returns control immediately to the caller of IWM4DIS, and asynchronously performs server clean up. It purges all queued, but unselected, requests and attempts to terminate all associated server address spaces. Because workload management depends on server address spaces to terminate voluntarily when requested, and because workload management must wait for a server to request work prior to telling it to terminate, server address spaces could remain for a significant amount of time after the queueing manager terminates.

Managing the number of server instances per server address space

A server address space contains one or multiple server instances which all select work requests from a work queue. Without using the new interface IWMSINF, the server address space must tell WLM during start up how many server instances will be started (PARALLEL_EU parameter on IWM4CON).

The IWMSINF interface allows the application to obtain the number of server instances from WLM. Figure 18 shows an example of how the server manager address space can use IWMSINF.

1. To use the IWMSINF interface, the server manager address space connects to WLM with IWM4CON specifying the MANAGE_TASK=YES option. All server address spaces that connect to the same application environment must specify the same setting of MANAGE_TASK. The SERVER_MANAGER=YES and SERVER_TYPE=QUEUE options must also be defined.

2. After connecting, the server manager address space must invoke the IWMSINF service to obtain the number of server instances to be started initially.
3. The server address space starts the server instances which select work from WLM by using IWM4SSL.

4. The server manager address space again invokes IWMSINF to listen for recommendations from WLM for the number of tasks to start.

5. IF WLM wants to terminate one or multiple server instances, it resumes IWM4SSL with a new return code telling the server instance to terminate.

6. If WLM wants to terminate the server address space, it resumes IWM4SSL and IWMSINF with a return code that tells the server to terminate.

Note: WLM can only manage the number of server instances per server address space if there is a linear relationship between the number of instances in an address space and the virtual storage consumed in the address space. This implies that all instances allocate about the same amount of virtual storage.

**Directing work requests to a specific server region**

Existing workload manager interfaces allow a control region to queue work requests to a pool of server regions for a service class. The underlying assumption is that each work request represents one or multiple contiguous transactions. This transaction is represented by an enclave which is created when the work request is inserted and which is removed when the application completed its processing for the work request. It is assumed that no information is left in any temporary structure in the system for following work requests.

But there are cases where information must be preserved across multiple "independent" work requests. The information left behind lives only in the virtual storage of the address space. Following work requests requiring this information must now be directed to the server region which has this information.

The solution is that the server region is able to obtain a region token at select time (IWM4SSL) or connect (IWM4CON) and passes this region token to the queue manager. The queue manager is now able to route subsequent requests directly to this server region by specifying the region token on IWM4QIN. The IWM4TAF interface allows the server or control region to mark the server region as being needed by follow-on work requests. WLM will ensure that server region stays alive until all temporal affinities have been removed.

Note:

1. The requests which are directly routed to server regions are outside of the control scope of WLM. Therefore WLM is not able to manage the number of server regions properly if the majority of requests is directly routed to the regions and not queued for being picked up by the WLM managed server pool. It is assumed that requests which are outside of the scope of WLM represent only a minor portion of all work requests processed by the application.

2. The application should carefully use the IWM4TAF interface. WLM will not terminate a server region if it is marked of having a temporal affinity. This can significantly delay the behavior of WLM operator commands such as refresh and quiesce for these application environments. It is assumed that temporal affinities live only a short period (a few minutes) in the system and that they do not represent the majority of the work requests of the application (see also Note 1.)
Updating a service definition with application environment information

When a customer installs a subsystem that makes use of the queueing manager services, the service administrator must define one or more application environments in the workload management service definition. An application environment is a group of application functions requested by a client which execute in a server address space. Workload management dynamically adjusts the number of address spaces servicing the application environment to meet the goals of the work.

If you use the queueing manager services, make sure to document the information needed by the customer’s service administrator to define the application environments. For example, you should provide the following:

- A technique for grouping work into application environments
  Each application environment should represent a named group of server functions that require access to the same application libraries. Having a named group facilitates library security, application program change control, performance management, and system operation.
  For example, a set of related payroll applications might be grouped into one application environment because of their similar runtime requirements. The customer can name the application environment for these payroll applications in the service definition. Workload management then starts and stops server address spaces to process the work in the payroll applications.
- The queueing manager subsystem type
  The queueing manager specifies the subsystem type in the SUBSYS parameter of the IWM4CON service. A service administrator defines the subsystem type when specifying the application environment in the service definition. Make sure you do not use a subsystem type already in use by another subsystem.
- Samples of JCL start procedures and start parameters for a server address space
  You should provide your customer with sample procedures and start parameters for the server address spaces.

For more information about how to define an application environment and a list of subsystem types currently used, see z/OS MVS Planning: Workload Management.

Note: When defining an application environment, you must specify whether or not workload management can start multiple address spaces for the subsystem. In the case of a queueing manager, you can only choose Option 1, Managed by WLM, or Option 2, Limited to a single address space per system. For more information, see the “Defining Application Environments” chapter in z/OS MVS Planning: Workload Management.

Using the queueing manager connect exit

A queueing manager can optionally provide the name of an exit routine on the QMGR_EXIT parameter of IWM4CON when it connects to workload management. Through this exit, the queueing manager is informed when workload management has had to delete queued work requests associated with the queueing manager. Workload management deletes all queued requests when:

- The installation deletes the application environment (that is, activates a service policy that does not contain the application environment).
- The queueing manager address space disconnects.

When the exit routine is invoked, register 1 contains the address of a parameter list mapped by the list form of the IWMQCXIT macro. The parameter list includes an
indicator of what action workload management has taken and the input values specified previously by the queueing manager when it queued the work request using IWM4QIN.

The execute and standard form of IWMQCXIT are intended for use only by the operating system.

**Exit routine environment**

The queueing manager connect exit routine receives control in the following environment:

<table>
<thead>
<tr>
<th>Authorization</th>
<th>Supervisor state and PSW key 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross-memory mode</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks held</td>
</tr>
<tr>
<td>Serialization</td>
<td>None</td>
</tr>
<tr>
<td>Location</td>
<td>The connect exit must be a resident routine callable from any address space and must remain available after the queueing manager disconnects or terminates. Input parameter list is in the primary address space.</td>
</tr>
<tr>
<td>Exit Recovery</td>
<td>The system may discontinue calling the exit upon repetitive, abnormal completions, that is, where an error within the exit percolates to the system recovery routine. The exit may optionally establish a functional recovery routine (FRR) or ESTAEX for any needed recovery or cleanup of its resources.</td>
</tr>
</tbody>
</table>

**Register usage**

Upon entry to the exit, the register contents are as follows:

- **0** Not defined
- **1** Address of the input parameter list
- **2-13** Not defined
- **14** Return address
- **15** Entry point address

Upon entry to the exit, the access register contents are undefined.

Upon return from the exit, the register contents are expected to be:

- **0** Reason code if GR15 return code is non-zero
- **1-14** Not defined (need not be restored to value on entry)
- **15** Return code
Upon return from the exit, the access register contents are unchanged.

**Restrictions**

The exit routine should not invoke functions or suspend execution which could prevent return to the caller for a protracted period. This includes the use of system services which either explicitly or implicitly give control back to the system. In this context, “protracted period” means durations of one second or longer. When such processing is required, the exit should use asynchronous techniques.

**Example**

The following example shows how to invoke the IWMQCXIT macro instruction and the resulting parameter list mapping. This parameter list is passed to the queueing manager connect exit specified on the **QMGR_EXIT** parameter of IWM4CON.

```
IWMQCXIT MF=(L,MYQCXITPL)
```

```

```
Chapter 6. Using the routing manager services

A **routing manager** is a subsystem that establishes and manages connections between a client and a server address space. The routing manager handles these connections rather than individual work requests; the requests are processed only after they arrive in the server address space. The routing manager is responsible for balancing the client connections across a set of eligible servers, with the assistance of the routing manager services.

Routing manager services perform two main functions:
- Automatically starting and maintaining server address spaces as needed by the workload across the sysplex. Installations then do not have to manage the address spaces manually, nor do they have to monitor workload fluctuations that change the number of address spaces needed. Workload management automatically adjusts to changes in the workload.
- Balancing the workload among the servers in the sysplex by deciding on the best server and providing the server routing information when a server is requested by the routing manager.

Routing manager services differ from sysplex routing services in the following ways:
- Routing manager services provide automatic management of address spaces.
- Routing manager services include the server's performance index when selecting the best available servers.
- With routing manager services, workload management decides on a server and passes its identity to the routing manager, instead of offering the routing manager a choice of several servers.

This chapter presents a model of how the routing manager services are intended to be used. Routing manager services combine the use of the “find server” function with application environments and enclaves. See “Updating a service definition with application environment information” on page 77 for a discussion of defining policies for application environments.

**Note:** When defining an application environment, you must specify whether workload management can start multiple or single address spaces for the subsystem. In the case of a routing manager, both Option 1, Managed by WLM, and Option 3, Limited to a single address space per sysplex are valid. For more information, see the “Defining Application Environments” chapter in e/OS MVS Planning: Workload Management.

It is strongly recommended that server address spaces associated with a routing manager use enclave services to manage the work requests according to goals set by the customer. Be aware that enclaves are mutually exclusive with the execution delay monitoring services described in earlier chapters. For a discussion of enclaves and a comparison to delay monitoring, see Chapter 3, “Creating and using enclaves,” on page 33.
A routing manager model

This section presents a model of a routing manager which uses workload management services to accomplish the following objectives:

- Isolate different types of requests into separate server address spaces for integrity, security, and operational reasons.
- Have MVS adjust the number of server address spaces to meet the goals of the workload.
- Have MVS balance the workload across a sysplex by selecting the best system on which to start a server.
- Associate work coming into the server with a service class goal.
- Report goals versus actuals.
- Report response time information.

Figure 19 on page 83 shows the suggested services for a routing manager for managing server address spaces and balancing workload.
Figure 19 shows a routing manager connecting to workload management and establishing itself as a routing manager. It then issues a “find server” for each client request for server location. Workload management is then able to create server address spaces as needed and keep track of the servers across the sysplex. When the client contacts the server, the server creates an enclave on behalf of the client so the work request can be managed to the customer goals.

The detailed sequence of events in Figure 19 is:

1. **Establish the routing manager.**

   The routing manager address space starts up through either a manual start or customer automation. During its initialization, it issues the IWM4CON service with the ROUTER=YES parameter to indicate the intent to use routing manager services. The routing manager supplies the subsystem type (SUBSYS parameter)
and subsystem name (SUBSYSNM parameter). These parameters identify the type of work associated with the routing manager.

2. **Request server routing information.**

   Once initialized in step 1, the routing manager is ready to receive requests to locate servers. In response to such a request, the routing manager calls the IWMSRFSV service, passing the desired application environment name (via the APPLENV parameter). The output returned will be the routing information needed for the client to contact the selected server directly. (The specific content of this information is defined by the client and passed by the server via the SERVER_DATA parameter, as described in step 3.)

   If no eligible servers exist, workload management will proceed to step 3 to start a server.

3. **Establish the server.**

   If this step is necessary, the client program will be suspended until the new server address space is created (possibly on another MVS image). For an application environment defined for a routing server, workload management starts at most one server address space per system instance in the sysplex. The first server is started on the system with the most available capacity at the lowest importance level. Subsequent servers are started on other systems in the sysplex when the work running in the existing servers is not meeting its goals. However, if the workload diminishes for a routing manager, workload management does not decrease the number of servers in the sysplex. The number of servers remains at the high water mark.

   It is possible to run more than one instance of a subsystem in the sysplex, meaning they have the same subsystem type, and therefore the same application environments, but different subsystem names as specified on IWM4CON. The above rules for starting servers apply separately to each subsystem instance. In other words, for each instance, you can have up to one server per system per application environment.

   During server initialization, the server invokes the IWM4CON service with the SERVER_MANAGER=YES and SERVER_TYPE=ROUTER parameters, and information in the SERVER_DATA parameter to uniquely identify the server. The subsystem type and name specified must match that of the associated routing manager instances which will route clients to the server (as defined in step 1). The WORK_MANAGER parameter must remain the default YES so that the server can create independent enclaves in the next step. In addition, the address of an exit routine must be identified on the SRV_MGR_EXIT parameter. See "Using the routing server connect exit" on page 85. Workload management invokes this exit to initiate the shutdown of the server address space. The exit is expected to initiate the shutdown of the server address space. Input to the exit is mapped by the list form of the IWMSCXIT macro instruction. For more information on the quiesce process for an application environment, see step 6 below, as well as the “Defining Application Environments” chapter in z/OS MVS Planning:

4. **Create an enclave.**

   The server address space receives a work request directly from the client and uses the IWM4ECRE service to create an enclave (normally one per request, depending on the definition of the request).

   For the duration of the processing of a request, the client task is joined to the enclave via the IWMEJOIN service so that it can be managed to the installation performance objectives. While the task is part of the enclave, it should only be doing work on behalf of the enclave. Upon completion of the request, the task leaves the enclave via the IWMELEAV service.
Note: While IWM4STBG and IWM4STEN are similar in many ways to IWMEJOIN and IWMELEAV, they cannot be used here, as queueing services are not involved.

5. **Delete the enclave.**
   When work is completed, the server address space informs workload management via the IWM4EDEL service.

6. **Terminate the server address space.**
   Under normal circumstances, it is expected that a server address space terminates only when directed to do so by workload management through the connect exit. Possible reasons for the exit being invoked could be:
   - The operator entered a VARY WLM,QUIESCE or VARY WLM,REFRESH command.
   - A policy was activated from a new service definition which no longer includes the application environment associated with the server.
   - WLM determined that the server is not needed to meet the goals of the enclave's service class.

   The server is expected to complete any active work requests, clean up, and then disconnect and terminate from workload management through the IWM4DIS service.

   If the server encounters a failure that forces it to terminate, it should disconnect from workload management as part of its shutdown. If the server address space terminates without explicitly disconnecting from workload management, workload management detects the termination and performs the IWM4DIS processing at that time.

7. **Terminate the routing manager address space.**
   When the routing manager terminates normally, it is expected to quiesce its activities and disconnect from workload management using the IWM4DIS service. If the routing manager address space terminates without first disconnecting from workload management, workload management detects the termination and performs the IWM4DIS processing at that time. The disconnect and termination of a routing manager does not cause the related server address spaces to terminate. It is the responsibility of the subsystem to coordinate termination processing between the routing manager address space and the servers.

---

**Using the routing server connect exit**

A routing server must provide the name of an exit routine on the `SRV_MGR_EXIT` parameter of IWM4CON when it connects to workload management. The exit is invoked when workload management needs to inform the server to terminate during quiesce or refresh processing. When the exit routine is invoked, register 1 contains the address of a parameter list mapped by the list form of the IWMSCXIT macro instruction. The parameter list includes an indicator of the action the exit is to take and the connect token associated with the IWM4CON macro issued previously by the server.

The execute and standard form of IWMSCXIT are intended for use only by the operating system.

**Exit routine environment**

The server connect exit routine receives control in the following environment:

<table>
<thead>
<tr>
<th>Authorization</th>
<th>Supervisor state key 0</th>
</tr>
</thead>
</table>

Chapter 6. Using the routing manager services 85
### Dispatchable unit mode

SRB

### Cross-memory mode

PASN=HASN=SASN with the current home address space the same as when the server issued the IWM4CON macro instruction.

### AMODE

31-bit

### ASC mode

Primary

### Interrupt status

Enabled for I/O and external interrupts

### Locks

No locks held

### Serialization

It is possible for the exit to be called before the caller has received control back from IWM4CON. The exit or any program it drives (synchronously or asynchronously) must synchronize with the program issuing IWM4CON to ensure that IWM4CON has returned a connect token prior to issuing IWM4DIS (disconnect) or any other service that requires the connect token.

### Location

The server exit must be a resident routine callable from the server address space and must remain available after the server manager disconnects or after the termination of the server task which issued the IWM4CON. The exit need not persist after termination of the server address space.

The input parameter list is in pageable storage addressable in the primary address space, but should not be changed by the exit.

### Exit Recovery

The system may cause the server to become ineligible to be recommended by IWMRSFSV (find server) if there have been repetitive errors in calling the exit. The exit may optionally establish a functional recovery routine (FRR) or ESTAEX for any needed recovery or cleanup of its resources.

### Register usage

Upon entry to the exit, the register contents are as follows:

<table>
<thead>
<tr>
<th>Register</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Not defined</td>
</tr>
<tr>
<td>1</td>
<td>Address of the input parameter list</td>
</tr>
<tr>
<td>2-13</td>
<td>Not defined</td>
</tr>
<tr>
<td>14</td>
<td>Return address</td>
</tr>
<tr>
<td>15</td>
<td>Entry point address</td>
</tr>
</tbody>
</table>

Upon entry to the exit, the access register contents are undefined.

Upon return from the exit, the register contents are expected to be:

<table>
<thead>
<tr>
<th>Register</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code, if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1-14</td>
<td>Not defined (need not be restored to value on entry)</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

Upon return from the exit, the access register contents are unchanged.
Example

The following example shows how to invoke the IWMSCXIT macro instruction and the resulting parameter list mapping. This is the parameter passed to the routing server exit routine specified on the `SRV_MGR_EXIT` parameter of IWM4CON.

```asm
IWMSCXIT MF=(L,MYSCXITPL)
+MYSCXITPL DS 0D ++ IWMSCXIT PARAMETER LIST
+MYSCXITPL_XVERSION DS XL1 ++ INPUT
+MYSCXITPL_XRSV0001 DS CL1 ++ RESERVED

```
Chapter 7. Using the scheduling environment services

A scheduling environment is a list of resource requirements and their required states. It allows you to manage the scheduling of work in an asymmetric sysplex where the systems differ in installed applications or installed hardware facilities. If an MVS image satisfies all of the requirements in the scheduling environment associated with a given unit of work, then that unit of work can be assigned to that MVS image. If any of the resource requirements are not satisfied, then that unit of work cannot be assigned to that MVS image. See z/OS MVS Planning: Workload Management for information on using the WLM application to define scheduling environments.

Obtaining scheduling environment definitions

Use the IWMSEQRY service to obtain scheduling environment and resource definitions and status on each system in the sysplex. This service can be used by a program to produce alternative displays to those provided by the DISPLAY WLM command.

In Figure 20 on page 90, IWMSEQRY returns the resource requirements in the DB2LATE scheduling environment (DB2A must be ON, PRIME TIME must be OFF), and the resource state settings on each of the four systems in the sysplex. Because DB2A is set to ON and PRIME TIME is set to OFF on SYS2, that system is identified as the appropriate system for work associated with the DB2LATE scheduling environment.
Manipulating resource state settings

Use the IWMSESET service to change resource state settings. The resource state can be changed only on the system in which the program is executing.

The resource states can be set to:
- ON, which will satisfy a resource state requirement of ON.
- OFF, which will satisfy a resource state requirement of OFF.
- RESET, which will not satisfy any resource state requirement.

In Figure 21 on page 91, a program executing on SYS3 invokes IWMSESET to change the value of DB2A from OFF to ON. SYS3 now satisfies the DB2LATE
A model work flow

Figure 22 on page 92 shows how a multisystem work scheduler can use the IWMSEVAL and IWMSEDES services to implement support of scheduling environments.
In Figure 22, work request ZJOB9 is submitted and associated with the DB2LATE scheduling environment.

The scheduler calls the IWMSEVAL service to verify that the scheduling environment name is valid. If there is no such scheduling environment known to workload management, then the scheduler fails the work request. If the scheduling environment name is valid, then the scheduler accepts the work request.
The scheduler creates a queue element for the work request. The scheduling environment name is included in that queue element, as well as a resource affinity mask. For each system in the sysplex, IWMSEDES will indicate whether that system satisfies the scheduling environment in question. The scheduler can then build the resource affinity mask, which is simply a 32-bit string of ones and zeros. A one means that the system satisfies the scheduling environment, and a zero means that the system does not satisfy the scheduling environment. The scheduler must keep an ordered list of system names corresponding to the bit positions in the mask.

In Figure 22 on page 92 the resource affinity mask for DB2LATE reads 0100, because only SYS2 satisfies the DB2LATE scheduling environment.

Scheduling environment definitions and resource state settings can change at any moment. The scheduler must be aware of these changes so that it can adjust its decision making accordingly. The scheduler listens for two ENF event codes, 41 and 57, which signal these changes:

<table>
<thead>
<tr>
<th>Code</th>
<th>Event description</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>A new service definition has been activated.</td>
</tr>
<tr>
<td></td>
<td>When a new service definition is activated, resource names can be added to, or removed from, a scheduling environment. A particular scheduling environment or resource name may even have been deleted from the service definition altogether. (See note below.)</td>
</tr>
<tr>
<td>57</td>
<td>A scheduling environment has changed state on a system.</td>
</tr>
<tr>
<td></td>
<td>Either it was previously not available and is now available, or vice versa.</td>
</tr>
</tbody>
</table>

For more information about ENF, see z/OS MVS Programming: Authorized Assembler Services Guide.

For either event, the scheduler must reevaluate the status of each work request on the queue. It must rebuild the resource affinity masks to reflect the new scheduling environment definitions or the new resource state settings.

If a scheduling environment no longer exists, the scheduler can either delete the associated work requests or place them in a hold state for installation action. The latter choice is appropriate if it is important for the installation to be able to recover the work requests. The installation could recover by installing a new service definition that includes the deleted scheduling environment.

The final step in this work flow is when the work request moves from the queue to the appropriate system for execution. In Figure 22 on page 92 the ZJOB9 work request is scheduled on SYS2, as that is the only system that satisfies the DB2LATE scheduling environment.
Chapter 8. Using the sysplex routing services

The sysplex routing services allow work associated with a server to be distributed across a sysplex. They are intended for use by clients and servers.

A client is any application or product in the network that requests a service. The service could be a request for data, a program to be run, or access to a database or application. In terms of the sysplex routing services, a client is any program routing work to a server. A server is any subsystem address space that provides a service on an MVS image.

The sysplex routing services provide the following functions:
- The IWMSRSRG macro lets a caller register as a server.
- The IWMSRSRS macro provides a caller with a list of registered servers and the number of requests that should be routed to each server.
- The IWMSRDRS macro lets a caller deregister when it is no longer available as a server.
- The IWMSRDNS macro provides the caller with list of location names for all registered servers known to the system on which the service is invoked.
- The IWM4SRSC macro provides the caller with server-specific information about the performance and capacity of a specific server before work gets routed to it from WLM. This information can be used for balanced routing decisions.

Why use the sysplex routing services?

The sysplex routing services enable distributed client/server environments to balance work among multiple servers. These services help the distributed programs make the routing decisions, rather than having each installation have to make the decisions.

The sysplex routing services provide information for more intelligent routing. They do not route or distribute work requests. The server must use its existing routing mechanisms.

When to use the sysplex routing services

When a server is available to receive work requests, it issues the IWMSRSRG macro to register. You should issue IWMSRSRG once per initialization of a server. The system makes this information available asynchronously to all MVS images in the sysplex.

When a client wants to route work to a server, it issues the IWMSRSRS macro for a list of registered servers. To help the client decide where to route the request, IWMSRSRS returns the relative number of work requests that can be routed to each server in the list.

When a server is no longer available to receive work requests, it issues the IWMSRDRS macro to deregister. A server should issue IWMSRDRS once per address space termination.

The following section explains each of the services in more detail.
Registering as an eligible server

A server can use IWMSRSRG to register that it is available for receiving work requests. A server should issue IWMSRSRG at address space initialization time. The server identifies itself by a triplet consisting of the following:

- Location name
- Network id
- LU name

Servers with the same location name are considered to be related and to provide equal service. The server must also specify an address space token (STOKEN) identifying the server address space token. Because the propagation of registration to all systems in the sysplex is asynchronous, a newly registered server is not immediately available for selection on other systems.

For complete information about the IWMSRSRG macro, see “IWMSRSRG — Register a server for sysplex routing” on page 396.

Determining where to route work

The IWMSRSRS macro returns a list of eligible servers, and for each server, an associated weight. From this list, a client can determine where to route work. See z/OS MVS Data Areas, Vol 3 for the mapping.

The weights provided allow changes in system conditions and server availability to be factored into the distribution of work. The weights represent the relative number of requests each server should receive. Various capacity considerations are used to calculate the weights.

A client can route the work to the servers as ordered in the list, and can route the number of requests as suggested for each server. A caller should be aware of other clients in the sysplex issuing the IWMSRSRS macro, and route work properly.

For example, consider the following list of servers and weights:

<table>
<thead>
<tr>
<th>Server</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>NETID1.LUNAMEA</td>
<td>3</td>
</tr>
<tr>
<td>NETID2.LUNAMEB</td>
<td>8</td>
</tr>
<tr>
<td>NETID3.LUNAMEC</td>
<td>2</td>
</tr>
</tbody>
</table>

The client should route the first three requests to NETID1.LUNAMEA, the next eight to NETID2.LUNAMEB, and so on. When the client has gone through the list, the client can either invoke IWMSRSRS again for a refreshed list, or rotate through the list again.

Acceptable weights are from 1 to 64. If a server is busy and not available to receive any work requests, it will not appear in the list. If work is routed to the server and it is not able to process the request, the request is not processed.

Clients should issue this macro on a regular basis, so that the list is refreshed every one to three minutes. This way, a client can stay current with changing system loads and server viability.

For complete information about the IWMSRSRS macro, see “IWMSRSRS — Sysplex routing information” on page 405.
Deregistering as an eligible server

When a server is no longer available for processing work, the server should issue the IWMSRDRS macro to deregister. A server should issue IWMSRDRS at address space termination. This makes the system aware that the server is no longer a candidate for future work requests, and can remove it from the list of eligible servers.

For complete information about the IWMSRDRS macro, see "IWMSRDRS — Deregister a server for sysplex routing" on page 382.

Example of using the sysplex routing services

Figure 23 shows an example of the sysplex routing services.

In the figure, there are three servers, and one client program. Each of the servers registers at address space initialization using the IWMSRSRG macro. Suppose the first server registered, with the following defined:

LOCATION1 DS CL18 location
NETWORKID1 DS CL8 network id
LU NAME1 DS CL8 LU name
STOKEN1 DS CL8 token of server address space

The first server uses the IWMSRSRG macro as follows:

IWMSRSRG LOCATION=location1,
NETWORK_ID=networkid1,
LU_NAME=luname1,
STOKEN=stoken1

Meanwhile, the client program wants the list of address spaces available for processing work. The client issues IWMSRSRS once for the length of the area required for the list. The length required is in the QUERYLEN output parameter. The client issues:

Figure 23. Example of using sysplex routing services
IWMSRSRS SYSINFO_BLOCK=sysinfo_block,
    ANSLEN=anslen,
    QUERYLEN=querylen,
    LOCATION=location

Note: The QUERYLEN value is a snapshot taken when IWMSRSRS is issued. That value can change between calls due to other servers registering. To compensate, it is recommended that you add a few entries extra length to the size resulting from the first IWMSRSRS call.

The client then obtains the required amount of storage, and issues IWMSRSRS again for the list of eligible servers and their weights:
IWMSRSRS SYSINFO_BLOCK=sysinfo_block,
    ANSLEN=anslen,
    QUERYLEN=querylen,
    LOCATION=location

The caller receives the list, mapped by IWMWSYSR, as follows:

<table>
<thead>
<tr>
<th>Server</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>NETID3.LUNAME3</td>
<td>4</td>
</tr>
<tr>
<td>NETID1.LUNAME1</td>
<td>6</td>
</tr>
<tr>
<td>NETID2.LUNAME2</td>
<td>2</td>
</tr>
</tbody>
</table>

The client routes the first 4 work requests it receives to NETID3.LUNAME3, the first in the list. The client routes the next 6 requests to NETID1.LUNAME1, and then the following 2 to NETID2.LUNAME2. The client opted to issue the IWMSRSRS macro every three minutes. Once the client has received 12 requests, it will route the 13th through the 16th requests to NETID3.LUNAME3, and go down the list again until the three minutes are over.

**WLM sysplex workload distribution**

When WLM is called by DNS or sysplex distributor for advice on where to route work in a sysplex, WLM returns a list of eligible servers with a weight assigned to each server. Work is then routed to the server proportionally to its weight so the higher weight servers receive more work. For example, if four servers A, B, C, and D are returned by WLM with weights of 2, 2, 4, and 8 respectively, DNS will route one-eighth of the requests to each of servers A and B, one-fourth of the requests to server C, and one-half the requests to server D.

The weights are calculated as follows. WLM first assigns a weight to each system, with a higher weight to systems with the most available capacity. The weights are proportional to the amount of available capacity on each system. Then WLM divides the weight for a system equally among the registered servers on that system. In the case of DNS, there can be multiple servers registered with WLM per system image. For sysplex distributor, however, the WLM server registration is done by the TCP/IP stack so there is only one server per system image. This means the server weight always equals the system weight for sysplex distributor. If all systems are running at or near 100% utilization, then higher weights are given to the systems running less important work. The objective is to send work where there is available capacity or, if there is no available capacity, where the least important work will be displaced. Servers on systems that are in a serious storage shortage (SQA, fixed frame, auxiliary storage) are not recommended unless all systems are in a shortage.
Calculation of server weights

The basis for WLM's weight calculation is the CPU consumption table (see Table 18) for each goal-mode system in the sysplex. More than half of the systems in the sysplex need to be in goal mode for WLM to calculate weights. Otherwise, all weights are set equal to one. The table has one row for each level of work in the system. The levels are:

**Level** | **Usage**
---|---
0 | Service consumed by the system
1-5 | Externally defined importance levels
6 | Discretionary work
7 | Unused service (equivalent number of service units)

Each row contains the following fields:

- Number of service units (SUs) consumed in three minutes at the given importance level and below.
- Percentage of total capacity consumed in three minutes at given importance level and below. For example, Level 4 in the table has the service units consumed by importance 4, importance 5, and discretionary work plus unused capacity.)

WLM calculates weights as:

1. WLM scans the rows in the table in reverse starting with Level 7 until it finds a level where one or more systems have at least 5% cumulative service units of capacity. WLM then uses this table level for all goal mode systems to assign relative weights.

2. WLM calculates a system weight for each system in the sysplex using the SU value in the selected row in the table, as:

\[
\text{System weight} = \frac{\text{SUs for this system at selected level} \times 64}{\text{total SUs for all systems at selected level}}
\]

3. WLM calculates a server weight, as:

\[
\text{Server weight} = \frac{\text{System weight}}{\text{number of servers on system}}
\]

Example

For this example, consider the consumption table shown in Table 18.

<table>
<thead>
<tr>

<tr>
<td>7</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
There are three goal-mode systems in the sysplex, all running at 100% CPU utilization. Each system has two DNS servers running for a particular application. To assign weights to the three systems, WLM scans the CPU consumption table from the bottom up, looking for a level where at least one system has 5% or greater cumulative CPU consumption.

In this case, the Level 5 row is used because System A exceeds the 5% minimum (and so does System B). Level 5 is then used to calculate the weight for all systems including System C. So, the system weights are determined by the amount of importance 5 and discretionary work each system is running. Because there are two servers on each system, the server weight is the system weight divided by 2.

<table>
<thead>
<tr>
<th>System weight</th>
<th>Server weight</th>

</tr>
<tr>
<td>System B weight = 400 × 64 / 640 = 40</td>
<td>Server weight = 40 / 2 = 20</td>
</tr>
<tr>
<td>System C weight = 40 × 64 / 640 = 4</td>
<td>Server weight = 4 / 2 = 2</td>
</tr>
</tbody>
</table>

The IWMSRSRS service supports the function code SPECIFIC, which allows for calculated weights to also take the server-specific information into account. If the IWMSRSRS service is called with FUNCTION=SPECIFIC, then the weight calculated as previously described is additionally multiplied by a Performance Index (PI) factor and a queue time factor. The value of these two factors is calculated as:

**PI factor**

is 1 if the server has a PI <= 1, which means that it achieves its goals. The PI factor will become < 1 if the PI indicates that the server does not achieve its goal.

**Queue time factor**

becomes < 1 if the server is the owner of enclaves and those enclaves have reported queue times relative to their total elapsed times. This means that their arrival time differs from the enclaves create time, when the enclave was created.

A *health factor* is also multiplied into the weight calculation. The health factor is set for the server address space either by the IWMSRSRG registration service or by the IWM4HLTH health service. For more information about these services, see to “IWMSRSRG — Register a server for sysplex routing” on page 396 and “IWM4HLTH — Setting server health indicator” on page 535.
Chapter 9. Using the workload reporting services

The workload reporting services are intended for monitoring or reporting products to collect performance data. They replace some of the existing methods of collecting data, and provide a means to collect data for the goal-oriented processing with the service policy.

When to use the workload reporting services

Because the data collection is cumulative, performance monitors can collect information based on their own reporting intervals. But the collection is stopped and re-started when a significant change occurs in workload management, such as when a new policy is activated, or a system failure occurs. Performance monitors should “bookend” their intervals when such a significant change occurs in workload management. For each of these events, event notification facility (ENF) signals are issued. SRM samples the states of address spaces, and an ENF signal is issued when a new set of samples is available. The performance monitor can use the ENF signals to guide its reporting interval. For example, when an ENF code for a new policy activation is issued, the performance monitor can end its last reporting interval, and start the next reporting interval for the newly activated service policy.

To enable the performance monitor to know when a workload reporting change is taking place, such as when a policy is activated, there is a ENF system event code. ENF event code 41 and its related qualifiers indicate when changes are taking place related to service policies. ENF code 41 guides the performance monitor’s reporting intervals, and helps it to issue the services at the appropriate times.

Using ENF signals to guide data collection

Because all performance data is continually collected until a significant change takes place in workload management, the performance monitor must know when the collection is reset. Workload management resets its collecting when:

- A service policy is activated (VARY WLM, POLICY)
- A system error occurs

ENF signals are issued for these events, and for each ENF, a listener is notified synchronously at the start of a change, and at the completion of a change. There is an ENF code qualifier indicating a change started, an ENF code qualifier indicating a change completed, and an ENF code qualifier indicating a change has failed.

When a change is started, workload management captures a last copy of workload data. The performance monitor can listen for the “start” event code, and then invoke IWMRCOLL to get the last available data. The workload data remains the same until either the change completes, or the change fails. Based on the “start” event code, the performance monitor should save this data, end its current interval, and wait for the next code.

Note: Because the ENF signal is issued synchronously, the listener should complete processing as quickly as possible. For example, if the ENF is issued broadcasting the start of policy activation, the policy activation is held up until all listeners for that ENF have relinquished control.
If the change is completed, the performance monitor should invoke the proper services, as shown in Table 19. A performance monitor should always complete its last interval with the data collected when it received the “start” event code. If the change failed, the performance monitor can continue to use the data it saved when it received the start event code. Regardless of whether the event has completed or failed, the performance monitor should reinitialize all of its workload activity information. Then the performance monitor should issue:

- IWMPQRY for a copy of the active policy
- IWMRCOLL for workload activity information

This way, the performance monitor does not need to do two different things for completions and failures.

There is also an asynchronous ENF signal issued when the IWMWRQAA information is available. That way, a performance monitor can synchronize its sampling interval for address space states with workload management's sampling interval.

**ENF event code 41**

Table 19 shows the ENF event code and its qualifiers. The table also outlines what a performance monitor could do when the ENF code is heard.

<table>
<thead>

Using the IWMRCOLL service

The IWMRCOLL service allows a performance monitor to obtain a variety of performance data from a single system. Although IWMRCOLL provides information about a single system, the performance monitor can combine the information to provide a sysplex view.

Table 20 shows how you can use the workload reporting services together with IWMRCOLL to get workload activity information on a single system. "Using the information in IWMWRCAA" explains how to use the information returned by IWMRCOLL.

</table>

Using the information in IWMWRCAA

By using IWMRCOLL, a performance monitor can obtain the following kinds of information:

- Resource consumption information
- Response time and distribution information, and special reporting data
- General delay information
- Subsystem work manager delay state information
The information that is provided is mapped by the IWMWRCAA data area. Information is returned on a service class and report class basis. "Using the subsystem work manager delay state information" explains how to use the response time data and the subsystem work manager delay state information.

Header data
The header data present in the RCAA consists of:
- Data specific to the workload management mode in effect, such as which service policy is active.
- General information such as bookkeeping information.

Resource data
Resource information is available for address spaces and there is a distinction between transactions and server address spaces. A server address space is any address space that does work on behalf of a transaction manager or a resource manager. For example, a server address space might be a CICS AOR, or an IMS™ control region. Service classes that represent CICS or IMS transactions, as opposed to address spaces, have no resource data. The resources that are being consumed by such transactions are reported in the service class of the server address space.

Delay data
There are two types of delay information that is returned by IWMRCOLL: general execution delays, and subsystem work manager delays. All data is sampled.

The general execution delays are address space oriented while the subsystem work manager execution delays are service class oriented. They show delays that are encountered by service classes that represent transactions. The subsystem work manager execution delays are in the subsystem work manager state samples section of IWMWRCAA. The state samples are available only for subsystem work managers that use the execution delay monitoring services.

To assist in determining whether a service class has execution delay state sampling information, the header data indicates which type of delay information is available for a service class. You can use address space delay data to calculate execution velocity.

Response time data
There is response time information and response time distributions for transactions. Both are reported for service classes and report classes.

You can calculate average response times by using the information that is provided in this section. Total completed transactions (both normal and abnormal) are provided, as well as total transaction completion time. This same information is available for the execution phase of transactions.

In addition, special reporting data is provided for service and report classes.

Using the subsystem work manager delay state information
The delay information in IWMWRCAA represent delays encountered by subsystem work managers as they process transactions. Workload management can recognize those address spaces that process transactions on behalf of the transaction managers. Such address spaces are called server address spaces. Workload management manages the server address spaces to achieve the goals of the transactions the server is processing. If a server address space is managing more than one service class, workload management manages the address space to meet...
the most stringent service class goal. However, resource consumption and address space delays for server address spaces are reported in the server's service classes.

The delay information shows the different states server address spaces experience while processing transactions. The information is provided on a service and report class basis, in the service or report class representing the transactions. This way, the delay states show for the transactions being processed, not for the address spaces serving the transactions. The states include how many times the service or report class was seen active, ready, and waiting. There are several waiting states. Each of these is reported separately. Some other states include whether the transactions are continued somewhere else in the system, in the sysplex, or in the network.

**Using the continued state information**

The state information helps a performance monitor show a picture of how well transactions are being processed. Because multiple address spaces can be involved in processing a transaction, a delay could occur in any of several places. IWMWRCAA provides state information to help a performance monitor pin down when transactions experience delays. The states show whether a service class has continued:

- In the local system
- In the sysplex
- In the network

With the cooperation of the participating subsystem work managers, the information reported divides the life span of transactions into two phases: a begin-to-end phase, and an execution phase. A begin-to-end phase shows transaction states from the time the subsystem work manager receives a transaction, processes it, and ends it. An execution phase shows transaction states only during the time a subsystem work manager processes the transaction. Delay states may not always appear in each phase. It depends on how a subsystem work manager is reporting the delays it encounters while processing.

For example, for CICS transactions, delay states are recorded from the time the TOR receives the transaction and begins processing, through the time the transaction is processed in the AOR, FOR, or elsewhere, and ended back in the TOR. The phase where the TOR receives the transaction, and ends it is called the begin-to-end phase. The phase where the transaction moves into the AOR, FOR, or elsewhere and is processed is called the execution phase.

The delay states for both the begin-to-end and the execution phase are reported together in the service class of the CICS transactions processed. For example, Figure 24 on page 106 shows the delay states sampled for both begin-to-end phase and the execution phase for one CICS service class representing CICS transactions.

If the execution phase occurs on the same MVS image as the begin-to-end phase, then (barring some statistical anomalies), the amount of time the service class spends in the continued - LOCAL state of the begin-to-end phase should approximately equal the amount of time the service class spends in the execution phase.
The execution phase could be in the same system as the begin-to-end phase, but could also be on another system in the sysplex, or in the network.

By combining the information collected on each system for a given service class, the performance monitor can resolve the states where the transactions in the service class continued elsewhere in the sysplex. For transactions continued elsewhere in the network, workload management cannot know any more information. Only the count of how many were switched out through the network is provided.

Figure 24 shows how the performance monitor could view the state information to provide a sysplex view. In this example, the states are reported for the CICSFAST service class. In this example, the number of samples of transactions continued somewhere in the sysplex should equal the number of transaction states sampled in the sysplex (summed from each system in the sysplex). The performance monitor can combine all the state data from all the systems in the sysplex to provide a sysplex view, correlating the data by service class.

Figure 24. Using states for presenting CICS delay information

The execution phase could be in the same system as the begin-to-end phase, but could also be on another system in the sysplex, or in the network.

By combining the information collected on each system for a given service class, the performance monitor can resolve the states where the transactions in the service class continued elsewhere in the sysplex. For transactions continued elsewhere in the network, workload management cannot know any more information. Only the count of how many were switched out through the network is provided.

Figure 25 on page 107 shows how the performance monitor could view the state information to provide a sysplex view. In this example, the states are reported for the CICSFAST service class. In this example, the number of samples of transactions continued somewhere in the sysplex should equal the number of transaction states sampled in the sysplex (summed from each system in the sysplex). The performance monitor can combine all the state data from all the systems in the sysplex to provide a sysplex view, correlating the data by service class.
Using delay states to report subsystem interactions

Not only are multiple address spaces involved in processing transactions, but those address spaces may be part of different subsystems. For example, a CICS TOR may give control to a CICS AOR who in turn may do a query to IMS DLI. Workload management can keep track of subsystems that communicate with each other, and provides the information so that a performance monitor can present the subsystem interactions in processing transactions.

The CICS transaction used in the previous example has a begin-to-end phase and an execution phase. The execution phase could be split among several subsystems, and the delays associated with each distinct subsystem are reported separately. The performance monitor should combine all information by service class by subsystem to provide a sysplex view.

Delay data are presented for as many distinct subsystems as participated in processing each service class. The data are available for both the begin-to-end phase and the execution phase.

A performance monitor could provide a timeline with the various pieces and phases of the work represented differently. In Figure 26 on page 108 the performance monitor sees that the biggest delays encountered are in the Waiting state and the Continued Local state. The performance monitor could show further information about the Continued Local states by presenting the information found in the execution phase on that system.
In the example, the performance monitor shows that there are execution delays attributed to **Active**, **Waiting**, and **Continued** states. Notice that of the 35 delay states reported in the original display as being **Continued Local**, only 33 of them show up in the execution phase. This is one of the shortcomings of sampling.

In Figure 27, there are two subsystems represented in the execution phase. This means that during this interval, both subsystem A and subsystem B performed work on behalf of service class xyz. Again, notice that there is 1 state sample missing due to statistical anomalies. The performance monitor could determine the specific reason for subsystem B **Waiting** states from the delay states.
Using the response time information

To provide a picture of how a performance group was performing, SRM previously reported total transaction time for use in calculating standard deviation. This information is provided for transaction execution time. Response time distributions are provided for both service classes and report classes.

These distributions consist of 14 buckets of information. There is a header explaining the contents of the buckets that is provided once. The header contains the value of the particular bucket, which is a percentage of the specified goal (that is, 50 equates to 50% of the goal; 150 equates to 150%, of the goal). One bucket always maps exactly to the specified goal, with a value of 100%.

In each bucket is the number of transactions that completed in the amount of time that is represented by that bucket.

In Table 21, each of the 14 buckets represents a percentage of the specified 1-second goal. For instance, bucket 2 represents all transactions that completed in 50% to 60% of the goal, or 500 - 600 milliseconds, while bucket 8 contains the number of transactions that completed in 110% to 120% of the goal, or 1.1 to 1.2 seconds. Notice that bucket 6 falls exactly on the goal (100% of goal, or 1 second). This bucket captures all those transactions that complete in 900-1000 milliseconds.

The two end buckets (buckets 1 and 14) have special meaning. Bucket 1 contains the total number of transactions that completed in up to 50% of the goal. Bucket 14 contains the number of transactions that completed in greater than 4 times the goal.

In addition to the response times, special reporting data is available in this section for service and report classes. With classification rules, you can associate your work with a special reporting attribute. This attribute can be used to report on subsets of transactions that are running in a service or report class. For more information, see the topic on defining special reporting options for workload reporting in z/OS MVS Planning: Workload Management. Special reporting data for a service or report class contains service consumption on general-purpose processors and offload engines for each value of the reporting attribute. In contrast to other data in the IWMWRCAA answer area, these values might not be cumulative. Due to reaccounting of transaction processor usage that arises from the WLM execution delay monitoring services, values might shrink from one invocation of IWMRCOLL to the other.

Interpreting report class data

Through classification rules WLM allows you to associate transactions with report classes for reporting purposes only. Report classes can be used to report on a subset of transactions running in a single service class but also combine
transactions running in different service classes within one report class. In the first case a report class is called homogeneous, and in the second case it is called heterogeneous.

Before z/OS V1R2, WLM only returned a report class summary.

Since z/OS V1R2 WLM returns report class periods. A report class period is homogeneous if there is only one service class found contributing to this report class period in a given report interval. To allow a reporting product to determine whether a report class period is homogeneous in its reporting interval, WLM offers two indicators returned by IWMRCOLL:

**mixed-class-indication timestamp**
This timestamp indicates when workload data associated with a different service class last contributed data to a report class period that was currently collecting data from another service class (see Figure 28).

**service class index**
This index indicates the last service class whose data was collected in the report class period.

Figure 28 illustrates the concept of the mixed-class-indication timestamp in relation to the time interval in which a caller collects workload data.

A caller invokes IWMRCOLL twice in order to get interval data, first at time t₀ to start the interval and second at time t₁ to end collecting data. With the second invocation at t₁, the caller gets back the mixed-class-indication timestamp. If the returned timestamp is ≥ t₀, as it is for caller 1, it means that transaction data from a different service class started contributing data to the same report class period. The report class is heterogeneous. If the returned timestamp is outside the interval (smaller than t₀), as it is for caller 2, it means that the report class remained homogenous during the calling interval.

Being able to see that a period is homogeneous allows the reporting product to format response time distribution buckets and work manager delay data for this
period while it would not report this data for a heterogeneous period. If the timestamp indicates that the report class is heterogeneous, it is recommended to collapse the periods which means to report the data as if the report class had only one period.

**Using the IWMIRQRY service**

The IWMIRQRY service provides sampled data on address spaces including:

- Address space state samples
- Server information

To see when an address space is serving more than one service class, information is provided for server address spaces in the general execution delay portion of the IWMWRCAA. This information includes:

- The service classes being served by an address space.
- The number of samples of address spaces serving a particular service class.

For example, address space ACSFOR1 is seen serving service class CICSSLOW 60 times, and service class CICSFAST 40 times.

The data returned is mapped by the IWMWRQAA data area. It represents the data collected during one sampling interval, an instantaneous, non-cumulative snapshot of the address space. The data is not tied to a particular job. Products using IWMIRQRY must decide whether to accumulate this latest state data with prior samples.

An asynchronous ENF signal is issued whenever a new copy of IWMWRQAA information is available. The performance monitor can use the ENF signal to determine when to issue IWMIRQRY.

Table 22 shows a sample sequence of what to do to get address space information using IWMIRQRY.

**Table 22. Using IWMIRQRY with the workload reporting services**

Chapter 10. Using the administrative application services

This information explains how to use the administrative application services. The services are intended for programs which provide an interface to define and edit a service definition. They include:

- IWMDINST, which allows a program to install a service definition on the WLM couple data set.
- IWMDEXTR, which allows a program to extract a service definition from the WLM couple data set.
- IWMPACT, which allows a program to activate a service policy.
- IWMCQRY, which allows a program to query the classification rules in effect.

For information about service definition concepts, see z/OS MVS Planning: Workload Management.

Installing a service definition

The IWMDINST macro allows a program to install a service definition onto a WLM couple data set. The service definition is moved onto the WLM couple data set as an area of storage, mapped by the IWMSERVD macro.

Mapping a service definition

The service definition is installed and extracted from the WLM couple data set either in XML format, or as a data area mapped by the IWMSERVD mapping macro. The XML structure is defined by the DTD described in Appendix C, “Structure of the XML service definition (DTD),” on page 817. The IWMSERVD macro points to the following sections:

- **IWMSVDEF**
  Maps the following service definition information:
  - Service policies
  - Workloads
  - Service classes
  - Report classes
  - Resource groups
  - Service definition coefficients

- **IWMSVDCR**
  Maps the service definition classification rule information.

- **IWMSVNPA**
  Maps the service definition notepad area.

- **IWMSVAEA**
  Maps the service definition application environments.

- **IWMSVSEA**
  Maps the service definition scheduling environments.
Adding program-specific extensions to a service definition

A program can add program-specific information to the service definition. For example, suppose you want to add a kind of reporting extension to a workload. In your program, you allow the service administrator to define this extension when defining workloads.

You can add extensions to each of the following:
- Service definition
- Service policies
- Workloads
- Service classes
- Service class attributes
- Report classes
- Resource groups
- Resource group attributes
- Application environments
- Scheduling environments
- Scheduling environment headers
- Scheduling environment resources
- Classifications
- Resources

Extensions can be specified in an XML service definition. For service definitions mapped by IWMSERV, a program can add extensions to IWMSVDEF, IWMSVDCR, IWMSVAEA, and IWMSVSEA. The following example illustrates extensions to IWMSVDEF. IWMSVDCR, IWMSVAEA, and IWMSVSEA all have roughly similar structures, and are extended in much the same way. For more details on these other structures see z/OS MVS Data Areas, Vol 3 or see the individual prologs for those macros.

To add the extensions to the service definition structure, the program must update the following fields in IWMSVDEF:

- **SVDEF_EXT_DATA_OFF**
  The offset to the extension data, from the beginning of IWMSVDEF

- **SVDEF_EXT_DATA_LEN**
  The total length of the extension data, from the beginning of IWMSVDEF

For each part of the service definition with extensions, the program must update IWMSVDEF with the following:
- The offset to the extension entries from the beginning of IWMSVDEF
- The number of extension entries
- The length of the extension entries

Each entry must have the following fields filled in:

- **SVDEFVID**
  Identifier of the product adding the extension.

- **SVDEFROB**
  The name of the related object. For example, if you are adding an extension to a service class, this field should contain the service class name.

- **SVDEFEPN**
  Related policy name, if the extension is for a service class or resource group. Otherwise, leave this field blank.
SVDEFEDL
The length of the extension data.

SVDEFEDO
The offset to the extension data.

**Example of service definition extensions**

Figure 29 shows the structure of IWMSVDEF for a service definition with extensions to workloads. In the example, there are two workload entries, and therefore two workload extensions. Remember that IWMSERVD points to the IWMSVDEF mapping macro.

![IWMSVDEF mapping for a service definition with workload extensions](image)

The program adding the workload extensions has updated the following fields in IWMSVDEF:

**SVDEF_WD_EXT_OFF**
The offset to the workload extension data header from the beginning of IWMSVDEF.

**SVDEF_WD_EXT_NUM**
The number of workload extension entries

**SVDEF_WD_EXT_SIZ**
The size of the workload extension entries

**SVDEF_EXT_DATA_OFF**
The offset to the beginning of the extension data, from the beginning of IWMSVDEF.

**SVDEF_EXT_DATA_LEN**
The total length of the extension data, not including the length of the extension entries.
For each extension, the program must create an entry with the following fields:

**SVDEFVID**
- Identifier of the your product.

**SVDEFROB**
- The name of the workload related to this extension.

**SVDEFEPN**
- Leave this field blank. Because this is a workload extension, it applies to all policies.

**SVDEFEDL**
- The length of the extension data.

**SVDEFEDO**
- The offset to the extension data from the start of the extension data.

**Maintaining the service definition**
Make sure your program maintains the service definition data structure. For example, your program has added an extension to service classes, and the service administrator deletes that service class, then your program must ensure that the service class extension is also deleted.

In order for customers to allow for the extra space this information may take up on the WLM couple data set, there are new keywords on the JCL utility to allocate a couple data set. If your program intends to use the service definition extensions, you should make sure customers know how to factor the extensions into the size of the WLM couple data set. For information about how a service administrator allocates a WLM couple data set, see [z/OS MVS Planning: Workload Management](https://www.ibm.com/support/docview/ittruemvsexciteid=SG24-6194).

**Checking a service definition using IWMDINST**
Before installing a service definition on the WLM couple data set, the IWMDINST macro checks to make sure the service definition is valid. For example, your program has added an extension to service classes, and the service administrator deletes that service class, then your program must ensure that the service class extension is also deleted.

In order for customers to allow for the extra space this information may take up on the WLM couple data set, there are new keywords on the JCL utility to allocate a couple data set. If your program intends to use the service definition extensions, you should make sure customers know how to factor the extensions into the size of the WLM couple data set. For information about how a service administrator allocates a WLM couple data set, see [z/OS MVS Planning: Workload Management](https://www.ibm.com/support/docview/ittruemvsexciteid=SG24-6194).

All data in a service definition must be valid to allow for the system to complete the installation. If the IWMDINST macro finds an error during parsing or validity checking, it issues a reason code in the `VALCHECK_RSN` parameter. IWMDINST also returns the offset to indicate where an error was found in the IWMSVDEF mapping macro or the XML string, respectively. Note that no valid offset is returned in case the service definition type is XML and the primary reason code returned is `xxxx083d`. IWMDINST identifies no more than one error per call.

[Appendix B. “Application validation reason codes,” on page 801](https://www.ibm.com/support/docview/ittruemvsexciteid=SG24-6194) contains a list of the reason codes, and their explanations. Table 23 shows an example of the information provided for reason code 1B01.

<table>
<thead>
<tr>
<th>Section</th>
<th>Reason</th>
<th>Offset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVDCRSST</td>
<td>1B01</td>
<td>entry</td>
<td>Service class for the subsystem type (SVDCRSCN) not found in the SVDEF</td>
</tr>
</tbody>
</table>

Table 23. SERVD validation reason codes

In this example, IWMDINST returned a reason code of 1B01 in the `VALCHECK_RSN` parameter. The error is in the SVDCRSST section of IWMSVDCR, and is in a
subsystem type entry. IWMDINST found a service class in the classification rules for the subsystem type that was not defined in the service definition. Your program could check the service definition for the undefined service class name, and could issue a message to the service administrator.

**Recommended validity checking**

In addition to using the validity checking provided by IWMDINST, a program should check for additional errors not covered by IWMDINST.

Your program should check the following conditions not checked by IWMDINST:

- No workloads defined.
- No service classes defined.
- The response time goal for a service class period does not exceed the response time goal for the previous period.
- Duplicate service class or resource group names. The names must be unique within a service definition.
- Some rule within a subsystem type refers to a service class, but there is no default service class specified for the subsystem type. If a subsystem type has classification rules defined, then there must be a service class default defined.
- A qualifier type is repeated in a sub-rule for a subsystem type in the classification rules. Only qualifier type longer than 8 characters can be repeated in a sub-rule.
- The classification rules for a subsystem type refer to a service class with multiple periods, but that subsystem type does not support multiple periods. The subsystem types which support multiple periods are JES, ASCH, OMVS, STC, TSO, and DDF.
- The classification rules for a subsystem type refer to a service class with a resource group, but that subsystem type does not support resource groups. The subsystem types which support resource groups are JES, ASCH, OMVS, STC, TSO, and DDF.
- An unreferenced classification group. The service administrator defined a classification group, but did not use it in the classification rules.
- The classification rules for a subsystem type refer to a qualifier type not supported by the subsystem type. For a list of the qualifier types supported by each subsystem, see [z/OS MVS Planning: Workload Management](https://www.ibm.com/docs/en/zos-mvs). 
- Subsystem type does not support discretionary or velocity goals. Service class with a discretionary or velocity goal was referred to in the classification rules for that subsystem type. Subsystem types which support discretionary and velocity goals are: JES, ASCH, OMVS, STC, TSO, and DDF.

**Preventing service definition overlays**

Suppose a service administrator extracts a service definition from the WLM couple data set, makes some changes, and in the meantime someone else has extracted, changed, and reinstalled the service definition. If the first user installs the service definition, any changes the second user made will be overwritten. To prevent the service administrator from overwriting the service definition, a program can use:

- The **COND** parameter on IWMDINST
- The ENQ macro

**Using the COND parameter on IWMDINST**
The optional **COND** parameter lets a caller specify whether or not to install the service definition if the service definition has not been changed since it was
extracted from the WLM couple data set. IWMDINST determines whether the service definition has changed by checking a service definition identifier.

The service definition identifier consists of the service definition name, and the time and date the service definition was installed.

Use COND=YES to install the service definition only if the identifier of the currently installed service definition matches the base identifier passed in the IN_BASEID parameter. If the identifiers do not match, your program can issue a message stating that the service definition has changed since the last extract. The message can also ask the service administrator to confirm the installation.

Use COND=NO to specify that the input service definition should be installed unconditionally.

When the service definition has been successfully installed on the WLM couple data set, the system issues ENF signal 41. A program can use the ENF macro to know when a service definition has been installed. For more information about how to use ENF signals, see z/OS MVS Programming: Authorized Assembler Services Reference EDT-IXG.

Using the ENQ macro
To ensure that two service definitions are not installed simultaneously on the WLM couple data set, a program can use the ENQ macro. Programs can serialize installation of the service definition onto the WLM couple data set by obtaining an exclusive ENQ on:

```
QNAME
    SYSZWLM
RNAME
    WLM_SERVICE_DEFINITION_INSTALL
SCOPE
    SYSTEMS
```

For more information about how to use the ENQ macro, see z/OS MVS Programming: Authorized Assembler Services Reference EDT-IXG.

Example of using IWMDINST to install a service definition
Suppose you have coded an application to define and edit a service definition mapped by the IWMSERVD mapping macro. To install the service definition onto the WLM couple data set, do the following:

- Check the service definition data structure and whether there are any storage overlay problems. If there are any problems, have the macro return the location of the error in the service definition.
- Specify that the service definition is to be installed only if the service definition installed on the WLM couple data set has not changed since the last extract.

To install the service definition, you specify:

```
IWMDINST SERVD_AREA=(R4),
    PRODUCT_ID=ProductIdArea,
    QRY_BASEID=(R5),
    VALCHECK_RSN=ValcheckRsn,
    VALCHECK_OFFSET=ValcheckOffset,
    COND=YES,
```
Extracting a service definition

The IWMDEXTR macro allows a program to extract a service definition from the WLM couple data set. Once the service definition is extracted, then a service administrator can make changes.

A caller should issue IWMDEXTR specifying QUERYLEN to determine the amount of storage required for the service definition. The service definition returned by IWMDEXTR is not serialized against future installs, so the length returned could change before a caller can issue IWMDEXTR again. The caller should issue IWMDEXTR in a loop, checking return and reason codes, and obtain a larger storage area, if necessary.

Example of using IWMDEXTR to extract a service definition

To extract a service definition from the WLM couple data set, specify:

```
IWMDEXTR ANSAREA=(R4),
   ANSLEN=StorSizeForServd,
   QUERYLEN=QueryLenForServd,
   RETCODE=Module_Rc,
   RSNCODE=Module_Rsn,
   MF=E
```

- StorSizeForServd DS 1F Storage size for service definition
- QueryLenForServd DS 1F Query length for service definition
- Module_Rc DS 1F Return code
- Module_Rsn DS 1F Reason code

Activating a service policy

You can also activate a service policy from your application by using the IWMPACT macro. The caller must provide the name of the service policy to be activated in the SERVICE_POLICY=service_policy parameter. The specified policy must exist in the service definition installed on the WLM couple data set.
A single policy can be activated at any one time, and the policy is activated synchronously.

A caller can optionally request the name of the system where another policy activation is taking place by specifying `SYSTEM_NAME=system_name`. Therefore, if a previous IMWPACT request is being processed and a new IMWPACT request is issued, the new request is rejected with an appropriate return and reason code. This occurs regardless of whether the requests were issued on the same system or different systems in the sysplex. Control is not returned to the caller until the policy has been activated on all systems in the sysplex or for some reason the policy activation could not be completed.

**Example of activating a policy using IMWPACT**

To activate a service policy, and if another policy activation is in progress, have IMWPACT return the name of the system that activated the policy, specify:

```
IMWPACT POLICY_NAME=policy,
SYSTEM_NAME=system,
RETCODE=Module_rc,
RSNCODE=Module_rsn
```

Where the following storage areas are defined:

- `policy` DS CL8 The policy name
- `system` DS CL8 System name where another policy is activating
- `Module_rc` DS 1F Return code
- `Module_rsn` DS 1F Reason code

**Querying the active classification rules**

IWMCQRY lets a caller query the classification rules associated with the active service policy. The classification rules determine how incoming work is assigned a service class and/or report class. The data returned by this macro is mapped by IWMSVDCR. For a description of the IWMSVDCR macro, see *z/OS MVS Data Areas, Vol 3*.

Optionally, a caller can request the active service policy identifier by specifying the `POLICY_ID` parameter. This is the active policy containing the classification rules returned by this macro. The caller can then compare the service policy ID with the policy identification information returned by the IWMPQRY macro to ensure they are the same.

Some data sections in the IWMSVDCR data area may not be available through IWMCQRY. For example, the time stamps indicating when a classification GROUP was last updated and by whom may not be available. For a complete list of fields that are not available refer to IWMSVDCR as described in *z/OS MVS Data Areas, Vol 3*. The complete classification rules associated with a service policy are returned by the IWMDEXTR macro and mapped by IWMSVDCR.

A caller can use the classification rules together with the active service policy to determine the goals associated with incoming work. The service class goals are in the active service policy mapping returned by the IWMPQRY macro.

The information returned is not serialized upon return to the caller, and so may be out of date if a service definition was modified, installed, and a new policy activated.
Example of IWMCQRY

To query the classification information associated with the active policy, specify:

IWMCQRY POLICY_ID=(R7),
    ANSAREA=(R5),
    ANSLEN=anslen,
    QUERYLEN=qry_len,
    RETCODE=RCODE,
    RSNCODE=RSN

Where the following storage areas are defined:

anslen   DS  1F   Length of the answer area
qry_len   DS  1F   Length required for answer area
RCODE     DS  1F   Return code
RSNCODE DS  1F   Reason code
Chapter 11. Using SMF record type 99

SMF record type 99 provides detailed audit information for work run on z/OS. You can use the type 99 records for analyzing the performance characteristics of work. The records contain performance data for each service class period, a trace of SRM actions, the data SRM used to decide which actions to take, and the internal controls SRM uses to manage work. This can help you determine in detail what SRM is doing to meet your work’s goals with respect to other work, and the types of delays the work is experiencing.

You should write SMF type 99 records only when you want this detailed information. For general reporting and tuning information for a system, you can use SMF type 72 records.

SRM writes type 99 records for each policy interval, or approximately once every 10 seconds.

SMF type 99 records have the following subtypes:

**Subtype 1**
Contains system level data, the trace of SRM actions, and data about resource groups. A subtype 1 record is written every policy interval.

**Subtype 2**
Contains data for service classes. A subtype 2 record is written every policy interval for each service class if any period in the service class had recent activity.

**Subtype 3**
Contains service class period plot data. A subtype 3 record is written every policy interval for each service class if any period in the service class had recent activity and plot data.

**Subtype 4**
Contains information about a device cluster. A device cluster is a set of service classes that compete to use the same DASD devices. A subtype 4 record is written every policy interval for each device cluster in the system.

**Subtype 5**
Contains data about monitored address spaces. A subtype 5 record is written each policy interval for each swapped in monitored address space.

**Subtype 6**
Contains summary information about each service class period, including the resource control settings for the next policy interval. A subtype 6 record is written each policy interval.

**Subtype 7**
Contains summary information for the Enterprise Storage Server® (ESS) with Parallel Access Volume (PAV) feature. A subtype 7 record is written every third policy interval.

**Subtype 8**
Contains summary information for LPAR CPU management. A subtype 8 record is written each policy interval, when in LPAR mode.
**Subtype 9**

Contains summary information for dynamic channel path management. A subtype 9 record is written each policy interval.

Some fields are used as input to adjust the policy. Those fields contain the data collected during the policy interval just prior to policy adjustment. Other fields are altered when the policy is adjusted. Those fields contain the data resulting from the policy adjustment. For example, a service class period dispatch priority field contains the dispatch priority for the next policy interval not the dispatch priorities from the previous policy interval.

---

**When to start SMF record type 99**

A type 99 record is written every policy interval, which is frequent. The records contain the data, plots, and tables that SRM uses to assess the effects of changes. So you should write type 99 records only for a time period in which you want this detailed audit information.

**Starting SMF record type 99**

You specify the SMF type 99 record in the SMFPRMxx parmlib member under SUBSYS STC.

Because SMF type 99 records are written approximately every 10 seconds, you should write them only for certain time periods. If you use NOTYPE in your SMFPRMxx parmlib member, you should include type 99 in your NOTYPE list. For example:

```
SUBSYS(STC,NOTYPE(99))
```

If you use TYPE in your SMFPRMxx parmlib member, make sure you add type 99 only when you want this level of detail. For example, add:

```
SUBSYS(STC,TYPE(99))
```

You should have an SMFPRMxx parmlib member for general audit information that does not specify type 99, and another for detailed audit information that specifies type 99. This way, you can write the frequently written SMF record types, like SMF type 99, only when you need them.

The IRASMF99 mapping macro for this record is supplied in SYS1.AMODGEN.

---

**Identifying work in SMF type 99 records**

You can identify work in SMF type 99 records by:

- Service class name
- Service class performance period number
- Resource group name
- Address space name

This information is as defined in the service policy at the time the type 99 record was written.

**Identifying server service classes**

Some service classes are server service classes, that is they are service classes representing address spaces doing work on behalf of transactions. You can determine whether a service class represented in the subtype 2 period data is a
server by first checking the goal type in the service class period section. If the goal type is 0, indicating a system or server service class, you next check whether there are any server data entries. If there are entries, then the service class period is a server, and the server data describes the service classes being served by this server.

If the goal type is 0, and there are no server entries, then the service class is a system service class.

Identifying internal service classes

SRM groups some work not defined in the service policy into internal service classes. The internal service class names are:

$SRMDI\text{nn} - resource group discretionary

Contains all work in a resource group with a discretionary goal. There is one $SRMDI\text{nn} class per resource group with discretionary work.

$SRMDI00 - general discretionary

Contains all work assigned a discretionary goal, but not assigned a resource group. There is always one $SRMDI00.

$SRMDISC - SYSOTHER service class

Contains all work not otherwise assigned to a service class.

$SRMS\text{nnn} - server

Contains all address spaces serving the same set of service classes. That is, the server address space(s) could be serving more than one service class. For example, two AORs may be serving the same three CICS service classes. Those AORs make up one $SRMS\text{nnn} service class.

An address space can belong to one internal server service class, but can move from one class to another. The number of $SRMS\text{nnn} service classes depends on how many external service classes are served and by how many combinations of server address spaces.

$SRMDUMP - SDUMP

Contains only SDUMP.

$SRMBEST - best

Contains the special system component address spaces, unless they are explicitly assigned to a service class in the service policy. This includes the SYSTEM service class.

$SRMGOOD - good

Contains the STC subsystem type default work, if there was no default service class specified in the classification rules for STC in the service policy. This is the SYSSTC service class.

$SRMGOD1-5 - good

Contains the work defined for service classes SYSSTC1, SYSSTC2, SYSSTC3, SYSSTC4, and SYSSTC5. For more information, see [z/OS MVS Planning: Workload Management](https://www.ibm.com/support/knowledgecenter/SSEPGG_2.11.0/com.ibm.mvs.plan/vpln/using_vpln.html).

Interpreting trace table entries

Subtype 1 contains a trace table. The trace codes describe which action SRM took or is considering taking to process work. This section describes the SRM concepts reflected in the trace codes. For a list and a brief explanation of the trace codes, see Appendix A, “SMF type 99 action codes,” on page 775.
Policy adjustment

Policy adjustment is how SRM:

- Selects work to help
- Selects performance bottlenecks to address
- Selects which work should donate resource to help other work
- Assesses whether it is worth it to help work.

The purpose of policy adjustment is to meet service class and resource group goals. Policy adjustment is done approximately every 10 seconds.

Resource adjustment

Resource adjustment is how SRM keeps system resources effectively utilized. Resource adjustment detects and addresses underutilized resources, overutilized resources, and shortage conditions. SRM handles resource adjustment algorithms within the constraints set by the policy adjustment algorithms. Resource adjustment is done approximately every 2 seconds.

Receivers and donors

A receiver is the service class period SRM is considering helping. SRM helps only one receiver during each policy interval, although it may assess multiple receivers before finding one to help. A donor is a service class period that donates resources to the receiver. Multiple donors may donate multiple resources to a single receiver during one policy interval.

The resources to help the receiver may also come out of what is referred to as discretionary resources. Discretionary resources are those that can be reallocated with little or no effect on the system's ability to meet performance goals.

Service class periods other than receivers and donors can also be affected by changes. These service class periods are referred to as secondary receivers and donors. SRM may decide not to help a receiver due to minimal net value for either a primary or secondary donor. Action trace example on page 135 explains an example in which there are secondary receivers and donors.

If a service class period is being served by one or more address spaces, it is called the goal receiver or donor. It is the service class period with the response time goals. To help such service class periods, SRM must donate resources to the server address spaces. The service class period serving a service class is called a resource receiver or donor. SRM adjusts resources for the resource receiver/donor to affect the performance of the goal receiver/donor.

Performance index

Performance index is a calculation of how well work is meeting its defined goal. For work with response time goals, the performance index is the actual divided by goal. For work with velocity goals, the performance index is goal divided by actual.

A performance index of 1.0 indicates the service class period is exactly meeting its goal. A performance index greater than 1 indicates the service class period is missing its goal. A performance index less than 1.0 indicates the service class period is beating its goal. Work with a discretionary goal is defined to have a performance index of .81.
Each service class period has a sysplex and a local performance index. The sysplex performance index represents the performance of a service class period across all the systems in the sysplex. The local performance index represents only the performance on the local system.

Within resource groups and importances, receivers are selected in performance index order. Donors are selected in the reverse order of receivers. The sysplex performance index is the primary criteria used for selecting receivers and donors and assessing changes.

**Receiver value**
A receiver is helped only if there is projected to be sufficient *receiver value*. Receiver value is a minimum performance index improvement, a minimum group service increase, or other minimum criteria designed to reject very small improvements. The reason to reject actions for too little receiver value is to get on to addressing other problems for other service class periods rather than continuing to make changes that yield only marginal improvements for a few service classes.

**Net value**
A receiver is only helped by a specific donor if SRM projects sufficient *net value* to the resource reallocation. SRM calculates the net value and uses it to determine if using a donor to help a receiver results in more projected harm to the donor than projected improvement to the receiver. If so, the condition is traced, and another donor is selected. The net value assessment considers all external service policy specifications (resource group capacity minimums and maximums, importance, and goals) for both primary and secondary donors.

**Small processor consumer**
Service class periods that consume little or no processor time are referred to as *small processor consumers*. Under some circumstances these small consumers are assigned a relatively high dispatching priority and not assessed for dispatching priority changes.

**Storage housekeeping**
The purpose of *storage housekeeping* is to decrease storage targets that are out of date or ineffective. Storage housekeeping will only reduce a target if it will not affect the ability of work to meet goals. There are four types of storage housekeeping.

- **Time driven**
  Reduce target when the projected effect is small and the service class period will still easily meet goals

- **Minimal effect**
  Reduce target slightly when the projected effect is very small

- **Unassessable**
  Reduce target slightly when the projected effect cannot be determined but the service class period is meeting goals easily

- **Slow mode**
  Reduce target slightly when the projected effect cannot be determined but keep the target close to the current allocation
Reverse housekeeping

A second type of housekeeping known as reverse housekeeping increases targets if these targets are significantly less than the resources the service class period or address space already owns. The targets are increased by reverse housekeeping so that if there is a sudden increase in the demand for resources the service class period or address space will have some protection until the policy adjustment can reevaluate the situation.

Interpreting management policy data

This section explains the controls that SRM uses to manage work, and where these controls can be found in SMF type 99 records. SRM algorithms set all the control values internally. All changes to the control values have trace entries in the subtype 1 record.

The SRM controls are:
• Dispatching priority
• MPL targets
• Swap protect time
• Storage targets
• Cap slices
• I/O priority
• Number of server address spaces
• Buffer pool management data

They are shown in the subtype 1, subtype 2, and subtype 5 records.

Dispatching priority

SRM defines dispatching priority for service class periods. All address spaces in a service class period have the same base dispatching priority. Multiple service class periods may have the same base dispatching priority. After a dispatching priority change, service class periods may be remapped to different dispatching priorities such that there is an unoccupied priority between each occupied priority. This process is referred to as priority unbunching.

The dispatching priority is recorded in the subtype 2 records.

MPL targets

SRM defines an MPL-in and MPL-out target for each service class period. MPL-in target represents the number of address spaces that must be in the swapped-in state for the service class period to meet its goals. MPL-out target is the maximum number of address spaces allowed in the swapped-in state.

The MPL targets are recorded in the subtype 2 records.

Swap protect time

SRM defines swap protect time for service class periods. Swap protect time is the time in milliseconds swapped-out address spaces will remain in processor storage before becoming candidates for swap to auxiliary storage.

The swap protect time is recorded in the subtype 2 records.
Storage target
To manage central storage, SRM defines a storage target of protective central. This specifies the number of frames that are protected in central storage. The system will not steal storage below this value.

The storage target assigned depends on the service class period goal.

For short response time goals, the service class period gets a protective processor storage target. Every address space in the service class period has the same target.

For long response time, velocity, or discretionary goals, or for server internal service classes ($SRMSnnn), SRM may define individual storage targets for the address spaces in the service class period. Each address spaces may have one or more of each type of storage targets. Storage targets for individual address spaces are recorded in subtype 5, in the monitored address space information section.

Cap slices
SRM defines cap slices for resource groups to enforce resource group maximums. Work is not dispatched during its cap slices in order to reduce access to the processor to enforce the resource group maximum. Each cap slice represents 1/64th of total time. All address spaces in all service class periods in a resource group are controlled by the same number of cap slices.

The number of cap slices is recorded in the subtype 1 records.

I/O priority
SRM defines an I/O priority for each service class period. All address spaces in a service class period have the same I/O priority. Multiple service class periods may have the same I/O priority. I/O priority is used to prioritize requests on IOS's UCB queues.

The I/O priority is recorded in the subtype 2 records.

Number of server address spaces
SRM manages the number of server address spaces for users of the queueing manager services (see Chapter 5, “Using the queueing manager services,” on page 69) and manages the number of initiators for WLM-managed JES job classes.

Information on how SRM manages these server address spaces is recorded in the subtype 2 records in the queue server data section and in the remote queue server data section.

Buffer pool management data
For each buffer pool that DB2® has registered to WLM for dynamic buffer pool management, the actual size, the used size, the minimum and maximum size, the target size and the adjustment size are shown together with the buffer pool name and the owning address space.
Interpreting plots

SRM creates the following plots to track how well work is being processed:

- System paging delay plot
- Period MPL delay plot
- Period ready user average plot
- Period swap delay plot
- Period paging rate plot
- Period proportional aggregate speed plot
- I/O delay plot
- Queue delay plot
- Address space paging plot
- I/O velocity plot
- Buffer pool hitratio plot

All plots except the address space paging plot are “one-curved” plots where one variable is plotted against another. The address space paging plot is a “three curved” plot where one variable is plotted against three variables.

System paging delay plot

SRM uses the system paging delay plot to determine if the paging configuration is close to capacity or if it can support additional work. There is one system paging plot per system. The plot can show the point at which additional page faults will start requiring a disproportionately longer time because the paging subsystem is becoming overloaded.

x axis
The system wide page fault rate, in page faults per second.

y axis
The system wide auxiliary storage delay sample rate, in samples per minute.

Page faults and delay samples are for all types: private area, common area, and cross memory.

The system paging delay plot is recorded in subtype 1 records.

Period MPL delay plot

SRM uses the period MPL delay plot to assess increasing or decreasing a service class period's MPL targets. The plot shows how response time may be improved by increasing MPL slots or how response time may be degraded by reducing MPL slots.

x axis
The percentage of ready users who have an MPL slot available to them.

y axis
The MPL delay per completion in milliseconds.

The period MPL delay plot is recorded in subtype 3 records.

Period ready user average plot

SRM uses the period ready user average plot to predict the number of ready users when assessing an MPL target change. The plot can show the point at which users...
will start backing up. The plot shows the approximate MPL target at which users would be disproportionately delayed due to MPL.

**x axis**
The number of MPL slots, times 16, available to the service class period.

**y axis**
The maximum number of ready users, times 16, averaged over a two second interval.

The period ready user average plot is recorded in subtype 3 records.

**Period swap delay plot**
SRM uses the period swap delay plot to assess increasing or decreasing swap protect time for a service class period. The plot shows how response time may be improved or degraded by increasing or decreasing a service class period's swap protect time.

**x axis**
The average time an address space in the service class period is logically swapped or swapped on expanded, in milliseconds.

**y axis**
The swap delay time per completion, in milliseconds.

The period swap delay plot is recorded in subtype 3 records.

**Period paging rate plot**
SRM uses the period paging rate plot to assess increasing or decreasing period wide storage isolation for a service class period.

**x axis**
The average address space size in frames.

**y axis**
The page fault rate in tenths of a page fault per departure from the period.

The period paging rate plot is recorded in subtype 3 records.

**Period proportional aggregate speed plot**
SRM uses the proportional aggregate speed plot to assess the effects of processor access or storage allocation changes for served service classes. Proportional aggregate speed is similar to velocity. Proportional aggregate speed applies to service class periods that are served while velocity applies to service class periods that are not served. The units for proportional aggregate speed are the same units as for velocity:

\[
\text{proportional aggregate speed} = \frac{\text{using samples}}{\text{samples + delay samples}} \times 100
\]

The samples are an aggregate of the samples of all internal server service classes that serve the service class. The server samples are apportioned to the served classes based on the relative amount of time, also determined by state sampling, that the server is serving the service class.

**x axis**
The *proportional aggregate speed* of a service class period

---

Chapter 11. Using SMF record type 99  
131
The period proportional aggregate speed plot is recorded in subtype 3 records for served service class periods.

**I/O delay plot**

SRM uses the I/O delay plot when assessing increasing or decreasing a service class period's I/O priority.

**x axis**

The combined maximum I/O demand of service class periods with I/O priorities above a given priority.

**y axis**

The ratio of I/O delay time to I/O using time at that priority scaled by 16.

Maximum I/O demand is the maximum percentage of time that work units in a service class period would use non-paging DASD devices if they were experiencing no I/O delay. Maximum I/O demand is represented as a percentage scaled by 10.

The I/O delay plots are recorded in the subtype 4 records.

**Queue delay plot**

SRM uses the queue delay plot to assess creating or removing server address spaces. The plot shows how queue delay for a service class period may be reduced by adding server address spaces for work running in the service class period or how queue delay may be increased by removed server address spaces for work running in the service class period.

**x axis**

The ratio of work requests that require a task in a server address space to the number of server tasks. This ratio is scaled by 100.

**y axis**

The queue delay per work request in milliseconds.

The queue delay plots are recorded in the subtype 3 records.

**Address space paging plots**

SRM uses address space paging plots when assessing whether to increase or decrease the central storage or processor storage allocated to an address space. There are two address space paging plots:

**Central storage plot**

SRM uses the central storage paging plot when assessing increasing or decreasing the central storage allocated to an address space.

**x axis**

Address space size in frames.

**y axis**

Each one of the following:

- Page-in rate per captured (task and SRB) second from auxiliary and expanded storage.
- Paging cost in milliseconds per elapsed second from auxiliary and expanded storage.
Processor storage plot
SRM uses the processor storage paging plot when assessing increasing or decreasing the processor storage allocated to an address space.

x axis
The address space size in frames.

y axis
Each one of the following:
- Page-in rate per captured (task+SRB) second from auxiliary storage.
- Paging cost in milliseconds per elapsed second from auxiliary storage.
- Captured time in milliseconds per elapsed second.

The address space paging plots are recorded in subtype 5 records.

I/O velocity plot
SRM uses the I/O velocity plot to keep track of the relationship between the number of channel paths connected to a subsystem (along with the channel path’s utilization) and the I/O velocity of that subsystem. There is one I/O velocity plot for each I/O subsystem (control unit).

x axis
The contention factor.

y axis
The I/O velocity.

If there is a single channel, the contention factor equals the channel utilization. If there are multiple channels, the contention factor is the utilization a single channel would have to have to be equivalent to the channels connected to the control unit, given the number of channels and their average utilization. In this case, “equivalent” means that an I/O operation would have the same probability of experiencing delay.

The I/O velocity plots are recorded in the subtype 9 records.

Buffer pool hit ratio plot
SRM uses the buffer pool hit ratio plot to keep track of the relation between the size of the buffer pool and the hit ratio of DB2 buffer pool accesses. The hit ratio is percentage of hits, when looking for data in the buffer pool, related to the total number of attempts to read data from the buffer pool. There is one plot per buffer pool.

x axis
The size of the buffer pool in Megabytes. This is not the absolute size of the buffer pool, instead this is the delta to the defined minimum size.

y axis
The hitratio.
Interpreting priority table data

Subtype 1 priority table data contains processor resource demand and consumption at each dispatching priority in use. Subtype 2 records contain similar data for each service class period. You can use the data in these two records to determine how much processor capacity is available to each service class period or to explain the actions being taken to increase or decrease access to the processor.

You can use the priority table data in subtype 1 to understand why dispatching priority change actions are rejected. When a dispatching priority change is made, the table shows the before and after demand and consumption data at each priority in use. The before data is actual data. The after data is projected data.

*Maximum demand* is the theoretical maximum percentage of total system processor time the address spaces in a service class period would consume if they were suffering no processor delays. This value is calculated for each service class period and accumulated for each priority.

*Achievable maximum demand* is the percentage of total system processor time the address spaces in a service class period are projected to use, given the maximum demand of all work at higher dispatching priorities. SRM calculates achievable maximum demand to assess dispatching priority changes.

Interpreting lack of action

Just as you can determine the actions SRM takes to manage work, you can determine lack of action from SMF type 99. You can use the resource group and service class period information in the subtype 1 and 2 records. If a service class period is having a problem meeting its goals and isn’t selected as a receiver, it could be one or more of the following:

- Other work is even worse off.
- The service class period is of lower importance than the receiver selected.
- The receiver selected may be in a resource group that is not meeting its minimum.

The importances and performance indexes for all service class periods are in the subtype 2 records. Resource group information is in the subtype 1 records.

In some cases, potential receivers may be skipped and not assessed as receivers. They are skipped when the service class period hasn’t accumulated any state samples that show it was delayed for any resource SRM manages during the last policy interval. You can determine this from the *needs help* indicator in the service class period data.

They are also skipped when a potential receiver’s *skip clock* hasn’t expired. If a receiver is assessed and all actions to help it are rejected, a skip clock (counter) is set and the service class period will not be selected as a receiver again until the skip clock expires.

In other cases, a service class period is selected as a receiver but not helped. It could be that there was no receiver value projected for a change. The subtype 1 trace entry indicates these cases with the *no receiver value* trace code.
For storage changes such as MPL targets, swap protect time, or storage targets, you can determine the reasons for insufficient receiver value from the service class period's current targets in the subtype 2 records and the plots in the subtype 3 and 5 records.

For rejected dispatching priority actions, you can determine the reasons from the service class period's dispatching priority, service, and maximum demand data in the subtype 2 records and at the priority table data in the subtype 1 records.

For no net value assessments, you can determine the reasons from the service class period data, plot data, and priority table data. From this data, you can also determine which service class periods are using the resources for which another service class period is delayed.

Examples of interpreting SMF record type 99

This section describes the following examples of interpreting the data in SMF type 99 records:

- Action trace
- MPL policy

The examples show information from SMF type 99 records that were combined and displayed in a report format.

Action trace example

This example shows how to use subtype 1 trace data with subtype 2 service class period data to understand what actions SRM is taking, why those actions are taken, and which work is affected.

The following example shows the subtype 1 trace data output:

<table>
<thead>
<tr>
<th>CLASS</th>
<th>P</th>
<th>SPI</th>
<th>LPI</th>
<th>ACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>NRBATCH</td>
<td>2</td>
<td>.02</td>
<td>.03</td>
<td>3610</td>
</tr>
<tr>
<td>TSO</td>
<td>1</td>
<td>.10</td>
<td>.11</td>
<td>2630</td>
</tr>
<tr>
<td>TSO</td>
<td>2</td>
<td>1.84</td>
<td>1.84</td>
<td>270</td>
</tr>
<tr>

<td>940</td>
</tr>
<tr>
<td>TSO</td>
<td>2</td>
<td>1.08</td>
<td>1.08</td>
<td>750</td>
</tr>
</tbody>
</table>

The data has the following headings:

CLASS
The service class name.

P The service period number within the service class.

SPI The sysplex performance index for the service class period traced.

LPI The local performance index for the service class period traced.

ACTION
The action code and mnemonic.

The following example shows the subtype 2 service class period output:

<table>
<thead>
<tr>
<th>CLASS</th>
<th>P</th>
<th>I</th>
<th>N</th>
<th>SC</th>
<th>GT</th>
<th>SPI</th>
<th>LPI</th>
<th>DP</th>
<th>MPLI</th>
<th>MPLO</th>
<th>SWPT</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPC</td>
<td>1</td>
<td>2</td>
<td>N</td>
<td>-99</td>
<td>SRT</td>
<td>1.10</td>
<td>1.10</td>
<td>251</td>
<td>0</td>
<td>999</td>
<td>468</td>
</tr>
<tr>
<td>APPC</td>
<td>2</td>
<td>2</td>
<td>N</td>
<td>-99</td>
<td>SRT</td>
<td>0</td>
<td>0</td>
<td>251</td>
<td>0</td>
<td>999</td>
<td>0</td>
</tr>
</tbody>
</table>
The subtype 2 service class policy period output has the following headings:

CLASS
The service class name.
P The service period number within the service class.
I The service class period’s importance, with 1 being highest.
N The “needs help” indicator:
Y The service class period needs help.
N The service class period does not need help.
SC The skip clock.
GT One of the following goal types:
SRT Short response time goals
LRT Long response time goals
VEL Velocity goals
DIS Discretionary goals
SPI The sysplex performance index for the service class period traced.
LPI The local performance index for the service class period traced.
DP Dispatching priority
MPLI MPL-in target
MPLO MPL-out target
SWPT Swap protect time

Interpreting the trace data
Based on the information in these subtypes, SRM took the following actions:

- `rv_hsk_inc_mpl`, reverse housekeeping, to increase the MPL targets for service class NRBATCH, period 2.
  
  This action code indicates the service class period was using significantly more MPL slots than guaranteed by its MPL control so its MPL in target was increased.

- `tdh_rem_prt`, time driven housekeeping, removing the swap protect time target from first period TSO.
  
  First period TSO is easily meeting its goals and was assessed to not need swap protect time.

- `pa_rec_cand` indicates TSO period 2 was chosen as the receiver.
  
  This shows the start of a series of actions where SRM is trying to improve the performance of TSO period 2 by increasing its dispatching priority. SRM selected TSO period 2 as the receiver because it had the worst performance index, 1.84, of all the work at the highest importance defined, 2. Service class NRBATCH,
period 1, had a worse performance index, 2.16, but it also had a lower
importance, 3, so it would be chosen as a receiver after TSO period 2 which had
a higher importance and was not meeting goals.

- `pa_pro_rdon_cand` indicates that TSO period 1 has been selected as the processor
donor to be assessed.

SRM selected TSO period 1 as the first donor candidate because it had the best
performance index of all service class periods that were running at a dispatching
priority higher than or equal to the receiver’s dispatching priority.

- `pa_pmuo_rec` indicates that the first dispatching priority move to be assessed is to
move TSO period 2 up to a higher dispatching priority.

- The next several `pa_pro_unc_sec_don` trace entries show the other service class
periods whose processor access will be affected by the move up of TSO period 2
even though their priority remains unchanged. These service class periods were
all secondary donors. TSO period 1 was the primary donor. This is indicated by
the `pa_pro_unc_don` action.

- `pa_pro_incp_rec` shows that the primary receiver, TSO period 2, received a
dispatching priority increase.

The sysplex and local performance index projections are shown with the final
action for each service class period affected.

**MPL policy example**

This example shows how to use subtype 2 service class period data to analyze a
first period TSO problem. The example shows how SRM used the data to resolve
the problem. You can use the data in the same way to analyze why SRM isn’t
solving a problem. From this kind of information, a service administrator can
decide whether to change goals or service class importance in the service policy.

This subtype 2 data shows the controls SRM is using for first period TSO, and the
resulting performance delays.

| Subtype 2: Service class TSO period data |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| CLASS: TSO PERIOD: 1 IMPORTANCE: 2 GOAL TYPE: SHORT RESPONSE TIME |
| TIME | SPI | LPI | DP | MPLI | MPLO | SWPT | PSI | EXP | POL | LARGEST DELAYS |
| 13:15:01 | .10  | .09  | 251 | 3 | 6 | 15952 | 0 S L S S | OTHR/60 | ASWP/55 | MPLD/2 |
| 13:15:11 | 6.18 | 6.73 | 251 | 6 | 9 | 15952 | 0 S L S S | ASWP/48 | CPUD/44 | MPLD/42 |
| 13:15:22 | 2.20 | 2.92 | 251 | 8 | 12 | 15952 | 0 S L S S | CPUD/38 | MPLD/34 | ASWP/2 |
| 13:15:32 | .06  | .06  | 251 | 8 | 12 | 15952 | 0 S L S S | OTHR/13 | CPUD/3 | MPLD/2 |
| 13:15:42 | .06  | .06  | 251 | 8 | 12 | 15952 | 0 S L S S | OTHR/22 | CPUD/3 | MPLD/2 |
| 13:15:52 | .16  | .16  | 251 | 8 | 12 | 15952 | 0 S L S S | OTHR/28 | MPLD/1 |
| 13:16:03 | .16  | .16  | 251 | 8 | 12 | 15952 | 0 S L S S | OTHR/53 | ASWP/6 | CPUD/2 |

At 13:15:01 TSO period 1 was meeting its goals easily. This is indicated by a
sysplex performance index (SPI) of 0.1 and a local performance index (LPI) of 0.09.
The dispatching priority (DP) was 251. The MPL in and out targets (MPLI/MPLO)
were 3 and 6. After being swapped out, work in the period was protected in
processor storage for 15.952 seconds (SWPT=15952). There was no period wide
storage isolation (PSI=0) and the expanded policy was space available for swap
working set, VIO, and hiperspace pages, and LRU for demand pages (EXP POL= S
L S S). At 13:15:01 TSO period 1 has a swap delay and an MPL delay but was
meeting its goals easily.

Conditions change between 13:15:01 and 13:15:11. The sysplex performance index
spiked to 6.18 and the local performance index was worse. This period needs help.
The delay samples show that the problem could be either swap delay, processor delay, or MPL delay. Because it is the work furthest from meeting its goals, it is selected as a receiver.

The following data, from the subtype 1 record at 13:15:11 shows what happens next. The fields are explained in the first example.

<table>
<thead>
<tr>
<th>Subtype 1: Trace data output</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS</td>
</tr>
<tr>
<td>TSO</td>
</tr>
<tr>
<td>TSO</td>
</tr>
<tr>
<td>TSO</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>TSO</td>
</tr>
</tbody>
</table>

TSO period 1 is selected as the receiver candidate. The trace entry, pa_rec_cand indicates this.

The largest delay is selected to be worked on first. In this case the largest delay in recent history is swap delay. The swap delay plot is shown below. ccc indicates the current plot point. The current plot point shows that only 89 milliseconds of swap delay per transaction could be eliminated even if all swap delay were eliminated. The pa_prt_na_rec_val trace entry indicates that there was insufficient receiver value to be gained by increasing the swap protect time. The swap delay plot data is from the subtype 3 record.

<table>
<thead>
<tr>
<th>Subtype 3: Swap delay plot</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS: TSO</td>
</tr>
<tr>
<td>PERIOD: 1</td>
</tr>
<tr>
<td>SWAP DELAY PLOT</td>
</tr>
<tr>
<td>ccc</td>
</tr>
<tr>
<td>SWAP DELAY</td>
</tr>
<tr>
<td>286 209 89 76 70 24 0</td>
</tr>
<tr>
<td>TIME IN PROC STOR</td>
</tr>
<tr>
<td>3572 4021 14407 23673 40803 71248 97323</td>
</tr>
</tbody>
</table>

The next largest delay is processor delay. However TSO period 1 is running alone at the highest dispatching priority in use. Therefore there is no work to donate processor time. This reason for lack of action is indicated by the pa_pro_na_no_donor trace. The dispatch priorities are from the subtype 2 records.

<table>
<thead>
<tr>
<th>Subtype 2: Dispatching priority data</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS</td>
</tr>
<tr>
<td>NRBATCH</td>
</tr>
<tr>
<td>NRBATCH</td>
</tr>
<tr>
<td>NRBATCH</td>
</tr>
<tr>
<td>OFFBATCH</td>
</tr>
<tr>
<td>TSO</td>
</tr>
<tr>
<td>TSO</td>
</tr>
<tr>
<td>TSO</td>
</tr>
<tr>
<td>TSO</td>
</tr>
<tr>
<td>$$HOLDISC</td>
</tr>
</tbody>
</table>

The third largest delay is MPL delay. The MPL delay plot below shows that here there is value to increasing the MPL. The third entry in the MPL plot, indicated by ccc shows that on average, only 48/100ths of the ready users have MPL slots. This results in an MPL delay of 202 milliseconds per completion. This plot is recorded in the subtype 3 record. The fact that MPL targets were increased is indicated by the pa_inc_mpl trace. The new MPL targets are recorded in the subtype 2 record.
At 13:15:22 the performance index was improving but there was still significant MPL delay and the MPL targets were increased again. At 13:15:32 the work was back to meeting its goals as shown by sysplex and local performance indexes of less than 1.0.
Part 2. Reference: Workload Management Services

The information in this part describes the Workload Management Services in detail.
Chapter 12. Workload management services

This chapter provides detailed information about the workload management services, including those that support both 31-bit and 64-bit addressing mode. Workload management services that support 64-bit addressing mode have names that start with IWM4xxxx.

For information about equivalent versions of some of these services that only support 31-bit addressing mode, see Appendix E, “WLM services supporting 31-bit addressing only,” on page 827.
IWMCNTN

IWMCNTN — WLM contention notification

The IWMCNTN service allows resource managers to notify WLM of changes to the list of resources, work units, or transactions involved with resources that have been in contention (waiters exist) for longer than a resource manager defined interval. The interval should be chosen so that only contention which has lasted long enough to be considered chronic for the issuing resource manager results in calling this service.

The caller can run in task or SRB mode.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
6. Because this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.

Restrictions

None.
IWMCNTN

**Input register information**

Before issuing the IWMCNTN macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMCNTN macro is as follows:

```
IWMCNTN name SUBSYS=subsys, SUBSYSNM=subsysnm

, RESOURCESCOPE=SINGLESYSTEM
, RESOURCESCOPE=MULTISYSTEM
, RESOURCEID=resourceid, RESOURCEID_LEN=resourceid_len

, INVOCATIONTYPE=UPDATE, REQUESTLIST=requestlist
, INVOCATIONTYPE=REPLACE, REQUESTLIST=requestlist
, INVOCATIONTYPE=ENDOFCONTENTION
, RETCODE=retcode
```
Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMCNTN macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**, INVOCATIONTYPE=UPDATE**

**, INVOCATIONTYPE=REPLACE**

**, INVOCATIONTYPE=ENDOFCONTENTION**

A required parameter, which indicates the type of operation requested.

**, INVOCATIONTYPE=UPDATE**

indicates that the operations described in the request list have to be applied to the resource. If contention information for the resource does not already exist, it is created. If after applying the operations there are no holders or waiters (local or remote), tracking of the resource is abandoned locally.

**, INVOCATIONTYPE=REPLACE**

same as UPDATE, except that any existing local resource topology is discarded first.

**, INVOCATIONTYPE=ENDOFCONTENTION**

indicates that all topology information for the resource is discarded.

**, MF=S**

**, MF=(L,list addr)**

**, MF=(L,list addr,attr)**

**, MF=(L,list addr,0D)**

**, MF=(E,list addr)**

**, MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\texttt{,list \textit{addr}}

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\texttt{,attr}

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code \textit{attr}, the system provides a value of 0D.

\texttt{,COMPLETE}

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\texttt{,PLISTVER=IMPLIED\_VERSION}
\texttt{,PLISTVER=MAX}
\texttt{,PLISTVER=0}

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED\_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED\_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED\_VERSION
- MAX
- A decimal value of 0

\texttt{,REQUESTLIST=\textit{requestlist}}

When INVOCATIONTYPE=UPDATE or REPLACE is specified, a required input parameter, which specifies a list of topology requests. For each request, you must specify:

- Whether you want to add or to delete the contention information
- Whether the work unit is holding the resource or is waiting for it,
- The identification of the entity in terms of STOKEN, TCB address or enclave token.

For each request the macro returns a return and a reason code. See IWMCNTRL for the mapping of the request list.
The work unit ID varies based on the resource ownership model (transaction or task resource) used by the IWMCNTN exploiter and the work unit type involved, as described in Table 24:

**Table 24. Work unit IDs**

<table>
<thead>
<tr>
<th>Work unit type</th>
<th>Exploiters using the transaction model will pass</th>
<th>Exploiters using the task resource model will pass</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global SRB, local SRB, preemptible SRB (but not a client or enclave SRB)</td>
<td>Home STOKEN, TCB=0, Etoken=0</td>
<td>Same as transaction resource ownership model</td>
</tr>
<tr>
<td>Client SRB</td>
<td>Client STOKEN, TCB=0, Etoken=0</td>
<td>Same as transaction resource ownership model</td>
</tr>
<tr>
<td>Enclave SRB</td>
<td>STOKEN=0, TCB=0, Etoken=e</td>
<td>Same as transaction resource ownership model</td>
</tr>
<tr>
<td>Non-enclave task</td>
<td>Home STOKEN, TCB=0, Etoken=0</td>
<td>Home STOKEN, TCB= t, Etoken=0</td>
</tr>
<tr>
<td>Enclave task</td>
<td>STOKEN=0, TCB=0, Etoken=e</td>
<td>Home STOKEN, TCB= t, Etoken=0</td>
</tr>
</tbody>
</table>

The following return/reason codes may be returned per request:

**Return_Code**
A 2-byte output field set based on whether or not the entity identification information passed validity checks.

- **0** Name: IwmRetCodeOk Meaning: Successful completion. Action: None required.
- **4** Name: IwmRetCodeWarning Meaning: Successful completion, unusual conditions noted. Action: Check reason code
- **8** Name: IwmRetCodeInvocError Meaning: Invalid invocation environment or parameters. Action: Check reason code

**Reason_Code**
A 2-byte output field set based on whether or not the entity identification information passed validity checks.

- **0448** Name: IwmRsnCodePossibleDeadlock Meaning: The specified chronic resource contention may have caused a deadlock: The holder of resource (A) is waiting for resource (B), which is currently held by another holder, which is waiting for resource (A). Action: Check for possible deadlock.
- **0807** Name: IwmRsnCodeBadSTOKEN Meaning: The specified STOKEN does not pass verification. Action: Check for possible storage overlay of the address space token.
083A Name: IwmRsnCodeBadEnclave Meaning: Enclave token does not pass verification. Action: Check for possible storage overlay of the enclave token.

0886 Name: IwmRsnCodeBadRequestCode Meaning: The request code must be either ADD or DELETE. Action: Correct the request code.

0887 Name: IwmRsnCodeBadEntityType Meaning: The entity type must be either HOLDER or WAITER. Action: Correct the entity type.

088A Name: IwmRsnCodeBadEntityId Meaning: The specified combination of STOKEN, TCB, and/or enclave token does not pass verification. Action: Correct the entity id.

088B Name: IwmRsnCodeBadTCB Meaning: The specified TCB address does not pass verification. Action: Correct the TCB address. Task may have terminated since the parameter list was built. TCB may not match STOKEN.

08A5 Name: IwmRsnCodeNoContention Meaning: The specified chronic resource contention is not stored in the topology. The DELETE request for this request list entry was not processed. Action: Correct the delete request.

08A8 Name: IwmRsnCodeDupContention Meaning: The specified chronic resource contention is already stored in the topology. The ADD request for this request list entry was not processed. Action: Correct the add request.

08AF Name: IwmRsnCodeDeadlock Meaning: The specified chronic resource contention caused a deadlock: The holder of resource (A) is waiting for resource (B), which is currently held by another holder, which is waiting for resource (A). The request list entry was not processed. Action: Remove the deadlock.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,RESOURCEID=resourceid
A required input parameter, which identifies the resource uniquely within all resources for a subsystem type and name.

For resources whose type is multisystem, the value must be unique within the subsystem type and name across all systems where the interface might ever be invoked for this resource.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,RESOURCEID_LEN=resourceid_len
A required input parameter, which contains the length of the resource identifier. A resource identifier may not exceed 264 bytes.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,RESOURCESCOPE=SINGLESYSTEM
,RESOURCESCOPE=MULTISYSTEM
An optional parameter, which identifies if the resource information is shared with other WLM instances in the cluster. The default is RESOURCESCOPE=SINGLESYSTEM.
\textbf{IWMCNTN}

\texttt{\textbf{RESOURCESCOPE=SINGLESYSTEM}}

Indicates that the resource information is used on the issuing system only.

\texttt{\textbf{RESOURCESCOPE=MULTISYSTEM}}

Indicates that the resource information is shared among other systems.

\textbf{Note:} This keyword is ignored. WLM contention notifications are processed with \texttt{RESOURCESCOPE=SINGLESYSTEM}, even if \texttt{RESOURCESCOPE=MULTISYSTEM} is specified.

\texttt{\textbf{RETCODE=retcode}}

An optional output parameter into which the return code is to be copied from GPR 15.

\textbf{To code:} Specify the RS-type address of a fullword field, or register (2)-(12).

\texttt{\textbf{RSNCODE=rsncode}}

An optional output parameter into which the reason code is to be copied from GPR 0.

\textbf{To code:} Specify the RS-type address of a fullword field, or register (2)-(12).

\texttt{\textbf{SUBSYS=subsys}}

A required input parameter, which contains the generic subsystem type (e.g. IMS, CICS, etc.).

\textbf{To code:} Specify the RS-type address, or address in register (2)-(12), of a 4-character field.

\texttt{\textbf{SUBSYSNM=subsysnm}}

A required input parameter, which identifies the subsystem instance.

\textbf{To code:} Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\section*{ABEND codes}

None.

\section*{Return codes and reason codes}

When the IWMCNTN macro returns control to your program:

- GPR 15 (and \texttt{recode}, when you code \texttt{RETCODE}) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and \texttt{rsncode}, when you code \texttt{RSNCODE}) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the \texttt{xxxx} value.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|p{10cm}|}
\hline
\textbf{Return Code} & \textbf{Reason Code} & \textbf{Equate Symbol, Meaning, and Action} \\
\hline
0 & - & \textbf{Equate Symbol: IwmRetCodeOk} \\
& & \textbf{Meaning: Successful completion.} \\
& & \textbf{Action: None required.} \\
\hline
4 & - & \textbf{Equate Symbol: IwmRetCodeWarning} \\
& & \textbf{Meaning: Successful completion, unusual conditions noted.} \\
\hline
\end{tabular}
\end{table}
<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 4           | xxxx0047    | Equate Symbol: IwmRsnCodeRequestListEntryWarning  
Meaning: The processing of at least one of the request list entries has caused a warning. Refer to the return code and reason code stored for this request list entry.  
Action: SRM continues with the request list processing. |
| 8           | —           | Equate Symbol: IwmRetCodeInvocError  
Meaning: Invalid invocation environment or parameters. |
| 8           | xxxx0803    | Equate Symbol: IwmRsnCodeDisabled  
Meaning: Caller is disabled.  
Action: Avoid requesting this function while disabled. |
| 8           | xxxx0804    | Equate Symbol: IwmRsnCodeLocked  
Meaning: Caller is locked.  
Action: Avoid requesting this function while locked. |
| 8           | xxxx080B    | Equate Symbol: IwmRsnCodeBadPl  
Meaning: Error accessing parameter list.  
Action: Check for possible storage overlay. |
| 8           | xxxx0824    | Equate Symbol: IwmRsnCodeAmode24  
Meaning: The caller invoked the service but was in 24-bit addressing mode.  
Action: Request this function only when you are in 31-bit addressing mode. |
| 8           | xxxx0825    | Equate Symbol: IwmRsnCodeAscModeNotPrimary  
Meaning: The caller invoked the service but was not DAT on primary ASC mode.  
Action: Avoid requesting this function in this environment. |
| 8           | xxxx0828    | Equate Symbol: IwmRsnCodeBadVersion  
Meaning: Version number in parameter list is not valid.  
Action: Check for possible storage overlay of the parameter list. |
| 8           | xxxx0888    | Equate Symbol: IwmRsnCodeBadRequestList  
Meaning: The request list does not pass verification. No request in the request list was processed.  
Action: Check the return and reason codes in the request list. |
| 8           | xxxx0889    | Equate Symbol: IwmRsnCodeBadResourceIdLen  
Meaning: The length of the resource id must not exceed 264 bytes.  
Action: Specify a correct resource id length. |

IWMCQRY — Query classification attributes

The Query Active Classification Rules routine is given control from the IWMCQRY macro. The Query Active Classification Rules macro will complete the parameter list with caller provided data and generate a stacking, space switching, program call to the query service.

The purpose of this routine is to return a representation of the classification rules that are associated with the active policy that is in effect for the sysplex. The data returned by this service describes the installation-defined rules that determine how incoming work is assigned a service class and/or report class by MVS.

The classification rule data returned by this service is mapped by macro IWMSVDCR. This macro is also used to map the classification rules associated with the WLM service definition. As a result, some data sections in this mapping will not be available (filled in) when it is obtained via this service. An example of some of the information that will not be available, are the timestamps indicating when a classification GROUP was last updated and by whom. For a complete list of fields that will not be available refer to the field comments in macro IWMSVDCR.

The classification rules can be used in conjunction with the active service policy to determine what performance goals will be associated with incoming work. The performance goals for a service class are contained within service policy mapping returned by the IWMPQRY service.

The information returned is not serialized upon return to the caller, and so may be out-of-date if a modified service definition was installed and a new policy activated.

The caller can optionally request that the identifier of the active policy that these classification rules are part of, be returned in an area specified by the POLICY_ID keyword. The caller can then compare the policy identification information returned with the policy data returned by the IWMPQRY macro to ensure they are in synch.

The Query Active Classification Rules macro is provided in list, execute, and standard form. The list form accepts no variable parameters and is used only to reserve space for the query parameter list. The standard form is provided for use with routines which do not require reentrant code. The execute form is provided for use with the list format for reentrant routines.

The parameter list must be in the caller's primary address space or be addressable by the dispatchable unit access list.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE</td>
<td>31-bit</td>
</tr>
</tbody>
</table>
### ASC mode

Primary or access register (AR) If in Access Register ASC mode, specify SYSSTATE ASCENV=AR before invoking this macro.

<table>
<thead>
<tr>
<th>Interrupt status</th>
<th>Enabled for I/O and external interrupts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Locks</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters</td>
<td>All parameter areas must reside in current primary or be addressable by the dispatchable unit access list.</td>
</tr>
</tbody>
</table>

#### Programming requirements

1. The macro CVT must be included to use this macro. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

#### Restrictions

The caller cannot have an EUT FRR established.

#### Input register information

Before issuing the IWMCQRY macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

#### Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>
Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMCQRY macro is as follows:

```
IWMCQRY name ANSAREA=ansarea, ANSLEN=anslen, QUERYLEN=querylen
```

```
POLICY_ID=policy_id, RETCODE=retcode, RSNCODE=rsncode
```

```
PLISTVER=IMPLIED_VERSION, PLISTVER=MAX, PLISTVER=0
```

```
MF=S, MF=(L, list addr, attr), MF=(E, list addr, COMPLETE)
```

**Parameters**

The parameters are explained as follows:

- **name**
  - An optional symbol, starting in column 1, that is the name on the IWMCQRY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

- **ANSAREA=ansarea**
  - A required output parameter, variable specifying an area to contain the data being returned by IWMCQRY. The answer area is defined by the IWMSVDCR macro.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

- **ANSLEN=anslen**
  - A required input parameter, variable which contains the length of the area provided to contain the data being returned by IWMCQRY.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

- **MF=S, MF=(L, list addr, attr), MF=(E, list addr, COMPLETE)**
  - An optional input parameter that specifies the macro form.
Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,\list addr
  The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,\attr
  An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code \attr, the system provides a value of 0D.

,\COMPLETE
  Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,\PLISTVER=IMPLIED_VERSION
,\PLISTVER=MAX
,\PLISTVER=0
  An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

  • IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
  • MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
    If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
  • 0, if you use the currently available parameters.

To code: Specify one of the following:
  • IMPLIED_VERSION
  • MAX
  • A decimal value of 0

,\POLICY_ID=\policy_id
  An optional output parameter, variable specifying an area to contain the
identifier of the active policy that these classification rules are a part of. This answer is mapped by the SVIDSSVP DSECT in the IWMSVIDS macro.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,QUERYLEN=querylen
A required output parameter, variable which contains the number of bytes needed to contain the classification rule information.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

ABEND codes

Reason Code
Explanation

X'0Axx0005'
An attempt to reference caller's parameters caused an OC4 abend.

Return codes and reason codes

When the IWMCQRY macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>

</table>
The extract service definition routine is given control from the IWMDEXTR macro. The extract service definition macro will complete the parameter list with caller provided data and generate a stacking, program call to the extract service.

The purpose of this routine is to return a representation of the Workload Management service definition currently installed in the WLM couple data set for the current sysplex. The service definition returned contains all the policies that are currently eligible to be activated in the sysplex.

The information returned can be used by an application to be presented and manipulated by an end user. The install service definition macro IWMDINST, may be used to install a service definition into the WLM couple data set.

The service definition can be extracted either in XML format, or as a data area mapped by the IWMSERVD mapping macro. The XML structure is defined by the DTD described in Appendix C, “Structure of the XML service definition (DTD),” on page 817. The IWMSERVD mapping is a single logical entity described by the service definition descriptor element, defined by IWMSERVD. The service definition descriptor element contains offsets to the 5 distinct areas that comprise the service definition:

- The general service definition data area.
  This data area contains general service definition information like the service definition name and description along with more detailed information like the policy, workload, service class and resource group information. This area is mapped by IWMSVDEF.
- The service definition classification rules data area.
  This data area contains the definitions of the classification rules and classification groups that define which service and report classes are associated with incoming work when the work enters MVS. This area is mapped by IWMSVDCR.
- The notepad data area.
  This data area contains any comments (or change history) that an installation chooses to associate with the service definition. This area is mapped by IWMSVNPA.
- The service definition application environment data area.
  This data area contains the definitions of the application environments. This area is mapped by IWMSVAEA.
- The service definition scheduling environment data area.
  This data area contains the definitions of the scheduling environments. This area is mapped by IWMSVSEA.

The caller must provide sufficient storage to contain the service definition data requested. If insufficient storage is passed, no data is returned, an appropriate return and reason code is set, and the length required is returned in the variable specified in the QUERYLEN keyword.

Because the data returned is not serialized against future installs, the length returned may still change before the extract is issued again. Therefore, the caller must issue the extract service in a loop, checking return and reason codes, and obtaining a larger storage area as necessary.
The extract service definition macro is provided in list, execute, and standard form. The list form accepts no variable parameters and is used only to reserve space for the extract parameter list. The standard form is provided for use with routines which do not require reentrant code. The execute form is provided for use with the list format for reentrant routines. The extract macro is provided in PL/AS and assembler formats.

The parameter list must be in the caller’s primary address space or be addressable by the dispatchable unit access list.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Minimum authorization</strong></td>
<td>Problem state, any PSW key. The caller must have read authority to the resource MVSADMIN.WLM.POLICY in the FACILITY class.</td>
</tr>
<tr>
<td><strong>Dispatchable unit mode</strong></td>
<td>Task</td>
</tr>
<tr>
<td><strong>Cross memory mode</strong></td>
<td>PASN=HASN=SASN</td>
</tr>
<tr>
<td><strong>AMODE</strong></td>
<td>31-bit</td>
</tr>
<tr>
<td><strong>ASC mode</strong></td>
<td>Primary or access register (AR) If in Access Register ASC mode, specify SYSSTATE ASCENV=AR before invoking this macro.</td>
</tr>
<tr>
<td><strong>Interrupt status</strong></td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td><strong>Locks</strong></td>
<td>No locks may be held.</td>
</tr>
<tr>
<td><strong>Control parameters</strong></td>
<td>All parameter areas must reside in current primary or be addressable by the dispatchable unit access list. In addition, all parameters must reside in storage of the same key as the caller is executing in when the macro is invoked unless the caller is in key 0.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

1. The caller cannot have an EUT FRR established.
2. This macro supports multiple versions. Some keywords are unique to certain versions. For further information, see the PLISTVER parameter description.
Input register information

Before issuing the IWMDEXTR macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMDEXTR macro is as follows:

```
IWMDEXTR
   name
   ,ANSAREA=ansarea
   ,ANSLEN=anslen
   ,QUERYLEN=querylen
   ,TYPE=HEX
   ,ANSAREA=ansarea
   ,ANSLEN=anslen
   ,QUERYLEN=querylen
   ,TYPE=XML
   ,RETCODE=retcode
   ,RSNCODE=rsncode
   ,PLISTVER=IMPLIED_VERSION
   ,PLISTVER=MAX
   ,PLISTVER=0
   ,PLISTVER=1
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMDEXTR macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

ANSAREA=ansarea
A required output parameter, variable specifying an area to contain the service definition data returned by the extract service. When TYPE=HEX is specified, this area is defined by the IWMSERVD macro. When TYPE=XML is specified, it is the area where the service definition XML stream is to be stored.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

Note: The specified address must not be 0.

,ANSLEN=anslen
A required input parameter, variable to contain the length of the area specified on ANSAREA keyword to contain the service definition data returned by the extract service.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

`attr`

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

`COMPLETE`

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

`PLISTVER=IMPLIED_VERSION`
`PLISTVER=MAX`
`PLISTVER=0`
`PLISTVER=1`

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports the following parameter and those from version 0:

  **TYPE**

  To code: Specify one of the following:

  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0, or 1

`QUERYLEN=querylen`

A required output parameter, variable which contains the number of bytes of service definition data returned by the extract service, or the number of bytes of storage required to contain the service definition if insufficient storage was provided.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

`RETCODE=retcode`

An optional output parameter into which the return code is to be copied from
GPR 15. If you specify 15, GPR15, REG15, or R15 (with or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12), or (15), (GPR15), (REG15), or (R15).

\[ \text{RSNCODE=rsncode} \]

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (with or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0), (REG00), or (R0).

\[ \text{TYPE=HEX} \]
\[ \text{TYPE=XML} \]

An optional parameter indicating in which format the service definition will be extracted. The default is TYPE=HEX.

\[ \text{TYPE=HEX} \]

The service definition will be returned in HEX format mapped by IWMSERVD (default).

\[ \text{TYPE=XML} \]

The service definition will be returned in XML format.

### ABEND codes

**Reason Code (Hex)**

**Explanation**

X’0Axx0005’

An attempt to reference caller's parameters caused an OC4 abend.

### Return codes and reason codes

When the IWMDEXTR macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

**Table 27. Return and Reason Codes for the IWMDEXTR Macro**

<table>
<thead>
<tr>
<th>Return Code</th>

**Meaning**: Internal error.  
**Action**: Contact IBM. |
The Install Service Definition routine is given control from the IWMDINST macro. The Install Service Definition macro will complete the parameter list with caller provided data and generate a stacking, program call to the install service.

The purpose of this routine is to install the WLM service definition supplied into the WLM couple data set for the current sysplex. After this service definition is installed in the couple data set all policies contained in it are eligible to be activated in the sysplex.

The service definition can be installed either in XML format, or as a data area mapped by the IWMSERVD mapping macro. The XML structure is defined by the DTD described in Appendix C, “Structure of the XML service definition (DTD),” on page 817. The IWMSERVD mapping is a single logical entity described by the service definition descriptor element, defined by IWMSERVD. The service definition descriptor element contains offsets to the 5 distinct areas that comprise the service definition:

**General service definition data area**
Contains general service definition information like the service definition name and description along with more detailed information like the policy, workload, service class and resource group information. This area is mapped by the IWMSVDEF.

**Service definition classification rules data area**
Contains the definitions of the classification rules and classification groups that govern which service and report classes are associated with incoming work when the work enters MVS. This area is mapped by IWMSVDCR.

**Notepad data area**
Contains any comments (or change history) that an installation chooses to associate with the service definition. This area is mapped by IWMSVNPA.

**Service definition application environment data area**
Contains the definitions of the application environments. This area is mapped by IWMSVNEA.

**Service definition scheduling environment data area**
Contains the definitions of the scheduling environments. This area is mapped by IWMSVSEA.

The service definition descriptor element and all five data areas of the service definition must be passed as input to the install service definition service. Even if certain data areas are non-applicable, for example no notepad information exists, the data area header information must still be completely filled in and pointed to by the descriptor element.

All input data areas must represent a valid service definition in order for the install to occur. If validity checking for any section of the service definition fails, the entire install process is aborted and a return and reason code indicating that validation of the service definition failed is returned. In addition, a reason code describing the specific error that was detected is returned in the variable specified on the keyword `VALCHECK_RSN` and an offset to the specific section of the service definition where the error was detected is returned in the variable specified on the `VALCHECK_OFFSET` keyword. Validity check processing occurs until the first error is detected and only a single error is identified on an invocation of this macro.
IWMDINST

The caller can also request that the install occurs only if the service definition that was used as a base for the definition being installed is still the currently installed service definition in the WLM couple data set. This allows the caller the ability to prevent inadvertent overwrites of service definition updates that some other user (caller) made in the window, from when the service definition was initially read, to when the current install with the updated service definition was issued. For more details, refer to the description of the COND keyword.

The parameter list must be in the caller’s primary address space or be addressable by the dispatchable unit access list.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state. Any PSW key. The caller must have update authority to the resource MVSADMIN.WLM.POLICY in the FACILITY class.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>PASN=HASN=SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary or access register (AR) If in Access Register ASC mode, specify SYSSTATE ASCENV=AR before invoking this macro.</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>All parameter areas must reside in current primary or be addressable by the dispatchable unit access list. In addition, all parameters must reside in storage of the same key as the caller is executing in when the macro is invoked unless the the caller is in key 0.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

1. The caller cannot have an EUT FRR established.
2. This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.
Input register information

Before issuing the IWMDINST macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMDINST macro is as follows:

```
<table>
<thead>
<tr>
<th>IWMDINST</th>
<th>SERVD_AREA=servd_area,TYPE=HEX</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>,TYPE=XML,XML_LEN=xml_len</td>
</tr>
</tbody>
</table>

|        |QRY_BASEID=qry_baseid,PRODUCT_ID=product_id,VALCHECK_RSN=valcheck_rsn |
|        |                   ,COND=YES,IN_BASEID=in_baseid |
|        |                   ,COND=NO               |

|        |VALCHECK_OFFSET=valcheck_offset       |
```

172  z/OS V2R2 MVS Programming: Workload Management Services
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMDINST macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**COND=**

- **COND=YES**
  A required parameter, which indicates whether checking is performed prior to the install, to determine if the service definition that the input definition was based on is still the currently installed service definition (i.e. another user has not made updates).

  **COND=YES**
  indicates that the input service definition should only be installed if the identifier of currently installed service definition matches the base identifier passed on IN_BASEID keyword. This allows the user to detect changes in the installed service definition, since the last extract was done, and allows the user to confirm whether the install should still occur.

- **COND=NO**
  indicates that the input service definition should be installed unconditionally.

**IN_BASEID=in_baseid**
When COND=YES is specified, a required input parameter, variable specifying an area that contains the identifier of the service definition that was used as a base for the service definition being installed. This area is mapped by the SVIDSSVD DESCT in macro IWMSVIDS.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

- **MF=S**
- **MF=(L,list addr)**
- **MF=(L,list addr,attr)**
- **MF=(L,list addr,0D)**
- **MF=(E,list addr)**
- **MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.
Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\texttt{list \ addr}

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\texttt{attr}

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

\texttt{COMPLETE}

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\texttt{PLISTVER=IMPLIED\_VERSION, PLISTVER=MAX, PLISTVER=0, PLISTVER=1}

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED\_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED\_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports the following parameters and those from version 0:

  \texttt{TYPE, XML\_LEN}

To code: Specify one of the following:

- **IMPLIED\_VERSION**
- **MAX**
- A decimal value of 0, or 1
PRODUCT_ID=product_id
A required input parameter, variable specifying an area that contains an identifier of the product (application) performing the install. The identifier should include information like product name, a unique version/release identifier, and any other information that can help identify your product. This area is mapped by the SVIDSPRD DSECT in the IWMSVIDS macro.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

QRY_BASEID=qry_baseid
An optional output parameter, variable specifying an area to contain the identifier of the service definition that is currently installed on the WLM couple data set. This area is mapped by the SVIDSSVD DSECT in macro IWMSVIDS. When this keyword is specified, the data is returned when the return code indicates successful completion (return code 0) regardless of whether COND(YES) or COND(NO) was specified. In addition, this data is returned on a conditional request (COND(YES)) if the return and reason code indicate that specified IN_BASEID does not match the baseid of the installed service definition (return code 4, reason code '0413'X).

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

TYPE=HEX
TYPE=XML
An optional parameter indicating in which format the service definition will be extracted. The default is TYPE=HEX.

TYPE=HEX
The service definition will be returned in HEX format mapped by IWMSERVD (default).

TYPE=XML
The service definition will be returned in XML format.

SERVD_AREA=servd_area
A required input parameter, variable specifying an area that contains the service definition data to be installed. When TYPE=HEX is specified, this area is defined by the IWMSERVD macro. When TYPE=XML is specified, it is the area where the service definition XML stream is to be stored.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

VALCHECK_OFFSET=valcheck_offset
A required output parameter. The variable will contain the offset identifying the specific error in the input service definition found during validity checking. If the primary reason code is xxxx083D and the service definition type is HEX, the variable contains the offset from the beginning of the service definition.
IWMDINST

IWMSERVD) to the section of the input service definition where validity check processing found an error described by the reason code returned in VALCHECK_RSN. If the primary reason code is xxxx083D and the service definition type is XML, the VALCHECK_OFFSET has no meaning. If the primary reason code is xxxx08B2 or xxxx08B5, the variable contains the offset from the beginning of the service definition in XML format. This offset is returned under the same conditions as when VALCHECK_RSN is returned.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

\*VALCHECK_RSN=valcheck_rsn

A required output parameter. The variable will contain the reason code identifying the specific error in the input service definition found during validity checking. This reason code is only returned if validation of the input service definition fails and a primary return code of 8 and reason code of xxxx083D, xxxx08B2, or xxxx08B5 is returned. If reason codes xxxx083D and xxxx08B5 are issued, refer to Appendix B, “Application validation reason codes,” on page 801 for an explanation. If the primary reason code is xxxx08B2, refer to "XML System Services Users Guide and Reference" for an explanation.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

\*xml_len=xml_len

When TYPE=XML is specified, a required input parameter. The variable contains the length of the area specified on the SERVD_AREA keyword to contain the service definition data in XML format.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

ABEND codes

Reason Code (Hex)

Explanation

0Axxx0005

An attempt to reference caller's parameters caused an OC4 abend.

Return codes and reason codes

When the IWMDINST macro returns control to your program:

- GPR 15 (and retnode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

### Table 28. Return and Reason Codes for the IWMDINST Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0829    | Equate Symbol: IwmRsnCodeBadOptions  
**Meaning:** Parameter list omits required parameters or supplies mutually exclusive parameters or provides data associated with options not selected.  
**Action:** Check for possible storage overlay of the parameter list. |
| 8           | xxxx0830    | Equate Symbol: IwmRsnCodeBadAlet  
**Meaning:** The caller has passed an invalid ALET.  
**Action:** Check for possible storage overlay of the parameter list or variable. |
| 8           | xxxx083D    | Equate Symbol: IwmRsnCodeBadServDI  
**Meaning:** The caller has passed a Service Definition area that failed validation.  
**Action:** See values in VALCHECK_RSN and VALCHECK_OFFSET parameters for more information concerning the specific failure. |
| 8           | xxxx0841    | Equate Symbol: IwmRsnCodeXMemMode  
**Meaning:** The caller is in cross-memory mode.  
**Action:** Invoke the function in non-cross memory mode. |
| 8           | xxxx085B    | Equate Symbol: IwmRsnCodeNoSERVDArea  
**Meaning:** The caller invoked the service without a required SERVD area or the SERVD area address is 0.  
**Action:** Check for possible storage overlay of the parameter list or variable. |
| 8           | xxxx08B2    | Equate Symbol: IwmRsnCodeParserError  
**Meaning:** The XML parser was not able to parse the service definition XML document.  
**Action:** See values in VALCHECK_RSN and VALCHECK_OFFSET parameters for more information concerning the specific failure. The XML parser reason codes can be found in the book: “XML System Services Users Guide and Reference”. |
| 8           | xxxx08B3    | Equate Symbol: IwmRsnCodeXmlZeroLen  
**Meaning:** The length of the provided XML service definition is zero.  
**Action:** Provide the correct length of the service definition. |
| 8           | xxxx08B5    | Equate Symbol: IwmRsnCodeXmlInvalid  
**Meaning:** The XML parser was not able to parse the service definition XML document.  
**Action:** See values in VALCHECK_RSN and VALCHECK_OFFSET parameters for more information concerning the specific failure. The reason codes can be found in “z/OS MVS Programming: Workload Management Services”. |
| C           | —           | Equate Symbol: IwmRetCodeEnvError  
**Meaning:** Environmental error. |

</tbody>
</table>
The IWMEBLK service allows work managers that participate in cross-platform enterprise workload management (EWLM) to indicate that processing of a work request is blocked while waiting for a work request in another application to complete.

The counterpart of this service to indicate that the processing of a work request is no longer blocked is IWMEUBLK.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th><strong>Minimum authorization:</strong></th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dispatchable unit mode:</strong></td>
<td>Task or SRB</td>
</tr>
<tr>
<td><strong>Cross memory mode:</strong></td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td><strong>AMODE:</strong></td>
<td>31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.</td>
</tr>
<tr>
<td><strong>ASC mode:</strong></td>
<td>Primary or access register (AR)</td>
</tr>
<tr>
<td><strong>Interrupt status:</strong></td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td><strong>Locks:</strong></td>
<td>No locks may be held.</td>
</tr>
<tr>
<td><strong>Control parameters:</strong></td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
6. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.
7. If the parameter EWLMMODE=EXPLICIT_SINGLE is specified, the following restrictions apply:
   - No other task or SRB is allowed to issue other enclave services for the same enclave concurrently.
   - The caller must be in primary ASC mode before invocation.
   - The parameter list, the classification parameters and the savearea pointed to by GPR13 must be addressable in AMODE 31 and primary ASC mode.
• No recovery environment is set up by the service. The caller is responsible to provide an appropriate error recovery environment to handle abnormal terminations.
• The enclave must have been created with option ESTRT=EXPLICIT_SINGLE on the IWM4ECRE (or IWMECREA) invocation.
• The caller must provide the ETOKEN parameter.

Restrictions

This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information

If the EWLMMODE=EXPLICIT_SINGLE parameter is specified, the caller must provide a standard 72-byte savearea pointed to by GPR13.

For all other cases the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.
**Syntax**

The syntax of the IWMEBLK macro is as follows:

```
IWMEBLK WORKREQ_HDL=workreq_hdl, BLOCK_HDL=block_hdl
```

```
.EWLMMODE=NORMAL, ETOKEN=NO_ETOKEN, RETCODE=retcode
```

```
.RSNCODE=rsncode
```

```
.MF=(L, list_addr, attr, COMPLETE)
```

```
.MF=(E, list_addr, attr)
```

**Parameters**

The parameters are explained as follows:

- **name**
  - An optional symbol, starting in column 1, that is the name on the IWMEBLK macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

- **.BLOCK_HDL=block_hdl**
  - A required output parameter that will receive the handle identifying the blocked work request.

    **To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

- **ETOKEN=etoken**

  **ETOKEN=NO_ETOKEN**
  - An optional input parameter that contains the enclave token of the enclave under which the work request is processed. The values of ETOKEN are:
    - **ETOKEN=etoken** is required, if the option EWLMMODE=EXPLICIT_SINGLE is specified.
    - **ETOKEN=NO_ETOKEN** indicates that no ETOKEN is passed. This is the default.

    **To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

- **.EWLMMODE=NORMAL**

  **.EWLMMODE=EXPLICIT_SINGLE**
  - An optional input keyword that indicates if the parameter EXPLICIT_SINGLE has been specified on the IWM4ECRE (or IWMECREA) call. Note that EWLMMODE=EXPLICIT_SINGLE can only be specified if the enclave was created with the ESTRT=EXPLICIT_SINGLE option. The values of EWLMMODE are:
- **EWLMMODE=NORMAL** indicates that the enclave was created with the ESTRT=EXPLICIT or with the ESTRT=IMPLIED option. EWLMMODE=NORMAL is the default.

- **EWLMMODE=EXPLICIT_SINGLE** indicates that the enclave was created with the ESTRT=EXPLICIT_SINGLE option which can only be used for a restricted environment. The caller must provide a standard 72-byte savearea, which is addressable in AMODE 31 and pointed to by GPR13. The parameter list and the classification parameters must also be addressable in AMODE 31.

- **MF=S**
- **MF=(L,list addr)**
- **MF=(L,list addr,attr)**
- **MF=(L,list addr,0D)**
- **MF=(E,list addr)**
- **MF=(E,list addr,COMPLETE)**

  An optional input parameter that specifies the macro form.

  Use **MF=S** to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. **MF=S** is the default.

  Use **MF=L** to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

  Use **MF=E** to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

- **list addr**
  The name of a storage area to contain the parameters. For **MF=S** and **MF=E**, this can be an RS-type address or an address in register (1)-(12).

- **attr**
  An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code **attr**, the system provides a value of 0D.

- **COMPLETE**
  Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

- **PLISTVER=IMPLIED_VERSION**
- **PLISTVER=MAX**
- **PLISTVER=0**
- **PLISTVER=1**

  An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
IWMEBLK

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports the following parameters and those from version 0:
  
  ETOKEN
  EWLMMODE

  To code: Specify one of the following:
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0, or 1

  \[ RETCODE=\text{retcode} \]

  An optional output parameter into which the return code is to be copied from GPR 15.

  To code: Specify the RS-type address of a fullword field, or register (2)-(12).

  \[ RSNCODE=\text{rsncode} \]

  An optional output parameter into which the reason code is to be copied from GPR 0.

  To code: Specify the RS-type address of a fullword field, or register (2)-(12).

  \[ WORKREQ_HDL=\text{workreq_hdl} \]

  A required input parameter that contains the handle which represents the work request. This handle was returned from a previous call to IWMESTRT or IWM4ECRE.

  To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMEBLK macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.
The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

**Table 29. Return and Reason Codes for the IWMEBLK Macro**

<table>
<thead>

  * WRHANDLE DS CL8 Work Request Handle  
  * BKHANDLE DS CL8 Work Request Block Handle
IWMEDREG — Deregister a WLM enclave

The IWMEDREG service allows the caller to deregister an enclave which it previously registered using the IWMEREG service. Deregistration is required as soon as the caller has finished using the enclave so that the enclave can eventually be deleted. If enclave deletion was requested while the enclave was registered, deletion occurs when the last deregistration takes place.

The caller can run in task or SRB mode.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state or program key mask (PKM) allowing keys 0-7. |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary or access register (AR) |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
6. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.

Restrictions

None.
**IWMEDREG**

**Input register information**

Before issuing the IWMEDREG macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMEDREG macro is as follows:

```
IWMEDREG REGTOKEN=regtoken,ETOKEN=etoken,RETCODE=retcode
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMEDREG macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ETOKEN=etoken
A required input parameter that contains the enclave token.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,MF=S
,LF=(L,list addr)
,LF=(L,list addr,attr)
,LF=(L,list addr,OD)
,LF=(E,list addr)
,LF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
IWMEDREG

,PLISTVER=MAX
,PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

REGTOKEN=regtoken
A required input parameter, which passes the registration token obtained in a previous call to service IWMEREG.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMEDREG macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.
The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the **xxxx** value.

**Table 30. Return and Reason Codes for the IWMEDREG Macro**

Meaning: Invalid invocation environment or parameters. |
| 8           | xxxx0803    | Equate Symbol: IwmRsnCodeDisabled  
Meaning: Caller is disabled.  
Action: Avoid requesting this function while disabled. |
| 8           | xxxx0804    | Equate Symbol: IwmRsnCodeLocked  
Meaning: The caller is locked.  
Action: Avoid requesting this function while locked. |
| 8           | xxxx080B    | Equate Symbol: IwmRsnCodeBadPl  
Meaning: Error accessing parameter list.  
Action: Check for possible storage overlay. |
| 8           | xxxx0824    | Equate Symbol: IwmRsnCodeAmode24  
Meaning: The caller invoked the service but was in 24-it addressing mode.  
Action: Request this function only when you are in 31-bit addressing mode. |
| 8           | xxxx0828    | Equate Symbol: IwmRsnCodeBadVersion  
Meaning: Version number in parameter list is not valid.  
Action: Check for possible storage overlay of the parameter list. |
| 8           | xxxx083A    | Equate Symbol: IwmRsnCodeBadEnclave  
Meaning: Enclave token does not pass verification.  
Action: Check for possible storage overlay of the enclave token, or asynchronous events which may have deregistered the enclave already. |
| 8           | xxxx0880    | Equate Symbol: IwmRsnCodeBadRegToken  
Meaning: The register token does not pass verification.  
Action: Check for possible storage overlay of the register token, or asynchronous events which may have deregistered the enclave already. |
| 10          | —           | Equate Symbol: IwmRetCodeCompError  
Meaning: Component error.  
Action: No action required. The function may be successful if invoked again. |
Example

IWMEDREG REGTOKEN=REGTKN,ETOKEN=ENCTKN

* Storage areas
* ENCTKN DS CL8 Enclave token
REGTKN DS CL8 Register token
IWMEGCOR — Retrieve a correlator

The IWMEGCOR service allows work managers that participate in cross-platform enterprise workload management (EWLM) to retrieve the correlator for a given work request handle or the maximum length of a correlator.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary or access register (AR)</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
6. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.
7. If the parameter EWLMMODE=EXPLICIT_SINGLE is specified, the following restrictions apply:
   • No other task or SRB is allowed to issue other enclave services for the same enclave concurrently.
   • The caller must be in primary ASC mode before invocation.
   • The parameter list, the classification parameters and the savearea pointed to by GPR13 must be addressable in AMODE 31 and primary ASC mode.
   • No recovery environment is set up by the service. The caller is responsible to provide an appropriate error recovery environment to handle abnormal terminations.
   • The enclave must have been created with option ESTRT=EXPLICIT_SINGLE on the IWM4ECRE (or IWMECREA) invocation.
   • The caller must provide the ETOKEN parameter.
Restrictions

This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information

If the EWLMMODE=EXPLICIT_SINGLE parameter is specified, the caller must provide a standard 72-byte savearea pointed to by GPR13.

For all other cases the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMEGCOR macro is as follows:

```
IWMEGCOR name
  GET=CORRELATOR, WORKREQ_HDL=workreq_hdl, EWLMM_CORR=ewlm_corr
  GET=MAXLENGTH, EWLMM_CORRML=ewlm_corrml
  ETOKEN=NO_ETOKEN
  ETOKEN=etoken
```

z/OS V2R2 MVS Programming: Workload Management Services
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMEGCOR macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

ETOKEN=etoken
ETOKEN=NO_ETOKEN
An optional input parameter that contains the enclave token of the enclave under which the work request is processed. The values of ETOKEN are:

- ETOKEN=etoken is required, if the option EWLMMODE=EXPLICIT_SINGLE is specified.
- ETOKEN=NO_TOKEN indicates that no ETOKEN is passed. This is the default.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,EWLM_CORR=ewlm_corr
When GET=CORRELATOR is specified, a required input parameter field where the service returns the correlator of the work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,EWLM_CORRML=ewlm_corrml
When GET=MAXLENGTH is specified, a required output parameter, which will receive the maximum length of a correlator.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,EWLMMODE=NORMAL
,EWLMMODE=EXPLICIT_SINGLE
An optional input keyword that indicates if the parameter EXPLICIT_SINGLE has been specified on the IWM4ECRE (or IWMECREA) call. Note that EWLMMODE=EXPLICIT_SINGLE can only be specified if the enclave was created with the ESTRT=EXPLICIT_SINGLE option. The values of EWLMMODE are:

- EWLMMODE=NORMAL indicates that the enclave was created with the ESTRT=EXPLICIT or with the ESTRT=IMPLIED option. EWLMMODE=NORMAL is the default.
- EWLMMODE=EXPLICIT_SINGLE indicates that the enclave was created with the ESTRT=EXPLICIT_SINGLE option which can only be used for a restricted environment. The caller must provide a standard 72-byte savearea,
which is addressable in AMODE 31 and pointed to by GPR13. The
classification parameters must also be addressable in
AMODE 31.

GET=CORRELATOR
GET=MAXLENGTH
A required parameter, which describes whether the correlator or the maximum
length of a correlator is returned.

GET=CORRELATOR
indicates that the correlator should be returned.

GET=MAXLENGTH
indicates that the maximum length of a correlator should be returned.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline
parameter list and generates the macro invocation to transfer control to the
service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter may be coded with the list form of
the macro.

Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
defined by the list form, and generates the macro invocation to transfer control
to the service.

,list addr
The name of a storage area to contain the parameters. For MF=S and
MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
,PLISTVER=1
An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports the following parameters and those from version 0:
  
  - ETOKEN
  - EWLMMODE

  **To code:** Specify one of the following:
  
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0, or 1

  **RETCODE=**\texttt{retcode} \footnote{An optional output parameter into which the return code is to be copied from GPR 15.} \footnote{**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).} \footnote{GPR 15 (and \texttt{retcode}, if you coded RETCODE) contains a return code.}

  **RSNCODE=**\texttt{rsncode} \footnote{An optional output parameter into which the reason code is to be copied from GPR 0.} \footnote{When the value in GPR 15 is not zero, GPR 0 (and \texttt{rsncode}, if you coded RSNCODE) contains reason code.}

  **WORKREQ_HDL=**\texttt{workreq_hdl} \footnote{When GET=CORRELATOR is specified, a required input parameter that contains the handle which represents the work request. This handle was returned on a previous invocation of IWMESTRT or IWM4ECRE.} \footnote{**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.}

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMEGCOR macro returns control to your program:

- GPR 15 (and \texttt{retcode}, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and \texttt{rsncode}, if you coded RSNCODE) contains reason code.
The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

**IWMEJOIN — Join WLM enclave**

The purpose of this service is to allow the task (TCB) invoking this service to join an enclave for the purpose of performance management. The scope of this service affects only a single TCB at the time the service is invoked unless \texttt{SUBTASKS=YES} is in effect. Any TCBS which are attached by the current TCB subsequently will also become part of the enclave environment. This inheritance of the enclave attribute will apply to any further level of newly attached subtasks as well. Unless \texttt{SUBTASKS=YES} is in effect, subtasks which exist at the time this service is invoked will not become part of the enclave environment nor will any subtasks which are created subsequently by these non-enclave TCBS become part of the enclave environment, unless they explicitly join.

Note that a task may only join an enclave if it is not already part of an enclave. In particular, a subtask which inherited the enclave attribute from its mother task (which may happen either as a result of the mother task issuing IWMEJOIN or IWM4STBG) is not allowed to use IWMEJOIN to explicitly join an enclave. This restriction is independent of whether the enclave specified is the same enclave as it is in, or a different enclave from the one it is in. Such a subtask which inherited the enclave attribute is also not allowed to use IWMELEAV to explicitly leave the enclave. The subtask would only leave the enclave upon its own (task) termination or when the enclave is deleted (IWM4EDEL). Also, a task which successfully establishes a Begin environment (IWM4STBG) may not invoke enclave Join, nor is the task allowed to use enclave Leave while this Begin environment exists.

Upon successful completion of this service, the CPU time for the TCB (and any subsequently attached subtasks) will be attributed to the enclave for the purpose of service unit calculations and performance period switches, rather than being attributed to the address space owning the TCB. Management and reporting for the enclave will include activity for the TCB until the TCB either leaves the enclave or the enclave is deleted.

**Environment**

The requirements for the caller are:

- **Minimum authorization:** Supervisor state or program key mask (PKM) allowing keys 0-7.
- **Dispatchable unit mode:** Task
- **Cross memory mode:** Otherwise: Any PASN, any HASN, any SASN
- **AMODE:** 31-bit
- **ASC mode:** Primary
- **Interrupt status:** Enabled for I/O and external interrupts
- **Locks:** No locks may be held.
- **Control parameters:** Control parameters must be in the primary address space.

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT
part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

5. All character data, unless otherwise specified, is assumed to be left justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

1. 
2. The caller cannot have an EUT FRR established.
3. This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information

Before issuing the IWMEJOIN macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.
IWMEJOIN

Syntax

main diagram

```
name
```

Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMEJOIN macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,**ENCLAVESERVER=YES**
,**ENCLAVESERVER=NO**

An optional parameter, for internal use only The default is ENCLAVESERVER=YES.

, **ENCLAVESERVER=YES**

for internal use only

,**ENCLAVESERVER=NO**

for internal use only

**ETOKEN=etoken**

A required input parameter, which contains the enclave token to be associated with the TCB as returned by IWM4ECRE.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,**MF=S**
,**MF=(L,list addr)**
,**MF=(L,list addr,attr)**
,**MF=(L,list addr,0D)**
,**MF=(E,list addr)**
,**MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.
Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\[ \text{list addr} \]

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\[ \text{attr} \]

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

\[ \text{COMPLETE} \]

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\[ \text{PLISTVER=IMPLIED_VERSION} \]
\[ \text{PLISTVER=MAX} \]
\[ \text{PLISTVER=0} \]
\[ \text{PLISTVER=1} \]

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports both the following parameters and those from version 0:

**ENCLAVESERVER**

To code: Specify one of the following:

- **IMPLIED_VERSION**
IWMEJOIN

- MAX
- A decimal value of 0, or 1

\texttt{,RETCODE=retcode}
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

\textbf{To code:} Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

\texttt{,RSNCODE=rsncode}
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

\textbf{To code:} Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

\texttt{,SUBTASKS=NO}, \texttt{,SUBTASKS=YES}
An optional parameter, which specifies if subtasks of the joining task are also to be processed. The default is SUBTASKS=NO.

\texttt{,SUBTASKS=NO}
 specifies that subtasks of the joining task are not to be processed.

\texttt{,SUBTASKS=YES}
 specifies that subtasks of the joining task that are not already joined to an enclave are to be joined to the enclave identified by this invocation's ETOKEN parameter. When a currently dispatched subtask is joined to the enclave, its CPU time for that dispatch is associated with the enclave rather than the address space. When the subtask is removed from the enclave, if it is currently dispatched, its CPU time for that dispatch is associated with the address space rather than the enclave.

If the caller does not have PASN=HASN, this is treated as SUBTASKS=NO. The caller is notified with a return and reason code combination.

If SYSEVENT REQSRMST does not indicate, via bit SRMSTSTS being on, that this function is available, this is treated as SUBTASKS=NO.

When SUBTASKS=YES is in effect, this task's corresponding IWMELEAV will also perform leave processing upon any subtasks that are implicitly associated with the enclave. This includes subtasks that were joined to the enclave due to this task's IWMEJOIN processing as well as subtasks that were joined to the enclave by ATTACH processing.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMEJOIN macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.
The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

**Table 32. Return and Reason Codes for the IWMEJOIN Macro**

IWMEJOIN

Chapter 12. Workload management services  207
IWMELEAV — Leave WLM enclave

The purpose of this service is to allow the task (TCB) invoking this service to leave an enclave. In addition, if the join of this task to the enclave specified SUBTASKS=YES, and the primary address space matches the home address space (PASN=HASN) on this leave request, then any subtasks that are implicitly joined to the enclave (by that join, or by ATTACH processing) leave the enclave. For the purpose of performance management, the task will become associated with its home address space. The scope of this service affects the current TCB at the time the service is invoked.

Note that a task may only leave an enclave if it explicitly joined the enclave. A subtask which inherited the enclave attribute from its mother task is not allowed to use IWMELEAV to explicitly leave the enclave. The subtask would leave the enclave upon its own (task) termination, when the enclave is deleted (IWM4EDEL) or when leave processing for SUBTASKS=YES is being performed. Also, a task which successfully establishes a Begin environment (IWM4STBG) may not invoke enclave Join, nor is the task allowed to use enclave Leave while this Begin environment exists.

Upon successful completion of this service, the CPU time for the TCB (and any subsequently attached subtasks) will be attributed to the home address space for the purpose of service unit calculations and performance period switches, rather than being attributed to the enclave.

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state or program key mask (PKM) allowing keys 0-7.
Dispatchable unit mode: Task
Cross memory mode: When the joining task had subtasks processed due to SUBTASKS=YES and subtask processing is needed: PASN=HASN Otherwise: Any PASN, any HASN, any SASN
AMODE: 31-bit
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: No locks may be held.
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

**Restrictions**

1. 
2. The caller cannot have an EUT FRR established.

**Input register information**

Before issuing the IWMELEAV macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

**main diagram**

```
IWMELEAV name=etoken=retcode
```
IWMELEAV

Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMELEAV macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**ETOKEN=etoken**
A required input parameter, which contains the enclave token associated with the work request as returned by IWM4ECRE.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**MF=S**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**list addr**
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
   Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
   An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
   • IMPLIED VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED VERSION is the default.
   • MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
     If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
   • 0, if you use the currently available parameters.

To code: Specify one of the following:
   • IMPLIED_VERSION
   • MAX
   • A decimal value of 0

,RETCODE=retcode
   An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

,RSNCODE=rsncode
   An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

ABEND codes

None.
Return codes and reason codes

When the IWMELEAV macro returns control to your program:
- GPR 15 (and retnode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

### Example

To cause the current task to leave its Enclave environment:

```
IWMELEAV ETOKEN=ENCTOKEN,RETCODE=RC,RSNCODE=RSN
```

* Storage areas
  * ENCTOKEN DS CL8 Contains the enclave token associated with the work request as returned by IWMECRE
  * RC DS F Return code
  * RSN DS F Reason code
IWMEQTME — Query enclave CPU time

The purpose of this service is to return the enclave processor times if the current dispatchable work unit is associated with an enclave.

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state. Any PSW key.
Dispatchable unit mode: Task, if CURRENT_DISP=YES; otherwise, task or SRB
Cross memory mode: Non-XMEM or XMEM. Any PASN, HASN, SASN.
AMODE: 31-bit
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts if CURRENT_DISP=YES, otherwise enabled or disabled for I/O and external interrupts
Locks: No locks are required.
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
4. Caller is responsible for error recovery.

Restrictions

This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information

Before issuing the IWMEQTME macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
</tbody>
</table>
When control returns to the caller, the ARs contain:

**Register**

**Contents**

- **0-1**: Used as work registers by the system
- **2-13**: Unchanged
- **14-15**: Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None

**Syntax**

**main diagram**
Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMEQTME macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**CPUTIME=cputime**

An optional output parameter, which will contain the total accumulated TCB and SRB time for the enclave that is associated with the current dispatchable workunit. The CPU time will be in TOD clock format.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**,CURRENT_DISP=NO**

**,CURRENT_DISP=YES**

An optional parameter indicating whether to call the dispatcher before querying the enclave processor times. Enclave processor times are only accumulated when an enclave loses the processor. So the processor times are the total accumulated times for the enclave up to the point when it was dispatched for the last time. Because the enclave being queried by the service is currently active on a processor, the processor times are not accurate; all processor times since the last dispatch of the enclave are missing. To make the enclave processor times returned by the service more accurate, the dispatcher can optionally be called to update the accumulated processor times before they are returned by the service.

This option provides benefit mostly for single-work-unit enclaves. For enclaves with multiple work units (tasks or SRBs) running in parallel, the benefit will be marginal because the call to the dispatcher will only update the times for the current (calling) workunit.

The default is CURRENT_DISP=NO.

**,CURRENT_DISP=NO**

The enclave processor times are queried without calling the dispatcher before. Which means that processor times since the last dispatch of the enclave are missing, leading to slightly too small results. In return invocation of the service is less costly, and has less prerequisites in the environment.

**,CURRENT_DISP=YES**

The enclave processor times are queried after calling the dispatcher. Which means that all processor times for the work unit up to invoking the service are returned. The price for getting more exact values is more cycles for invoking the service, and more restricted environments in which it can be invoked.

**,MF=S**

**,MF=(L,list addr)**

**,MF=(L,list addr,attr)**

**,MF=(L,list addr,0D)**

**,MF=(E,list addr)**

**,MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.
IWMEQTME

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\,list addr

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\,attr

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

\,COMPLETE

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\,PLISTVER=IMPLIED_VERSION
\,PLISTVER=MAX
\,PLISTVER=0
\,PLISTVER=1
\,PLISTVER=2

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, which supports all parameters except those specifically referenced in higher versions.

- **1**, which supports both the following parameters and those from version 0:
  - ZIIPONCPTIME
  - ZIIPQUALTIME
  - ZIIPTIME
IWMEQTME

- 2, which supports both the following parameters and those from version 0 and 1:
  - CURRENT_DISP
  - ZAAPONCPTIME
  - ZAAPNFACOR
  - ZAAPTIME

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
  - A decimal value of 0, 1, or 2

\textbf{,RETCODE=}\texttt{retcode}

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

\textbf{,RSNCODE=}\texttt{rsncode}

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

\textbf{,ZAAPNFACOR=}\texttt{zaapnfactor}

An optional output parameter, which will contain the normalization factor for application assist processors (zAAPs). If zAAPs are running at a different speed, multiply zAAP times with this factor and divide the result by 256 to normalize the values to the speed of regular CPs. Note however, that if there has been a speed change of zAAP processors during the life time of the enclave, this calculation will return imprecise data.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

\textbf{,ZAAPONCPTIME=}\texttt{zaaponcptime}

An optional output parameter, which will contain the total accumulated time spent on a regular CP for application assist processor (zAAP) eligible work for the enclave that is associated with the current dispatchable work unit. The time will be in TOD clock format, normalized to the regular processor speed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\textbf{,ZAAPTIME=}\texttt{zaaptime}

An optional output parameter, which will contain the total accumulated application assist processor (zAAP) time for the enclave that is associated with the current work unit. The value is not normalized to the speed of regular CPs, but is expressed in zAAP speed which might be different. You may use ZAAPNFACOR to normalize the value to the speed of regular CPs. Note however, that if the zAAP speed changed during the life time of the enclave, this value cannot be normalized precisely. The time will be in TOD clock format.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.
IWMEQTME

,ziiponcptime=ziiponcptime
An optional output parameter, which will contain the total accumulated time spent on a standard processor for zIIP eligible work for the enclave that is associated with the current dispatchable workunit. The time will be in TOD clock format, normalized to standard processor speed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,ziipqualtime=ziipqualtime
An optional output parameter, which will contain the total time the enclave that is associated with the current dispatchable workunit was qualified to run on an integrated information processor (zIIP). The time will be in TOD clock format.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,ziiptime=ziiptime
An optional output parameter, which will contain the total accumulated time spent on an integrated information processor (zIIP) for the enclave that is associated with the current dispatchable workunit. The zIIP time will be in TOD clock format, normalized to standard processor speed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

ABEND codes

Invoking IWMEQTME with parameter CURRENT_DISP=YES while being disabled for I/O and external interrupts results in ABEND 05D-08:

Explanation: A program issued a CALLDISP macro that is not valid. A hexadecimal reason code in register 15 explains the error: 08 The macro specified FRRSTK=SAVE while the program holds a lock, or the macro specified FRRSTK=NOSAVE while the program holds a lock other than the LOCAL lock or the cross memory local (CML) lock.

Invoking IWMEQTME with parameter CURRENT_DISP=YES while being in SRB mode results in ABEND 05D-10:

Explanation: A program issued a CALLDISP macro that is not valid. A hexadecimal reason code in register 15 explains the error: 10 The program was not in task control block (TCB) mode.

Return codes and reason codes

When the IWMEQTME macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.
Table 34. Return and Reason Codes for the IWMEQTME Macro

Examples

None.
IWMEREG — Register a WLM enclave

The IWMEREG service allows the caller to register an enclave in order to prevent it from being deleted. This is useful if the caller wants to schedule SRBs or join tasks to an enclave that is owned by another subsystem. Registration guarantees that the enclave will continue to exist until the corresponding deregistration is done, even if the other subsystem deletes the enclave. The system defers the enclave's deletion until after the last deregistration.

The address space identified as the home address space at the time of registration is held responsible for deregistration in case of abnormal termination of the job step, the job, or the address space itself.

The caller can run in task or SRB mode.

Environment

The requirements for the caller are:

| Minimum authorization:                     | Supervisor state or program key mask (PKM) allowing keys 0-7. |
| Dispatchable unit mode:                    | Task or SRB                                                   |
| Cross memory mode:                         | Any PASN, any HASN, any SASN                                  |
| AMODE:                                     | 31-bit                                                       |
| ASC mode:                                  | Primary or access register (AR)                              |
| Interrupt status:                          | Enabled for I/O and external interrupts                      |
| Locks:                                     | No locks may be held.                                       |
| Control parameters:                        | Control parameters must be in the primary address space.     |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
6. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.
Restrictions

This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

Input register information

Before issuing the IWMEREG macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contents</td>
</tr>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2-13</td>
</tr>
<tr>
<td>14</td>
</tr>
<tr>
<td>15</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contents</td>
</tr>
<tr>
<td>0-1</td>
</tr>
<tr>
<td>2-13</td>
</tr>
<tr>
<td>14-15</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMEREG macro is as follows:

```
IWMEREG --REGTOKEN=regtoken,--SUBSYS=subsys,--SUBSYSNM=subsysnm

IWMEREG --ETOKEN=etoken,--OWNER=HOME

IWMEREG --SUBSYSREQUEST=subsysrequest,--OWNER=PRIMARY
```
Parameters

The parameters are explained as follows:

name
   An optional symbol, starting in column 1, that is the name on the IWMEREG macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ETOKEN=etoken
   A required input parameter that contains the enclave token.

   To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
   An optional input parameter that specifies the macro form.

   Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

   Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

   Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,list addr
   The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
   An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

An optional parameter, for internal use only. The default is OWNER=HOME.

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 0, which supports all parameters except those specifically referenced in higher versions.
- 1, which supports the following parameter and those from version 0:

  OWNER

  To code: Specify one of the following:
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0, or 1

REGTOKEN=regtoken
A required output parameter that will receive the registration token

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).
A required input parameter, which contains the generic subsystem type (e.g. IMS, CICS, etc.).

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 4-character field.

- **SUBSYSNM=subsysnm**
  A required input parameter, which identifies the subsystem instance.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

- **SUBSYSREQUEST=subsysrequest**
  An optional input parameter that allows the caller to pass additional information in order to distinguish between different invocations by the same subsystem.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

### ABEND codes

None.

### Return codes and reason codes

When the IWMEREG macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

### Example

```
IWMEREG ETOKEN=ENCTKN,REGTOKEN=REGTKN,
          SUBSYS=SUBSTYPE,SUBSYSNM=SUBSNAME
*
* Storage areas
*
 ENCTKN DS CL8       Enclave token
 SUBSNAME DS CL8     Subsystem name
 SUBTYPE DS CL4       Subsystem type
 REGTKN DS CL8       Register token
```
IWMERES — Change an enclave

The IWMERES macro allows the caller to change the performance controls for work associated with an independent enclave. The caller can:

- Change the service class of work currently in execution, with the **SRVCLASS** keyword. Resetting to a new service class also resumes quiesced work.
- Quiesce work currently in execution, with the **QUIESCE** keyword.
- Reclassify work currently in execution according to the service policy in effect, with the **RESUME** keyword. The **RESUME** keyword also resumes quiesced work.

The system does not allow foreign enclaves or dependent enclaves to be reset. See "Restrictions" for details.

Environment

The requirements for the caller are:

- **Minimum authorization**: Supervisor state or program key mask (PKM) allowing keys 0-7.
- **Dispatchable unit mode**: Task or SRB
- **Cross memory mode**: PASN=HASN=SASN
- **AMODE**: 31-bit
- **ASC mode**: Primary
- **Interrupt status**: Enabled for I/O and external interrupts
- **Locks**: No locks may be held.
- **Control parameters**: Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. This macro may not be used prior to the completion of WLM address space initialization.
2. The caller cannot reset a dependent enclave. A dependent enclave can only be reset by resetting the address space that owns the enclave.
3. The caller cannot reset a work-dependent enclave. Such an enclave can only be reset by resetting the owning independent enclave.
4. The caller cannot reset a foreign enclave. A foreign enclave can only be reset by resetting the original enclave on the originating system (foreign independent enclave) or by resetting the remote owner address space (foreign dependent enclave).
5. The caller cannot reset an enclave that is implicitly quiesced because one or more address space currently serving the enclave is quiesced. An address space is serving an enclave when any of its tasks is joined to the enclave or when an
SRB is scheduled to the enclave and the SRB used the ENCASSOC-sysevent to establish an association with the address space.

**Input register information**

Before issuing the IWMERES macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMERES macro is as follows:

```
-> IWMERES ETOKEN=etoken,FUNCTION=RESET,SRVCLASS=srvclass

->,FUNCTION=QUIESCE,FUNCTION=RESUME

->,FUNCTION=QUIESCE

->,FUNCTION=RESUME

->,USERID=userid,PRODUCT=product

->,RETCODE=retcode,RSNCODE=rsncode
```
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMERES macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**ETOKEN=etoken**
A required input parameter that contains the enclave token. The enclave token must represent an original independent enclave.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**FUNCTION=RESET**
**FUNCTION=QUIESCE**
**FUNCTION=RESUME**
An optional parameter, which indicates the function to perform against the enclave. The default is FUNCTION=RESET.

**FUNCTION=RESET**
Requests that the enclave's service class be changed.

**FUNCTION=QUIESCE**
Requests that the enclave be quiesced.

**FUNCTION=RESUME**
Requests that the enclave be reclassified according to the service policy in effect. This undoes a prior request to reset the enclave to a particular service class, or to quiesce the enclave.

**MF=S**
**MF=(L,list addr)**
**MF=(L,list addr,attr)**
**MF=(L,list addr,0D)**
**MF=(E,list addr)**
**MF=(E,list addr,COMPLETE)**
**MF=(E,list addr,NOCHECK)**
**MF=(M,list addr)**
**MF=(M,list addr,COMPLETE)**
**MF=(M,list addr,NOCHECK)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.
IWMERES

Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter may be coded with the list form of
the macro.

Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
defined by the list form, and generates the macro invocation to transfer control
to the service.

Use MF=M together with the list and execute forms of the macro for service
routines that need to provide different options according to user-provided
input. Use the list form to define a storage area; use the modify form to set the
appropriate options; then use the execute form to call the service.

IBM recommends that you use the modify and execute forms of IWMERES in
the following order:

- Use IWMERES ...MF=(M,list-addr,COMPLETE) specifying appropriate
  parameters, including all required ones.
- Use IWMERES ...MF=(M,list-addr,NOCHECK), specifying the parameters
  that you want to change.
- Use IWMERES ...MF=(E,list-addr,NOCHECK), to execute the macro.

list addr
The name of a storage area to contain the parameters. For MF=S, MF=E,
and MF=M, this can be an RS-type address or an address in register
(1)-(12).

attr
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code attr, the system provides a value of 0D.

COMPLETE
Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

NOCHECK
Specifies that the system is not to check for required parameters and is not
to supply defaults for omitted optional parameters.

PLISTVER=IMPLIED VERSION
PLISTVER=MAX
PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and
with the same value on all of the macro forms. The values are:

- IMPLIED VERSION, which is the lowest version that allows all parameters
  specified on the request to be processed. If you omit the PLISTVER
  parameter, IMPLIED VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible.
  This size might grow from release to release and affect the amount of
  storage that your program needs.
If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- 0, if you use the currently available parameters.

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

\[PRODUCT=product\]
A required input parameter, which contains the product name that is requesting the enclave be changed. The product name is included in the SMF 90 subtype 30 record created by IWMERES.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\[RETCODE=retcode\]
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

\[RSNCODE=rsncode\]
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

\[SRVCLASS=srvclass\]
When FUNCTION=RESET is specified, a required input parameter, which is the service class to be assigned to the enclave. Resetting to a new service class also resumes quiesced work.

To code: Specify the RS-type address of an 8-character field.

\[USERID=userid\]
A required input parameter, which contains the id of the user who is requesting the enclave be changed. The user ID is included in the SMF 90 subtype 30 record created by IWMERES. If there is no user ID available, the caller should pass blanks.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**
None.

**Return codes and reason codes**
When the IWMERES macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.
The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

**Table 36. Return and Reason Codes for the IWMERES Macro**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>

### Table 36. Return and Reason Codes for the IWMERES Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| C           | xxxx0C32    | **Equate Symbol**: IwmRsnCodeNotEligibleForSrvClass  
**Meaning**: The active job in the specified address space or the specified enclave is not eligible for reset into the specified system service class. Only address spaces created with the ASCRE HIPRI attribute are eligible for reset into the SYSTEM service class.  
**Action**: Record or report the error if appropriate. |
| 10          | —           | **Equate Symbol**: IwmRetCodeCompError  
**Meaning**: Component error.  
**Action**: Contact your system programmer. |

### Example

To change the service class of the enclave identified by the token TOKEN:

```
IWMERES ETOKEN=TOKEN,SRVCLASS=SCNAME,USERID=USR,PRODUCT=PROD
```

* Storage areas

<table>
<thead>
<tr>
<th>TOKEN</th>
<th>DS</th>
<th>CL8</th>
<th>Contains the enclave token</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCNAME</td>
<td>DS</td>
<td>CL8</td>
<td>Contains the service class name to assign to the job</td>
</tr>
<tr>
<td>USR</td>
<td>DS</td>
<td>CL8</td>
<td>Contains the id of the user who is requesting the change</td>
</tr>
<tr>
<td>PROD</td>
<td>DS</td>
<td>CL8</td>
<td>Contains the product name of the code invoking IWMERES</td>
</tr>
</tbody>
</table>
IWMESQRY — Query enclave state

The purpose of this service is to query whether or not the current dispatchable work unit is associated with an enclave. The output is either the enclave token or the STOKEN of the address space associated with the caller's work unit.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state. Any PSW key. |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Non-XMEM or XMEM. Any PASN, HASN, SASN. |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled or disabled for I/O and external interrupts |
| Locks: | No locks are required. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
4. The caller is responsible for the error recovery.

Restrictions

This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information

Before issuing the IWMESQRY macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>
When control returns to the caller, the ARs contain:

Register Contents

- 0-1 Used as work registers by the system
- 2-13 Unchanged
- 14-15 Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMESQRY macro is as follows:

```
IWMESQRY
  name
  ETOKEN=etoken
  TOKEN=token,
  IMPORTANCE=importance
  
  RETCODE=retcode
  RSNCODE=rsncode
  
  ,PLISTVER=IMPLIED_VERSION
  ,PLISTVER=MAX
  ,PLISTVER=0
  ,PLISTVER=1

  MF=S
  
  ,MF=(L,list addr
  ,attr)
  ,MFE=(E,list addr
  ,attr,COMPLETE)
```

Parameters

The parameters are explained as follows:

```
name
  An optional symbol, starting in column 1, that is the name on the IWMESQRY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

ETOKEN=etoken
  A required output parameter, which will receive the enclave token if the current dispatchable work unit is associated with an enclave. If it is not
associated with an enclave, the field is set to 0. This parameter is deprecated and supported for compatibility reasons only. The TOKEN parameter should be used instead.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

`,IMPORTANCE=importance`

An optional output parameter that will receive the importance value of the service class to which the unit of work is classified.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a halfword field.

`,MF=S`

`,MF=(L,list addr)
`,MF=(L,list addr,attr)
`,MF=(L,list addr,0D)
`,MF=(E,list addr)
`,MF=(E,list addr,COMPLETE)`

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

`,list addr`

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

`,attr`

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

`,COMPLETE`

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

`,PLISTVER=IMPLIED_VERSION`

`,PLISTVER=MAX`

`,PLISTVER=0`

`,PLISTVER=1`

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
• **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

• **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

• **0**, which supports all parameters except those specifically referenced in higher versions.

• **1**, which supports the following parameter and those from version 0:

  IMPORTANCE

  To code: Specify one of the following:

  • IMPLIED_VERSION
  
  • MAX
  
  • A decimal value of 0, or 1

• **RETCODE=retcode**

  An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (with or without parentheses), the value will be left in GPR 15.

  To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

• **RSNCODE=rsncode**

  An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (with or without parentheses), the value will be left in GPR 0.

  To code: Specify the RS-type address of a fullword field, or register (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

• **TOKEN=token**

  A required output parameter which will receive either the enclave token if the current dispatchable work unit is associated with an enclave (as indicated by return code 0), or the STOKEN of the address space the work unit is associated with (return code 4).

  To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMESQRY macro returns control to your program:

• GPR 15 (and retcode, if you coded RETCODE) contains a return code.

• When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.
The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Table 37. Return and Reason Codes for the IWMESQRY Macro

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeOk</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Successful completion.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Action: None required.</td>
</tr>
<tr>
<td>4</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeWarning</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Successful completion, unusual conditions noted.</td>
</tr>
<tr>
<td>4</td>
<td>xxxx041C</td>
<td>Equate Symbol: IwmRsnCodeNotEnclave</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: The current dispatchable work unit is not associated with an enclave. The returned token is the STOKEN of the associated address space.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Action: None required.</td>
</tr>
</tbody>
</table>

Example

To query whether the current dispatchable work unit is associated with an enclave or an address space, specify:

```
IWMESQRY TOKEN=MYTOKEN,RETCODE=RC,RSNCODE=RSN
```

* Storage areas

```
* MYTOKEN DS CL8 Enclave token or STOKEN
RC DS F Return code
RSN DS F Reason code
```
IWMESTOP — Stop a work request

The IWMESTOP service allows work managers that participate in cross-platform enterprise workload management (EWLM) to explicitly indicate the stop of an EWLM work request. Using this service the application work request model is decoupled from WLM’s enclave model.

The counterpart of this service to indicate the start of an EWLM work request is IWMESTRT.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state or program key mask (PKM) allowing keys 0-7 |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31- and 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro. |
| ASC mode: | Primary or access register (AR) |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of 31-bit register 0, and the reason code variable when specified, may be non-zero and represent diagnostic data which is not part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
6. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.
7. If the parameter EWLMMODE=EXPLICIT_SINGLE is specified, the following restrictions apply:
   • No other task or SRB is allowed to issue other enclave services for the same enclave concurrently.
   • The caller must be in primary ASC mode before invocation.
   • The parameter list, the classification parameters and the savearea pointed to by GPR13 must be addressable in AMODE 31 and primary ASC mode.
No recovery environment is set up by the service. The caller is responsible to provide an appropriate error recovery environment to handle abnormal terminations.

The enclave must have been created with option ESTRT=EXPLICIT_SINGLe on the IWM4ECRE (or IWMECREA) invocation.

The caller must provide the ETOKEN parameter.

**Restrictions**

None.

**Input register information**

If the EWLMODE=EXPLICIT_SINGLe parameter is specified, the caller must provide a standard 72-byte savearea pointed to by GPR13.

For all other cases the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.
Syntax

The syntax of the IWMESTOP macro is as follows:

```
IWMESTOP ETOKEN=etoken WORKREQ_HDL=workreq_hdl
```

```
,WORKREQ_STA=0 ,EWLMMODE=NORMAL ,RETCODE=retcode
```

```
,WORKREQ_STA=workreq_sta ,EWLMMODE=EXPLICIT_SINGLE
```

```
,RSNCODE=rsncode ,PLISTVER=IMPLIED VERSION
```

```
,MF=S ,MF=(L,list addr)
```

```
,MF=(E,list addr)
```

```
,MF=COMPLETE
```

Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMESTOP macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**ETOKEN=etoken**

A required input parameter that contains the enclave token of the enclave under which the work request is processed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**,EWLMMODE=NORMAL**

**,EWLMMODE=EXPLICIT_SINGLE**

An optional input keyword that indicates if the parameter EXPLICIT_SINGLE has been specified on the IWM4ECRE (or IWMECREA) call. Note that EWLMMODE=EXPLICIT_SINGLE can only be specified if the enclave was created with the ESTRT=EXPLICIT_SINGLE option. The values of EWLMMODE are:

- **EWLMMODE=NORMAL** indicates that the enclave was created with the ESTRT=EXPLICIT or with the ESTRT=IMPLIED option. EWLMMODE=NORMAL is the default.
- **EWLMMODE=EXPLICIT_SINGLE** indicates that the enclave was created with the ESTRT=EXPLICIT_SINGLE option which can only be used for a restricted environment. The caller must provide a standard 72-byte savearea, which is addressable in AMODE 31 and pointed to by GPR13. The parameter list and the classification parameters must also be addressable in AMODE 31.
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

`list addr`

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

`attr`

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

`COMPLETE`

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

`PLISTVER=IMPLIED_VERSION`

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

To code: Specify one of the following:
IWMESTOP

- IMPLIED_VERSION
- MAX
- A decimal value of 0

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

WORKREQ_HDL=workreq_hdl
A required input parameter that contains the handle which represents the work request. This handle was returned from a previous call to IWMESTRT or IWM4ECRE.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,WORKREQ_STA=workreq_sta
,WORKREQ_STA=0
An optional input parameter, which contains the completion status code of the work request. Available completion status codes are described in the EWLM ARM interface specification. The use of symbolic constants IwmEwlArmStatusGood, IwmEwlArmStatusAborted, IwmEwlArmStatusFailed, IwmEwlArmStatusUnknown (defined in macro IWMYCON) is recommended.

The default is 0. This indicates successful completion.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

ABEND codes
None.

Return codes and reason codes
When the IWMESTOP macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>

Table 38. Return and Reason Codes for the IWMESTOP Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0897    | **Equate Symbol**: IwmRsnCodeTranStatusInvalid  
**Meaning**: Passed work request completion status is not valid.  
**Action**: Check the EWLM ARM interface specification for valid completion status values. |
| 8           | xxxx08A0    | **Equate Symbol**: IwmRsnCodeNotExplicitSingle  
**Meaning**: The service has been invoked with option EWLMMODE=EXPLICIT_SINGLE but the enclave has not been created with the ESTRT=EXPLICIT_SINGLE option or vice versa.  
**Action**: If ESTRT=EXPLICIT_SINGLE was coded on the IWM4ECRE or IWMECREA call, EWLMMODE=EXPLICIT_SINGLE must also specified on the IWMEBLK call. If ESTRT=EXPLICIT OR ESTRT=IMPLIED was coded on the IWM4ECRE or IWMECREA call, EWLMMODE=NORMAL must be specified on the IWMEBLK call (or the EWLMMODE parameter can be omitted). |
| 10          | —           | **Equate Symbol**: IwmRetCodeCompError  
**Meaning**: Component error.  
**Action**: No action required. The function may be successful if invoked again. |

**Example**

```lisp
IWMESTOP ETOKEN=ENCTKN,WORKREQ_HDL=WRHANDLE,  
           WORKREQ_STA=WRSTATUS
```

* Storage areas
  * **ENCTKN** DS CL8 Enclave token  
  * **WRHANDLE** DS CL8 Work Request Handle  
  * **WRSTATUS** DS CL4 Work Request Completion Status
IWMESTRT — Start a work request

The IWMESTRT service allows work managers that participate in cross platform Enterprise Workload Management (EWLM) to explicitly indicate the start of an EWLM work request. Using this service, the application work request model is decoupled from the WLM enclave model.

The counterpart of this service to indicate the end of an EWLM work request is IWMESTOP.

Environment

The requirements for the caller are:

- **Minimum authorization:** Supervisor state or program key mask (PKM) allowing keys 0-7.
- **Dispatchable unit mode:** Task or SRB
- **Cross memory mode:** Any PASN, any HASN, any SASN
- **AMODE:** 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
- **ASC mode:** Primary or access register (AR)
- **Interrupt status:** Enabled for I/O and external interrupts
- **Locks:** No locks may be held.
- **Control parameters:** Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of 31-BIT register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
6. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.
7. If the parameter EWLMODE=EXPLICIT_SINGLE is specified, some restrictions apply:
   - No other task or SRB is allowed to issue other enclave services for the same enclave concurrently.
   - The caller must be in primary ASC mode before invocation.
   - The parameter list and the save area pointed to by GPR13 must be addressable in AMODE 31 and primary ASC mode.
   - No recovery environment is set up by the service. The caller is responsible to provide an appropriate error recovery environment to handle abnormal terminations.
   - The enclave must have been created with option ESTRT=EXPLICIT_SINGLE on the IWM4ECRE(or IWMECREA) invocation.
All data in the optional classify parameter list (CLSFY=xxx) are ignored, including the EWLM_CORR. If the application wants to specify an EWLM parent correlator or classification attributes for an EWLM hop0 work request, these data have to be passed in the classification parameter list on the IWM4ECRE (IWMECREA) call and thus will be the same for all work requests on the enclave.

Restrictions

None

Input register information

If EWLMODE=EXPLICIT_SINGLE is specified, the caller must provide a standard 72-Byte savearea pointed to by R13.

For all other cases the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.
### Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMESTRT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**,ARRIVALTIME=arrivaltime**

An optional input parameter, which contains the time when the work request actually started. This time is used to calculate the response time of the work request. The format of the field is STCK. The default is NO_ARRIVALTIME, indicates that no arrival time is passed.

*To code:* Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

**,CLSFY=clsfy**

An optional input parameter, which contains the classification information in the format of the parameter list for IWMCLSFY or IWM4CLSY. NOTE that this name is the data area name, not its pointer. IWM4CLSY or IWMCLSFY MF(M) should be used to initialize the area prior to invocation of IWMESTRT. If the EWLM_CORR field within that classification information is non-zero, a sub-work request is started.

Note that the variable length fields associated with the classify parameter list given by the CLSFY keyword have the following limitations in addition to those documented in IWMCLSFY or IWM4CLSY:

- SUBSYSMP is limited to 255 bytes
- COLLECTION is limited to 18 bytes
- CORRELATION is limited to 12 bytes
IWMESTRT

Note: If EWLMMODE=EXPLICIT_SINGLE is specified, all data in the optional classify parameter list (CLSFY=xxx) are ignored, including the EWLM_CORR. If the application wants to specify an EWLM parent correlator or classification attributes for an EWLM hop0 work request, these data have to be passed in the classification parameter list on the IWM4ECRE (IWMECREA) call and thus will be the same for all work requests on the enclave. The default is NO_CLSFY. indicates that no classify parameter list is passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

**ETOKEN= etoken**
A required input parameter that contains the enclave token of the enclave under which the work request is processed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,**EWLMODE=NORMAL**
,**EWLMODE=EXPLICIT_SINGLE**
An optional parameter that indicates, if the parameter EXPLICIT_SINGLE has been specified on the IWM4ECRE (or IWMECREA) call. The EWLMODE parameter has to be omitted (or the default value NORMAL must be specified), if the enclave was not created with the ESTRT=EXPLICIT_SINGLE option and vice versa. Otherwise the results may be unpredictable. The default is EWLMODE=NORMAL.

,**EWLMODE=NORMAL**
indicates that the enclave was created with the ESTRT=EXPLICIT or ESTRT=IMPLIED option.

,**EWLMODE=EXPLICIT_SINGLE**
indicates that the enclave was created with the ESTRT=EXPLICIT_SINGLE option which can only be used for a restricted environment. The caller must also provide a standard 72-Byte savearea (addressable in AMODE 31) pointed to by GPR13. Moreover the parameter list and the classification parameters must also be addressable in AMODE 31.

,**MF=S**
,**MF=(L,list addr)**
,**MF=(L,list addr,attr)**
,**MF=(L,list addr,OD)**
,**MF=(E,list addr)**
,**MF=(E,list addr,COMPLETE)**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.
,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
  • IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
  • MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs. If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
  • 0, if you use the currently available parameters.

To code: Specify one of the following:
  • IMPLIED_VERSION
  • MAX
  • A decimal value of 0

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

,WORKREQ_HDL=workreq_hdl
A required output parameter that will receive the handle which represents the
work request. The application must pass this handle to the other work request services IWMESTOP, IWMEBLK, IWMEUBLK, and IWMEGCOR.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMESTRT macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>

Table 39. Return and Reason Codes for the IWMESTRT Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol Meaning and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx08A0    | **Equate Symbol:** IwmRsnCodeNotExplicitSingle  
**Meaning:** The service has been invoked with option EWLMMODE=EXPLICIT_SINGLE, but the enclave has not been created with the ESTRT=EXPLICIT_SINGLE option or vice versa.  
**Action:** If ESTRT=EXPLICIT_SINGLE was coded on the IWM4ECRE or IWMECREA call, EWLMMODE=EXPLICIT_SINGLE must also be specified on the IWMESTRT call. If ESTRT=EXPLICIT OR ESTRT=IMPLIED was coded on the IWM4ECRE or IWMECREA call, EWLMMODE=NORMAL must be specified on the IWMESTRT call (or the EWLMMODE parameter can be omitted). |

| 10          | —           | **Equate Symbol:** IwmRetCodeCompError  
**Meaning:** Component error.  
**Action:** No action required. The function may be successful if invoked again. |

**Example**

* Before calling IWMESTRT initialize classification attributes in CLFSY  
  * IWMESTRT ETOKEN=ENCTKN,CLSFY=CLFSY,  
    WORKREQ_HDL=WRHANDLE,ARRIVALTIME=ATIME  
  * Storage areas  
  * IWM4CLSY PLISTVER=MAX,MF=(L,CLFSY,0D)  
    ENCTKN DS CL8 Enclave token  
    ATIME DS CL8 Arrival time  
    WRHANDLE DS CL8 Work Request Handle
IWMEUBLK — Work request no longer blocked

The IWMEUBLK service allows work managers that participate in cross-platform enterprise workload management (EWLM) to indicate that processing of a work request is no longer blocked.

The counterpart of this service to indicate that the processing of a work request is blocked is IWMEBLK.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state or program key mask (PKM) allowing keys 0-7 |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31- or 64-bit. If in 64-bit addressing mode, code SYSSYSTAT AMODE64=YES before invoking this macro. |
| ASC mode: | Primary or access register (AR) |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of 31-bit register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSN_CODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
6. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.
7. If the parameter EWLMMODE=EXPLICIT_SINGLE is specified, the following restrictions apply:
   • No other task or SRB is allowed to issue other enclave services for the same enclave concurrently.
   • The caller must be in primary ASC mode before invocation.
   • The parameter list, the classification parameters and the savearea pointed to by GPR13 must be addressable in AMODE 31 and primary ASC mode.
- No recovery environment is set up by the service. The caller is responsible to provide an appropriate error recovery environment to handle abnormal terminations.
- The enclave must have been created with option ESTRT=EXPLICIT_SINGLE on the IWM4ECRE (or IWMECREA) invocation.
- The caller must provide the ETOKEN parameter.

**Restrictions**

This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

**Input register information**

If the EWLMMODE=EXPLICIT_SINGLE parameter is specified, the caller must provide a standard 72-byte savearea pointed to by GPR13.

For all other cases the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.
IWMEUBLK

Syntax

The syntax of the IWMEUBLK macro is as follows:

```
IWMEUBLK
  WORKREQ_HDL=workreq_hdl,
  BLOCK_HDL=block_hdl,
  ETOKEN=etoken,
  RETCODE=retcode,
  EWLMMODE=NORMAL,
  EWLMMODE=EXPLICIT_SINGLE,
  RSNCODE=rsncode,
  PLISTVER=IMPLIED_VERSION,
  PLISTVER=MAX,
  PLISTVER=0,
  PLISTVER=1,
  MF=S,
  MF=(L,list addr,attr,COMPLETE),
  MF=(E,list addr)
```

Parameters

The parameters are explained as follows:

`name`

An optional symbol, starting in column 1, that is the name on the IWMEUBLK macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`,BLOCK_HDL=block_hdl`

A required output parameter that will receive the handle identifying the blocked work request. This handle was returned from a previous call to IWMEUBLK.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

`ETOKEN=etoken`

`ETOKEN=NO_ETOKEN`

Is the name (RS-type), or address in register (2)-(12), of an optional 8-character input variable that contains the enclave token of the enclave under which the work request is processed. The values of ETOKEN are:

`ETOKEN=etoken`

required, if the option EWLMMODE=EXPLICIT_SINGLE is specified.

`ETOKEN=NOTOKEN`

indicates that no ETOKEN is passed. This is the default.

`,EWLMMODE=NORMAL`

`,EWLMMODE=EXPLICIT_SINGLE`

An optional input keyword that indicates if the parameter EXPLICIT_SINGLE has been specified on the IWM4ECRE (or IWMECREA) call. Note that EWLMMODE=EXPLICIT_SINGLE can only be specified if the enclave was created with the ESTRT=EXPLICIT_SINGLE option. The values of EWLMMODE are:
• **EWLMMODE=NORMAL** indicates that the enclave was created with the
  ESTRT=EXPLICIT or with the ESTRT=IMPLIED option.
  EWLMMODE=NORMAL is the default.

• **EWLMMODE=EXPLICIT_SINGLE** indicates that the enclave was created
  with the ESTRT=EXPLICIT_SINGLE option which can only be used for a
  restricted environment. The caller must provide a standard 72-byte savearea,
  which is addressable in AMODE 31 and pointed to by GPR13. The
  parameter list and the classification parameters must also be addressable in
  AMODE 31.

```
,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,OD)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
```

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline
parameter list and generates the macro invocation to transfer control to the
service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter may be coded with the list form of
the macro.

Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
defined by the list form, and generates the macro invocation to transfer control
to the service.

```
,list addr
    The name of a storage area to contain the parameters. For MF=S and
    MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
    An optional 1- to 60-character input string that you use to force boundary
    alignment of the parameter list. Use a value of 0F to force the parameter
    list to a word boundary, or 0D to force the parameter list to a doubleword
    boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
    Specifies that the system is to check for required parameters and supply
    defaults for omitted optional parameters.
```

```
,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
,PLISTVER=1
```

An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and
with the same value on all of the macro forms. The values are:
• **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

• **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

• **0**, which supports all parameters except those specifically referenced in higher versions.

• **1**, which supports the following parameters and those from version 0:

  ETOKEN
  EWLMMODE

  To code: Specify one of the following:

  • IMPLIED_VERSION
  • MAX
  • A decimal value of 0, or 1

• **RETCODE=retcode**

  An optional output parameter into which the return code is to be copied from GPR 15.

  To code: Specify the RS-type address of a fullword field, or register (2)-(12).

• **RSNCODE=rsncode**

  An optional output parameter into which the reason code is to be copied from GPR 0.

  To code: Specify the RS-type address of a fullword field, or register (2)-(12).

• **WORKREQ_HDL=workreq_hdl**

  A required input parameter that contains the handle which represents the work request. This handle was returned from a previous call to IWMESTRT or IWM4ECRE.

  To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMEUBLK macro returns control to your program:

• GPR 15 (and retcode, if you coded RETCODE) contains a return code.

• When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.
The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

    BLOCK_HDL=BKHANDLE

* Storage areas
  *
  WRHANDLE DS CLB Work Request Handle
  BKHANDLE DS CLB Work Request Block Handle
IWMEXPT — Export a WLM enclave

The IWMEXPT macro exports an enclave to all systems in a parallel sysplex. This enables dispatchable units on other systems to import and join the enclave. The macro returns an export token which the caller must pass to other systems where it wants to import and join the enclave.

The caller must invoke the IWMUEXPT macro when other systems no longer need access to the exported enclave.

The primary address space must have connected to WLM using the IWM4CON macro.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state or program key mask (PKM) allowing keys 0-7. |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any HASN, any SASN. PASN must be the address space which connected to WLM. |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

It is not supported to export work-dependent enclaves.

Input register information

Before issuing the IWMEXPT macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMEXPT macro is as follows:

```
IWMEXPT ETOKEN=etoken,XTOKEN=xtoken,CONNTKN=conntkn,
          RETCODE=retcode,RSNCODE=rsncode,
          PLISTVER=IMPLIED_VERSION,PLISTVER=MAX,PLISTVER=0,
          MF=S,0D,\n          MF=(L,list addr,attr,COMPLETE),
          MF=(E,list addr,attr)\n```

Parameters

The parameters are explained as follows:
name
An optional symbol, starting in column 1, that is the name on the IWMEXPT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,CONNTKN=conntkn
A required input parameter that contains the connect token for the primary address space's connection to WLM.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

ETOKEN=etoken
A required input parameter that contains the enclave token of the enclave to be exported.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an
IWMEXPT

optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

`RETCODE=retcode`

An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

`RSNCODE=rsncode`

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

`XTOKEN=xtoken`

A required output parameter that contains an export token which uniquely identifies the exported enclave throughout the parallel sysplex.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMEXPT macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Connect token
IWMGCORF — Get correlator flags

The IWMGCORF service allows to check whether or not certain Application Response Measurement (ARM) flags in a provided EWLM correlator are set. These flags are contained in byte 3 of the ARM correlator format.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state or supervisor state.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No restriction.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high-order halfword of bits 0-31 of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

None.

Input register information

Before issuing the IWMGCORF macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
</tbody>
</table>
When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMGCORF macro is as follows:

```
IWMGCORF
```

Parameters

The parameters are explained as follows:

- **name**
  - An optional symbol, starting in column 1, that is the name on the IWMGCORF macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

- **,ASYNC_FLAG=async_flag**
  - An optional output parameter, which receives the indication whether or not the asynchronous flow flag is set. A value of 1 is returned, if the asynchronous flow flag is set. Otherwise 0 is returned. The caller must initialize the ASYNC_FLAG field before issuing the macro because IWMGCORF will not modify it if the EWLM_CORR field contains an invalid ARM correlator.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

- **EWLM_CORR=ewlm_corr**
  - A required input parameter, which contains an EWLM correlator. If the correlator is invalid (the architected length in the first two bytes is less than 4 or greater than 512), a call to this macro acts as a no-operation and no change to the ASYNC_FLAG or INDEP_FLAG is made.
**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

**,INDEP_FLAG=indep_flag**  
An optional output parameter, which receives the indication whether or not the independent flag is set. A value of 1 is returned, if the independent flag is set. Otherwise 0 is returned. The caller must initialize the INDEP_FLAG field before issuing the macro because IWMGCORF will not modify it if the EWLM_CORR field contains an invalid ARM correlator.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**ABEND codes**

None.

**Return codes and reason codes**

None.

**Example**

To extract the setting of the asynchronous and the independent flag from a storage area holding an ARM correlator, specify the following:

```
LHI 2,-1 INIT TO CATCH INVALID CORRELATOR
ST 2,ASYNCHRO
ST 2,INDEPEND
IWMGCORF
  EWLM_CORR=MYCORR,
  ASYNC_FLAG=ASYNCHRO,
  INDEP_FLAG=INDEPEND
L 2,ASYNCHRO LOAD ASYNCHRONOUS INDICATOR
LTR 2,2 TEST ASYNC RESULT
JP ASYN_ON ASYNC FLAG IS ON
JZ ASYN_OFF ASYNC ON, BUT NOT INDEPENDANT
CORR_INVA DS OH NOT A VALID ARM CORRELATOR
:
:
ASYN_ON L 3,INDEPEND LOAD INDEPENDENT INDICATOR
  LTR 3,3 TEST INDEP (RELEVANT, IF ASYN)
  JP INDE_ON
INDE_OFF DS OH ASYNC ON, BUT NOT INDEPENDANT
:
:
ASYNCHRO DS F STORAGE AREA FOR ASYNC FLAG
INDEPEND DS F STORAGE AREA FOR INDEP FLAG
MYCORR DS CL512 STORAGE AREA FOR ARM CORRELATOR
```
The IWMIMPT macro imports an enclave that has been previously exported using the IWMEXPT macro.

The caller must invoke the IWMUIMPT macro when it no longer needs access to the enclave.

The primary address space must have connected to WLM using the IWM4CON macro.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>Any HASN, any SASN. PASN must be the address space which connected to WLM.</td>
</tr>
<tr>
<td>AMODE</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

None.

**Input register information**

Before issuing the IWMIMPT macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:
IWMIMPT

Register

Contents

0  Reason code if GR15 return code is non-zero
1  Used as work registers by the system
2-13  Unchanged
14  Used as work registers by the system
15  Return code

When control returns to the caller, the ARs contain:

Register

Contents

0-1  Used as work registers by the system
2-13  Unchanged
14-15  Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMIMPT macro is as follows:

```plaintext
IWMIMPT XTOKEN=xtoken,ETOKEN=etoken,CONNTKN=conntkn,

,RETCODE=retcode,RSNCODE=rsncode,

,PLISTVER=IMPLIED_VERSION,

,PLISTVER=MAX,

,PLISTVER=0,

,MF=S,

,MF=(L,list addr,attr,COMPLETE),

```

Parameters

The parameters are explained as follows:

name

An optional symbol, starting in column 1, that is the name on the IWMIMPT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.
CONNTKN=conntkn
A required input parameter that contains the connect token for the primary
address space's connection to WLM.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit
field.

ETOKEN=etoken
A required output parameter that contains the enclave token for the imported
enclave. The caller can pass this token as input to all enclave services except
IWM4EDEL. The enclave token is valid on the local system only.

To code: Specify the RS-type address, or address in register (2)-(12), of an
8-character field.

MF=S
MF=(L, list addr)
MF=(L, list addr, attr)
MF=(L, list addr, 0D)
MF=(E, list addr)
MF=(E, list addr, COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline
parameter list and generates the macro invocation to transfer control to the
service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter may be coded with the list form of
the macro.

Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
defined by the list form, and generates the macro invocation to transfer control
to the service.

list addr
The name of a storage area to contain the parameters. For MF=S and
MF=E, this can be an RS-type address or an address in register (1)-(12).

attr
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code attr, the system provides a value of 0D.

COMPLETE
Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

PLISTVER=IMPLIED_VERSION
PLISTVER=MAX
PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and
with the same value on all of the macro forms. The values are:
- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

  **To code:** Specify one of the following:
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0

  `RETCODE=retcode`

  An optional output parameter into which the return code is to be copied from GPR 15.

  **To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

  `RSNCODE=rsncode`

  An optional output parameter into which the reason code is to be copied from GPR 0.

  **To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

  `XTOKEN=xtoken`

  A required input parameter that contains the export token which identifies the exported enclave.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMIMPT macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.

- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.
<table>

### Example

```
IWMIMPT XTOKEN=EXPORTT,ETOKEN=ENCLAVET,CONNTKN=CONNECTT

* Storage areas
ENCLAVET DS CL8 Enclave token
EXPORTT DS CL32 Export token
CONNECTT DS CL4 Connect token
```
IWMMXDC — Exit for resource data collection

IWMMXDC invokes the resource data collection exit specified. This exit returns information about the usage of the buffer pool or other resources which may be responsible for delays to work requests. The return and reason codes for IWMMXDC are those set by the exit invoked.

The exit environment is described in the following. The parameter list is in the same key as the PSW at the time of invocation and is in pageable storage addressable from the current address space. Upon entry to the exit, the register contents are as follows:

- Register 0 = not defined
- Register 1 contains the address of a parameter list as formatted by the list form of this macro, IWMMXDC MF=(L).
- Registers 2-13 = not defined
- Register 14 = return address
- Register 15 = entry-point address

Upon entry to the exit, the access register contents are undefined.

Upon return from the exit, the register contents are as follows:

- Register 0 = Reason code if GR15 return code is non-zero
- Registers 1-14 = not defined (need not be restored to value on entry)
- Register 15 = Return code

Upon return from the exit, the access register contents are unchanged.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Programming requirements

The list form of the macro is intended for use by products supplying a data collection exit.

The execute form of the macro is intended for use by z/OS.
The assembler execute form only initializes the parameter list and calls the exit routine. The following restrictions apply:

- The invoker must save registers required before invoking the macro
- The invoker must restore registers required immediately after invoking the macro, without depending on the exit to preserve any registers
- The invoker must copy the output results directly from the parameter list to local variables and NOT use macro keywords to do this

**Restrictions**

None.

**Input register information**

Before issuing the IWMMXDC macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unpredictable in assembler form, unchanged in PL/X form</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMMXDC macro is as follows:
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMMXDC macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

- **MF=S**
- **MF=(L,list addr)**
- **MF=(L,list addr,attr)**
- **MF=(L,list addr,0D)**
- **MF=(E,list addr)**
- **MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.
Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\[ \text{list addr} \]

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\[ \text{attr} \]

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code \text{attr}, the system provides a value of 0D.

\[ \text{COMPLETE} \]

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\[ \text{OWNER_TKN=} \text{owner_tkn} \]

When RESOURCE_TYPE=BUFFER_POOL is specified, a required input parameter, which contains data associated with the resource that was passed to registration (IWM4MREG).

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\[ \text{PLISTVER=IMPLIED_VERSION} \]
\[ \text{PLISTVER=MAX} \]
\[ \text{PLISTVER=0} \]

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

\[ \text{RES_#HITS=} \text{res_#hits} \]

When RESOURCE_TYPE=BUFFER_POOL is specified, an optional output parameter, which contains the number of hits among the references to the
bufferpool since the last invocation of the data collection exit. The corresponding field in the parameter list (IWMMXDC MF=(L)) must be set by the exit.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,RES_REFERENCES=res REFERENCES
When RESOURCE_TYPE=BUFFER_POOL is specified, an optional output parameter, which contains the number of references to the bufferpool since the last invocation of the data collection exit. The corresponding field in the parameter list (IWMMXDC MF=(L)) must be set by the exit.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,RES_CUR_SIZE=res cur size
When RESOURCE_TYPE=BUFFER_POOL is specified, an optional output parameter, which contains the current size (in 4K pages) associated with the specified resource. The corresponding field in the parameter list (IWMMXDC MF=(L)) must be set by the exit.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,RES_DATA_EXIT@=res data exit@
A required input parameter that contains the address of the resource data collection exit to be invoked.

To code: Specify the RS-type address, or address in register (2)-(12), of a pointer field.

,RES_INUSE_SIZE=res inuse size
When RESOURCE_TYPE=BUFFER_POOL is specified, an optional output parameter, which contains the current in use size (in 4K pages) associated with the specified resource. The corresponding field in the parameter list (IWMMXDC MF=(L)) must be set by the exit.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

RESOURCE_TKN=resource tkn
A required input parameter, which contains the associated WLM resource token which is returned by the registration (IWM4MREG).

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,RESOURCE_TYPE=BUFFER_POOL,
,RESOURCE_TYPE=NULL
A required parameter, which indicates the type of resource being registered.

,RESOURCE_TYPE=BUFFER_POOL
indicates that a bufferpool is being collected.

,RESOURCE_TYPE=NULL
indicates that no exit is to be called.

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMMXDC macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td>Equate Symbol: IwmRetCodeOk</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Successful completion.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Action: None required.</td>
</tr>
</tbody>
</table>

**Example**

To register a resource for delay monitoring, specify:

```plaintext
IWMMXDC
    RESOURCE_TKN=RSCTOKEN,
    RES_DATA_EXIT@=DATAEXIT@,
    RESOURCE_TYPE=BUFFER_POOL,
    OWNER_TKN=OWNERTKN,
    RETCODE=RC,RSNCODE=RSN
```

* Storage areas

* RSCTOKEN DS CL8 WLM resource token
* DATAEXIT@ DS AL4 contains the address of the Resource Data Collection Exit
* OWNERTKN DS CL8 Contains data maintained by the user
* RC DS F Return code
* RSN DS F Reason code
IWMMXRA — Exit for resource adjustment

IWMMXRA invokes the resource adjustment exit. This exit makes the adjustments indicated for the buffer pool or other resources which may be responsible for delays to work requests. The return or reason codes for IWMMXRA are those set by the exit invoked.

The exit environment is described in the following. The parameter list is in pageable storage addressable in the current address space, but is not guaranteed to be in the key of the exit because it is not expected to be changed by the exit. Upon entry to the exit, the register contents are as follows:

- Register 0 = not defined
- Register 1 contains the address of a parameter list as formatted by the list form of this macro, IWMMXRA MF=(L).
- Registers 2-13 = not defined
- Register 14 = return address
- Register 15 = entry-point address

Upon entry to the exit, the access register contents are undefined.

Upon return from the exit, the register contents are as follows:

- Register 0 = Reason code if GR15 return code is non-zero
- Registers 1-14 = not defined (need not be restored to value on entry)
- Register 15 = Return code

Upon return from the exit, the access register contents are unchanged.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state with the same PSW key as at the time of registration (IWMM4MREG).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross-memory mode:</td>
<td>PASN=HASN=SASN. The current home address space must be the same as at the time of registration (IWMM4MREG).</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held. FRRs may be established.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

The list form of the macro is intended for use by products supplying a resource adjustment exit.

The execute form of the macro is intended for use by z/OS.

The assembler execute form only initializes the parameter list and calls the exit routine. The following restrictions apply:
The invoker must save registers required before invoking the macro
The invoker must restore registers required immediately after invoking the
macro, without depending on the exit to preserve any registers.

Restrictions
None.

Input register information
Before issuing the IWMMXRA macro, the caller does not have to place any
information into any register unless using it in register notation for a particular
parameter, or using it as a base register.

Output register information
When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unpredictable in assembler form, unchanged in PL/X form</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after
issuing a service. If the system changes the contents of registers on which the caller
depends, the caller must save them before issuing the service, and restore them
after the system returns control.

Performance implications
None.

Syntax
The syntax of the IWMMXRA macro is as follows:

```
main diagram
```

IWMMXRA

Chapter 12. Workload management services 287
PARAMETERS

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMMXRA macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**list addr**
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

**COMPLETE**
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

**OWNER_TKN=owner_tkn**
When RESOURCE_TYPE=BUFFER_POOL is specified, a required input parameter, which contains data associated with the resource that was passed to registration (IWM4MREG).

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**PLISTVER=IMPLIED_VERSION**
**PLISTVER=MAX**
**PLISTVER=0**
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

**RES_ADJ_EXIT@=res_adj_exit@**
A required input parameter that contains the address of the resource adjustment exit to be invoked.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a pointer field.

**RES_CUR_SIZE= res_cur_size**
When RESOURCE_TYPE=BUFFER_POOL is specified, an required input parameter, which contains the current size (in 4K pages) associated with the specified resource.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.
When RESOURCE_TYPE=BUFFER_POOL is specified, a required input parameter, which contains the new size (in 4K pages) to be associated with the specified resource.

**To code**: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

RESOURCE_TKN=resource_tkn

A required input parameter, which contains the associated WLM resource token which is returned by the registration (IWM4MREG).

**To code**: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,RESOURCE_TYPE=BUFFER_POOL
,RESOURCE_TYPE=NULL

A required parameter, which indicates the type of resource being registered.

,RESOURCE_TYPE=BUFFER_POOL
indicates that buffer pool adjustments are needed.

,RESOURCE_TYPE=NULL
indicates that no exit is to be called.

,RETCODE=retcode

An optional output parameter into which the return code is to be copied from GPR 15.

**To code**: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code**: Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMMXRA macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code.

**Table 44. Return and Reason Codes for the IWMMXRA Macro**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeOk</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Successful completion.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Action: None required.</td>
</tr>
</tbody>
</table>
**Example**

To call a resource adjustment exit, specify the following:

```plaintext
IWMMXRA
RES_ADJ_EXIT=ADJEXIT0, X
OWNER_TKN=OWNERTKN, X
RESOURCE_TYPE=BUFFER_POOL, X
RESOURCE_TKN=RSCTOKEN, X
RES_CUR_SIZE=RESCURSIZE, X
RES_NEW_SIZE=RESNEWSIZE, X
RETCODE=RC, RSNCODE=RSN
```

* Storage areas
  * RESCURSIZE DS FL4 contains the current size of the
    * specified resource in 4K pages
  * RESNEWSIZE DS FL4 contains the new target size of the
    * specified resource in 4K pages
  * ADJEXIT0 DS AL4 contains the address of the
    * Resource Adjustment Exit
    * to be invoked
  * OWNERTKN DS CL8 Contains data maintained by
    * the user
  * RSCTOKEN DS CL8 WLM resource token
  * RC DS F Return code
  * RSN DS F Reason code
IWMPACT — Activate service policy

The Activate Service Policy routine is given control from the IWMPACT macro. The Activate Service Policy macro will complete the parameter list with caller-provided data and generate a stacking, program call to the activate policy service.

The purpose of this routine is to activate a service policy in the sysplex. The name of the service policy to be activated must be provided as input. The specified policy must exist in the current WLM service definition installed on the WLM couple data set.

The Activate Service Policy service causes a service policy to be activated synchronously. In other words, control will not be returned to the caller until the policy has been activated on all systems in the sysplex or for some reason the policy activation could not be completed.

Note that only a single policy activation request can be processed at any one time. Therefore, if a previous policy activation request is being processed and a new activation request is issued, the new request will be rejected with an appropriate return and reason code. This will occur regardless of whether the two requests were issued on the same system or different systems in the sysplex. The user can optionally request that the name of the system where another policy activation is taking place be returned in the variable specified in the SYSTEM_NAME keyword.

The Activate Service Policy macro is provided in list, execute, and standard form. The list form accepts no variable parameters and is used only to reserve space for the activate policy parameter list. The standard form is provided for use with routines which do not require reentrant code. The execute form is provided for use with the list format for reentrant routines.

Environment

The requirements for the caller are:

| Minimum authorization: | Problem state. Any PSW key. The caller must have update authority to the resource MVSADMIN.WLM.POLICY in the FACILITY class. |
| Dispatchable unit mode: | Task |
| Cross memory mode: | PASN=SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | All parameter areas must reside in current primary. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is not part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values that are described above. The constant IWMRSNCODE_MASK_CONST, defined in IWMYCON, may be used for this purpose.

Restrictions

The caller cannot have an EUT FRR established.

Input register information

Before issuing the IWMPACT macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMPACT macro is as follows:

```
IWMPACT name
  POLICY_NAME=policy_name
  CHECKHISTORY=CHECKALL
  CHECKHISTORY=IGNORE_CR
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMPACT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

CHECKHISTORY=CHECKALL
CHECKHISTORY=IGNORE_CR
An optional input parameter that applies only if the WLM policy to be activated with this request is the same policy that was active previously, that is, if this is a request to reactivate a WLM policy. As a result of the changes in effect with the reactivated policy, due to a changed WLM service definition on the CDS, WLM might discard historical data for service class periods. Among the criteria that cause WLM to discard historical data are the following:
- Classification groups are added, changed in content, or removed.
- Classification rules are added, changed, or removed.
CHECKHISTORY changes the criteria that WLM applies to make that decision.

CHECKALL
Leave WLM’s behavior unchanged. Historical data is discarded when classification groups or classification rules are changed. This is the default.

IGNORE_CR
Requests that WLM not check for changes in classification groups or changes in classification rules when making the decision about whether or not to discard historical data. Use this option if the only changes to your WLM service definition are in the categories listed above and if keeping the historical data does not negatively impact your workload.

MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.
Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.
Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\texttt{list addr}

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\texttt{attr}

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code \texttt{attr}, the system provides a value of 0D.

\texttt{COMPLETE}

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\texttt{PLISTVER=IMPLIED\_VERSION}

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form.

When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

\begin{itemize}
  \item \textbf{IMPLIED\_VERSION}, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED\_VERSION is the default.
  \item \textbf{MAX}, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
  \item \textbf{0}, if you use the currently available parameters.
\end{itemize}

\texttt{To code: Specify one of the following:}

\begin{itemize}
  \item IMPLIED\_VERSION
  \item MAX
  \item A decimal value of 0
\end{itemize}

\texttt{POLICY\_NAME=policy\_name}

A required input parameter, variable specifying the name of the service policy to be activated. The specified service policy must exist in the current service definition that is installed on the WLM couple data set.

\texttt{To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.}
IWMPACT

\texttt{,RETCODE=\textit{retcode}}

An optional output parameter into which the return code is to be copied from GPR 15.

\textbf{To code:} Specify the RS-type address of a fullword field, or register (2)-(12).

\texttt{,RSNCODE=\textit{rsncode}}

An optional output parameter into which the reason code is to be copied from GPR 0.

\textbf{To code:} Specify the RS-type address of a fullword field, or register (2)-(12).

\texttt{,SYSTEM\_NAME=\textit{system\_name}}

An optional output parameter, variable where the name of the system where another policy activation is taking place will be returned. This variable is only filled in when a return code of 4 and a reason code of xxxx0415 is returned.

\textbf{To code:} Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\textbf{ABEND codes}

\textbf{Reason Code (Hex)}

\textit{Explanation}

\textsc{X'0Axx0005'}

An attempt to reference caller’s parameters caused an OC4 abend.

\textbf{Return codes and reason codes}

When the IWMPACT macro returns control to your program:

\begin{itemize}
  \item GPR 15 (and \textit{retcode}, if you coded RETCODE) contains a return code.
  \item When the value in GPR 15 is not zero, GPR 0 (and \textit{rsncode}, if you coded RSNCODE) contains reason code.
\end{itemize}

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the \textit{xxxx} value.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|l|}
\hline
\textbf{Return Code} & \textbf{Reason Code} & \textbf{Equate Symbol, Meaning, and Action}  \\
\hline
0 & — & \textbf{Equate Symbol: \textit{IwmRetCodeOk}}  \\
 & & \textbf{Meaning: Successful completion.}  \\
 & & \textbf{Action: None required.}  \\
\hline
4 & — & \textbf{Equate Symbol: \textit{IwmRetCodeWarning}}  \\
 & & \textbf{Meaning: Successful completion, unusual conditions noted.}  \\
\hline
4 & xxxx0414 & \textbf{Equate Symbol: \textit{IwmRsncCodeNullCDS}}  \\
 & & \textbf{Meaning: This request could not be completed because no Service definition has been installed on the WLM CDS.}  \\
 & & \textbf{Action: None required.}  \\
\hline
\end{tabular}
\end{table}
### Table 45. Return and Reason Codes for the IWMPACT Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 4           | xxxx0415     | **Equate Symbol:** IwmRsnCodePolicyActInProgress  
**Meaning:** This request could not be completed because another policy activation request is currently being processed. If specified, the SYSTEM_NAME parameter will contain the name of the system on which policy activation is in progress.  
**Action:** None required. If this service is re-invoked at a later time it may be successful. |
| 4           | xxxx0416     | **Equate Symbol:** IwmRsnCodePolicyUndefined  
**Meaning:** The service policy specified could not be found in the service definition currently installed on the WLM couple data set. The service policy was not activated.  
**Action:** None required. Verify that the policy was specified correctly. |
| 8           | —            | **Equate Symbol:** IwmRetCodeInvocError  
**Meaning:** Invalid invocation environment or parameters. |
| 8           | xxxx0801     | **Equate Symbol:** IwmRsnCodeSrbMode  
**Meaning:** The caller is in SRB mode.  
**Action:** Avoid requesting this function while in SRB mode. |
| 8           | xxxx0803     | **Equate Symbol:** IwmRsnCodeDisabled  
**Meaning:** Caller is disabled.  
**Action:** Avoid requesting this function while disabled. |
| 8           | xxxx0804     | **Equate Symbol:** IwmRsnCodeLocked  
**Meaning:** The caller is locked.  
**Action:** Avoid requesting this function while locked. |
| 8           | xxxx0810     | **Equate Symbol:** IwmRsnCodeEutFrr  
**Meaning:** The caller has EUT FRR established.  
**Action:** Avoid requesting this function with an EUT FRR set. |
| 8           | xxxx0823     | **Equate Symbol:** IwmRsnCodeDatoff  
**Meaning:** The caller invoked the service while DATOFF  
**Action:** Avoid requesting this function in this environment. |
| 8           | xxxx0824     | **Equate Symbol:** IwmRsnCodeAmode24  
**Meaning:** The caller invoked the service but was in 24-bit addressing mode.  
**Action:** Request this function only when you are in 31-bit addressing mode. |
| 8           | xxxx0827     | **Equate Symbol:** IwmRsnCodeRsVdNot0  
**Meaning:** Reserved field in parameter list was non-zero.  
**Action:** Check for possible storage overlay of the parameter list. |
### Table 45. Return and Reason Codes for the IWMPACT Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0828    | Equate Symbol: IwmRsnCodeBadVersion  
Meaning: Version number in parameter list is not valid or the length specified is incorrect.  
Action: Check for possible storage overlay of the parameter list. |
| 8           | xxxx0841    | Equate Symbol: IwmRsnCodeXMemMode  
Meaning: The caller is in cross memory mode.  
Action: Invoke the function in non-cross memory mode. |
| C           | —           | Equate Symbol: IwmRetCodeEnvError  
Meaning: Environmental error. |
| C           | xxxx0C01    | Equate Symbol: IwmRsnCodeNoStg  
Meaning: Storage is not available for the request.  
Action: There is a storage shortage. The function may work successfully at a later time. |
| C           | xxxx0C0E    | Equate Symbol: IwmRsnCodeInsufAccess  
Meaning: The caller does not have update authority to the RACF resource MVSADMIN.WLM.POLICY in the FACILITY class.  
Action: Invoke the function when the condition is fulfilled. |
| C           | xxxx0C0F    | Equate Symbol: IwmRsnCodeCDSNotAvail  
Meaning: A couple data set for WLM has not been defined or it has been defined but this system does not have connectivity to the data set.  
Action: No action required. |
| C           | xxxx0C10    | Equate Symbol: IwmRsnCodeCDSTooSmall  
Meaning: WLM CDS is too small to process the request.  
Action: No action required. |
| C           | xxxx0C11    | Equate Symbol: IwmRsnCodeOneSystemUnable  
Meaning: At least one system in the sysplex was unable to activate the policy. One or more systems may have been successful in activating the policy.  
Action: No action required. |
| C           | xxxx0C13    | Equate Symbol: IwmRsnCodePolicyNotAvail  
Meaning: The service policy specified could not be verified because the service definition retrieved from WLM CDS has failed validation. The service policy was not activated.  
Action: No action required. |
<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| C           | xxxx0C1E      | **Equate Symbol:** IwmRsncodeHigherVersionLevel  
**Meaning:** The policy cannot be activated on this system because the service definition in the WLM couple data set is at a higher level than the WLM code on this system. A system with a lower level version cannot activate this service policy because it is not capable of handling all the function in the service definition.  
**Action:** None required. If necessary, reinvoke the service on a higher level system. |
| 10          | —             | **Equate Symbol:** IwmRetCodeCompError  
**Meaning:** Component error.  
**Action:** No action required. The function may be successful if invoked again. |
IWMPQRY — Query active service policy

The query active service policy routine is given control from the IWMPQRY macro. The query active service policy macro will complete the parameter list with caller-provided data and generate a stacking, space switching, program call to the query service.

The purpose of this routine is to return a representation of the active policy which could be used to explain how the system/sysplex is being managed and could be used in conjunction with current measurements to evaluate the condition of the system/sysplex. The information returned is not serialized upon return to the caller, and so may be out-of-date due to a change in policy.

The Query Active Service Policy macro is provided in list, execute, and standard form. The list form accepts no variable parameters and is used only to reserve space for the query parameter list. The standard form is provided for use with routines which do not require reentrant code. The execute form is provided for use with the list format for reentrant routines.

The parameter list must be in the caller’s primary address space or be addressable by the dispatchable unit access list.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary or access register (AR) If in Access Register ASC mode, specify SYSSTATE ASCENV=AR before invoking this macro.</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>All parameter areas must reside in current primary or be addressable by the dispatchable unit access list.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
Restrictions

The caller cannot have an EUT FRR established.

Input register information

Before issuing the IWMPQRY macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2-13</td>
</tr>
<tr>
<td>14</td>
</tr>
<tr>
<td>15</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
</tr>
<tr>
<td>2-13</td>
</tr>
<tr>
<td>14-15</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMPQRY macro is as follows:

```
IWMPQRY name

ANSAREA=ansarea
ANSLEN=anslen
QUERYLEN=querylen

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0

,RETCODE=retcode
,RSNCODE=rsncode
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMPQRY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

ANSAREA=ansarea
A required output parameter, variable specifying an area to contain the data being returned by IWMPQRY. The answer area is defined by the IWMSVPOL macro.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

ANSLEN=anslen
A required input parameter, variable which contains the length of the area provided to contain the data being returned by IWMPQRY.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

MF=S
MF=(L,list addr)
MF=(L,list addr,attr)
MF=(L,list addr,0D)
MF=(E,list addr)
MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code **attr**, the system provides a value of 0D.

**,COMPLETE**

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

**,PLISTVER=IMPLIED_VERSION**

**,PLISTVER=MAX**

**,PLISTVER=0**

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

**,QUERYLEN=querylen**

A required output parameter, variable which contains the number of bytes needed to contain the policy information.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**,RETCODE=retcode**

An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

**,RSNCODE=rsncode**

An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**

IWMQCXIT — Queue manager connect exit

IWMQCXIT will invoke the Queue Manager Connect exit specified. This exit is responsible for taking the action indicated for the associated Queue Manager. The return/reason codes for IWMQCXIT are those set by the exit invoked.

The list form of IWMQCXIT is intended for use by the exit routine to map the input parameters. The execute and standard form of IWMQCXIT are intended for use only by the operating system.

The exit environment is described in the environment description below. The parameter list is in pageable storage addressable in the current address space, but is not guaranteed to be in the key of the exit as it is not expected to be changed by the exit. Upon entry to the exit, the register contents are as follows:

- Register 0 = not defined
- Register 1 contains the address of a parameter list as formatted by the list form of this macro, IWMQCXIT MF=(L).
- Registers 2-13 = not defined
- Register 14 = return address
- Register 15 = entry point address

Upon entry to the exit, the access register contents are undefined.

Upon return from the exit, the register contents are as follows:

- Register 0 = Reason code if GR15 return code is non-zero
- Registers 1-14 = not defined (need not be restored to value on entry)
- Register 15 = Return code

Upon return from the exit, the access register contents are unchanged.

**Environment**

The requirements for the caller are:

- **Minimum authorization:** Supervisor state key 0.
- **Dispatchable unit mode:** Task
- **Cross memory mode:** Any PASN, any HASN, any SASN
- **AMODE:** 31-bit
- **ASC mode:** Primary
- **Interrupt status:** Enabled for I/O and external interrupts
- **Locks:** No locks may be held.
- **Control parameters:** Control parameters must be in the primary address space.

**Programming requirements**

The list form of the macro is intended for use by products supplying a Queue Manager Connect exit.

The execute form of the macro is intended for use by MVS. The assembler execute form only initializes the parameter list and calls the exit routine, and has the following restrictions:

- the invoker must save registers required before invoking the macro
• the invoker must restore registers required immediately after invoking the
macro, without depending on the exit to preserve any registers.

Restrictions
• The exit routine may not invoke functions or suspend execution which prevents
return to the caller for a protracted timeframe. This includes the use of system
services which either explicitly or implicitly give control back to the system. In
this context, protracted would include durations of one second or longer. When
the need for such activities is required, the exit should use asynchronous
techniques.

Input register information
Before issuing the IWMQCXIT macro, the caller does not have to place any
information into any register unless using it in register notation for a particular
parameter, or using it as a base register.

Output register information
When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unpredictable in assembler form, unchanged in PL/X form</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after
issuing a service. If the system changes the contents of registers on which the caller
depends, the caller must save them before issuing the service, and restore them
after the system returns control.

Performance implications
None

Syntax
main diagram

```

```

Chapter 12. Workload management services 307
IWMQCXIT

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
</table>

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMQCXIT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**ACTION=QDEL**
**ACTION=NUll**
A required parameter, which indicates the type of action requested. The exit should make an explicit check for the action indicated to anticipate the introduction of new values in later releases.

**ACTION=QDEL**
indicates that exit is being called for the deletion of a previously queued work element. The exit will only be called once per queued work element. If the exit should end abnormally, the system will not invoke the exit again for the same queued work element. In the event of an abnormal termination of the exit routine, the system may chose to call the exit for any remaining queued work elements, or may chose to discontinue use of the exit upon some threshold number of errors.

**ACTION=NUll**
indicates that no exit is to be called. The exit routine need not check for this action.

**APPLENV=applenv**
A required input parameter, which contains the application environment name associated with the queued work request or blanks if not available.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

**ETOKEN=etoken**
A required input parameter, which contains the Enclave token associated with the work request at the time the work request was queued or binary zeros when the system knows the Enclave no longer exists or the system no longer knows which Enclave was associated with the work request.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

** MF=S**
, MF=(L, list addr)

---

308  z/OS V2R2 MVS Programming: Workload Management Services
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

`list addr`

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

`attr`

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

`COMPLETE`

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

`PLISTVER=IMPLIED_VERSION`

`PLISTVER=MAX`

`PLISTVER=0`

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

To code: Specify one of the following:
**IWMQ CXIT**

- IMPLI ED_VERSION
- MAX
- A decimal value of 0

**QMGR_EXIT=qmgr_exit**
A required input parameter that contains the address of the Queue Manager Connect Exit to be invoked.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a pointer field.

**RETCODE=retcode**
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

**RSNCODE=rsncode**
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

**SECUSER=NO**
**SECUSER=YES**
An optional parameter, which specifies whether the security environment of a user was associated with the queued work request. The default is SECUSER=NO.

**SECUSER=NO**
No security environment was to be established.

**SECUSER=YES**
The specified userid was to be used to establish a security environment.

**USERDATA=userdata**
A required input parameter, which contains data passed to Queue Insert. The format is undefined to MVS.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

**USERID=userid**
When SECUSER=YES is specified, a required input parameter, which contains the requester's userid.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMQ CXIT macro returns control to your program:
- GPR 15 (and *retcode*, when you code RETCODE) contains a return code.
When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code.

**Table 47. Return and Reason Codes for the IWMQCXIT Macro**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>—</td>
<td>IwmRetCodeOk</td>
<td>Successful completion.</td>
<td>None required.</td>
</tr>
</tbody>
</table>

**Example**

To call a Queue Manager connect exit:

```plaintext
IWMQCXIT X
QMGR_EXIT=CONEXIT@, X
ACTION=QDEL, X
ETOKEN=ENCTOKEN, X
USERDATA=USERDATA,APPLENV=APPLENV,SECUSER=NO, X
RETCODE=RC,RSNCODE=RSN
```

* Storage areas

CONEXIT@ DS AL4 Contains the address of the Queue Manager Connect Exit to be invoked

ENCTOKEN DS CL8 Contains the Enclave token associated with the work request as returned by IWMECREA

USERDATA DS CL16 Contains data maintained by the user

APPLENV DS CL32 Contains the application environment name

RC DS F Return code
RSN DS F Reason code
IWMRCOLL — Collect workload activity data

With the IWMRCOLL macro, a performance monitor can get the following workload activity information:

- Resource consumption information
- Response time and distribution information
- General delay information
- Subsystem work manager delay state information

For a detailed description, refer to Chapter 9, “Using the workload reporting services,” on page 101.

To help the caller keep track of changes in workload management, this service returns a token, ANSTOKN. ANSTOKN is a required input on all subsequent calls to IWMRCOLL. When a change occurs in workload management, for example, when a new policy is activated, IWMRCOLL returns a new token value. The caller’s code should check the reason codes to see if the ANSTOKN has changed since the last call to IWMRCOLL. If the token has changed, the performance monitor should reset its reporting interval. If the token has not changed, the performance monitor can continue with its existing reporting interval.

There are also some ENF event codes to keep track of changes in workload management. For information about the ENF codes, see z/OS MVS Programming: Authorized Assembler Services Reference EDT-IXG.

The caller must provide a storage area in the ANSAREA=ansarea and the length of that area in the ANSLEN=anslen for IWMRCOLL to place the workload activity information. This area may reside in either address space related storage or dataspace storage. IWMRCOLL returns the information, which is mapped by IWMWRCAA.

You must also specify the MINLEN and MAXLEN parameters. IWMRCOLL fills in the minimum and maximum amount of storage required for the answer area.

The caller should issue the IWMPQRY macro for active service policy information to map the workload activity information.

If the caller does not provide enough storage to contain all of the workload activity data, no data is returned. IWMRCOLL returns the minimum length of the storage required in the ANSLEN field, and issues the appropriate return and reason code.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
</tbody>
</table>
ASC mode: Primary or access register. If in access register ASC mode, specify SYSTAT ASCENV = AR before invoking IWMRCOLL.

Interrupt status: Enabled for I/O and external interrupts

Locks: No locks held.

Control parameters: Control parameters must be in the primary address space.

The caller of IWMRCOLL must provide storage for an answer area mapped by IWMWRCAA. This answer area may reside in the caller’s primary address space, or in a dataspaces accessible via the current unit of work’s dispatchable unit access list (DUal).

Programming requirements

You must include the CVT and the IWMYCON mapping macros in the program.

Restrictions

The caller cannot have an EUT FRR established.

Input register information

Before issuing the IWMRCOLL macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, using it as a base register, or using it to provide the ALET of the storage area.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if the GP 15 return code is non-zero.</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
<td>Used as work registers by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14 - 15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller
depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMRCOLL macro is as follows:

```
main diagram

```

```
parameters-1

```

```
Parameters

The parameters are explained as follows:

```
name

An optional symbol, starting in column 1, that is the name on the IWMRCOLL macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ANSAREA=ansarea

A required output parameter that contains the address of a storage area to hold the information returned by IWMRCOLL. The area is mapped by the IWMWRCAA mapping macro.

  To code: Specify the RS-type address, or address in register (2)-(12) of a character field.

,ANSLEN=anslen

A required input parameter that contains the length of the storage area (answer area) you are providing on ANSAREA.

  To code: Specify the RS-type address, or address in register (2)-(12) of a fullword field.

,ANSTOKN=anstoken,

A required input/output parameter that contains a token value. On your first
call to IWMRCOLL, you specify ANSTOKEN as an output parameter. IWMRCOLL provides a token value that is required for subsequent calls to IWMRCOLL.

To code: Specify the RS-type address, or address in register (2)-(12) of an 8-character field.

ICS=NO
ICS=YES

An optional parameter that specifies whether IWMRCOLL should return ICS information, or workload activity information. The default is ICS=NO.

ICS=NO
Specifies that IWMRCOLL should return workload activity information.

ICS=YES
Specifies that IWMRCOLL should return ICS information. It is valid for systems prior to z/OS R3 only.

ICSAREA=icsarea
When ICS=YES is specified, a required output parameter that is valid for systems prior to z/OS R3 only.

To code: Specify the RS-type address, or address in register (2)-(12) of a character field.

ICSLEN=icslen
When ICS=YES is specified, a required input parameter that is valid for systems prior to z/OS R3 only.

To code: Specify the RS-type address, or address in register (2)-(12) of a fullword field.

ICSQLEN=icsqlen
When ICS=YES is specified, a required output parameter that is valid for systems prior to z/OS R3 only.

To code: Specify the RS-type address, or address in register (2)-(12) of a fullword field.

MAXLEN=maxlen
A required output parameter that contains the maximum length of the storage area required by IWMRCOLL to contain all the performance data for transactions that might run while the ANSTOKN is valid.

To code: Specify the RS-type address, or address in register (2)-(12) of a fullword field.

MF=S
MF=(L,list addr)
MF=(L,list addr,attr)
MF=(L,list addr,OD)
MF=(E,list addr)
MF=(E,list addr,COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,,list addr

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,,attr

An optional 1 to 60 character input string that you use to force boundary alignment of the parameter list. Use a value of X'0F' to force the parameter list to a word boundary, or X'0D' to force the parameter list to a doubleword boundary. If you do not code ,,attr, the system provides a value of X'0D'.

,,COMPLETE

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,,MINLEN=minlen

A required output parameter that contains the minimum length of the storage area required by IWMRCOLL to contain all existing performance data.

To code: Specify the RS-type address, or address in register (2)-(12) of a fullword field.

,,PLISTVER=IMPLIED_VERSION
,,PLISTVER[MAX]
,,PLISTVER=0

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

IMPLIED_VERSION

Is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

MAX

Specify PLISTVER=MAX if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

0

Specify PLISTVER=0 to use the currently available parameters.

To code: Specify one of the following:
IWMRCOLL

- IMPLIED_VERSION
- MAX
- A decimal value of 0

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (with or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12), or (15), (GPR15), (REG15), or (R15).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (with or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

ABEND codes
None.

Return codes and reason codes

When the IWMRCOLL macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Table 48. Return and Reason Codes for the IWMRCOLL Macro

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Return Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
### Table 48. Return and Reason Codes for the IWMRCOLL Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Return Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxx0833     | **Equate Symbol:** IwmRsnCodeNotInCompatMode  
**Meaning:** IWMRCOLL was invoked with a parameter list specifying ICS=YES. WLM no longer supports compatibility mode, and therefore no longer returns ICS information.  
**Action:** Reinvoke IWMRCOLL with ICS=NO specified. |
| C           | —           | **Equate Symbol:** IwmRetCodeEnvError  
**Meaning:** Environmental error |
| C           | xxx0C01     | **Equate Symbol:** IwmRsnCodeNoStg  
**Meaning:** Storage is not available for the request.  
**Action:** There is a storage shortage. The function may work successfully at a later time. |
| C           | xxx0C0A     | **Equate Symbol:** IwmRsnCodeSuspended  
**Meaning:** Data collection is suspended as a result of a component error. No data can be returned for this IWMRCOLL invocation, future invocations may be successful.  
**Action:** Reinvoke this service. |
| 10          | —           | **Equate Symbol:** IwmRetCodeCompError  
**Meaning:** Component error  
**Action:** No action required. The function may work successfully if invoked again. |

### Example

For workload activity information from a system running in goal mode, specify:

```plaintext
IWMRCOLL  ICS=NO,ANSAREA=(R6),ANSLEN=(R8),  
           MINLEN=QMINLEN,MAXLEN=QMAXLEN,  
           RSNCODE=RSN,MF=(E,MFRCOLL)
```
IWMRESET — Change a job

The IWMRESET macro allows the caller to perform the same functions as the RESET system command. If the system is running in workload management goal mode, the caller can:

- Change the service class of work currently in execution, with the SRVCLASS keyword. Resetting to a new service class also resumes quiesced work.
- Quiesce work currently in execution, with the QUIESCE keyword.
- Reclassify work currently in execution according to the service policy in effect, with the RESUME keyword. The RESUME keyword also resumes quiesced work.

The system does not allow every address space to be reset. The IWMRESET service has the same restrictions as the RESET system command. Refer to z/OS MVS System Commands for more information.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>PASN=HASN=SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK CONST defined in IWMYCON, may be used for this purpose.

Restrictions

The caller cannot have an EUT FRR established.

Input register information

Before issuing the IWMRESET macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

Register
Contents
0  Reason code if GR15 return code is non-zero
1  Used as work registers by the system
2-13  Unchanged
14  Used as work registers by the system
15  Return code

When control returns to the caller, the ARs contain:

Register
Contents
0-1  Used as work registers by the system
2-13  Unchanged
14-15  Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMRESET macro is as follows:

```
IWMRESET [JOBNAME=jobname] [ASID=asid] [FUNCTION=RESET|QUIESCE|RESUME] [SRVCLASS= srvclass] [USERID=userid] [PRODUCT=product] [RETCODE=retcode] [RSNCODE=rsncode] [PLISTVER=IMPLIED_VERSION|MAX|0]
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMRESET macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

ASID=asid
A parameter which contains the address space identifier (ASID) of the job you want to change.

To code: Specify the RS-type address, or address in register (2)-(12), of a halfword field.

FUNCTION=RESET
FUNCTION=QUIESCE
FUNCTION=RESUME
An optional parameter, which indicates the function to perform against the job. The default is FUNCTION=RESET.

FUNCTION=RESET
Requests that the job's service class or performance group be changed.

FUNCTION=QUIESCE
Requests that the job be quiesced. If the job is non-swappable, it is given the lowest possible performance characteristics.

FUNCTION=RESUME
Requests that the job be reclassified according to the service policy in effect. This undoes a prior request to reset the job to a particular service class, or to quiesce the job.

JOBNAME=jobname
A required input parameter which contains the jobname of the job you want to change. If there is more than one executing job with this jobname, you must specify the ASID parameter to identify the specific job.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.
IWMRESET

\texttt{,MF=(M,list\ addr,COMPLETE)}
\texttt{,MF=(M,list\ addr,NOCHECK)}

An optional input parameter that specifies the macro form.

Use \texttt{MF=S} to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. \texttt{MF=S} is the default.

Use \texttt{MF=L} to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use \texttt{MF=E} to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

Use \texttt{MF=M} together with the list and execute forms of the macro for service routines that need to provide different options according to user-provided input. Use the list form to define a storage area; use the modify form to set the appropriate options; then use the execute form to call the service.

IBM recommends that you use the modify and execute forms of IWMRESET in the following order:

- Use IWMRESET \texttt{...MF=(M,\text{list-addr},COMPLETE)} specifying appropriate parameters, including all required ones.
- Use IWMRESET \texttt{...MF=(M,\text{list-addr},NOCHECK)}, specifying the parameters that you want to change.
- Use IWMRESET \texttt{...MF=(E,\text{list-addr},NOCHECK)}, to execute the macro.

\texttt{,list\ addr}

The name of a storage area to contain the parameters. For \texttt{MF=S}, \texttt{MF=E}, and \texttt{MF=M}, this can be an RS-type address or an address in register (1)-(12).

\texttt{,attr}

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code \texttt{attr}, the system provides a value of 0D.

\texttt{,COMPLETE}

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\texttt{,NOCHECK}

Specifies that the system is not to check for required parameters and is not to supply defaults for omitted optional parameters.

\texttt{,PLISTVER=IMPLIED\_VERSION}
\texttt{,PLISTVER=MAX}
\texttt{,PLISTVER=0}

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
IWMRESET

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

\`(PRODUCT=product\`

A required input parameter, which contains the product name that is requesting the job be changed. The product name is included in the SMF 90 subtype 30 record created by IWMRESET.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\`(RETCODE=retcode\`

An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

\`(RSNCODE=rsncode\`

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

\`(SRVCLASS=srvclass\`

When FUNCTION=RESET is specified, a required input parameter which is the service class to be assigned to the job. Resetting to a new service class also resumes quiesced work.

When you reset a server to a new service class, the goals associated with that service class are ignored. However the resource group associated with the new service class is honored. The one exception where the goal for a server is honored is when the transactions it is serving have been assigned a discretionary goal.

**To code:** Specify the RS-type address of an 8-character field.

\`(USERID=userid\`

A required input parameter, which contains the ID of the user who is requesting the job be changed. The user ID is included in the SMF 90 subtype 30 record created by IWMRESET. If there is no user ID available, the caller should pass blanks.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.
ABEND codes

None.

Return codes and reason codes

When the IWMRESET macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeOk</td>

<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| C           | xxxx0C2F    | **Equate Symbol**: IwmRsnCodeSystemSpace  
**Meaning**: The input address space is either a system component address space or a privileged address space. It cannot be reset.  
With APAR OA12625 installed, the restriction for privileged address spaces has been removed, meaning that privileged address spaces can be reset. The system component address space still cannot be reset.  
**Action**: Record or report the error if appropriate. |
| C           | xxxx0C30    | **Equate Symbol**: IwmRsnCodeDuplicateJobs  
**Meaning**: There is more than one job active with the same jobname.  
**Action**: Specify the ASID parameter to identify the specific job. |
| C           | xxxx0C31    | **Equate Symbol**: IwmRsnCodeWrongASID  
**Meaning**: The active job in the specified address space has a different jobname than the one passed by the caller.  
**Action**: Record or report the error if appropriate. |
| C           | xxxx0C32    | **Equate Symbol**: IwmRsnCodeNotEligibleForSrvClass  
**Meaning**: The active job in the specified address space is not eligible for reset into the specified system service class. Only address spaces created with the ASCRE HIPRI attribute are eligible for reset into the SYSTEM service class.  
**Action**: Record or report the error if appropriate. |
| 10          | —           | **Equate Symbol**: IwmRetCodeCompError  
**Meaning**: Component error.  
**Action**: Contact your system programmer. |

Example

To change the service class of the job executing in the ASID at location JOBASID, specify:

```
IWMRESET ASID=JOBASID,SRVCLASS=SCNAME,USERID=USR,PRODUCT=PROD
```

* Storage areas

<table>
<thead>
<tr>
<th>JOBASID</th>
<th>DS</th>
<th>H</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCNAME</td>
<td>DS</td>
<td>CL8</td>
</tr>
<tr>
<td>USR</td>
<td>DS</td>
<td>CL8</td>
</tr>
<tr>
<td>PROD</td>
<td>DS</td>
<td>CL8</td>
</tr>
</tbody>
</table>

* Contains the address space id of the job
* Contains the service class name to assign to the job
* Contains the id of the user who is requesting the change
* Contains the product name of the code invoking IWMRESET

---

Chapter 12. Workload management services 327
IWMRQRY — Collect address space delay information

IWMRQRY is the interface reporting products should use to obtain address space related general execution delays. Enclave related information may optionally be requested.

The macro will complete the parameter list with caller specified data and invoke a stacking, space switching PC routine in the WLM address space. Address space related data collected will be aggregated on an address space basis, while enclave related data (if requested) will be aggregated by enclave.

If a user does not know the size of the answer area required by the service, he should code issue IWMRQRY with ANSLEN set to zero. The length of the answer area will be placed in QRYLEN.

The IWMRQRY macro is provided in list, execute, and standard form. The list form accepts no variable parameters and is used only to reserve space for the parameter list. The standard form is provided for use with routines which do not require reentrant code. The execute form is provided for use with the list format for reentrant routines.

The parameter list must be in the caller's primary address space, or in a dataspace accessible by the current unit of work's dispatchable unit access list (DUal).

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary or access register (AR) Any P,S,H.</td>
</tr>
<tr>
<td></td>
<td>If in Access Register ASC mode, specify SYSSTATE ASCENV=AR</td>
</tr>
<tr>
<td></td>
<td>before invoking this macro.</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>The caller of IWMRQRY must provide storage for an answer area mapped by IWMWRQAA. This answer area may reside in the caller's primary address space, or in a dataspace accessible via the current unit of work's dispatchable unit access list (DUal).</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT
part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

The caller cannot have an EUT FRR established.

Input register information

Before issuing the IWMRQRY macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMRQRY macro is as follows:

```
.IWMRQRY
```

Chapter 12. Workload management services  329
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMRQRY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ANSAREA=ansarea
A required output parameter, variable specifying an area to contain the data returned by the query service. If the length of the output area is insufficient, no data is returned.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,ANSLEN=anslen
A required input parameter, which contains the length of the answer area.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,ASID=asid
When INFO=ONE is specified, a required input parameter, which contains the ASID of the address space to be queried.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,ENCLAVES=None
,ENCLAVES=ALL
,ENCLAVES=ONE
An optional parameter, which indicates whether enclave information is requested. The default is ENCLAVES=None.

,ENCLAVES=NONE
indicates that no enclave information is requested.

,ENCLAVES=ALL
indicates that information for all enclaves should be returned.

,ENCLAVES=ONE
indicates that enclave information is requested for a particular enclave.
When ENCLAVES=ONE is specified, a required input parameter, which contains the enclave token of the enclave to be queried.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

INFO=ALL
INFO=ONE

A required parameter, which indicates what information the query service is to return.

INFO=ALL
indicates that information for all address spaces should be returned.

INFO=ONE
indicates that address space information is requested for a particular asid.

,ETOKEN=etoken
When ENCLAVES=ONE is specified, a required input parameter, which contains the enclave token of the enclave to be queried.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

INFO=ALL
INFO=ONE

A required parameter, which indicates what information the query service is to return.

INFO=ALL
indicates that information for all address spaces should be returned.

INFO=ONE
indicates that address space information is requested for a particular asid.

,ETOKEN=etoken
When ENCLAVES=ONE is specified, a required input parameter, which contains the enclave token of the enclave to be queried.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

INFO=ALL
INFO=ONE

A required parameter, which indicates what information the query service is to return.

INFO=ALL
indicates that information for all address spaces should be returned.

INFO=ONE
indicates that address space information is requested for a particular asid.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,OD)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
,PLISTVER=1

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use only the following parameters:

  - ANSAREA
  - ASID
  - INFO
  - ANSLEN
  - ENCLAVES
  - QUERYLEN

- **1**, if you use the following parameter and those of version 0:

  - ETOKEN

**ETOKEN**

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0 or 1

\[ \text{QUERYLEN} = \text{querylen} \]

A required output parameter, which contains the length of the storage area required by the IWMRQRY service. The length of the area may change between invocations.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

\[ \text{RETCODE} = \text{retcode} \]

An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

\[ \text{RSNCODE} = \text{rsncode} \]

An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**

None.
Return codes and reason codes

When the IWMRQRY macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Table 50. Return and Reason Codes for the IWMRQRY Macro

</tbody>
</table>
IWMSCORF — Set correlator flags

This service allows to set or clear certain correlator flags in a provided EWLM correlator. These flags are contained in byte 3 of the architected Application Response Measurement (ARM) correlator format.

Environment

The requirements for the caller are:

- **Minimum authorization:** Problem state or supervisor state.
- **Dispatchable unit mode:** Task or SRB
- **Cross memory mode:** Any PASN, any HASN, any SASN
- **AMODE:** 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
- **ASC mode:** Primary
- **Interrupt status:** Enabled for I/O and external interrupts
- **Locks:** No locks may be held. No restriction.
- **Control parameters:** Control parameters must be in the primary address space.

Programming requirements

None.

Restrictions

1. The caller is responsible for error recovery.
2. The caller must serialize to prevent any correlator from being accessed concurrently.

Input register information

Before issuing the IWMSCORF macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work register by the system</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>
Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

main diagram

```
name IWMSCORF b EWLM_CORR=ewlm_corr

,SET_ASYNC_FLAG=NO_SET_ASYNC,SET_INDEP_FLAG=NO_SET_INDEP

,SET_ASYNC_FLAG=OFF,SET_INDEP_FLAG=OFF

,SET_ASYNC_FLAG=ON,SET_INDEP_FLAG=ON

,RETCODE=retcode,RSNCOE=rsncode

,MF=(M,list addr,COMPLETE,NOCHECK)
```

Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMSCORF macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**EWLM_CORR=ewlm_corr**

A required input/output parameter, which contains an EWLM (ARM) correlator. If the correlator is invalid (architected length in the first two bytes is less than 4 or greater than 512) a call to this macro acts as a no-operation and no change to the EWLM_CORR field is made.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

**RETCODE=retcode**

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

**RSNCOE=rsncode**

An optional output parameter into which the reason code is to be copied from
GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

,SET_ASYNC_FLAG=NO_SET_ASYNC
,SET_ASYNC_FLAG=OFF
,SET_ASYNC_FLAG=ON
An optional parameter, which requests to update the asynchronous flow flag. The default is SET_ASYNC_FLAG=NO_SET_ASYNC.

,SET_ASYNC_FLAG=NO_SET_ASYNC
indicates that parameter SET_ASYNC_FLAG has not been specified and the asynchronous flow flag in the EWLM correlator will not be changed.

,SET_ASYNC_FLAG=OFF
requests to clear the asynchronous flow flag. The independent flag is also cleared, since the independent flag may only be ON, if the asynchronous flag is ON.

,SET_ASYNC_FLAG=ON
requests to set the asynchronous flow flag to ON.

,SET_INDEP_FLAG=NO_SET_INDEP
,SET_INDEP_FLAG=OFF
,SET_INDEP_FLAG=ON
An optional parameter, which requests to update the independent flag. The default is SET_INDEP_FLAG=NO_SET_INDEP.

,SET_INDEP_FLAG=NO_SET_INDEP
indicates that parameter SET_INDEP_FLAG has not been specified and the independent flag in the EWLM correlator will not be changed.

,SET_INDEP_FLAG=OFF
requests to clear the independent flag.

,SET_INDEP_FLAG=ON
requests to set the independent flag to ON. The independent flag should be set only if the asynchronous flag is already set or will be set by this request.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMSCORF macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

**Examples**
IWMSCXIT

IWMSCXIT — Server manager connect exit

IWMSCXIT will invoke the Server Manager Connect exit specified. This exit is responsible for taking the action indicated on behalf of the current connected server address space. The return and reason codes for IWMSCXIT are set by the exit that was invoked.

The list form of IWMSCXIT is intended for use by the exit routine to map the input parameters. The execute and standard form of IWMSCXIT are intended for use only by the operating system.

Note that it may be possible for the exit to be called before the caller has received control back from IWMCONN. The exit or any program it drives (synchronously or asynchronously) must synchronize with the program issuing IWMCONN to ensure that IWMCONN has returned a connect token prior to issuing IWMDISC (disconnect) or any other services that need the connect token.

The exit environment is described in the environment description below. The parameter list is in pageable storage addressable in the current address space, but is not guaranteed to be in the key of the exit as it is not expected to be changed by the exit. Upon entry to the exit, the register contents are as follows:

- Register 0 = not defined
- Register 1 will contain the address of a parameter list as formatted by the list form of this macro, IWMSCXIT MF=(L).
- Registers 2-13 = not defined
- Register 14 = return address
- Register 15 = entry point address

Upon entry to the exit, the access register contents are undefined.

Upon return from the exit, the register contents are as follows:

- Register 0 = Reason code if GR15 return code is non-zero
- Registers 1-14 = not defined (need not be restored to value on entry)
- Register 15 = Return code

Upon return from the exit, the access register contents are unchanged.

Environment

The requirements for the caller are:

- **Minimum authorization**: Supervisor state key 0.
- **Dispatchable unit mode**: SRB
- **Cross memory mode**: PASN=HASN=SASN The current home address space must be the same as at time of Connect (IWMCONN).
- **AMODE**: 31-bit
- **ASC mode**: Primary
- **Interrupt status**: Enabled for I/O and external interrupts
- **Locks**: No locks may be held. FRRs may be established.
- **Control parameters**: Control parameters must be in the primary address space.
**Programming requirements**

The list form of the macro is intended for use by products supplying a Server Manager Connect exit.

The execute form of the macro is intended for use by MVS. The assembler execute form only initializes the parameter list and calls the exit routine, and has the following restrictions:

- The invoker must save registers required before invoking the macro.
- The invoker must restore registers required immediately after invoking the macro, without depending on the exit to preserve any registers.

**Restrictions**

None.

**Input register information**

Before issuing the IWMSCXIT macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unpredictable in assembler form, unchanged in PL/X form</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.
Syntax

main diagram

![Diagram of IWMSCXIT parameters and syntax]

Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMSCXIT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**,ACTION=QUIESCE**
A required parameter, which indicates the type of action requested. The exit should explicitly check to see which action value was specified, as new values may be introduced in later releases.

**,ACTION=QUIESCE**
Indicates that the exit is to cause the server space to perform an orderly shutdown and terminate. Disconnect should be invoked during the shutdown phase.

**,ACTION=RESUME**
Indicates that the exit may ignore a previous request to perform an orderly shutdown and terminate. The server space is now eligible to be chosen via invocation of IWMSRFSV and may resume normal operation.

**,ACTION=NULL**
Indicates that no exit is to be called. The exit need not check for this action.

**CONNTKN=conntkn**
A required input parameter, which contains the WLM Connect token which was returned for the server by Connect (IWMCNN).

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

**,MF=S**

**,MF=(L,list addr)**

**,MF=(L,list addr,attr)**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

`list addr`

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

`attr`

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

`COMPLETE`

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

`PLISTVER=IMPLIED_VERSION`
`PLISTVER=MAX`
`PLISTVER=0`

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- 0, if you use the currently available parameters.

**To code:** Specify one of the following:

- IMPLIED_VERSION
IWMSCXIT

- MAX
- A decimal value of 0

,.RETCODE=retcode
An optional output parameter into which the return code is to be copied from
GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without
parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or
(15), (GPR15), (REG15), or (R15).

,.RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from
GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or
without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or
(2)-(12), (00), (GPR0), (GPR00), REG0), (REG00), or (R0).

,.SRV_MGR_EXIT@=srv_mgr_exit@
A required input parameter that contains the address of the Server Manager
Connect Exit to be invoked.

To code: Specify the RS-type address, or address in register (2)-(12), of a
pointer field.

ABEND codes

None.

Return codes and reason codes

When the IWMSCXIT macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code
RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the
equate symbol associated with each reason code.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol Meaning and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeOk</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Successful completion.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Action: None required.</td>
</tr>
</tbody>
</table>

Example

To call a Server Manager Connect exit:

```
IWMSCXIT
  SRV_MGR_EXIT@ =CONEXIT@,
  CONNTKN=OWNRCTKN,
  ACTION=QUIESCE,
  RETCODE=QUIESCE,RSNCODE=RSN
```

</tbody>
</table>
IWMSEDES — Scheduling environments determine execution service

The IWMSEDES service determines if a scheduling environment is available on a specified system. A scheduling environment is a list of resource names and their required states. If all of the resources are in the required state, the scheduling environment is available. If any of the resources is not in the required state, the scheduling environment is not available.

The caller can use the IWMSEDES service to perform certain work only when a particular scheduling environment is available.

If the scheduling environment is available, the caller receives return code IwmRetCodeOK. If the scheduling environment is not available, the caller receives return code IwmRetCodeWarning and reason code IwmRsnCodeSCHENVNotAvailable.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state or program key mask (PKM) allowing keys 0-7. |
| Dispatchable unit mode: | Task |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

None.

Input register information

Before issuing the IWMSEDES macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMSEDES macro is as follows:

```
/IWMSEDES name=SchENV=schenv,SYSTEM_NAME=system_name,RETCODE=retcode

,,RSNCODE=rsncode,,PLISTVER=IMPLIED_VERSION

,,PLISTVER=MAX,,PLISTVER=0

,,MF=S

,,MF=(L,list addr,attr,COMPLETE)

,,MF=(E,list addr)
```

Parameters

The parameters are explained as follows:
name
An optional symbol, starting in column 1, that is the name on the IWMSEDES macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,**MF=S**
,**MF=(L,list addr)**
,**MF=(L,list addr,attr)**
,**MF=(L,list addr,0D)**
,**MF=(E,list addr)**
,**MF=(E,list addr,COMPLETE)**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,**list addr**
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,**attr**
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,**COMPLETE**
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,**PLISTVER=IMPLIED_VERSION**
,**PLISTVER=MAX**
,**PLISTVER=0**
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX
ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

- 0, if you use the currently available parameters.

**To code:** Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

`RETCODE=retcode`
An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

`RSNCODE=rsncode`
An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

`SCHENV=schenv`
A required input parameter, which contains the scheduling environment name to be checked.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

`SYSTEM_NAME=system_name`
A required input parameter, which contains the system name to be checked.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

### ABEND codes

None.

### Return codes and reason codes

When the IWMSEDES macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

**Table 52. Return and Reason Codes for the IWMSEDES Macro**

<table>
<thead>
<tr>

<td>DS</td>
<td>1F</td>
<td>Return code</td>
</tr>
<tr>
<td>RSNICODE</td>
<td>DS</td>
<td>1F</td>
<td>Reason code</td>
</tr>
</tbody>
</table>
IWMSEQRY — Scheduling environments query service

IWMSEQRY returns information about the scheduling environments and resources that are defined in the active service policy. The information includes the current state of each scheduling environment and resource on the current system and on other systems in the sysplex.

The information is obtained without serialization. Data may not be available for all systems in the sysplex.

The information is returned in a work area that you specify. The work area must be located in the caller's primary address space. The format of the work area is mapped by the IWMSET macro. IWMSEQRY checks if the specified work area length (ANSLEN) is large enough to receive the output. If so, IWMSEQRY returns the information in the work area and returns the actual length of the information in the QUERYLEN parameter. If the storage provided is not large enough, the caller receives reason code 040A, and IWMSEQRY returns the required amount of storage in the QUERYLEN parameter.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

The caller cannot have an EUT FRR established.
Input register information

Before issuing the IWMSEQRY macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMSEQRY macro is as follows:

```
IWMSEQRY name,ANSLEN=anslen,ANSAREA=ansarea,QUERYLEN=querylen
```

```
,RETCODE=retcode,RSNCODE=rsncode,PLISTVER=IMPLIED_VERSION
```

```
,PLISTVER=MAX,PLISTVER=0
```
The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMSEQRY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**ANSAREA=ansarea**
A required input/output parameter, of an area to contain the data returned by IWMSEQRY. The area is mapped by macro IWMSET.

To code: Specify the RS-type address, or address in register (2)-(12), of a field.

**ANSLEN=anslen**
A required input parameter, which contains the length of the area provided to contain the data returned by IWMSEQRY.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**MF=S, MF=(L,list addr), MF=(L,list addr,attr), MF=(L,list addr,0D), MF=(E,list addr), MF=(E,list addr,COMPLETE)**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**list addr**
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION,
,PLISTVER=MAX,
,PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 0, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

,QUERYLEN=querylen
A required output parameter, which contains the number of bytes needed to contain the scheduling environment information.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

ABEND codes
None.
Return codes and reason codes

When the IWMSEQRY macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>

Chapter 12. Workload management services  355
IWMSESET — Scheduling environments set resource service

IWMSESET allows the caller to modify the state of a resource. A resource is an abstract element that can represent an actual physical entity (such as a peripheral device), or an intangible quality (such as a certain time of day). A resource has an ON, OFF, or RESET state.

A resource is a component of a scheduling environment. A scheduling environment is a list of resource names and their required states. By modifying the state of a resource you can:

- Change a scheduling environment such that the resources are in the required state thereby allowing work to be scheduled.
- Change a scheduling environment such that the resources are not in the required state thereby preventing work from being scheduled.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state or program key mask (PKM) allowing keys 0-7. |
| Dispatchable unit mode: | Task |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

None.

Input register information

Before issuing the IWMSESET macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMSESET macro is as follows:

```
IWMSESET RESOURCE=resource,,STATE=ON,,STATE=OFF,,STATE=RESET,,RETCODE=retcode

RSNCODE=rsncode,,PLISTVER=IMPLIED_VERSION,,PLISTVER=MAX,,PLISTVER=0

MF=S,,MF=(L,,list addr,,attr,,COMPLETE),,,MF=(E,,list addr,,attr)
```

Parameters

The parameters are explained as follows:
IWMSESET

**name**

An optional symbol, starting in column 1, that is the name on the IWMSESET macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**MF=S**

```
MF=S
```

**MF=(L,list addr)**

```
MF=(L,list addr)
```

**MF=(L,list addr,attr)**

```
MF=(L,list addr,attr)
```

**MF=(L,list addr,0D)**

```
MF=(L,list addr,0D)
```

**MF=(E,list addr)**

```
MF=(E,list addr)
```

**MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**list addr**

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

**COMPLETE**

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

**PLISTVER=IMPLIED_VERSION**

**PLISTVER=MAX**

**PLISTVER=0**

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX
ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

- 0, if you use the currently available parameters.

**To code:** Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

**RESOURCE**=`resource`
A required input parameter, which contains the resource name to be modified.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

**RETCODE**=`retcode`
An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**RSNCODE**=`rsncode`
An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**STATE**=`ON`
**STATE**=`OFF`
**STATE**=`RESET`
A required parameter, which sets the state of the resource.

- **STATE**=`ON`
  sets the resource to the ON state.

- **STATE**=`OFF`
  sets the resource to the OFF state.

- **STATE**=`RESET`
  sets the resource to the RESET state.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMSESET macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.
### Table 54. Return and Reason Codes for the IWMSESET Macro

### Example

To set the resource specified at location RESNAME to the ON state specify:

```plaintext
IWMSESET RESOURCE=RESNAME,
          STATE=ON,
          RETCODE=RETCODE,
          RSNCODE=RSNCODE
```

* Storage areas

```
RESNAME DS CL16       Resource name
RETCODE DS 1F         Return code
RSNCODE DS 1F         Reason code
```
The IWMSEVAL service validates a scheduling environment name. The caller can validate a scheduling environment prior to associating it with a work item (such as a job or transaction).

If the scheduling environment is valid, the caller receives return code IwmRetCodeOK. If the scheduling environment is not valid, the caller receives return code IwmRetCodeWarning and reason code IwmRsnCodeSCHENVNotFound.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

None.

**Input register information**

Before issuing the IWMSEVAL macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMSEVAL macro is as follows:

\[
\text{IWMSEVAL}\text{name}\text{,RETCODE=retcode}\text{,RSNCODE=rsncode}\text{,SCHENV=schenv}\text{,PLISTVER=IMPLIED\_VERSION}\text{,PLISTVER=MAX}\text{,PLISTVER=0}\text{,MF=S}\text{,MF=(L,\text{list addr})}\text{,MF=(L,\text{list addr},\text{attr})}\text{,MF=(L,\text{list addr},0D)}\text{,MF=(E,\text{list addr})}\text{,MF=(E,\text{list addr,COMPLETE})}\n\]

**Parameters**

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMSEVAL macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`,MF=S`

`,MF=(L,\text{list addr})`

`,MF=(L,\text{list addr,attr})`

`,MF=(L,\text{list addr},0D)`

`,MF=(E,\text{list addr})`

`,MF=(E,\text{list addr,COMPLETE})`

An optional input parameter that specifies the macro form.
Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,,COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,,PLISTVER=IMPLIED VERSION
,,PLISTVER=MAX
,,PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 0, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED VERSION
- MAX
- A decimal value of 0
IWMSEVAL

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.
To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.
To code: Specify the RS-type address of a fullword field, or register (2)-(12).

SCHENV=schenv
A required input parameter, which contains the scheduling environment to be validated.
To code: Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

ABEND codes
None.

Return codes and reason codes
When the IWMSEVAL macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Table 55. Return and Reason Codes for the IWMSEVAL Macro

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeOk:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Successful completion.</td>
</tr>
</tbody>
</table>
| 4           | —           | Equate Symbol: IwmRetCodeWarning:
|              |             | Meaning: Successful completion, unusual conditions noted. |
| 4           | xxxx0425    | Equate Symbol: IwmRsnCodeNoSCHENV: |
|              |             | Meaning: The system does not support scheduling environments services. This return code is set for releases prior to OS/390 Release 4. |
|              |             | Action: Avoid requesting this function on releases prior to OS/390 Release 4. |
| 4           | xxxx0426    | Equate Symbol: IwmRsnCodeSCHENVNotFound: |
|              |             | Meaning: The scheduling environment specified by SCHENV does not exist. |
|              |             | Action: Check the specification of the SCHENV parameter. If the SCHENV parameter is correct, check whether the scheduling environment is defined in the active service policy. |
**Table 55. Return and Reason Codes for the IWMSEVAL Macro (continued)**

IWMSINF — WLM server manager inform service

The IWMSINF service should be used to obtain the number of server instances to be started from WLM. The caller must have previously connected to WLM using the IWM4CON service specifying SERVER_MANAGER=YES, SERVER_TYPE=QUEUE, and MANAGE_TASKS=YES.

The caller can use the service in the following ways:

**MODE=SUSPEND**

The calling task is suspended until WLM wants the caller to start additional server instances. The caller must re-invoke the service after it starts the server instances to wait for the next notification. The caller cannot rely upon asynchronous exits receiving control while the task is suspended.

**MODE=POST**

The calling task is not suspended by WLM. WLM returns the number of additional server instances to start now. WLM will post the caller's ECB when the number of server instances should be increased. After the ECB is posted the caller must re-invoke IWMSINF to obtain the number of server instances to start.

**MODE=INFORM**

The calling task is not suspended by WLM. WLM returns the number of additional server instances to start now. This form should only be used the first time the service is invoked immediately after connect because at this time the service will always return a value.

**MODE=ECBCANCEL**

The calling task is not suspended by WLM. This invocation should only be used to inform WLM that it should not post a caller's ECB any more. The form can be used for error recovery purposes in conjunction with MODE=POST.

WLM stops server instances by returning reason code IwmRsnCodeStopTask from IWM4SSL.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state. Any PSW key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>PASN=HASN=SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. Make sure no EUT FRRs are established.
2. The macro CVT must be included to use this macro.
3. The macro IWMYCON must be included to use this macro.
4. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.

5. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions
1. This macro may not be used during task/address space termination.
2. Only a single invocation is allowed to be active for a given address space at any given time.
3. Before using this macro the caller must connect to WLM via IWM4CON
   Server_Manager=YES, Server_Type=Queue, Manage_Tasks=Yes.

Input register information

Before issuing the IWMSINF macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

Register Contents
0 Reason code if GR15 return code is non-zero
1 Used as work registers by the system
2-13 Unchanged
14 Used as work registers by the system
15 Return code

When control returns to the caller, the ARs contain:

Register Contents
0-1 Used as work registers by the system
2-13 Unchanged
14-15 Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.
IWMSINF

Syntax

The syntax of the IWMSINF macro is as follows:

```
IWMSINF
```

```
/MODE=SUSPEND+,SRVINST_TO_STRT=srvinst_to_strt
/MODE=POST+,SRVINST_TO_STRT=srvinst_to_strt
/MODE=INFORM+,SRVINST_TO_STRT=srvinst_to_strt
/MODE=ECBCANCEL
```

```
,ECB=NO_ECB
```

```
,ECB=ecb
```

```
,RETCODE=retcode
```

```
,RSNCODE=rsncode
```

```
,PLISTVER=IMPLIED_VERSION
```

```
,PLISTVER=MAX
```

```
,PLISTVER=0
```

```
,MF=S
```

```
,MF=(L,list addr,attr)
```

```
,MF=(L,list addr,0D)
```

```
,MF=(E,list addr)
```

```
,MF=(E,list addr,COMPLETE)
```

Parameters

The parameters are explained as follows:

`name`
An optional symbol, starting in column 1, that is the name on the IWMSINF macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`ECB=ecb`
`ECB=NO_ECB`
When `MODE=POST` is specified, an optional input parameter, to specify the ECB which should be posted if WLM wants to inform the caller that the number of server instances have changed. The caller re-invokes IWMSINF after the ECB was posted by WLM to obtain number of server instances to start. The default is `NO_ECB`, which indicates that no ECB has been specified by the caller.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

`MF=S`
`MF=(L,list addr)`
`MF=(L,list addr,attr)`
`MF=(L,list addr,0D)`
`MF=(E,list addr)`
`MF=(E,list addr,COMPLETE)`
An optional input parameter that specifies the macro form.
Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

MODE=SUSPEND
MODE=POST
MODE=INFORM
MODE=ECBCANCEL
A required parameter that indicates how the caller uses the service

MODE=SUSPEND indicates that the caller wants to get suspended by WLM to listen for additional server instances to start. WLM will resume the caller if the number of server instances should be increased.

MODE=POST indicates that the caller wants to get posted if additional server instances should be started. If the caller gets posted it must re-invoke IWMSINF to obtain the value.

The caller is not suspended by WLM and WLM will also return the number of additional server instances on this call.

MODE=INFORM indicates that the caller wants to obtain the number of server instances without being suspended by WLM. This form is useful during initialization after IWM4CON if the caller wants to use the POST form but is not able to provide an ECB yet. It is expected that the caller will provide an ECB on the next invocation of the service.

MODE=ECBCANCEL indicates that a caller who passed an ECB to WLM wants to cancel the ECB address to avoid being posted in the future by WLM.

This form is useful during termination or recovery of server address spaces if a previous ECB address is no longer valid.
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

**RETCODE**=**retcode**

An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**RSNCODE**=**rsncode**

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**SRVINST_TO_STRT**=**srvinst_to_strt**

When **MODE=SUSPEND** is specified, a required output parameter that returns the number of server instances to start by the caller.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**SRVINST_TO_STRT**=**srvinst_to_strt**

When **MODE=POST** is specified, a required output parameter that returns the number of server instances to start by the caller.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**SRVINST_TO_STRT**=**srvinst_to_strt**

When **MODE=INFORM** is specified, a required output parameter that returns the number of server instances to start by the caller.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.
ABEND codes

None.

Return codes and reason codes

When the IWMSINF macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>

**Meaning**: Environmental error. |
| C           | xxxx0C14    | **Equate Symbol**: IwmRsnCodeNoWorkShutDown  
**Meaning**: No work selected. The caller is to shutdown.  
**Action**: Caller must disconnect by invoking the IWM4DIS macro. |
| 10          | —           | **Equate Symbol**: IwmRetCodeCompError  
**Meaning**: Component error.  
**Action**: Contact your system programmer. |

### Example

To obtain information about the number of server instances to start from WLM, specify the following:
IWMA4CON
WORK_MANAGER=YES,
SERVER_MANAGER=YES,
PARALLEL_EU=EUNITS,
SERVER_TYPE=QUEUE,
MANAGE_TASKS=YES,
SERVER_LIMIT=MAXTASKS,
CONNTKN=CTKN, CONNTKNKEY=PSWKEY,
RETCODE=RC, RSNPCODE=RSN

IWMSINF
MODE=SUSPEND,
SRVINST_TO_STRT=NUMINST,
RETCODE=RC, RSNPCODE=RSN

* * Storage areas
* *
EUNITS  DS  F  Number of Tasks which will be started
*  if the application environment is not managed.
MAXTASKS  DS  F  Maximum Number of Tasks up to which
*  WLM adjusts the number of server
*  instances for the server AS
CTKN  DS  FL4  Connect Token
NUMINSTS  DS  F  Number of server instances to start
RC  DS  F  Return code
RSN  DS  F  Reason code
IWMSRDNS

IWMSRDNS — Get sysplex routing location list

IWMSRDNS will return a list of location names for all registered servers which have been registered with a host name, known to the system on which the service is invoked. Servers which have deregistered, via IWMSRDRS, may still be present in the output list, due to the asynchronous nature of deregistration. Conversely, some registered servers may not appear for this same reason.

Environment

The requirements for the caller are:

| Minimum authorization: | Problem state with any PSW key. |
| Dispatchable unit mode: | Task |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. FRRs may be established. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

None.

Input register information

Before issuing the IWMSRDNS macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:
Register

Contents

0    Reason code if GR15 return code is non-zero
1    Used as work register by the system
2-13 Unchanged
14   Used as work register by the system
15   Return code

When control returns to the caller, the ARs contain:

Register

Contents

0-1   Used as work registers by the system
2-13  Unchanged
14-15 Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMSRDNS macro is as follows:

```
IWMSRDNS

LOCATION_NAMES=location_names,ANSLEN=anslen

,ENTRY_COUNT=entry_count,QUERYLEN=querylen

,RETCODE=retcode

,RSNCODE=rsncode,PLISTVER=IMPLIED_VERSION

,PLISTVER=MAX,PLISTVER=0

,MF=S

,MF=(L,,list addr,attr,COMPLETE)

,MF=(E,,list addr)
```

Parameters

The parameters are explained as follows:
IWMSRDNS

name
An optional symbol, starting in column 1, that is the name on the IWMSRDNS macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ANSLEN=anslen
A required input parameter, which contains the length of the LOCATION_NAMES in bytes.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,ENTRY_COUNT=entry_count
An optional output parameter, which will hold the number of location entries returned by the service. This is the number of entries in the SYSL_INFO array (see IWMWSYSL).

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

LOCATION_NAMES=location_names
A required input parameter, which specifies the name of the area to be filled in with the list of location names for the registered, active, LUs in the SYSPLEX registered with a host name.

The area must be large enough to contain at least 1 entry. The format of this area is mapped by IWMWSYSL.

To code: Specify the RS-type address, or address in register (2)-(12), of a field.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

*,COMPLETE*

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

*,PLISTVER=IMPLIED_VERSION*

*,PLISTVER=MAX*

*,PLISTVER=0*

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

*,QUERYLEN=querylen*

A required output parameter, variable which contains the number of bytes needed for all data requested.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

*,RETCODE=retcode*

An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

*,RSNCODE=rsncode*

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**

None.
Return codes and reason codes

When the IWMSRDNS macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Table 57. Return and Reason Codes for the IWMSRDNS Macro

**Meaning**: Storage is not available for the request.  
**Action**: There is a storage shortage. The function may work successfully at a later time. |
| 10          | —            | **Equate Symbol**: IwmRetCodeCompError  
**Meaning**: Component error.  
**Action**: No action required. The function may be successful if invoked again. |

**Example**

To list all locations registered with a host name, specify:

IWMSRDNS LOCATION_NAMES=DATA,  
ANSLEN=SIZE,  
ENTRY_COUNT=E,  
QUERYLEN=Q,  
RETCODE=RC,RSNCODE=RSN

* Storage areas

*  
DATA DS CL200 Area to receive output  
SIZEEQU EQU */DATA Equate for size of Data  
E DS F Field to receive entry count  
Q DS F Field to receive query length  
RC DS F Return code  
RSN DS F Reason code  
SIZE DC A(SIZEEQU) Field to hold size
IWMSRDRS — Deregister a server for sysplex routing

IWMSRDRS will deregister a server that had previously registered via IWMSRSRG, the Sysplex Router Registration macro, for sysplex workload balancing. Deregistration removes the specified server as a candidate from the Sysplex Routing Selection service, IWMSRSRS. Since the propagation of the deregistration to other systems is asynchronous, a newly deregistered triplet will continue to be eligible for selection by other systems for a period of time after return from the IWMSRDRS invocation. If the server was registered with a host name the caller must provide the host name in order to deregister the server.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state with any PSW key if the server address space to be deregistered is the home address space. If resource BPX.WLMSERVER is defined in the FACILITY class, an unauthorized caller requires access authority to this resource or the IWM.SERVER.REGISTER resource in the FACILITY class.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If the server to be deregistered is not the home address space, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Supervisor state.</td>
</tr>
<tr>
<td></td>
<td>• Program key mask (PKM) allowing at least one of the keys 0-7.</td>
</tr>
<tr>
<td></td>
<td>• The caller has access authority to the resource IWM.SERVER.REGISTER in the FACILITY class. If this resource is not defined, access authority to the FACILITY class resource BPX.WLMSERVER is required.</td>
</tr>
</tbody>
</table>

| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any PASN, any HASN, any SASN. |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts: |
| Locks: | No locks held. FRRs may be established. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

None.

Restrictions

1. This macro may not be used prior to the completion of WLM address space initialization
2. All parameter areas must reside in current primary.

Output register information

When control returns to the caller, the GPRs contain:
Register

Contents
0  Reason code if GR15 return code is non-zero
1  Used as a work register by the macro
14 Used as a work register by the macro
15  Return code

When control returns to the caller, the ARs contain:

Register

Contents
0  Used as a work register by the macro
1  Used as a work register by the macro
14 Used as a work register by the macro
15  Used as a work register by the macro

Some callers depend on register contents remaining the same before and after using a service. If the system changes the contents of registers on which the caller depends, the caller must save them before calling the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMSRDRS macro is as follows:

```plaintext
IWMSRDRS LOCATION=location,NETWORK_ID=network_id,LUNAME=luname
      ,HOST=NO_HOST,HOST=host,RETCODE=retcode,RSNCODE=rsncode
      ,PLISTVER=IMPLIED_VERSION,PLISTVER=MAX,PLISTVER=0
      ,MF=FILTER,0D,LIST=FILTER=attr,COMPLETE
```

Parameters

The parameters are explained as follows:

`name`

An optional symbol, starting in column 1, that is the name on the IWMSRDRS macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`,`HOST=host`
IWMSRDRS

 HOST=NO_HOST
An optional input parameter, which contains the server HOST name associated with the address space to be deregistered. The value should be padded on the right with blanks for any unused characters. The default is NO_HOST, which indicates that a HOST name was not passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-character field.

LOCATION=location
A required input parameter, which contains the server LOCATION associated with the registered address space.

To code: Specify the RS-type address, or address in register (2)-(12), of a 18-character field.

LUNAME=luname
A required input parameter, which contains the server Logical Unit name associated with the registered address space.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

MF=S
MF=(L,list addr)
MF=(L,list addr,attr)
MF=(L,list addr,0D)
MF=(E,list addr)
MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.
A required input parameter, which contains the Network ID associated with the registered address space.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**PLISTVER**

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use only the following parameters:

<table>
<thead>
<tr>
<th>LOCATION</th>
<th>LUNAME</th>
<th>NETWORK_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **1**, if you use the following parameter and those from version 0:

  **HOST**

  **To code:** Specify one of the following:
  - **IMPLIED_VERSION**
  - **MAX**
  - A decimal value of 0 or 1

**RETCODE**

An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**RSNCODE**

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**

None.
Return codes and reason codes

When the IWMSRDRS macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes. IBM support personnel may request the entire reason code, including the xxxx value.

**Meaning**: The caller is not authorized by SAF to deregister a service.  
**Action**: Unauthorized callers (problem state or none of the authorized keys 0 to 7) require access authority to the RACF resource IWM.SERVER.REGISTER in the FACILITY class. If this resource is not defined, access authority to the FACILITY class resource BPX.WLM.SERVER is required. |
| 10          | —           | **Equate Symbol**: IwmRetCodeCompError  
**Meaning**: Component error (no reason codes) |
IWMSRFSV — Sysplex routing find server routine

IWMSRFSV will find a server associated with the specified application environment and return the associated server data which was passed at the time the server connected to WLM (via IWM4CON). The only eligible servers are those that have connected to WLM with a specification of `IWM4CON SERVER_MANAGER=YES,SERVER_TYPE=ROUTING`, and whose application environment matches the input value passed to IWMSRFSV, which implies that the server belongs to the same subsystem type as the caller. The server chosen is considered a best choice to run work in terms of a variety of system conditions which are monitored.

When no eligible servers are already started, and the service policy allows MVS to start a server, and certain other conditions apply, MVS will start a new server on behalf of the request. Circumstances such as this imply that the program calling this service may be suspended until the request can be resolved. When no eligible servers exist and none can be started the caller will receive a return code to reflect this.

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state or program key mask (PKM) allowing keys 0-7.
Dispatchable unit mode: Task
Cross memory mode: PASN=HASN=SASN
AMODE: 31-bit
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: No locks may be held.
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRNSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
4. All character inputs are assumed to be padded on the right with blanks, when needed to fill out the entire length.

Restrictions

1. This macro may not be used during task/address space termination.
2. NO FRRs may be established.
3. The Connect token from the input parameter list must be owned by the current home address space.
4. The address space from which this service is invoked must have previously connected to WLM, using IWM4CON Router=Yes. The input application environment must be associated in the current service policy with the subsystem type specified through IWM4CON.

**Input register information**

Before issuing the IWMSRFSV macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

The task issuing this service may be suspended while a new server address space is being started, possibly on another MVS image.

**Syntax**

- **main diagram**

  ```plaintext
  name IWMSRFSV CONNTKN=conntkn,APPLENV=applenv
  ```
IWMSRFSV

Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMSRFSV macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,**APPLENV=applenv**

A required input parameter, which contains the application environment under which work requests are to be served.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,**CONNTKN=conntkn**

A required input parameter, which contains the connect token for the current home space.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,**MF=S**

,**MF=(L,list addr)**

,**MF=(L,list addr,attr)**

,**MF=(L,list addr,OD)**

,**MF=(E,list addr)**

,**MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code _attr_, the system provides a value of 0D.

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
- **0**, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

A required output parameter, which contains the data needed to uniquely...
identify the chosen server. The structure of this data is undefined to MVS, and is the same data passed when the server connected using IWM4CON SERVER_MANAGER=YES, SERVER_TYPE=ROUTING, SERVER_DATA=... 

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMSRFSV macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning and Action</th>
</tr>
</thead>
</table>

</tr>
</thead>
</table>
| C           | xxxx0C01    |               | **Equate symbol:** IwmRsnCodeNoStg  
**Meaning:** Storage is not available for the request.  
**Action:** There is a storage shortage. The function may work successfully at a later time. |
| C           | xxxx0C1A    |               | **Equate symbol:** IwmRsnCodeApplNotDefined  
**Meaning:** The application environment name is not defined in the active WLM policy.  
**Action:** Check whether the correct application environment name is being used. If so, a service administrator must define the application environment in the WLM service definition. |
| C           | xxxx0C1B    |               | **Equate symbol:** IwmRsnCodeApplNotSST  
**Meaning:** The application environment name is defined for use by a different subsystem type in the active WLM policy.  
**Action:** Check whether the correct application environment name is being used. If so, a service administrator must change the application environment in the WLM service definition to specify the correct subsystem type. |
| C           | xxxx0C1C    |               | **Equate symbol:** IwmRsnCodeServerNotStarted  
**Meaning:** No server exists for the specified application environment and no server could be started.  
**Action:** No action required. The function may be successful if invoked again. |
| C           | xxxx0C22    |               | **Equate symbol:** IwmRsnCodeApplEnvQuiesced  
**Meaning:** The specified application environment has been quiesced, server cannot be started for the request.  
**Action:** Restart the application environment and then retry the request. |
| C           | xxxx0C23    |               | **Equate symbol:** IwmRsnCodeIndLocalSystem  
**Meaning:** Local system is not running with the current WLM policy, new server cannot be started for the request.  
**Action:** Avoid requesting this function while the local system is not running with the current WLM policy. |
| C           | xxxx0C24    |               | **Equate symbol:** IwmRsncodeProcNameBlank  
**Meaning:** Server procname is blank, server cannot be started for the request.  
**Action:** Check the server procname, fix it, and then retry the request. |
### Table 59. Return and Reason Codes for the IWMSRFSV Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning and Action</th>
</tr>
</thead>
</table>
| C           | xxxx0C25    |               | **Meaning:** WLM has given up trying to start a server because of failures. The associated application environment has been internally stopped.  
**Action:** Restart the application environment and then retry the request. |
| C           | xxxx0C26    |               | **Meaning:** Either there is no router exists for the requested server or the router exists but not active. No server can be selected/started on this system.  
**Action:** Re-connect the router for the requested application environment to WLM and then retry the request. |
| C           | xxxx0C27    |               | **Meaning:** Reserved. |
| 10          | —           |               | **Meaning:** Component error.  
**Action:** No action required. The function may be successful if invoked again. |

### Example

To determine a best server to which to route work:

```
IWMSRFSV CONNTKN=CTKN, X  
APPLENV=AENAME, X  
SERVER_DATA=SVRDATA, X  
RETCODE=RC, RSNCODE=RSN
```

*    
*    * Storage areas  
CTKN DS F  Contains the connect token for  
the current home space  
AENAME DS CL32  Contains the application  
environment name  
SVRDATA DS CL32  Contains the output server data  
RC DS F  Return code  
RSN DS F  Reason code
IWMSRSRG — Register a server for sysplex routing

The purpose of the IWMSRSRG service is to register a server that wishes to participate in sysplex workload balancing. The service allows the caller to identify an address space to be associated with a triplet, corresponding to location name, network id and LU name. This triplet is expected to be unique across all registered spaces in the sysplex, and, should be unique across all networks. The caller can additionally associate the triplet with a host name. Specifying a host name is optional, and if it is not coded it is set to blanks by the system. A list of eligible servers is made available to IWMSRSRS. These work requests include enclaves owned by the space as well as the address space's activity itself.

If this macro is issued to register a LOCATION.NETWORK_ID.LU_NAME that already exists on the issuing MVS image, the second registration will be ignored (IWMSRDRS should first be used to deregister the triplet). This condition will be identified through a unique return and reason code. Due to timing considerations, sysplex-wide uniqueness is not enforced, and so is the responsibility of the caller.

The caller can additionally associate the server with a health indicator. This is a value between 0 and 100, that indicates the percentage up to which the server is capable of performing its normal work. This health indicator is used by the routing service to modify the routing recommendations according to this indicator. It can be modified by calling this service again with another HEALTH value. In this case the return and reason code for already registered servers will not be returned.

After a server registers by issuing this macro, the sysplex routing service IWMSRSRS can be issued to return a weighted list of registered servers in the sysplex to which work could be directed. Alternatively, IWMSRSRS can be used to obtain a complete list of servers associated with a given location or to obtain the user data associated with each server. Since the propagation of the registration to other systems is asynchronous, a newly registered triplet will not be immediately visible to other systems.

A server is automatically deregistered during job termination or memory termination.
Environment

The requirements for the caller are:

**Minimum authorization:**
Problem state with any PSW key if the address space token specified with STOKEN=stoken equals the address space token of the home address space. If resource BPX.WLMSERVER is defined in the FACILITY class, an unauthorized caller requires access authority to this resource or the IWM.SERVERREGISTER resource in the FACILITY class.

If the address space token specified with STOKEN=stoken is not the address space token of the home address space, one of the following:
- Supervisor state.
- Program key mask (PKM) allowing at least one of the keys 0-7.
- The caller has access authority to the resource IWM.SERVERREGISTER in the FACILITY class. If this resource is not defined, access authority to the FACILITY class resource BPX.WLMSERVER is required.

**Dispatchable unit mode:** Task or SRB

**Cross memory mode:** Any PASN, any HASN, any SASN

**AMODE:** 31-bit

**ASC mode:** Primary

**Interrupt status:** Enabled for I/O and external interrupts

**Locks:** No locks may be held. FRRs may be established.

**Control parameters:** Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

This macro may not be used prior to the completion of WLM address space initialization.
Input register information

Before issuing the IWMSRSRG macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMSRSRG macro is as follows:

```
IWMSRSRG
```

```
LOCATION=location,NETWORK_ID=network_id,LUNAME=luname
```

```
STOKEN=stoken,USERDATA=NO_USERDATA,HOST=NO_HOST,HEALTH=NO_HEALTH
```

```
USERDATA=userdata
```

```
HOST=host
```

```
HEALTH=health
```
Parameters

The parameters are explained as follows:

`name`
An optional symbol, starting in column 1, that is the name on the IWMSRSRG macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`,HEALTH=health`
`,HEALTH=NO_HEALTH`
An optional input parameter, which contains the health factor associated with the address space. This is a value, that reflects, up to which percentage this address space is capable to handle requests. NO_HEALTH indicates that no health indicator was passed. This is the default. In this case, a health value of 100 is assumed, when the server is registered.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

`,HOST=host`
`,HOST=NO_HOST`
An optional input parameter, which contains the host name associated with the address space to be registered. The value should be padded on the right with blanks for any unused characters. NO_HOST indicates that no host name was passed. This is the default.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-character field.

`LOCATION=location`
A required input parameter, which contains the server LOCATION associated with the address space to be registered. The value should be padded on the right with blanks for any unused characters.

To code: Specify the RS-type address, or address in register (2)-(12), of a 18-character field.

`,LUNAME=luname`
A required input parameter, which contains the server Logical Unit name associated with the address space to be registered.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

`,MF=S`
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

list addr

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

attr

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

COMPLETE

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

NETWORK_ID=network_id

A required input parameter, which contains the Network ID associated with the address space to be registered.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

PLISTVER=IMPLIED_VERSION

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
• MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

• 0, which supports all parameters except those specifically referenced in higher versions.

• 1, which supports the following parameter and those from version 0:

  USERDATA

• 2, which supports the following parameter and those from version 0 and 1:

  HOST

• 3, which supports the following parameter and those from version 0, 1 and 2:

  HEALTH

To code: Specify one of the following:

• IMPLIED_VERSION

• MAX

• A decimal value of 0, 1, 2, or 3

,RETCODE=retcode

An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode

An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,STOKEN=stoken

A required input parameter, which contains the space token of the server to be registered.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

,userdata

,USERDATA=NO_USERDATA

An optional input parameter, which contains data meaningful to the user of this service. This user data is available to callers of the IWMSRSRS service.

The format is undefined to MVS. The default is NO_USERDATA, which indicates that no user data was passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-character field.

ABEND codes

None.
Return codes and reason codes

When the IWMSRSRG macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>

### Example

To register an instance of a given location, specify:

```
IWMSRSRG LOCATION=LOC,NETWORK_ID=NET,LUNAME=LU,
STOKEN=STKN,HOST=HST,HEALTH=HLTH,
USERDATA=DATA,RETCODE=RC,RSNCODE=RSN
```

* Storage areas
* 
LOC DS CL1B Contains the Location associated with the server instance
* NET DS CL8 Contains the Network Id associated with the server instance
* LU DS CL8 Contains the LU name associated with the server
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>

<td>CL8</td>
<td>Contains the STOKEN associated with the server instance</td>
</tr>
<tr>
<td>DATA</td>
<td>DS</td>
<td>CL64</td>
<td>Contains the user data associated with the server instance</td>
</tr>
<tr>
<td>HST</td>
<td>DS</td>
<td>CL64</td>
<td>Contains the Host name associated with the server instance</td>
</tr>
<tr>
<td>HLTH</td>
<td>DS</td>
<td>F</td>
<td>Contains the Health indicator associated with the server instance</td>
</tr>
<tr>
<td>RC</td>
<td>DS</td>
<td>F</td>
<td>Return code</td>
</tr>
<tr>
<td>RSN</td>
<td>DS</td>
<td>F</td>
<td>Reason code</td>
</tr>
</tbody>
</table>
IWMSRSRS provides three functions: SELECT, QUERY and SPECIFIC. All return a list of registered servers known to the system on which the service is invoked. Servers which have deregistered, via IWMSRDRS, may still be present in the output list, due to the asynchronous nature of deregistration. Conversely, some registered servers may not appear for this same reason.

When either the SELECT or the SPECIFIC function is chosen, IWMSRSRS will return a list of servers in the sysplex which are associated with the input Location name along with a relative weighting for each server. These servers are identified by their Network id and LU name, which were previously registered using the sysplex router register macro, IWMSRSRG. Note that some servers may not appear in the output list due to balancing decisions, so this service should not be used as a general query service to find all currently registered servers for the input location.

Next to each server in the list will be a weight which tells the caller the relative number of requests to send to each entry. For example, the caller might send the indicated number of requests to each LU in the list before routing to the next LU in the list.

<table>
<thead>
<tr>
<th>Server</th>
<th>Weight</th>
<th>CPU Weight</th>
<th>zAAP Weight</th>
<th>zIIP Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>NETIDA.LUNAME1</td>
<td>4</td>
<td>3</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>NETIDB.LUNAME2</td>
<td>7</td>
<td>8</td>
<td>3</td>
<td>9</td>
</tr>
<tr>
<td>NETIDC.LUNAME3</td>
<td>1</td>
<td>3</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>NETIDD.LUNAME43</td>
<td>4</td>
<td>5</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>NETID4.LUNAME2</td>
<td>2</td>
<td>1</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>

The requestor could then choose to send the first 4 requests to NETIDA.LUNAME1, the next 7 requests to NETIDB.LUNAME2, the next request to NETIDC.LUNAME3, and so forth. When the list is exhausted, the requestor could invoke this macro again and get a whole new list or could rotate through the list again. It is expected that the requestor would invoke this macro frequently to get current system views for work balancing. For example, it would be appropriate for the caller to invoke this service approximately every 1 to 3 minutes, so that the list will remain current with changing system conditions and server availability.

Starting with z/OS V1R9, three new output weights are available: the CPU weight, the zAAP weight and the zIIP weight. The CPU weight is computed the same way as the weight was prior to V1R9, taking only CPU data into account. The zAAP and the zIIP weights are computed when taking only zAAP, respectively zIIP, data into account. The weight is a combination of these three processor weights.

Starting with z/OS V1R11, an optional input keyword METHOD selects how the weight (also referred to as "mixed" weight) is computed. The default is METHOD=PROPORTIONAL, which calculates the weight as a combination of these 3 processor weights (CPU, zAAP and zIIP). It is the same method as prior to V1R11. With METHOD=EQUICPU, WLM computes the weight by trying to simulate a 100% usage of the system capacity, and determining the capacity of a CPU-only system having equivalent resource consumption.

Both methods can be specified with keyword IL_WEIGHTING, and EQUICPU by COST_ZAAP_ON_CP and COST_ZIIP_ON_CP, too.
When the QUERY function is requested, IWMSRSRS will return the list of all servers in the sysplex which are associated with the input Location name along with a fixed weight of one for each server. The format of the output is the same as for SELECT.

When using the QUERY function, the CPU, zAAP and zIIP weights are always set to 0.

When using the SELECT or the SPECIFIC function, the mixed weight is a combination of the CPU, zAAP and zIIP weights with the relative use of the CPU, zAAP and zIIP by the server. Moreover, the mixed weights are scaled up, so that their sum is 64. Due to rounding errors, the sum of the mixed weights is usually as low as 64-(number of servers).

If there are pre-V1R9 systems in the sysplex, the zAAP and zIIP weights are automatically set to 0, and the weight is equal to the CPU weight, because pre-V1R9 systems do not have such weights and could not be correctly compared to V1R9 systems.

The Sysplex Routing Service (IWMSRSRS) can be used to obtain the userdata associated with each server.

When the SPECIFIC function is issued, IWMSRSRS returns a list of servers in the sysplex which are associated with the input Location name along with a relative weighting for each server. In contrast to the weights in the SELECT function, the weights in the SPECIFIC function do not only consider available capacity values and the number of servers on the same system.

With the SPECIFIC function, the following additional factors are taken into account:

- The performance index that indicates the achievement of the WLM defined goals of the server, that is its related work. A server that achieves its goal is preferred over one that does not achieve its goal.
- If the server owns independent enclaves those also take the delays into account that the work is subject to, due to the queue times of the owned enclaves. A server with less average queue times for its enclaves is preferred over one with higher queue times.
- The health factor of this server. It is dependent on the health indicator which was reported to WLM for this server by the IWM4HLTH service or by IWMSRSRG. If no health indicator was reported, this factor is also neutral.

**Environment**

The requirements for the caller are:

Minimum authorization: Problem state with any PSW key.
Dispatchable unit mode: Task
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31-bit
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: No locks may be held. FRRs may be established.
Control parameters: Control parameters must be in the primary address space.
Programming requirements
1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions
This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information
Before issuing the IWMSRSRS macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information
When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.
Performance implications

None.

Parameters

The parameters are explained as follows:

`name`
An optional symbol, starting in column 1, that is the name on the IWMSRSRS macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`ANSLEN=anslen`
A required input parameter, which contains the length of the SYSINFO_BLOCK in bytes.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.
An optional input parameter, which is used in conjunction with 
METHOD=EQUICPU. It describes the additional cost of executing 
zAAP-eligible work on a CPU instead of on a zAAP processor.

If the caller wants to use the full system capacity, independently of the cost, 
then it should set COST_ZAAP_ON_CP=1. With high values of this cost 
parameter, WLM considers that a system having used up its free zAAP 
capacity should offload less work to the CPU, and gives this system a smaller 
output weight.

This cost parameter must be in the range from 1 to 100. If the specified value is 
outside of this range, WLM will instead use the nearest valid integer (1 or 100) 
as cost parameter. The default is 1.

To code: Specify the RS-type address, or address in register (2)-(12), of a 
fullword field, or specify a literal decimal value.

An optional input parameter, which is used in conjunction with 
METHOD=EQUICPU. It describes the additional cost of executing zIIP-eligible 
work on a CPU instead of on a zIIP processor.

If the caller wants to use the full system capacity, independently of the cost, 
then it should set COST_ZIIP_ON_CP=1. With high values of this cost 
parameter, WLM considers that a system having used up its free zIIP capacity 
should offload less work to the CPU, and gives this system a smaller output 
weight.

This cost parameter must be in the range from 1 to 100. If the specified value is 
outside of this range, WLM will instead use the nearest valid integer (1 or 100) 
as cost parameter. The default is 1.

To code: Specify the RS-type address, or address in register (2)-(12), of a 
fullword field, or specify a literal decimal value.

An optional output parameter, which will hold the number of server entries 
returned by the service. This is the number of entries in the SYSR_INFO array 
(see IWMWSYSR).

To code: Specify the RS-type address, or address in register (2)-(12), of a 
fullword field.

An optional parameter, which describes whether the format of the output area 
named by SYSINFO_BLOCK includes the extended section or not (see 
IWMWSYSR). The default is EXTENDED_DATA=NO.

EXTENDED_DATA=NO
indicates that the format of the output area named by SYSINFO_BLOCK 
includes only the standard information mapped by the SYSR, which 
consists of an array of entries described by SYSR_INFO.

EXTENDED_DATA=YES
indicates that the format of the output area given by SYSINFO_BLOCK 
includes first the standard information mapped by the SYSR, which
IWMSRSRS

consists of an array of entries described by SYSR_INFO, followed immediately by the header for the extension section and any other data described by the header.

FUNCTION=SELECT
FUNCTION=SPECIFIC

An optional parameter, which describes which set of servers are of interest to the caller. The default is FUNCTION=SELECT.

FUNCTION=SELECT

indicates that the servers best suited to receive work are to be returned.

FUNCTION=QUERY

indicates that all servers associated with the input LOCATION are to be returned.

FUNCTION=SPECIFIC

indicates that all servers in the sysplex which are associated with the input Location name along with a relative weighting for each server are returned.

IL_WEIGHTING=il_weighting
IL_WEIGHTING=0

An optional input parameter, which controls how WLM weights available capacity at importance levels (ILs) lower than the currently selected one. The value of IL_WEIGHTING should be in the range from 0 to 3. If the passed value is outside of this range, WLM will instead use the nearest valid integer (0 or 3) as IL_WEIGHTING.

When this parameter is set to 0 (the default value), all free capacities used by levels less important than the current one are weighted the same. This means that the free capacity below the current level is considered to be totally free, and this is equivalent to what WLM did prior to V1R11.

When this parameter is set to 1, free capacity at the lowest ILs is weighted more than the current IL, with a weighting growing proportionally to the square root of the IL difference + 1. For example, with a selected IL of 1, free capacity at IL 5 is weighted about 2.236 times more than free capacity at IL 1.

When this parameter is set to 2, free capacity at the lowest ILs is weighted more than the current IL, with a weighting growing proportionally to the IL difference + 1. For example, with a selected IL of 1, free capacity at IL 5 is weighted 5 times more than free capacity at IL 1.

When this parameter is set to 3, free capacity at the lowest ILs is weighted more than the current IL, with a weighting growing proportionally to the square of the IL difference + 1. For example, with a selected IL of 1, free capacity at IL 5 is weighted 25 times more than free capacity at IL 1. The default is 0.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

LOCATION=location

A required input parameter, which contains the LOCATION associated with the registered address spaces which are candidates to receive work.

To code: Specify the RS-type address, or address in register (2)-(12), of a 18-character field.

METHOD=PROPORTIONAL
An optional parameter, which selects the method for computing the output weights. The default is METHOD=PROPORTIONAL. The default is METHOD=PROPORTIONAL.

**METHOD=PROPORTIONAL**

Calculates the output weights as a proportion of the 3 processor types weights.

**METHOD=EQUICPU**

Calculates a CPU equivalent of the systems before computing the output weights.

In order for METHOD=EQUICPU to be active, all systems in sysplex must run at least z/OS V1R11. Otherwise WLM automatically switches back to METHOD=PROPORTIONAL.

**MF=S (S optional)**

**MF=(L,list addr)**

**MF=(L,list addr,attr)**

**MF=(L,list addr,0D)**

**MF=(E,list addr)**

**MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**list addr**

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

**COMPLETE**

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

**PLISTVER=IMPLIED_VERSION**

**PLISTVER=MAX**

**PLISTVER=0**

**PLISTVER=1**

**PLISTVER=2**

An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports both the following parameters and those from version 0:
  - ENTRY_COUNT
  - EXTENDED_DATA
  - FUNCTION
- **2**, which supports both the following parameters and those from version 0 and 1:
  - COST_ZAAP_ON_CP
  - IL_WEIGHTING
  - COST_ZIIP_ON_CP
  - METHOD

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0, 1, or 2

**QUERYLEN=querylen**  
A required output parameter, variable which contains the number of bytes needed for all data requested, taking into account the format specified via the EXTENDED_DATA keyword.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**RETCODE=retcode**  
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

**RSNCODE=rsncode**  
An optional output parameter into which the reason code is to be copied from
GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

**SYSINFO_BLOCK=sysinfo_block**

A required input parameter, of the area to be filled in with the system information for the registered, active, LUs in the SYSPLEX associated with the input location.

The area must be large enough to contain at least 1 entry. The format of this area is mapped by IWMWSYSR. The EXTENDED_DATA keyword describes the desired format. The FUNCTION keyword describes which servers are candidates for inclusion.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMSRSRS macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol Meaning and Action</th>
</tr>

**Example**

To register an instance of a given location:

IWMSRSRS SYSINFO_BLOCK=DATA,
EXTENDED_DATA=YES,
ANSLEN=SIZE,
ENTRY_COUNT=E,
QUERYLEN=Q,
LOCATION=LOC,
FUNCTION=QUERY,RETCODE=RC,RSNCODE=RSN

* Storage areas
  * DATA DS CL200 Area to receive output
  * SIZEEQU EQU *=DATA Equate for size of Data
  * E DS F Field to receive entry count
  * Q DS F Field to receive query length
  * LOC DS CL18 Contains the Location
  * associated with the server
  * instance
  * RC DS F Return code
  * RSN DS F Reason code
  * SIZE DC A(SIZEEQU) Field to hold size
IWMUXPT — WLM undo export

The IWMUXPT macro undoes an earlier request to export an enclave via the IWMUXPT macro.

The caller is expected to invoke IWMUXPT after all importing systems have invoked IWMUXMPT. If IWMUXPT is invoked while other systems have imported the enclave, WLM loses the ability to manage the multisystem enclave as a unit. Also the enclave owner’s SMF 30 record will not contain all of the CPU time used by the enclaves on the other systems.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Requirement Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum authorization</td>
<td>Supervisor state or program key mask (PKM) allowing keys 0-7.</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>Any HASN, any SASN. PASN must be the address space which connected to WLM.</td>
</tr>
<tr>
<td>AMODE</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNICODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

None.

Input register information

Before issuing the IWMUXPT macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMUEXPT macro is as follows:

```
    name IWMUEXPT XTOKEN=xtoken, CONNTKN=conntkn, RETCODE=retcode
    , RSNCODE=rsncode
    , PLISTVER=IMPLIED_VERSION
    , PLISTVER=MAX
    , PLISTVER=0
    , MF=S
    , MF=(L, list addr, attr, COMPLETE)
```

Parameters

The parameters are explained as follows:
**IWMUXEPT**

*name*
An optional symbol, starting in column 1, that is the name on the IWMUXEPT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

*,CONNTKN=conntkn*
A required input parameter that contains the connect token for the primary address space’s connection to WLM.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

*,MF=S*
*,MF=(L,list addr)*
*,MF=(L,list addr,attr)*
*,MF=(L,list addr,0D)*
*,MF=(E,list addr)*
*,MF=(E,list addr,COMPLETE)*
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

*,list addr*
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

*,attr*
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

*,COMPLETE*
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

*,PLISTVER=IMPLIED_VERSION*
*,PLISTVER=MAX*
*,PLISTVER=0*
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
**IWMUEXPT**

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

  **To code:** Specify one of the following:
  
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0

  **,RETCODE=retcode**
  
  An optional output parameter into which the return code is to be copied from GPR 15.

  **To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

  **,RSNCODE=rsncode**
  
  An optional output parameter into which the reason code is to be copied from GPR 0.

  **To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

  **XTOKEN=xtoken**
  
  A required input parameter that contains the export token which identifies the exported enclave.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMUEXPT macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeOk</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Successful completion.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Action: None required.</td>
</tr>
</tbody>
</table>
Table 62. Return and Reason Codes for the IWMUEXPT Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 4           | —           | **Equate Symbol**: IwmRetCodeWarning  
**Meaning**: Successful completion, unusual conditions noted. |
| 4           | xxxx0432    | **Equate Symbol**: IwmRsnCodeUnknownExportToken  
**Meaning**: No enclave matching the export token was found. The enclave may have been unexported or deleted, or the WLM coupling facility structure may have been lost.  
**Action**: None. |
| 8           | —           | **Equate Symbol**: IwmRetCodeInvokeError  
**Meaning**: Invalid invocation environment or parameters. |
| 8           | xxxx0803    | **Equate Symbol**: IwmRsnCodeDisabled  
**Meaning**: Caller is disabled.  
**Action**: Avoid requesting this function while disabled. |
| 8           | xxxx0804    | **Equate Symbol**: IwmRsnCodeLocked  
**Meaning**: The caller is locked.  
**Action**: Avoid requesting this function while locked. |
| 8           | xxxx080B    | **Equate Symbol**: IwmRsnCodeBadPl  
**Meaning**: Error accessing parameter list.  
**Action**: Check for possible storage overlay. |
| 8           | xxxx0821    | **Equate Symbol**: IwmRsnCodeBadConn  
**Meaning**: Input connect token does not pass validity checking.  
**Action**: Make sure the primary address space connected to WLM using the IWM4CON service. Make sure the connect token returned by IWM4CON is passed correctly. |
| 8           | xxxx0824    | **Equate Symbol**: IwmRsnCodeAmode24  
**Meaning**: The caller invoked the service but was in 24-bit addressing mode.  
**Action**: Request this function only when you are in 31-bit addressing mode. |
| 8           | xxxx0825    | **Equate Symbol**: IwmRsnCodeAscModeNotPrimary  
**Meaning**: The caller invoked the service but was not in primary ASC mode.  
**Action**: Avoid requesting this function in this environment. |
| 8           | xxxx0827    | **Equate Symbol**: IwmRsnCodeRsvdNot0  
**Meaning**: Reserved field in parameter list was non-zero.  
**Action**: Check for use of keywords that are not supported by the MVS release on which the program is running. |
| 8           | xxxx0828    | **Equate Symbol**: IwmRsnCodeBadVersion  
**Meaning**: Version number in parameter list is not valid.  
**Action**: Check for possible storage overlay of the parameter list. |
### Table 62. Return and Reason Codes for the IWMUEXPT Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0840    | **Equate Symbol**: IwmRsnCodeServiceNotEnabled  
**Meaning**: The caller’s connection is not enabled for this service.  
**Action**: Make sure that EXPTIMPT=YES is specified on the IWM4CON macro invocation. |
| 8           | xxxx0842    | **Equate Symbol**: IwmRsnCodeNoWLMConnect  
**Meaning**: The caller’s primary address space is not connected to WLM.  
**Action**: Invoke the IWM4CON macro before invoking this macro. |
| 8           | xxxx0870    | **Equate Symbol**: IwmRsnCodeBadExportToken  
**Meaning**: The export token is not validly formatted.  
**Action**: Check for possible storage overlay of the export token. |
| 8           | xxxx0871    | **Equate Symbol**: IwmRsnCodeDidNotExportOrImport  
**Meaning**: The primary address space did not export the enclave.  
**Action**: Invoke IWMUEXPT from the correct address space. |
| C           | —           | **Equate Symbol**: IwmRetCodeEnvError  
**Meaning**: Environmental error. |
| 10          | —           | **Equate Symbol**: IwmRetCodeCompError  
**Meaning**: Component error.  
**Action**: Contact your system programmer. |

**Example**

```plaintext
IWMUEXPT XTOKEN=EXPORTT, CONNTKN=CONNECTT
*
* Storage areas
*
EXPORTT DS CL32 Export token
CONNECTT DS CL4 Connect token
```
The IWMUIMPT macro undoes an earlier request to import an enclave via the IWMIMPT macro.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any HASN, any SASN. PASN must be the address space which connected to WLM.</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

None.

**Input register information**

Before issuing the IWMUIMPT macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>
When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMUIMPT macro is as follows:

```
IWMUIMPT XTOKEN=xtoken,CONNTKN=conntkn,RETCODE=retcode

RSNCODE=rncode

PLISTVER=IMPLIED_VERSION

PLISTVER=MAX

PLISTVER=0

MF=S

MF=(L ,list addr)

attr

MF=(E ,list addr)

attr

COMPLETE
```

**Parameters**

The parameters are explained as follows:

- **name**
  
  An optional symbol, starting in column 1, that is the name on the IWMUIMPT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

- **CONNTKN=conntkn**
  
  A required input parameter that contains the connect token for the primary address space’s connection to WLM.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

A list addr

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

A attr

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

A COMPLETE

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

A PLISTVER=IMPLIED_VERSION
A PLISTVER=MAX
A PLISTVER=0

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

XTOKEN=xtoken
A required input parameter that contains the export token which identifies the exported enclave.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

ABEND codes
None.

Return codes and reason codes

When the IWMUIMPT macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeOk</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Successful completion.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Action: None required.</td>
</tr>
<tr>
<td>4</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeWarning</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Successful completion, unusual conditions noted.</td>
</tr>
<tr>
<td>4</td>
<td>xxxx0432</td>
<td>Equate Symbol: IwmRsnCodeUnknownExportToken</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: No enclave matching the export token was found. The enclave may have been unexported or deleted, or the WLM coupling facility structure may have been lost.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Action: None.</td>
</tr>
</tbody>
</table>

### Example

```plaintext
IWMUIMPT XTOKEN=EXPORTT,CONNTKN=CONNECTT
```

* Storage areas

```plaintext
EXPORTT DS CL32 Export token
CONNECTT DS CL4 Connect token
```
IWMWMCON — WLM modify connect

The purpose of this service is to modify a particular connection to WLM with respect to the associated subsystem type and/or name for work manager services, described below, and so could replace the use of the pair of services disconnect (IWM4DIS) and connect (IWM4CON) for the new values of subsystem type and/or name. This change only affects work manager related services, and does not affect the subsystem identify for queue manager or server manager services. For this reason, the caller must be connected to the WLM work management services, i.e. IWM4CON WORK_MANAGER=YES must be specified. Queue manager and/or server manager may also be specified at connect, but are not affected by use of IWMWMCON. The PSW key and topology list associated with the connect may not be changed via this service.

Use of this service needs to be coordinated with the use of other work manager services which depend on the connect token and the associated subsystem related information to ensure that the desired results are obtained. Among these services are classify (IWMCLSFY), report (IWMRPT), notify (IWMMNTFY) where it is an optional input, and enclave create (IWM4ECRE). Note that use of IWMWMCON is not appropriate prior to creation of enclaves with TYPE(Dependent) or TYPE(Montkn).

Environment

The requirements for the caller are:

- **Minimum authorization**: Supervisor state or program key mask (PKM) allowing keys 0-7.
- **Dispatchable unit mode**: Task or SRB
- **Cross memory mode**: Any P,S. Current Home address space must be the same as Home when the corresponding Connect was invoked.
- **AMODE**: 31-bit
- **ASC mode**: Primary
- **Interrupt status**: Enabled for I/O and external interrupts
- **Locks**: No locks may be held.
- **Control parameters**: Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. If the key specified on IWM4CON was a user key (8-F), then the following must ALL be true:
IWMWMCON

- caller must be in non-cross-memory mode (P=S=H). This implies that the current primary must match the primary at the time that IWM4CON was invoked. Running in a subspace is not supported.
- must be in TCB mode (not SRB)
- current TCB must match the TCB at the time that IWM4CON was invoked.

2. It is the caller's responsibility to serialize use of this service with use of IWMCLSFY and other services using the connect token. Failure to do so may result in classification to a service and/or report class which is other than the intended one.

3. This service should not be invoked while in a RTM termination routine (resource manager) for the TCB owning the connect token since MVS will have its own resource cleanup routine and unpredictable results would occur. It is legitimate to use this service while in a recovery routine, however, or in mainline processing.

Input register information

Before issuing the IWMWMCON macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2-13</td>
</tr>
<tr>
<td>14</td>
</tr>
<tr>
<td>15</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
</tr>
<tr>
<td>2-13</td>
</tr>
<tr>
<td>14-15</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None
IWMWMCON

Syntax

main diagram

Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMWMCON macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

CONNTKN=conntkn
A required input parameter, which contains the connect token for the environment to be modified.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

MF=S
MF=(L,list addr)
MF=(L,list addr,attr)
MF=(L,list addr,0D)
MF=(E,list addr)
MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same value of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).
,,SUBSYS={subsys}
A required input parameter, which contains the generic subsystem type (e.g., IMS, CICS, etc.).

To code: Specify the RS-type address, or address in register (2)-(12), of a 4-character field.

,,SUBSYSNM={subsysnm}
A required input parameter, which contains the name of the specific subsystem instance.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

ABEND codes

None.

Return codes and reason codes

When the IWMWMCON macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>

**Examples**

To override the subsystem name and subsystem type provided on a previous call to IWM4CON, specify:

```plaintext
IWMWMCON SUBSYS=GENSUB, SUBSYSN=SUBNAME, CONNTKN=CONNTOKEN, RETCODE=RC, RSNCODE=RSN,
```

Where the following are declared:

- `GENSUB DS CL4` Generic subsystem type
- `SUBNAME DS CL8` Subsystem name
- `CONNTOKEN DS FL4` Connect token
IWMWQRY — Query service

IWMWQRY provides information to help the subsystem work manager make work routing and scheduling decisions. IWMWQRY allows the caller to obtain the service class goals and importance for a service class by performance period.

The caller must provide an area of storage in the ANSAREA=ansarea and the length of that area in the ANSLEN=anslen for IWMWQRY to place the service class goal and importance information. IWMWQRY returns the actual length of the information in the QUERYLEN=querylen parameter.

The answer area is mapped by the IWMSVPOL and IWMSVPCD data areas. The data areas are described in z/OS MVS Data Areas, Vol 3.

The first time the caller invokes this macro, you should specify QUERYLEN. The service returns the length required for the service class information.

The information returned is not serialized upon return to the caller, and so may be out of date due to a change in service policy.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state, or problem state. Any PSW key.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary or Access Register (AR) mode.</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled</td>
</tr>
<tr>
<td>Locks:</td>
<td>Unlocked</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

- Make sure no EUT FRRs are established.
- If you are in AR mode, you must specify SYSSTATE ASCENV=AR before invoking IWMWQRY.
- You must include the CVT and the IWMYCON mapping macros in the calling program.

Restrictions

None.

Input register information

Before issuing the IWMWQRY macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2 - 13</td>
</tr>
<tr>
<td>14</td>
</tr>
<tr>
<td>15</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
</tr>
<tr>
<td>2 - 13</td>
</tr>
<tr>
<td>14 - 15</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMWQRY macro is as follows:

```
IWMWQRY name

IWMWQRY SERVCLS=sercls,ANSLEN=anslen,ANSAREA=ansarea

QUERYLEN=querylen

,RETCODE=retcode

,RSNCODE=rsncode

,MF=S

,MF=(L,MFCTRL

,mfattr)

,MF=(E,MFCTRL

,complete)
```

Parameters

The parameters are explained as follows:
SERVCLS=servcls
Required input parameter that specifies the token representing the service
class, and if there is one, the report class.

To code: Specify the RS-type name or address (using a register from 2 to 12) of
a 32 bit field containing the service class token.

ANSLEN=anslen
Required input parameter containing the length of the area provided to hold
the data returned by IWMWQRY.

To code: Specify the RS-type name or address (using a register from 2 to 12) of
a 32 bit field containing the length of the area provided.

ANSAREA=ansarea
Required output parameter that specifies the area provided to contain the data
being returned by IWMWQRY.
The area is mapped by the IWMSVPCD mapping macro and the service class
period definition section in the IWMSVPO1 mapping macro. The IWMSVPDC
part of the answer area contains the offset to the class data, the size of the class
data, and the size of each period entry. The IWMSVPO1 part of the answer
area contains the service class definition section, and the service class period
definition of the service class.

To code: Specify the RS-type name or address (using a register from 2 to 12) of
a character field specifying an area to contain the data returned by the query
service.

QUERYLEN=querylen
Required output parameter that specifies the number of bytes needed to
contain the service class information.

To code: Specify the RS-type name or address (using a register from 2 to 12) of
a fullword field to contain the required number of bytes.

RETCODE=retcode addr
Optional output parameter that specifies where the system is to store the
return code. The return code is also in GPR 15.

To code: Specify the name (RS-type) or address (using a register from 2 to 12)
of a fullword to contain the return code.

RSNCODE=rsncode addr
Optional output parameter that specifies where the system is to store the
reason code. The reason code is also in GPR 0.

To code: Specify the name (RS-type) or address (using a register from 2 to 12)
of a fullword to contain the reason code (if any).

MF=S
MF=(L,mfctrl,mfattr)
MF=(E,mfctrl,COMPLETE)
Use MF=S to specify the standard form, which places parameters into an inline
parameter list and invokes the IWM4CON macro service.

Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require re-entrant code. The
list form defines an area of storage that the execute form uses to store the
parameters.

Use MF=E to specify the execute form of the macro. Use the execute form with
the list form of the macro for applications that require re-entrant code. The
execute form stores the parameters into the storage area defined by the list form and generates the macro invocation to transfer control to the service.

`mfctrl`

Use this output parameter to specify the name of the storage area to contain the parameters.

**To code:** Specify the name (RS-type) or address (using a register from 2 to 12) of the storage area containing the parameter list.

`mfattr`

Use this input parameter to specify the name of a 1 to 60 character storage area that can contain any value that is valid on an assembler DS pseudo-op. You can use this parameter to force boundary alignment of the parameter list. If you do not code `mfattr` the system provides a value of 0D, which forces the parameter on a doubleword boundary.

`COMPLETE`

Use this input parameter to specify that the system check for required parameters and supply defaults for omitted optional parameter.

**ABEND codes**

None.

**Return codes and reason codes**

When IWMWQRY macro returns control to your program, GPR 15 contains a return code. When the return code is non-zero, then GPR 0 contains a reason code.

<table>
<thead>
<tr>
<th>Hexadecimal Return Code</th>
<th>Hexadecimal Reason Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td></td>
<td><strong>Meaning:</strong> Warning.</td>
</tr>
<tr>
<td>04</td>
<td>040A</td>
<td><strong>Meaning:</strong> Warning. The output area supplied is too small to receive all the available information.</td>
</tr>
<tr>
<td>04</td>
<td>0410</td>
<td><strong>Meaning:</strong> Warning. The input service class token does not reflect a service class in the current service policy.</td>
</tr>
<tr>
<td>08</td>
<td>0801</td>
<td><strong>Meaning:</strong> Program error. The caller is in SRB mode.</td>
</tr>
<tr>
<td>08</td>
<td>0803</td>
<td><strong>Meaning:</strong> Program error. The caller is disabled.</td>
</tr>
<tr>
<td>08</td>
<td>0804</td>
<td><strong>Meaning:</strong> Program error. The caller is locked.</td>
</tr>
<tr>
<td>08</td>
<td>080D</td>
<td><strong>Meaning:</strong> Program error. Input service class is not valid.</td>
</tr>
<tr>
<td>08</td>
<td>0810</td>
<td><strong>Meaning:</strong> Program error. The caller has EUT FRR established.</td>
</tr>
<tr>
<td>08</td>
<td>0830</td>
<td><strong>Meaning:</strong> Program error. The caller has passed an invalid ALET.</td>
</tr>
</tbody>
</table>

**Example**

For information related to the service class represented by the service class token in the SERVCLS field, specify:

```
IWMWQRY ANSAREA=ANSAREA,ANSLEN=ANSLEN,SERVCLS=SERVCLS
QUERYLEN=QUERYLEN,RETCODE=RCODE,
RSNCODE=RSN,MF=(E,MFWQRY)
```
A work manager can use IWMWQWRK to help identify where its transactions may be executing. A caller can issue this for a work manager address space that is having trouble executing transactions, and wants to find out where transaction ABENDs are occurring.

A caller can narrow in on where the problem is occurring by using the LU 6.2 token information contained in monitoring environments.

With this service, a caller can get:

- A list of LU 6.2 tokens
  Specify SEARCH_BY=CONNTKN, and get a list of LU 6.2 tokens for all work requests reflected in monitoring environments owned by the current home address space. To do this, the caller should provide the connect token of the address space in the CONNTKN parameter.

- A list of ASIDs and/or STOKENs
  Specify SEARCH_BY=LU62TKN and provide a list of LU 6.2 tokens, and IWMWQWRK returns a list of ASIDs and/or STOKENs representing owners of monitoring environments initialized (via IWM4MINI) with an LU 6.2 token in the list.

  The list of LU 6.2 tokens must have been obtained on a previous call to IWMWQWRK.

  Monitoring environments owned by the home address space which are related (by IWMMRELA) to other monitoring environments are not searched.

  Optionally, to narrow the search, a caller can also provide the subsystem type or the subsystem instance in the SUBSYS and SUBSNSM parameters.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state, or problem state. Any PSW key.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>PASN = HASN = SASN, unless all monitoring environments owned by the current home address space were created only in system keys. If the current home address space owns any monitoring environments created in a user key (8-F), then PASN = HASN = SASN.</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>Unlocked</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

You must include the IWMYCON mapping macro in the calling program.
Restrictions

None.

Input register information

Before issuing the IWMQWRK macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if the return code in GPR 15 is not 0, otherwise, used as a work register by the system.</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14 - 15</td>
<td>Used as a work register by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMQWRK macro is as follows:

```
main diagram
```

IWMQWRK
SEARCH_BY= CONNTKN parameters-1
LU62TKN parameters-2
,RETCODE= retcode

z/OS V2R2 MVS Programming: Workload Management Services
The parameters are explained as follows:

**SEARCH_BY=CONNTKN**

Required input parameter that specifies the type of search for the information about work.

Use `SEARCH_BY=CONNTKN` to indicate that the information about work associated with the input connect token should be returned. The information returned is a list of LU 6.2 tokens, contained in LU62_LIST, and a return code.

**SEARCH_BY=LU62TKN**

Use `SEARCH_BY=LU62TKN` to indicate that information about work associated with the input list of LU 6.2 tokens (which the caller must provide in the LU62_LIST=lu62_list) should be returned.
You define the input list with the LU62_LIST and LU62_LISTSIZE keywords. The list must be the output of a prior call to IWMWQWRK specifying SEARCH_BY=CONNTKN.

The information returned is a return code indicating whether work reflected in any monitoring environment owned by the current home address space is associated with ANY LU 6.2 token in the list of token provided in the LU62_LIST.

CONNTKN=conntkn
Required input parameter for SEARCH_BY=CONNTKN that specifies the connect token returned by IWM4CON. The connect token (CONNTKN) must be owned by the current home address space.

To code: Specify the RS-type name or address in register (2)-(12), of a 32 bit field containing the connect token.

QUERYLEN=querylen
Required output parameter for SEARCH_BY=CONNTKN that specifies the number of bytes needed to contain the information for the input connect token (CONNTKN=conntkn).

To code: Specify the RS-type name or address in register (2)-(12), of a fullword containing the number of bytes to contain the information.

SUBSYS=subsys
Optional input parameter for SEARCH_BY=LU62TKN that specifies the generic subsystem type (ie CICS, IMS) This keyword helps narrow the search for the matching LU 6.2 token further.

To code: Specify the RS-type name or address in register (2)-(12), of a 4 character field containing the generic subsystem type.

SUBSYSNM=subsysnm
Optional input parameter for SEARCH_BY=LU62TKN that specifies the subsystem instance name. This keyword helps narrow the search for the matching LU 6.2 token further.

To code: Specify the RS-type name or address in register (2)-(12), of an 8 character field containing the subsystem instance name.

LU62_LIST=lu62_list
Optional input/output parameter specifying the area for the list of LU 6.2 tokens when you specify CONNTKN. When you specify LU62TKN, this parameter is required. To specify an input LU62_LIST, you must have previously invoked this macro to receive an output LU62_LIST, and provide the list on a subsequent invocation.

To code: Specify the RS-type name or address in register (2)-(12), of a character field specifying the area for the LU 6.2 token list.

LU62_LISTSIZE=lu62_listsize
Required input parameter for LU62_LIST=lu62_list specifying the length of the area provided to contain the data returned by IWMWQWRK.

To code: Specify the RS-type name or address in register (2)-(12), of a fullword field containing the length of the LU 6.2 token list.

ASID_LIST=asid_list
**IWMWQWRK**

**ASID_LIST=NO_ASID_LIST**
Optional input/output parameter that specifies an area for the list of ASIDs. Each entry (ASID) is 2 bytes. Only ASIDs for regions known to be involved in some work request are returned. Regions which could not be interrogated are reflected only in the SKIP_REGIONS parameter.

ASID_LIST=NO_ASID_LIST indicates that no list area is provided.

To code: Specify the RS-type name or address in register (2)-(12), of a character field specifying the area for the list of ASIDs.

**ASID_LISTSIZE=asid_listsize**
Required input parameter for ASID_LIST=asid_list that specifies the length of the area provided for the ASIDs returned by IWMWQWRK.

To code: Specify the RS-type name, or address in register (2)-(12), of a fullword containing the length of the area.

**ASID_SIZENEED=asid_sizeneed**
Required output parameter for ASID_LIST=asid_list that specifies the number of bytes needed for the output list of ASIDs.

To code: Specify the RS-type name or address in register (2)-(12), of a fullword to contain the number of bytes needed for the ASID list.

**STOKEN_LIST=stoken_list**
STOKEN_LIST=NO_STOKEN_LIST area is provided.
Option input/output parameter for that specifies the area for the list of STOKENs. Only STOKENs for regions known to be involved in some work request are returned. Regions which could not be interrogated are only reflected in the SKIP_REGIONS variable.

To code: Specify the name (RS-type), or address in register (2)-(12), of a character field specifying an area for the list of STOKENs.

**STOKEN_LISTSIZE=stoken_listsize**
Required input parameter for STOKEN_LIST=stoken_list that contains the length of the area provided for the STOKEN list being returned by IWMWQWRK.

To code: Specify the name (RS-type), or address in register (2)-(12), of a fullword containing the length of the area.

**STKN_SIZENEED=stkn_sizeneed**
Required input parameter for STOKEN_LIST=stoken_list that specifies the number of bytes needed for the output list of STOKENs.

To code: Specify the RS-type name or address in register (2)-(12), of a fullword containing the number of bytes.

**SKIP_REGIONS=skip_regions**
Optional output parameter for STOKEN_LIST=stoken_list that contains the number of address spaces skipped and therefore not included in the output list of ASIDs/STOKENs. If the caller wants to re-invoke IWMWQWRK when SKIP_REGIONS is non-zero, it may be desirable to ensure that ASID_SIZENEED + 2*SKIP_REGIONS <= ASID_LISTSIZE, AND that STKN_SIZENEED + 8*SKIP_REGIONS <= STKN_LISTSIZE when these output areas are passed.

**RETCODE=retcode addr**
Optional output parameter that specifies where the system is to store the return code. The return code is also in GPR 15.
**IWMWQWRK**

**To code:** Specify the name (RS-type) or address (using a register from 2 to 12) of a fullword to contain the return code.

```
,RSNCRDE=rsncode addr
```

Optional output parameter that specifies where the system is to store the reason code. The reason code is also in GPR 0.

**To code:** Specify the name (RS-type) or address (using a register from 2 to 12) of a fullword to contain the reason code (if any).

```
,MF=S
,MF=(L,mfctrl,mfattr)
,MF=(E,mfctrl,COMPLETE)
```

Use MF=S to specify the standard form, which places parameters into an inline parameter list and invokes the IWM4CON macro service.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require re-entrant code. The list form defines an area of storage that the execute form uses to store the parameters.

Use MF=E to specify the execute form of the macro. Use the execute form with the list form of the macro for applications that require re-entrant code. The execute form stores the parameters into the storage area defined by the list form and generates the macro invocation to transfer control to the service.

```
,mfctrl
```

Use this output parameter to specify the name of the storage area to contain the parameters.

**To code:** Specify the name (RS-type) or address (using a register from 2 to 12) of the storage area containing the parameter list.

```
,mfattr
```

Use this input parameter to specify the name of a 1 to 60 character storage area that can contain any value that is valid on an assembler DS pseudo-op. You can use this parameter to force boundary alignment of the parameter list. If you do not code ,mfattr the system provides a value of 0D, which forces the parameter on a doubleword boundary.

```
,COMPLETE
```

Use this input parameter to specify that the system check for required parameters and supply defaults for omitted optional parameter.

**ABEND codes**

None.

**Return codes and reason codes**

When IWMWQWRK macro returns control to your program, GPR 15 contains a return code. When the return code is non-zero, then GPR 0 contains a reason code.

<table>

</tbody>
</table>

**Example**

To identify where the transactions associated with the input connect token are executing, specify:

```
IWMWQWRK SEARCH_BY=CONNTKN,CONNTKN=(R7),
    LU62_LIST=LIST1,LU62_LISTSIZE=SIZE1,
    QUERYLEN=(R9),RETCODE=RCODE,RSNCODE=RSN
```

LIST1 is a field containing the area for the list. SIZE1 is a field containing the length of the list.
IWMWSYSQ

IWMWSYSQ — Query system information

This service queries information about the systems in the sysplex that are in goal mode. The Query System Information service, IWMWSYSQ, returns a list of systems running in goal mode and information related to available CPU capacity and resource constraints.

The caller of IWMWSYSQ must provide storage to contain all of the system information. This storage area must reside in the caller’s primary address space.

It is possible that the storage required by IWMWSYSQ may change such that multiple IWMWSYSQ calls are required to obtain data. IWMWSYSQ users should take this into account when obtaining the amount of storage that the IWMWSYSQ service can use.

If the caller does not provide enough storage to contain all of the system information, this service will return a return/reason code pair indicating that the input SYSINFO_BLOCK is too small. Output data about the amount of storage required (QUERYLEN) will be set to reflect the required SYSINFO_BLOCK size. However, no system capacity information is returned.

Applications that schedule work across multiple systems in an MVS sysplex can use this service to:

- Locate the best (fastest or most idle) system in a sysplex for scheduling specific work.
- Avoid scheduling additional work to systems already critically overloaded.
- Factor WLM business importance level information into scheduling decisions.

The output of this service is a data area mapped by the IWMWSYSI macro, that provides a point-in-time snapshot of each system WLM is managing in goal mode within the sysplex. A scheduling application can interpret and use this information to schedule one or more types of work to systems with specific operating characteristics. Some examples of operating characteristics you can identify with IWMWSYSQ are:

- Fastest CP speed — Use the IWMWSYSI data area to identify the system having the fastest single CP speed.
- Multi-processing capability — Use the IWMWSYSI data area to identify the number of online CPs on each available system.
- Idle capacity — Use the IWMWSYSI data area to identify the system with the greatest idle capacity.

If a scheduling application can identify the IMPORTANCE LEVEL of the work it schedules the application can use IWMWSYSI to select the most appropriate system. IWMWSYSI provides a vector containing the amount of capacity consumed at each importance level on each system. Thus, if an application is scheduling importance level 3 work, it can use IWMWSYSI to identify the system that has the most capacity that is either idle or is handling importance level 4 or lower work.

An important use of a scheduling application is to avoid placing additional work on systems experiencing contention. IWMWSYSI provides an indicator for each system that, if on, signifies that the system should be avoided for scheduling additional work. This contention indicator is set if an auxiliary storage, fixed
storage, or SQA shortage exists. Also, if work to be scheduled may consume large quantities of CSA, you can use IWMWSYSI to determine the amount of CSA and ECSA that is available on each system.

Notes:

- Multiple applications may simultaneously use the same IWMWSYSQ information to make work scheduling decisions. These multiple applications will have no direct cooperation and will compete for the available systems. It is recommended that before an application schedules a large amount of work it activate a small quantity of work, wait for a built-in delay, and then use IWMWSYSQ to determine the effect of the added work before scheduling the additional work.
- Field SYSI_CPU_UP in macro IWMWSYSI returns the speed of an individual CP on the system, adjusted to compensate for MP effects. However, the CP speed of an LPAR is influenced by the CEC LPAR configuration. Variables such as the number of LPARs, the CP mode (shared or dedicated), capping controls, and the logical to physical CP ratio will all influence the actual CP speed. SYSI_CPU_UP is not adjusted for such LPAR configuration effects and therefore the actual performance may differ. See the PR/SM manual for more details.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state. Any PSW key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary or access register (AR)</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

None.
IWMWSYSQ

Input register information

Before issuing the IWMWSYSQ macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMWSYSQ macro is as follows:

```
IWMWSYSQ
  name
  SYSINFO_BLOCK=sysinfo_block
  EXTENDED_DATA=NO
  EXTENDED_DATA=YES
  ANSLEN=anslen
  QUERYLEN=querylen
  RETCODE=retcode
  RSNCODE=rsncode
```
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMWSYSQ macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**ANSLEN=anslen**
A required input parameter, which contains the length of the SYSINFO_BLOCK in bytes.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**EXTENDED_DATA=NO**
**EXTENDED_DATA=YES**
An optional input parameter, which describes whether the format of the output area named by SYSINFO_BLOCK includes the extended section or not (see IWMWSYSL). The default is EXTENDED_DATA=NO.

**EXTENDED_DATA=NO**
indicates that the format of the output area named by SYSINFO_BLOCK includes only the standard information mapped by the SYSI, which consists of an array of entries described by SYSI_ENTRY.

**EXTENDED_DATA=YES**
indicates that the format of the output area given by SYSINFO_BLOCK includes first the standard information mapped by the SYSI, which consists of an array of entries described by SYSI_ENTRY, followed immediately by the header for the extension section and another array of entries described by SYSI_EXT_Entry.

The EXTENDED_DATA parameter is only available to callers of the IWMWSYSQ service when invoked on a system running z/OS R9 or higher.

**MF=S**
**MF=(L,list addr)**
**MF=(L,list addr,attr)**
**MF=(L,list addr,OD)**
**MF=(E,list addr)**
**MF=(E,list addr,COMPLETE)**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,,list addr
  The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,,attr
  An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,,COMPLETE
  Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,,PLISTVER=IMPLIED_VERSION
,,PLISTVER=MAX
,,PLISTVER=2
  An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
  - IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
  - MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
    If you can tolerate the size change, IBM recommends that you always specify PLISTVER[MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
  - 2, if you use the currently available parameters.
  To code: Specify one of the following:
    - IMPLIED_VERSION
    - MAX
    - A decimal value of 2

,,QUERYLEN=querylen
  A required output parameter, variable which contains the output area size that must be provided by the caller to contain all of the active systems in the sysplex that are in goal mode (i.e. the amount of data returned by the IWMWSYSQ service).
  To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.
,RETCODE=retcode
An optional output parameter into which the return code is to be copied from
GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from
GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

SYSINFO_BLOCK=sysinfo_block
A required input parameter that is to contain the address of an output area to
contain information provided by this service. The format of this area is
mapped by IWMWSYSI and should only be considered valid upon return code
zero from this service.

To code: Specify the RS-type address, or address in register (2)-(12), of a
pointer field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMWSYSQ macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded
  RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the
equate symbol associated with each reason code. IBM support personnel may
request the entire reason code, including the xxxx value.

**Table 65. Return and Reason Codes for the IWMWSYSQ Macro**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>

### Example

To query system information, specify:

```plaintext
IWMWSYSQ SYSINFO_BLOCK=SYSINFO,ANSLEN=ANSLEN, X
   QUERYLEN=QUERYLEN,RETCODE=RC,RSNCODE=RSN
```

Where the following are declared:

- `SYSINFO` DS F SYSINFO_BLOCK address
- `ANSLEN` DS F Length of the SYSINFO_BLOCK area
- `QUERYLEN` DS F Query length
- `RC` DS F Return code
- `RSN` DS F Reason code
IWM4AEDF — WLM define dynamic application environments

The IWM4AEDF service defines dynamic application environments to WLM. The service can be used by queue manager address spaces to add new application environments after they connected to WLM and to delete the dynamic application environments before they disconnect from WLM.

Furthermore, the service can be used to define the method how server spaces should be resumed for static and dynamic application environments.

Before using this service, the caller must connect to WLM using the IWM4CON service, specifying Work_Manager=Yes, and Queue_Manager=Yes.

Environment

The requirements for the caller are:

- **Minimum authorization:** Supervisor state or program key mask (PKM) allowing keys 0-7.
- **Dispatchable unit mode:** Task or SRB
- **Cross memory mode:** Any HASN, any SASN. PASN must be the address space which connected to WLM (i.e. the address space that was home when IWM4CON was issued for Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue).
- **AMODE:** 31- or 64-bit
- **ASC mode:** Primary
- **Interrupt status:** Enabled for I/O and external interrupts
- **Locks:** No locks may be held.
- **Control parameters:** Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

None
### Input register information

Before issuing the IWM4AEDF macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

### Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

### Performance implications

None

### Syntax

**main diagram**

```plaintext
  name
  <main diagram>
  parameters
  <main diagram>
  .FUNC=ADD
  .FUNC=DELETE
  .FUNC=MODIFY
  .DISTRIBUTE_WORK=FIRST_AVAILABLE
  .DISTRIBUTE_WORK=ROUND_ROBIN
  .STATIC=NO
  .STATIC=YES
  .PLISTVER=IMPLIED_VERSION
  .PLISTVER=MAX
  .PLISTVER=0
  .RETCODE=retcode
  .RSNCODE=rsncode
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4AEDF macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,APPLENV=applenv
When FUNC=ADD is specified, a required input parameter, which contains the name of the dynamic application environment.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,APPLENV=applenv
When FUNC=DELETE is specified, a required input parameter, which contains the name of the dynamic application environment.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,APPLENV=applenv
When FUNC=MODIFY is specified, a required input parameter, which contains the name of the static or dynamic application environment.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

CONNTKN=conntkn
A required input parameter, which contains the connect token returned by the IWM4CON macro.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,DISTRIBUTE_WORK=FIRST_AVAILABLE
,DISTRIBUT WORK=ROUND_ROBIN
When FUNC=ADD is specified, an optional parameter that controls how
workload management resumes bound server spaces that are waiting for work. The default is `DISTRIBUTE_WORK=FIRST_AVAILABLE`.

- **DISTRIBUTE_WORK=FIRST_AVAILABLE**
  Workload management wakes up the server space that has been suspended first (default).

- **DISTRIBUTE_WORK=ROUND_ROBIN**
  Workload management wakes up the server space that has the smallest number of affinities. If there are several server spaces with the same number of affinities, workload management will start the server space with the smallest number of active server tasks.

**JCLPARMS=jclparms**
When `FUNC=ADD` is specified, an optional input parameter, which contains the parameters which are passed to the start procedure of the server manager address spaces by WLM. The default is 0.

**JCLPROC=jclproc**
When `FUNC=ADD` is specified, a required input parameter, which contains the name of the start procedure which is used by WLM to start server manager address spaces for the application environment.
When FUNC=ADD is specified, an optional parameter, which specifies whether the server address spaces for the application environment should be started as 'SYSTEM' or 'JOB' address spaces. System address spaces are defined in the RACF STARTED class as jobname.jobname. Job address spaces are defined in the RACF STARTED class as procname.jobname. The default is JOBSPACE=NO.

JOBSPACE=NO
Server address spaces will be started as system address spaces. This is the default.

JOBSPACE=YES
Server address spaces will be started as job address spaces.

MF=S
MF=(L,list addr)
MF=(L,list addr,attr)
MF=(L,list addr,0D)
MF=(E,list addr)
MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

PLISTVER=IMPLIED_VERSION
PLISTVER=MAX
PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

**,RETCODE=**retcode**

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

**,RSNCODE=**rsncode**

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0), (REG00), or (R0).

**,SELECT_POLICY=**select_policy**

When FUNC=ADD is specified, an optional input parameter, which tells WLM how to select work if work requests are directly routed to the server address space. Only 0,1 and 2 are valid select policies. 0 is the default which is also selected if an invalid policy is specified.

The select policy options 0,1 and 2 have the following meaning:

- **0** Default, the oldest request on either the service class or server address space queue is selected first.
- **1** The request on the server address space queue (if present) is selected first independently of the times the requests have been inserted.
- **2** The request on the service class queue is always selected first.

The default is 0.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a one-byte field.

**,SINGLE_SERVER=**NO**
When FUNC=ADD is specified, an optional parameter indicating whether one
or multiple server spaces should be started for the application environment
The default is SINGLE_SERVER=NO.

SINGLE_SERVER=NO
Multiple server spaces should be started for the application environment
(default).

SINGLE_SERVER=YES
Only one server space should be started for the application environment.

STATIC=NO
STATIC=YES
When FUNC=MODIFY is specified, an optional parameter that controls
whether a static or dynamic application environment should be updated
The default is STATIC=NO.

STATIC=NO
indicates that the caller wants to modify a dynamic application
environment (default).

STATIC=YES
indicates that the caller wants to modify a static application environment.

ABEND codes
None.

Return codes and reason codes
When the IWM4AEDF macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code
  RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the
equate symbol associated with each reason code. IBM support personnel may
request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning and Action</th>
</tr>
</thead>
</table>

### Example

To add a dynamic application environment:

```plaintext
IWM4AEDF CONNTKN=CONNTOKEN,  X
   FUNC=ADD,  X
   APPLENV=APPLENV  X
   JCLPROC=JCLPROC  X
   RETCODE=RC,RSNCODE=RSN
```

* Storage areas
* Contents the connect token associated with the use of WLM
* Queuing services as returned by
**IWM4AEDF**

</tbody>
</table>
IWM4CLSY — Classify work

The purpose of the IWM4CLSY service is to factor in available information about an arriving work request in order to associate a service class and possibly a report class with it.

Note: This service was previously called IWMCLSFY for 31-bit addressing only (see “IWMCLSFY — Classify work request” on page 837).

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Requirement Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum authorization</td>
<td>Either problem state or supervisor state. PSW key must either be 0 or match the value supplied on IWM4CON.</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE</td>
<td>31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.</td>
</tr>
<tr>
<td>ASC mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks</td>
<td>Unlocked or locked.</td>
</tr>
<tr>
<td>Control parameters</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The caller is responsible for error recovery.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

1. This macro may only be used on z/OS V2R1, or higher.
2. FRRs are allowed.
3. This macro may not be used during task/address space termination for the connect owner.
4. If the key specified on IWM4CON was a user key (8-F), then the current primary must equal the primary at the time that IWM4CON was invoked.
5. Only limited checking is done of the connect token obtained from IWM4CON.
6. Parameters SOURCELU, CLIENTIPADDR and NETID/LUNAME are mutually exclusive.

7. Parameters EWLM_OUTCORR, EWLM_CHCORR and EWLM_CHCTKN are all mutually exclusive.

8. There is no restriction on the length of data passed as a parameter value, but all storage between the start and end must be allocated (getmain).

**Input register information**

Before issuing the IWM4CLSY macro, the caller must ensure that the following general purpose registers (GPRs) contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>The address of a 216-byte standard save area in the primary address space</td>
</tr>
</tbody>
</table>

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWM4CLSY macro is as follows:

```
IWM4CLSY name
    TRXNAME=NO_TRXNAME
    TRXNAME=trxname
    USERID=NO_USERID
    USERID=userid
```

Chapter 12. Workload management services 465
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4CLSY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ACCTINFO=acctinfo

,ACCTINFO=NO_ACCTINFO
An optional input parameter, which contains the accounting information. For environments where accounting information is available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_ACCTINFO. The default is NO_ACCTINFO, which indicates that no accounting information was passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.
When ACCTINFO=acctinfo is specified, a required input parameter, which contains the length of the accounting information field. The maximum value supported is 143.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,CLIENTACCT=clientacct
,CLIENTACCT=NO_CLIENTACCT
An optional input parameter, which contains the accounting information. For environments where accounting information is available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_CLIENTACCT. The default is NO_CLIENTACCT, which indicates that no accounting information was passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,CLIENTACCT_L=clientacct_l
When CLIENTACCT=clientacct is specified, a required input parameter, which contains the length of the client accounting information field. The maximum value supported is 512.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

,CLIENTIPADDR=clientipaddr
,CLIENTIPADDR=NO_CLIENTIPADDR
An optional input parameter, which contains the source client IPv6 address, which is left-justified and represented as a colon hexadecimal address. An example of an IPv6 address is: X'2001:0DB8:0000:0000:0008:0800:200C:417A'.

The compressed format is not supported for classifications. For environments where the source client IPv6 address may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_CLIENTIPADDR.

SOURCELU, CLIENTIPADDR and NETID/LUNAME are mutually exclusive. The default is NO_CLIENTIPADDR, which indicates that no CLIENTIPADDR name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 39-character field.

,CLIENTTRXNM=clienttrxnm
,CLIENTTRXNM=NO_CLIENTTRXNM
An optional input parameter, which contains the client transaction name for the work request, as known by the work manager. For environments where the transaction name is available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_CLIENTTRXNM. The default is NO_CLIENTTRXNM, which indicates that no client transaction name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,CLIENTTRXNM_L=clienttrxnm_l
When CLIENTTRXNM=clienttrxnm is specified, a required input parameter, which contains the length of the client transaction name field. The maximum value supported is 255.
To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

\texttt{CLIENTUSERID=clientuserid}
\texttt{CLIENTUSERID=NO_CLIENTUSERID}

An optional input parameter, which contains the value of the client user ID which may be different than USERID and provided from the client information that is specified for the connection. For environments where the client user ID name may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_CLIENTUSERID. The default is NO_CLIENTUSERID, which indicates that no CLIENTUSERID name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{CLIENTUSERID_L=clientuserid_l}

When CLIENTUSERID=clientuserid is specified, a required input parameter, which contains the length of the client user ID name field. The maximum value supported is 128.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

\texttt{CLIENTWKSTNM=clientwkstnm}
\texttt{CLIENTWKSTNM=NO_CLIENTWKSTNM}

An optional input parameter, which contains the value of the client workstation name or host name from the client information that is specified for the connection. For environments where the client workstation name may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_CLIENTWKSTNM. The default is NO_CLIENTWKSTNM, which indicates that no CLIENTWKSTNM name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{CLIENTWKSTNM_L=clientwkstnm_l}

When CLIENTWKSTNM=clientwkstnm is specified, a required input parameter, which contains the length of the client workstation name field. The maximum value supported is 255.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

\texttt{COLLECTION=collection}
\texttt{COLLECTION=NO_COLLECTION}

An optional input parameter, which contains the customer defined name for a group of associated packages. For environments where the collection name may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_COLLECTION. The default is NO_COLLECTION, which indicates that no COLLECTION name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{COLLECTION_L=collection_l}

When COLLECTION=collection is specified, a required input parameter, which contains the length of the collection name. The maximum value supported is 18.
To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or a literal decimal value.

\texttt{CONNECTION=connection}\newline
\texttt{CONNECTION=NO\_CONNECTION}\newline
An optional input parameter, which contains the name associated with the environment creating the work request, which may reside anywhere within the network. For environments where the connection name may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO\_CONNECTION. The default is NO\_CONNECTION, which indicates that no CONNECTION name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\texttt{CONNTKN=conntkn}\newline
A required input parameter, which is returned by IWM4CON for use by the classify routine.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

\texttt{CORRELATION=correlation}\newline
\texttt{CORRELATION=NO\_CORRELATION}\newline
An optional input parameter, which contains the name associated with the user/program creating the work request, which may reside anywhere within the network. For environments where the correlation name may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO\_CORRELATION. The default is NO\_CORRELATION, which indicates that no CORRELATION name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{CORRELATION\_L=correlation\_l}\newline
When CORRELATION=correlation is specified, a required input parameter, which contains the length of the correlation identifier. The maximum value supported is 12.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

\texttt{EWLM\_CHCORR=ewlm\_chcorr}\newline
An optional output parameter, which contains the cross-platform Enterprise Workload Management (EWLM) child correlator associated with the instantiated sub work request. Specifying this parameter indicates that a sub work request will be created.

Note:
1. Currently z/OS V2R1 only uses the first 64 bytes of the EWLM\_CHCORR field.
2. The EWLM\_OUTCORR, EWLM\_CHCORR and EWLM\_CHCTKN parameters are mutually exclusive.

To code: Specify the RS-type address, or address in register (2)-(12), of a 512-character field.

\texttt{EWLM\_CHCTKN=ewlm\_chctkn}\newline
An optional output parameter, which contains the cross-platform Enterprise Workload Management (EWLM) child correlator token associated with the instantiated sub work request. Specifying this parameter indicates that a sub
work request will be created. An EWLM child correlator token must not be passed outside of the EWLM management domain.

The EWLM_OUTCORR, EWLM_CHCORR and EWLM_CHCTKN parameters are mutually exclusive.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-character field.

 EWLM_CLTOKEN=ewlm_cltoken
 EWLM_CLTOKEN=NO_EWLM_CLTOKEN

An optional input parameter, which contains internal EWLM classification information to be passed from EWLM to WLM. This parameter is used internally by WLM and must not be used by application programs. The default is NO_EWLM_CLTOKEN, which indicates that no EWLM classification information was passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 40-character field.

 EWLM_CORR=ewlm_corr
 EWLM_CORR=NO_EWLM_CORR

An optional input parameter, which contains the cross-platform Enterprise Workload Management (EWLM) correlator associated with the work request. If this parameter is specified and a valid EWLM correlator is passed, the EWLM transaction class can be used for WLM classification purposes. The default is NO_EWLM_CORR which indicates that no EWLM correlator is passed.

The EWLM correlator also serves as the input correlator for the EWLM_CHCORR, EWLM_CHCTKN, EWLM_OUTCORR parameters.

Note:
1. The architected length field of an ARM correlator in the first two bytes must contain a value between 4 (X'0004') and 512 (X'0200').
2. For environments where the EWLM correlator may be available on some, but not all flows, providing a data area with the first four bytes set to binary zeroes is equivalent to specifying NO_EWLM_CORR.
3. The EWLM_OUTCORR, EWLM_CHCORR and EWLM_CHCTKN parameters are mutually exclusive.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

 EWLM_OUTCORR=ewlm_outcorr

An optional output parameter which receives a validated EWLM correlator on return. The execution form of IWM4CLSY validates the passed correlator in EWLM_CORR and provides a valid EWLM correlator in EWLM_OUTCORR as follows:

- If the EWLM_CORR parameter is specified and the correlator in EWLM_CORR is a valid ARM correlator in EWLM format, it will be copied to EWLM_OUTCORR.
- If the correlator in EWLM_CORR is not a valid EWLM ARM correlator or the EWLM_CORR parameter is omitted, a new classify correlator will be returned within the EWLM_OUTCORR field.

Note:
1. Specifying EWLM_OUTCORR (unlike EWLM_CHCORR or EWLM_CHCTKN) does not indicate the beginning of a sub work request.
2. Currently z/OS V2R1 only uses the first 64 bytes of the EWLM_OUTCORR field.

3. The application may specify the same parameter for both EWLM_CORR and EWLM_OUTCORR, which means that the EWLM correlator can be validated or replaced in place.

4. The EWLM_OUTCORR, EWLM_CHCORR and EWLM_CHCTKN parameters are mutually exclusive.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 512-character field.

```
,LUNAME=luname
,LUNAME=NO_LUNAME
```

An optional input parameter, which contains the local LU name associated with the requestor. For environments where the local LU name may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_LUNAME.

SOURCELU, CLIENTIPADDR and LUNAME are mutually exclusive. The default is NO_LUNAME, which indicates that no local LU name is passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

```
,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
,MF=(E,list addr,NOCHECK)
,MF=(M,list addr)
,MF=(M,list addr,COMPLETE)
,MF=(M,list addr,NOCHECK)
```

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

Use MF=M together with the list and execute forms of the macro for service routines that need to provide different options according to user-provided input. Use the list form to define a storage area; use the modify form to set the appropriate options; then use the execute form to call the service.

IBM recommends that you use the modify and execute forms of IWM4CLSY in the following order:
Use IWM4CLSY ...MF=(M,list-addr,COMPLETE) specifying appropriate parameters, including all required ones.

Use IWM4CLSY ...MF=(M,list-addr,NOCHECK), specifying the parameters that you want to change.

Use IWM4CLSY ...MF=(E,list-addr,NOCHECK), to execute the macro.

`list addr`

The name of a storage area to contain the parameters. For MF=S, MF=E, and MF=M, this can be an RS-type address or an address in register (1)-(12).

`attr`

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

`COMPLETE`

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

`NOCHECK`

Specifies that the system is not to check for required parameters and is not to supply defaults for omitted optional parameters.

`NETID=netid`

An optional input parameter, which contains the network identifier associated with the requestor. For environments where the network identifier may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_NETID.

SOURCELU, CLIENTIPADDR and NETID are mutually exclusive with NETID. The default is NO_NETID, which indicates that no network identifier is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

`PACKAGE=package`

An optional input parameter, which contains the package name for a set of associated SQL statements. Products using this attribute must chose a specific package name to be associated with the work request, for example, the first package name used in the unit of work. Individual product documentation will describe how this choice is made to allow the installation to use the WLM administrative application. For environments where the package name may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_PACKAGE The default is NO_PACKAGE, which indicates that no PACKAGE name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

`PACKAGE_L=package_L`

When PACKAGE=package is specified, a required input parameter, which contains the length of the package information field. The maximum value supported is 128.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.
An optional input parameter, which contains the performance group number (PGN) associated with the work request. If specified, the performance group number value must be within the range of 1-999, represented as character data, left-justified and padded with blanks on the right. For environments where the perform value may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_PERFORM. The default is NO_PERFORM, which indicates that no PERFORM value is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

An optional input parameter, which contains the access plan name for a set of associated SQL statements. For environments where the plan name may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_PLAN. The default is NO_PLAN, which indicates that no PLAN name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 0, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

An optional input parameter, which contains the DB2 Stored SQL Procedure name associated with the work request. For environments where the SQL procedure name may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_PRCNAME. The default is NO_PRCNAME, which indicates that no PRCNAME value is passed.
To code: Specify the RS-type address, or address in register (2)-(12), of a 18-character field.

PRCNAME_L=prcname_l
When PRCNAME=prcname is specified, a required input parameter, which contains the length of the procedure name. The maximum value supported is 128.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

PRIORITY=priority
PRIORITY=NO_PRIORITY
An optional input parameter, which contains the priority associated with the work request. For environments where the priority value may be available on some, but not all flows, providing a data area initialized to X'80000000' (the largest negative integer) is equivalent to specifying NO_PRIORITY. The default is NO_PRIORITY, which indicates that no PRIORITY value is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

PROCESSNAME=processname
PROCESSNAME=NOPROCESSNAME
An optional input parameter, which contains the process name associated with the work request. The default is NOPROCESSNAME, which indicates that no PROCESSNAME value is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

PROCESSM_L=processnm_l
When PROCESSNAME=processname is specified, a required input parameter, which contains the length of the process name. The maximum value supported is 32.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (with or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12), or (15), (GPR15), (REG15), or (R15).

RPTCLSNAME=rptclsname
An optional output parameter, which is to receive the output report class name.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (with or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

SCHEDENV=schedenv
SCHEDENV=NO_SCHEDENV
An optional input parameter, which contains the scheduling environment value associated with the work request. The default is NO_SCHEDENV, which indicates that no scheduling environment value is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

SCHEDENV_L=schedenv_l
When SCHEDENV=schedenv is specified, an optional input parameter, which contains the length of the scheduling environment. The maximum value supported is 16.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

SERVCLS=servcls
A required output parameter, which is to receive the output token which represents the service and report class for the work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

SOURCELU=sourcelu
SOURCELU=NO_SOURCELU
An optional input parameter, which contains the LU name associated with the requestor. This may be the fully qualified NETID.LUNAME, for example, network name (1-8 bytes), followed by a period, followed by the LU name for the requestor (1-8 bytes). It may also be the 1-8 byte local LU name, with no network qualifier.

For environments where the LU name may be available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_SOURCELU.

SOURCELU, CLIENTIPADDR and NETID/LUNAME are mutually exclusive. The default is NO_SOURCELU, which indicates that no source LU name was passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

SOURCELU_L=sourcelu_l
When SOURCELU=sourcelu is specified, a required input parameter, which contains the length of the source LU name field. The maximum value supported is 17.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

SRMTOKEN=srmtoken
An optional output parameter, token for SRM internal use only.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

SRVCLSNM=srvclsnm
An optional output parameter, which is to receive the output service class name.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.
SUBCOLN=NO_SUBCOLN
An optional input parameter, which contains the subsystem collection name associated with the work request. The default is NO_SUBCOLN, which indicates that no subsystem collection name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

SUBSYSPM=subsyspm
SUBSYSPM=NO_SUBSYSPM
An optional input parameter, which contains character data related to the work request which is passed by the work manager for use in classification. The nature of the contents of this data must be documented for customer use. For environments where the subsystem parameter is available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_SUBSYSPM. The default is NO_SUBSYSPM, which indicates that no parameter was passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

TRXCLASS=trxclass
TRXCLASS=NO_TRXCLASS
An optional input parameter, which contains a class name within the subsystem. This can be any meaningful value that the installation can recognize and specify to match the value presented by the work manager. For environments where the transaction class is available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_TRXCLASS. The default is NO_TRXCLASS, which indicates that no transaction class was passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

TRXNAME=trxname
TRXNAME=NO_TRXNAME
An optional input parameter, which contains the transaction name for the work request, as known by the work manager. For environments where the transaction name is available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_TRXNAME. The default is NO_TRXNAME, which indicates that no transaction name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

TTRACETOKEN=ttracetoken
An optional output parameter, which is to receive the output transaction trace token associated with the work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

USERID=userid
USERID=NO_USERID
An optional input parameter, which contains the user ID associated with the work request. For environments where the user ID is available on some, but not all flows, providing a data area initialized to all blanks is equivalent to specifying NO_USERID. The default is NO_USERID, which indicates that no user ID is passed.
To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4CLSY macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>

Table 67. Return and Reason Codes for the IWM4CLSY Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0895    | Equate Symbol: IwmRsnCodeEWLMServNotEnabled  
Meaning: Service is not enabled because the caller invoked the IWMCONN service with EWLM=NO.  
Action: Specify the parameter EWLM_CORR only when connected with EWLM=YES. |
| C           | —           | Equate Symbol: IwmRetCodeEnvError  
Meaning: Environmental error. |
| C           | xxxx0C01    | Equate Symbol: IwmRsnCodeNoStg  
Meaning: Storage is not available for the request.  
Action: There is a storage shortage. The function may work successfully at a later time. |
| 10          | —           | Equate Symbol: IwmRetCodeCompError  
Meaning: Component error.  
Action: No action required. The function may be successful when invoked again. |

Examples

Suppose the transactions processed by a subsystem work manager have the following qualifiers:  
• User ID  
• Transaction name  
• Transaction class

To get the service class associated with an incoming work request, specify:

IWM4CLSY USERID=AUSERID,TRXCLASS=ATRXCLS,TRXNAME=ATRXNM,  
CONNTKN=(R7),SERVCLS=(R9),  
RETCODE=RETCODE,RSNCODE=RSNCODE

Where the following are declared:

AUSERID DS CL8  
ATRXCLS DS CL8  
ATRXNM DS CL8
The purpose of this service is to connect a calling address space to WLM. This service returns a token which is needed to invoke other services. This service can be used to:

- Request that WLM work management services be available to the connecting address space and optionally to pass topology information to WLM.
- Request that WLM work queuing services be available to the connecting address space.
- Request that WLM work execution services be available to the connecting address space.
- Request that WLM work balancing services be available to the connecting address space.
- Request that WLM export and import services be available to the connecting address space.

Notes:

- The space which is connected is the current home address space.
- Only a single connection is allowed to be active for a given address space at any given time.
- For each connected task/space, WLM will establish a dynamic resource manager (RESMGR) to be associated with the current task/space. When it receives control, it will free any accumulated resources and delete any enclaves associated with the connect token. This implies that the resource manager will logically perform the disconnect function and the connect token can no longer be passed to WLM services.

Note: This service was previously called IWMCONN for 31-bit addressing only (see “IWMCONN — Connect to workload management” on page 853).

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>For WORK_MANAGER=YES or ROUTER=YES, QUEUE_MANAGER=YES or EXPT1MPT=YES, supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>For SERVER_MANAGER=YES, problem state with any PSW key.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Dispatchable unit mode:</th>
<th>Task</th>
</tr>
</thead>
</table>

| Cross memory mode:     | Non-XMEM when input key is a user key or SERVER_MANAGER = YES, otherwise XMEM, any P,S,H. |

| AMODE:                 | 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro. |

<table>
<thead>
<tr>
<th>ASC mode:</th>
<th>Primary</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Interrupt status:</th>
<th>Enabled for I/O and external interrupts</th>
</tr>
</thead>
</table>

| Locks:                 | No locks may be held.                    |

| Control parameters:    | Control parameters must be in the primary address space. |
Programming requirements
1. Make sure no EUT FRRs are established.
2. The macro CVT must be included to use this macro.
3. The macro IWMYCON must be included to use this macro.
4. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
5. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
6. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions
1. This macro may not be used during task/address space termination.
2. Only a single connection is allowed to be active for a given address space at any given time.
3. Specification of both Queue_Manager=Yes and Server_Manager=Yes requires Server_Type=Queue; specification of Server_Type=Routing is rejected.
4. Specification of both Router=Yes and Server_Manager=Yes requires Server_Type=Routing; specification of Server_Type=Queue is rejected.
5. If the caller’s recovery routine should get control as a result of requesting this service, the function cannot be guaranteed to be complete. It is possible that a token has been saved in the parameter list where the connect token would reside upon successful completion. This token may be passed to IWM4DIS to prevent the address space from being disabled from future IWM4CON requests, but the token should not be used for other services. IWM4DIS in these circumstances may give a warning return code indicating that no connection was established.
6. If the key specified on IWM4CON is a user key (8-F) or SERVER_MANAGER=YES was specified, then the caller must be in non-cross-memory mode (P=S=H)
7. While not a restriction for IWM4CON, it should be noted that when the key specified is a user key (8-F), the connect token may only be passed to IWM4CLSY, IWMRPT, or IWMMNTFY services, when the current primary matches primary at the time IWM4CON is invoked.
8. This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information
Before issuing the IWM4CON macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information
When control returns to the caller, the GPRs contain:

Register | Contents
IWM4CON

0  Reason code if GRI5 return code is non-zero
1  Used as work registers by the system
2-13 Unchanged
14  Used as work registers by the system
15  Return code

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWM4CON macro is as follows:

```plaintext
main diagram
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4CON macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,APPLENV=applenv
When SERVER_MANAGER=YES is specified, a required input parameter, which contains the application environment under which work requests are served.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,CONNTKN=conntkn
A required output parameter, which will receive the connect token.
To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

,CONNTKNKEY=conntknkey
When CONNTKNKEY=VALUE and WORK_MANAGER=YES are specified, a required input parameter. It contains the key for which the various branch entry services using the CONNTKN returned by IWM4CON must have PSW update authority. These other services include Classify (IWM4CLS), Report (IWMRPT), Notify (IWMMNTFY). Create (IWM4MCRE) is a PC interface and hence is excluded. The low order 4 bits (bits 4-7) contain the key value. The high-order 4 bits (bits 0-3) must be zeros.

During the Connect with IWM4CON WLM creates a control block to hold the information. The CONNTKNKEY is the storage key, which is used for the allocation of the control block. The WLM services Classify (IWM4CLS), Report (IWMRPT) and Notify (IWMMNTFY) get invoked via branch. These WLM services have to run in the same key otherwise these services cannot update the control block allocated during Connect (IWM4CON).

Note however that there are other services that use the connect token, for which the CONNTKNKEY does not relate to PSW update authority but must be a system key (0-7) rather than a user key (8-15).

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-bit field.

,CONNTKNKEY=VALUE
,CONNTKNKEY=PSWKEY
When WORK_MANAGER=YES is specified, a required parameter, which describes how the input key should be obtained.

,CONNTKNKEY=VALUE
indicates that the key is passed explicitly via CONNTKNKEY.

,CONNTKNKEY=PSWKEY
indicates that the current PSW key should be used.

,DYNAMIC=NO
,DYNAMIC=YES
When SERVER_MANAGER=YES is specified, an optional parameter indicating whether the server manager connects to a dynamic or static application environment. The default is DYNAMIC=NO.

,DYNAMIC=NO
The server manager connects to a static application environment. This is the default.

,DYNAMIC=YES
The server manager connects to a dynamic application environment.

,EWLM=NO
,EWLM=YES
When WORK_MANAGER=YES is specified, an optional parameter, which indicates if this work manager intends to participate in cross-platform enterprise workload management (EWLM). The default is EWLM=NO.

,EWLM=NO
The work manager interacts only with WLM and no interaction with EWLM takes place. This is the default.
The work manager participates in cross-platform enterprise workload management and interacts with EWLM.

An optional parameter indicating whether the space needs access to the export and import services (IWMEXPT, IWMUEXPT, IWMIMPT, IWMUIMPT). The default is EXPTIMPT=NO.

The connecting address space will not use the export and import services.

The connecting address space will use the export and import services.

An optional input parameter, which contains the name of an application group, for example, a group of similar or cooperating subsystem instances. A group name can be up to 255 characters long. Provision of a data area initialized to all blanks is equivalent to specification of NO_GROUPNM. The default is NO_GROUPNM. This indicates that no group name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

When GROUPNM=groupnm is specified, a required input parameter, which contains the length of the group name. A group name can be up to 255 characters long.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

When SERVER_TYPE=QUEUE and SERVER_MANAGER=YES are specified, an optional parameter indicating that WLM will manage the server instances (tasks), selecting work from a work queue.

If YES is specified, the caller must use service IWMSINF to obtain the number of server instances to start from WLM.

The meaning of PARALLEL_EU changes in this case. PARALLEL_EU is only used to determine the number of tasks to start if the application environment cannot be managed by WLM. Otherwise PARALLEL_EU can be used to limit the number of server tasks to start initially.

The server can define the SERVER_LIMIT parameter to specify a limit for the number of server tasks supported by the application.

The connecting address space starts the number of server instances as provided with PARALLEL_EU. This is the default.

The connecting address space uses IWMSINF to obtain the number of server instances to start from WLM.
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of X'0F' to force the parameter list to a word boundary, or X'0D' to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of X'0D'.

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

An optional input parameter, which contains the node name to be used for classifying work requests when Work_Manager=Yes is specified or taken as default. The node name identifies a specific subcomponent of the generic subsystem type.

When Server_Manager=Yes and Server_Type=Queue is specified, the node name should match the node name specified on the corresponding Connect for the Queue_Manager, for example, all servers associated with the Queue_Manager have identical node names.

If a product chooses to use both Work_Manager=Yes and Server_Manager=Yes on a single invocation of IWM4CON for a space, then the rules for Server_Manager apply, for example, the node name refers to the node name of the space playing the role of Queue_Manager.

If the caller connects to the WLM work queueing services, the combination of the subsystem type, node name and the subsystem name must be unique to that MVS system. Node name can be omitted. The default is NO_NODENM.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

When TOPOLOGY=topology and WORK_MANAGER=YES are specified, a
required input parameter, which contains the number of ASCBs in the list passed via xTOPOLOGY. While there is no restriction on the number of entries in the list, the current support will only look at the first 10 entries. The number specified must be positive (hence also non-zero).

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,PARALLEL_EU=parallel_eu
When SERVER_MANAGER=YES is specified, a required input parameter, which contains the maximum number of tasks (TCBs) within the address space which will be used to concurrently process distinct work requests if MANAGE_TASKS=YES is not in effect. When Select (IWM4SSL) is used to obtain a work request, which might then be passed to another task (TCB) for processing under a Begin (IWM4STBG) environment, this count represents the number of tasks (TCBs) which can be running concurrently against these work requests, that is the number of concurrent Begin environments. It is important that this count should represent the actual number of tasks (TCBs) which can be utilized, and not merely some approximate upper bound, as this value will influence system algorithms.

If MANAGE_TASKS=YES is in effect, the application environment managed by WLM PARALLEL_EU is not used. In this case the parameter is only used as described above if no procedure name was defined for the application environment.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
,PLISTVER=1
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- 0, which supports all parameters except those specifically referenced in higher versions.
- 1, which supports the following parameter and those from version 0:

  REGION_TOKEN

To code: Specify one of the following:
• IMPLIED_VERSION
• MAX
• A decimal value of 0, or 1

\texttt{,QMGR\_EXIT@=qmgr\_exit@}
\texttt{,QMGR\_EXIT@=NO\_QMGR\_EXIT@}

When \texttt{QUEUE\_MANAGER=YES} and \texttt{ROUTER=NO} are specified, an optional input parameter that is to contain the address of the Queue Manager Connect Exit to be invoked when the system wishes to inform the queue manager of actions it should perform. The exit will be called in enabled, unlocked TCB mode with no FRRs set, but may be called in a cross-memory environment. The mapping of the parameter list for the exit and its invocation environment is given by the list form of the IWMQEXIT macro.

The system may choose to discontinue calling the exit upon repetitive abnormal completions, i.e. where the system recovery routine is percolated to from an error within the exit. The exit must be callable from any address space and remain available after the queue manager disconnects or terminates. The default is \texttt{NO\_QMGR\_EXIT@}, which indicates that no queue manager exit is provided.

To code: Specify the RS-type address, or address in register (2)-(12), of a pointer field.

\texttt{,QUEUE\_MANAGER=NO}
\texttt{,QUEUE\_MANAGER=YES}

When \texttt{ROUTER=NO} is specified, an optional parameter indicating that WLM Work Queuing services be available to the connecting address space. For example:
• Insert (IWM4QIN)
• Delete (IWM4QDE)

If YES is specified, the combination of the subsystem type and the subsystem name must be unique to that MVS system. The default is \texttt{QUEUE\_MANAGER=NO}.

\texttt{,QUEUE\_MANAGER=NO}

The connecting address space will not use the WLM Work Queuing services.

\texttt{,QUEUE\_MANAGER=YES}

The connecting address space will be using the WLM Work Queuing services.

\texttt{,REGION\_TOKEN=region\_token}

When \texttt{SERVER\_MANAGER=YES} is specified, an optional 16-character output parameter, which contains a region token. A queueing manager can use the region token to queue work requests to a specific server region. These work requests are considered to belong to a set of the work request all needing access to some status information which exists only in the virtual storage of the server region. They are selected using the IWM4SSL macro. It is assumed that the application uses the service IWM4TAF to tell WLM when the temporary affinity to the defined server region begins and ends.

To code: Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

\texttt{,RETCODE=retcode}

An optional output parameter into which the return code is to be copied from GPR 15.
To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,ROUTER=NO
,ROUTER=YES
An optional parameter, which describes whether recommendations for sysplex routing to servers associated with the same subsystem type and name are requested. The default is ROUTER=NO.

,ROUTER=NO
indicates that recommendations for sysplex routing via IWMSRFSV are not required.

,ROUTER=YES
indicates that recommendations for sysplex routing via IWMSRFSV is required. Note that only server spaces which have the same Subsystem type and name AND which specified Server_Type=Routing are considered when IWMSRFSV is invoked.

If YES is specified, the combination of the subsystem type and the subsystem name must be unique to that MVS system.

,RSN_CODE=rsn_code
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,SERVER_DATA=server_data
When SERVER_TYPE=ROUTING and SERVER_MANAGER=YES are specified, a required input parameter, which contains whatever data is needed to uniquely identify the server when recommended by MVS through use of the IWMSRFSV interface. The structure of this data is undefined to MVS, and will be returned to the program invoking IWMSRFSV when the server is returned.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,SERVER_LIMIT=server_limit
,SERVER_LIMIT=1000
When MANAGE_TASKS=YES, SERVER_TYPE=QUEUE and SERVER_MANAGER=YES are specified, an optional input parameter indicating the architectural limit of the application for the number of server instances which can be supported.

This parameter can be used to tell WLM the upper limit up to which WLM will recommend to start server instances. The default is 1000.

To code: Specify the RS-type address of a fullword field.

,SERVER_MANAGER=NO
,SERVER_MANAGER=YES
An optional parameter indicating whether the space needs access to a family of services specified by SERVER_TYPE.

,SERVER_MANAGER=NO
The connecting address space will not use any of the various server-related WLM services documented under SERVER_TYPE. This is the default.

,SERVER_MANAGER=YES
The connecting address space will be acting in the role of a server and needs access to the family of services specified by SERVER_TYPE.
Specification of both Queue_Manager=Yes, and Server_Manager=Yes requires that Server_Type=Queue. Specification of Server_Type=Routing is rejected.

Specification of both Router=Yes, and Server_Manager=Yes requires that Server_Type=Routing. Specification of Server_Type=Queue is rejected.

\[,SERVER_TYPE=QUEUE\]
\[,SERVER_TYPE=ROUTING\]

When SERVER_MANAGER=YES is specified, an optional parameter, which describes what type of services are used by the server.

\[,SERVER_TYPE=QUEUE\]

This is the default. Indicates that the server selects work from a queue, and thus requests that WLM Work Execution services be available to the connecting address space. For example:

- Select (IWM4SSL)
- Begin (IWM4STBG)
- End (IWM4STEN)

The server also has the WLM Work Queuing services available to the connecting address space when the corresponding Queue Manager with the same subsystem type and name is active on the same MVS image (see the following macros for macro-specific restrictions). For example:

- Insert (IWM4QIN)
- Delete (IWM4QDE)

\[,SERVER_TYPE=ROUTING\]

indicates that the server receives work by way of routing, and may be selected by the IWMSRFSV (Find Server) macro interface. Note that the space which invokes the IWMSRFSV service must Connect with Router=Yes.

Termination of the router with the same subsystem type and name on the same MVS image will not cause notification to the server to terminate. This coordination, if required, must be handled through a different protocol than use of Connect.

\[,SRV_MGR_EXIT@=srv_mgr_exit@\]

When SERVER_TYPE=ROUTING and SERVER_MANAGER=YES are specified, a required input parameter that is to contain the address of the Server Manager Connect Exit to be invoked when the system wishes to inform the server of actions it should perform. This exit will be called in SRB mode, with a non cross-memory environment, where HASN=SASN=PASN=HASN at the time IWM4CON was invoked. The mapping of the parameter list for the exit and its invocation environment is given by the list form of the IWMSCEXIT macro.

Note that it may be possible for the exit to be called before the caller has received control back from IWM4CON. The exit or any program it drives (synchronously or asynchronously) must synchronize with the program issuing IWM4CON to ensure that IWM4CON has returned a connect token prior to issuing IWM4DIS (disconnect) or any other services that need the connect token.

The system may cause the space to become ineligible to be recommended by IWMSRFSV upon repetitive errors in calling the exit specified. The exit must be callable from the server address space and remain available after the server
manager disconnects or the connecting server TCB terminates. The exit need not persist upon memory termination of the server.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a pointer field.

**,SUBSYS**=*subsys*

A required input parameter, which contains the generic subsystem type (e.g. IMS, CICS, etc.). When WORK_MANAGER=YES is specified, this is the primary category under which classification rules are grouped.

If the caller connects to the WLM work queueing services by specifying QUEUE_MANAGER=YES, or requests sysplex routing by specifying ROUTER=YES, the combination of the subsystem type and the subsystem name must be unique to that MVS system.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 4-character field.

,**SUBSYSNM**=*subsysnm*

A required input parameter, which contains the subsystem name to be used for classifying work requests when Work_Manager=Yes is specified or taken as default. The subsystem name identifies a specific instance of the generic subsystem type.

When Server_Manager=Yes and Server_Type=Queue is specified, the subsystem name should match the subsystem name specified on the corresponding Connect for the Queue_Manager, that is all servers associated with the Queue_Manager have identical subsystem names.

When Server_Manager=Yes and Server_Type=Routing is specified, the subsystem name should match the subsystem name specified on the corresponding Connect for Router=Yes, that is all servers associated with the Router have identical subsystem names.

If a product choses to use both Work_Manager=Yes and Server_Manager=Yes on a single invocation of IWM4CON for a space, then the rules for Server_Manager apply, that is the subsystem name refers to the subsystem name of the space playing the role of Queue_Manager or Router.

If the caller connects to the WLM work queueing services, or to sysplex routing services, the combination of the subsystem type and the subsystem name must be unique to that MVS system.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,**TOPOLOGY**=*topology*

**,TOPOLOGY**=NO_TOPOLOGY

When WORK_MANAGER=YES is specified, an optional input parameter, which represents a list of ASCB addresses for the address spaces which comprise the subsystem. This list should ONLY include address spaces which do NOT surface as the current home address space when IWM4MINI or IWMMRELA are used to establish the delay monitoring environments, but that may participate as dispatchable units (TCBs or SRBs) in serving work requests. If the current primary or home space is a space not surfaced in a monitoring environment and its execution can affect the response time of work flowing through the subsystem, then it should appear in the list. Neither current primary nor current home are defaults. While there are no limits on the number of address spaces, this information is less precise than that provided...
by monitoring environments. The default is NO_TOPOLOGY, which indicates that no topology information was passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

**WORK_MANAGER=**YES
**WORK_MANAGER=**NO

An optional parameter indicating that WLM Work Management services be available to the connecting address space. For example:
- Classify (IWM4CLS)
- Report (IWMRPT)
- Notify (IWMNNTFY)
- Enclave Create (IWM4ECRE)
- Modify Connect (IWMWMCON)

If NO is specified, the above services cannot be used, except for the form of Notify that does not pass an input connect token.

**WORK_MANAGER=**YES
The connecting address space will be using the WLM Work Management services. This the default.

**WORK_MANAGER=**NO
The connecting address space will not use the WLM Work Management services. Specifying this keyword may reduce the use of system resources.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4CON macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsn, if you coded RSN) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

**Table 68. Return and Reason Codes for the IWM4CON Macro**

<th>Meaning</th>
<th>Action</th>
</tr>
</thead>
</table>
| 8           | xxxx088F    | Equate Symbol: IwmRsnCodeApplNotSSN  
**Meaning:** The application environment name is defined for use by a different subsystem node.  
**Action:** Check whether the correct application environment name is being used. |
| C           | —           | Equate Symbol: IwmRetCodeEnvError  
**Meaning:** Environmental error. |
| C           | xxxx0C01    | Equate Symbol: IwmRsnCodeNoStg  
**Meaning:** Storage is not available for the request.  
**Action:** There is a storage shortage. The function may work successfully at a later time. |
| C           | xxxx0C09    | Equate Symbol: IwmRsnCodeNoResmgr  
**Meaning:** Resource manager could not be established.  
**Action:** No action required. This condition may be due to a storage shortage condition. |
| C           | xxxx0C14    | Equate Symbol: IwmRsnCodeNoWorkShutDown  
**Meaning:** No work selected. Caller is to shutdown.  
**Action:** The server should shut down (terminate). |
| C           | xxxx0C19    | Equate Symbol: IwmRsnCodeNotSecAuthConnect  
**Meaning:** The caller is not authorized by SAF to connect to WLM with SERVER_MANAGER=YES.  
**Action:** The security administrator must grant access to the appropriate resource. |
| C           | xxxx0C1A    | Equate Symbol: IwmRsnCodeApplNotDefined  
**Meaning:** The application environment name is not defined in the active WLM policy.  
**Action:** Check whether the correct application environment name is being used. If so, a service administrator must define the application environment in the WLM service definition. |
| C           | xxxx0C1B    | Equate Symbol: IwmRsnCodeApplNotSST  
**Meaning:** The application environment name is defined for use by a different subsystem type in the active WLM policy.  
**Action:** Check whether the correct application environment name is being used. If so, a service administrator must change the application environment in the WLM service definition to specify the correct subsystem type. |
| C           | xxxx0C1F    | Equate Symbol: IwmRsnCodeServerExists  
**Meaning:** A server exists for the specified application environment which only allows 1 such server in the sysplex.  
**Action:** Check whether the correct application environment name is being used. If so and the current server is shutting down, a retry may be successful after a delay. |
Table 68. Return and Reason Codes for the IWM4CON Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| C           | xxxx0C22    | Equate Symbol: IwmRsnCodeApplEnvQuiesced  
|             |             | Meaning: The specified application environment has been quiesced, server cannot be started for the request.  
|             |             | Action: Restart the application environment and then retry the request. |
| 10          | —           | Equate Symbol: IwmRetCodeCompError  
|             |             | Meaning: Component error.  
|             |             | Action: No action required. The function may be successful if invoked again. |

Examples

To connect to workload management with a key value of 8, and a list of 7 address spaces involved in processing work, specify:

```
IWM4CON SUBSYS=GENSUB,SUBSYSNM=SUBNAME,  
  TOPOLOGY=LISTASCBS,NUMBERASCBS=NUMSPACE  
  CONNTKN=CTKN,CONNTKNNKEYP=VALUE,CONNTKNNKEY=KEY,  
  RETCODE=RC,RSNCODE=RSN,
```

Where the following are declared:

- `GENSUB` DS CL4 Generic subsystem type
- `SUBNAME` DS CL8 Subsystem name
- `LISTASCBS` DS CL28 List of 7 address spaces
- `NUMSPACE` DC F'7' Number of ASCBs
- `CTKN` DS FL4 Connect token
- `KEY` DS XL1 Key value
IWM4DIS — Disconnect from workload management

IWM4DIS allows the caller to disconnect from the workload management services. This means that the input connect token can no longer be passed to workload management macros such as IWM4CLSY and IWM4RPT. When a program disconnects, any enclaves associated with the input connect token are deleted from the system. Any SRBs running in the enclave are run as preemptible SRBs at the priority of the home address space. Any enclave TCBs are converted to ordinary TCBs.

You should issue this macro once during shutdown of the connecting address space.

Note: This service was previously called IWMDISC for 31-bit addressing only (see “IWMDISC — Disconnect from workload management” on page 872).

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>When the corresponding connect (IWM4CON) invocation specified WORK_MANAGER=YES or QUEUE_MANAGER=YES, ROUTER=YES, or EXPT1MPT=YES, supervisor state or program key mask (PKM) allowing keys 0-7. When the corresponding connect (IWM4CON) invocation specified WORK_MANAGER=NO, QUEUE_MANAGER=NO, ROUTER=NO, EXPT1MPT=NO, and SERVER_MANAGER=YES, problem state with any PSW key.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB When the corresponding connect (IWM4CON) invocation specified SERVER_MANAGER=YES, task mode.</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>The current Home address space must be the same as Home when the corresponding Connect was invoked. Any PASN, any SASN. When the corresponding connect (IWM4CON) invocation specified SERVER_MANAGER=YES, non-cross memory mode, P=S=H.</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held. When the corresponding connect (IWM4CON) invocation specified SERVER_MANAGER=YES, SERVER_TYPE=ROUTING, NO FRRs may be set.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>
### Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

### Restrictions

1. No FRRs may be set when calling to disconnect a space which is connected as a server manager with server type = routing.
2. If the key specified on IWM4CON was a user key (8-F), then the following must ALL be true:
   - The caller must be in non-cross-memory mode (P=S=H). This implies that the current primary must match the primary at the time that IWM4CON was invoked. Running in a subspace is not supported.
   - Must be in TCB mode (not SRB)
   - Current TCB must match the TCB at the time that IWM4CON was invoked.
3. This service should not be invoked while in a RTM termination routine (resource manager) for the TCB owning the connect token since MVS will have its own resource cleanup routine and unpredictable results would occur. It is legitimate to use this service while in a recovery routine, however, or in mainline processing.

### Input register information

Before issuing the IWM4DIS macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

### Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>
Unchanged

14-15 Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWM4DIS macro is as follows:

```
IWM4DIS CONNTKN=conntkn RETCODE=retcode RSNCODE=rsncode
```

Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4DIS macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

CONNTKN=conntkn
A required input parameter, which contains the connect token for the environment to be disconnected.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

,MF=S
,MF=(L, list addr)
,MF=(L, list addr, attr)
,MF=(L, list addr, 0D)
,MF=(E, list addr)
,MF=(E, list addr, COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,,list addr
    The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,,attr
    An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of X'0F' to force the parameter list to a word boundary, or X'0D' to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of X'0D'.

,,COMPLETE
    Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,,PLISTVER=IMPLIED_VERSION
,,PLISTVER=MAX
,,PLISTVER=0
    An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
    • IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
    • MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
    If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
    • 0, if you use the currently available parameters.
    To code: Specify one of the following:
    • IMPLIED_VERSION
    • MAX
    • A decimal value of 0

,,RETCODE=retcode
    An optional output parameter into which the return code is to be copied from GPR 15.
    To code: Specify the RS-type address of a fullword field, or register (2)-(12).
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4DIS macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>

| 10          | —           | **Equate Symbol**: IwmRetCodeCompError  
**Meaning**: Component error.  
**Action**: No action required. The function may be successful if invoked again. |
IWM4ECRE — Create an enclave

The purpose of this service is to create an enclave where possibly multiple SRBs and/or TCBs may be simultaneously executing or scheduled. For the duration of each enclave, all SRBs and TCBs associated with the enclave are treated as part of a single work request. All SRBs and/or TCBs associated with the enclave accumulate service as a single entity and are managed as a single entity. The address spaces where enclave SRBs are dispatched, as defined by the ENV parameter of IEAMSCHD, should be non-swappable.

For more information about managing address spaces with enclaves, see “Performance management of address spaces with enclaves” on page 46.

Note: An address space must be non-swappable if it has enclave SRBs dispatched and SYSEVENT ENCASSOC has not been issue.

For TYPE=INDEPENDENT enclaves, a new work business unit of work is created and classified according to the input Connect token's subsystem type and subsystem name, along with whatever other attributes are passed via the Classify parameter list. The current home address space is considered the owner.

For TYPE=DEPENDENT enclaves, SRM considers the enclave to be part of the current home address space's transaction, which then becomes the owning space. This space need not be connected to WLM via IWM4CON.

For TYPE=WORKDEPENDENT, SRM considers the new enclave to be a continuation of the creating unit of work's (TCB or SRB) transaction. The resulting enclave's type depends on the caller's execution environment: If the caller has joined or is scheduled into an enclave of type independent, the resulting enclave will be of type work-dependent and is regarded as an extension of the independent enclave's transaction. Classification and owner address space is adopted from the independent enclave. If the caller has joined or is scheduled into an enclave of type work-dependent, the resulting enclave will be of type work-dependent, as well. It is considered a part of the underlying independent enclave's transaction and inherits owner address space and classification from that independent enclave. If the caller has joined or is scheduled into a dependent enclave, the resulting enclave will be of type dependent. The new enclave is considered part of the creating enclave's (i.e., the enclave the caller is running in) owner address space's transaction and inherits its classification. The creating enclave's owner address space will become the owner of the new enclave. Finally, if no enclave has been joined when the service is called, the resulting enclave will be as if the service had been invoked with TYPE=DEPENDENT specified. Note that it is not allowed to invoke this service with TYPE=WORKDEPENDENT specified while running in a foreign enclave.

For TYPE=MONENV enclaves, SRM considers the enclave to be part of the address space's transaction which is delayed according to the input management monitoring environment, as set when IWM4MINI or IWM4MRLT was used. This space becomes the owning space. This space need not be connected to WLM via IWM4CON.

For both TYPE=MONENV and TYPE=DEPENDENT enclaves, SRM will change the enclave to TYPE=INDEPENDENT if the owning address space's transaction ends.

For both TYPE=MONENV and TYPE=DEPENDENT enclaves, SRM will check the enclave for period switch when the owning address space is swapped in. If the owning
address space is swapped out SRM will continue to accumulate service for any enclaves owned by the space, but will not check the address space or any owned enclave for period switch until the address space is swapped in again. The presence of enclaves does not make the address space appear to be ready from an SRM point of view.

Enclaves are deleted if the owning address space terminates. TYPE=INDEPENDENT enclaves are deleted if the owning address space disconnects or the TCB which connected terminates. Work-dependent enclaves are implicitly deleted when the owning independent enclave is deleted.

Enclaves should only be created when this environment is ready for execution, and should not be used when prolonged queueing effects are possible prior to the scheduling of the first SRB (IEAMSCHD) or the first TCB join (IWMEJOIN). “Prolonged” would certainly include times measured in seconds. The service allows the caller to pass the queueing time prior to creation of the Enclave so that this may be separately reported.

Note: This service was previously called IWMECREA for 31-bit addressing only (see “IWMECREA — Create an enclave” on page 885).

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state or program key mask (PKM) allowing keys 0-7.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
ASC mode: Primary or access register (AR)
Interrupt status: Enabled for I/O and external interrupts
Locks: No locks may be held.
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro CVT must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
6. Prior to release z/OS V1.11, the caller has to assure that work-dependent enclave support is available on the system before calling this macro with
IWM4ECRE

TYPE=WORKDEPENDENT. A flag (SRMSTWDP) in macro IRASRMST (which is returned by sysevent REQSRMST) indicates whether or not work-dependent enclaves can be created.

Restrictions

1. The Connect token from the input classify parameter list must be owned by the current home address space and must be associated with a system key (0-7), as specified on IWM4CON. The Classify parameter list and hence the connect token is only relevant for TYPE=INDEPENDENT enclaves.

2. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.

3. The variable length fields associated with the classify parameter list (the classify parameter list is only relevant for certain options) given by the CLSFY keyword have the following limitations in addition to those documented in IWMCLSFY:
   - SUBSYSMP is limited to 255 bytes
   - COLLECTION is limited to 18 bytes
   - CORRELATION is limited to 12 bytes

4. When TYPE(MONENV) is specified, the following apply:
   - If the key specified on IWM4MCRE was a user key (8-F), then primary or home addressability must exist to the performance block IWM4MCRE obtained. This condition is satisfied by ensuring that the current primary or home address space matches primary (=home) at the time that IWM4MCRE was invoked.
   - The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.
   - Only limited checking is done against the input monitoring token.
   - TYPE=MONENV enclaves cannot be created for report-only monitoring environments.

5. This macro may only be used on z/OS V2R1 or later levels for the MONTKN64 keyword.

6. This macro may only be used on OS/390 R12 or later levels for EXSTARTDEFER keyword.

7. This macro may only be used on z/OS V1R10 or later levels for the IMPORTANCE keyword.

8. This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information

Before issuing the IWM4ECRE macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

Register
  Contents
  0  Reason code if GR15 return code is non-zero
Used as work registers by the system

2-13  Unchanged

14  Used as work registers by the system

15  Return code

When control returns to the caller, the ARs contain:

Register

Contents

0-1  Used as work registers by the system

2-13  Unchanged

14-15  Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None

Syntax

main diagram

parameters-1

parameters-1

Chapter 12. Workload management services  509
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4ECRE macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

\( \text{ACCESS=PRIMARY} \)
When TYPE=MONENV is specified, a required parameter, which describes how to access the monitoring environment.

\( \text{ACCESS=HOME} \)
When TYPE=MONENV is specified, a required parameter, which describes how to access the monitoring environment.

\( \text{ARRIVALTIME=arrivaltime} \)
When TYPE=INDEPENDENT is specified, a required input parameter, which contains the work arrival time in STCK format. This is the time at which the business work request is considered to have arrived and from which point the system evaluates elapsed time for the work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

\( \text{CLSFY=clsfy} \)
When TYPE=INDEPENDENT is specified, a required input parameter, which contains the classification information in the format of the parameter list for IWM4CLS  or IWMCLSFY. NOTE that this name is the data area name, not its pointer. IWM4CLS MF(M) or IWMCLSFY MF(M) should be used to initialize the area prior to invocation of IWM4ECRE.

Note that the variable length fields associated with the classify parameter list given by the CLSFY keyword have the following limitations in addition to those documented in IWMCLSFY:
• SUBSYSPPM is limited to 255 bytes
• COLLECTION is limited to 18 bytes
• CORRELATION is limited to 12 bytes
To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{ESTRT=IMPLIED}

\texttt{ESTRT=EXPLICIT}

\texttt{ESTRT=EXPLICIT\_SINGLE}

\texttt{ESTRT=NEVER}

When TYPE=INDEPENDENT is specified, an optional parameter, which denotes how the work manager indicates the start and end point of an EWLM work request when participating in cross platform Enterprise Workload Management (EWLM). The default is ESTRT=IMPLIED.

\texttt{ESTRT=IMPLIED}

If the work manager previously connected to WLM with IWM4CON EWLM=YES, a work request is started implicitly when the enclave is created. If IWMESTOP was not invoked before, the work request will be stopped implicitly when the enclave is deleted.

\texttt{ESTRT=EXPLICIT}

The work manager indicates the start and end point of an EWLM work request by invoking the services IWMESTRT and IWMESTOP. NOTE that this option is only meaningful, if the work manager previously connected to WLM with IWM4CON EWLM=YES.

\texttt{ESTRT=EXPLICIT\_SINGLE}

Same as option EXPLICIT above, but the application ensures, that only one work request is active (no nested calls to IWMESTRT are allowed). If this option is specified the CPU consumption on all EWLM Enclave services (IWMEGCOR, IWMESTRT, IWMESTOP, IWMBLK, IWMEUBLK) will be reduced. If ESTRT=EXPLICIT\_SINGLE is specified on IWMECREA, the the application must also add the EWLMMODE=EXPLICIT\_SINGLE parameter on all calls to IWMEGCOR, IWMESTRT, IWMESTOP, IWMBLK and IWMEUBLK. If this parameter is used, the application has some restrictions on all calls to IWMEGCOR, IWMESTRT, IWMESTOP, IWMBLK and IWMEUBLK (see the corresponding macro descriptions for details).

\texttt{ESTRT=NEVER}

Indicates, that this enclave will never use any EWLM related enclave services (IWMEGCOR, IWMESTRT, IWMESTOP, IWMBLK, IWMEUBLK) after the enclave has been created, even if the work manager has registered (IWM4CON or IWMCODSV) with EWLM=YES. Moreover IWM4ECRE will not start an EWLM work request on the enclave and will not do any EWLM related processing.

\texttt{ETOKEN=etoken}

A required output parameter, which will receive the Enclave token.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\texttt{EXSTARTDEFER=NO}

\texttt{EXSTARTDEFER=YES}

When TYPE=INDEPENDENT is specified, an optional parameter, which indicates whether the Enclave execution start time should begin when the first IWM4STBG or IWMEJOIN is executed. The time between enclave create and the first IWM4STBG or IWMEJOIN is assumed to be the queue time. The default is EXSTARTDEFER=NO.
indicates that the Enclave execution start time should not begin when the first IWM4STBG or IWMEJOIN is executed.

,EXSTARTDEFER=YES

indicates that the Enclave execution start time should begin when the first IWM4STBG or IWMEJOIN is executed.

,FUNCTION_NAME=function_name

When TYPE=INDEPENDENT is specified, a required input parameter, which contains the descriptive name for the function for which the Enclave was created.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,IMPORTANCE=importance

An optional output parameter that will receive the importance value of the service class to which the unit of work is classified.

To code: Specify the RS-type address, or address in register (2)-(12), of a halfword field.

,INSERVCLS=inservcls

When TYPE=INDEPENDENT is specified, an optional input parameter, which contains the service class token of a previous classification call. The caller must ensure that the classification attributes of the work unit matches the service class token. If the service class token is still valid an enclave is created and associated with the service and report class information contained in the token. If the service class token is not valid IWM4ECRE will perform the full classification by using the information of the CLSFY parameter block and return code 4, reason code IwmRsnCodeNewServcls. The default is 0.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

When TYPE=MONENV is specified, a required input parameter which contains the delay monitoring token which describes the current business unit of work. If the monitoring environment is related to an address space, then it must be the current home address space.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

When TYPE=MONENV is specified, a required input parameter which contains the long delay monitoring token which describes the current business unit of work. If the monitoring environment is related to an address space, then it must be the current home address space.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports both the following parameters and those from version 0:
IMPORTANCE

- 2, which supports both the following parameters and those from version 0 and 1:

INSERVCLS MONTKN64

SERVCLS

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0, 1, or 2

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0), (REG00), or (R0).

,SERVCLS=servcls
When TYPE=INDEPENDENT is specified, an optional output parameter, when CLSFY has been specified which receives the service class token which matches the classification attributes. The token allows the caller to use fast path classification for work units which have the same classification attributes than the current work unit.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

TYPE=INDEPENDENT
TYPE=DEPENDENT
TYPE=WORKDEPENDENT
TYPE=MONENV
An optional parameter, which indicates the type of Enclave being created. The default is TYPE=INDEPENDENT.

TYPE=INDEPENDENT
indicates that the Enclave represents a new business unit of work with its own business objectives.

TYPE=DEPENDENT
indicates that the Enclave represents a continuation of the business unit of work represented by the current home address space.
**TYPE=WORKDEPENDENT**
Indicates that the enclave represents a continuation of the creating unit of
work's (TCB or SRB) transaction. The resulting enclave's type depends on
the caller's execution environment: If the caller has joined or is scheduled
into an enclave of type independent, the resulting enclave will be of type
work-dependent and is regarded as an extension of the independent
enclave's transaction. Classification and owner address space is adopted
from the independent enclave. If the caller has joined or is scheduled into
an enclave of type work-dependent, the resulting enclave will be of type
work-dependent, as well. It is considered a part of the underlying
independent enclave's transaction and inherits owner address space and
classification from that independent enclave. If the caller has joined or is
scheduled into a dependent enclave, the resulting enclave will be of type
dependent. The new enclave is considered part of the creating enclave's
(i.e., the enclave the caller is running in) owner address space's transaction
and inherits its classification. The creating enclave's owner address space
will become the owner of the new enclave. Finally, if no enclave has been
joined when the service is called, the resulting enclave will be as if the
service had been invoked with TYPE=DEPENDENT specified. Note that it
is not allowed to invoke this service with TYPE=WORKDEPENDENT
specified while running in a foreign enclave.

**TYPE=MONENV**
indicates that the Enclave represents a continuation of the business unit of
work represented by the input management monitoring environment.
TYPE=MONENV enclaves cannot be created for report-only monitoring
environments.

**WORKREQ_HDL=workreq_hdl**
When ESTRT=IMPLIED and TYPE=INDEPENDENT are specified, an optional
output parameter that will receive the handle which represents the work
request. The application must pass this handle to the other work request
services IWMESTOP, IWMEBLK, IWMUSBK, and IWMEGCOR.

To code: Specify the RS-type address, or address in register (2)-(12), of an
8-character field.

**ABEND codes**
None.

**Return codes and reason codes**
When the IWM4ECRE macro returns control to your program:
• GPR 15 (and retcode, when you code RETCODE) contains a return code.
• When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code
RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the
equate symbol associated with each reason code. IBM support personnel may
request the entire reason code, including the xxxx value.
### Table 70. Return and Reason Codes for the IWM4ECRE Macro

*Meaning:* Received a non-zero return code from the classification service, IWM4CLSY/IWMCLSYF.  
*Action:* No action required. Reinvoking the function later may succeed. |
| C           | xxxx0C0D    | Equate Symbol: IwmRsnCodeBadClsfy  
*Meaning:* Classification apparently can not access the current policy, possibly due to a policy switch in progress.  
*Action:* Invoke the function when the conditions are alleviated. |
| C           | xxxx0C20    | Equate Symbol: IwmRsnCodeDepClassifyFail  
*Meaning:* Unable to obtain classification attributes for a dependent enclave.  
*Action:* None required. |
| C           | xxxx0C21    | Equate Symbol: IwmRsnCodeNoMonEnvErr  
*Meaning:* Input monitoring token indicates no monitoring environment was established.  
*Action:* None required. |
| 10          | —           | Equate Symbol: IwmRetCodeCompError  
*Meaning:* Component error.  
*Action:* No action required. The function may be successful if invoked again. |
Examples

None.
IWM4EDEL — Delete an enclave

The purpose of this service is to delete an enclave, so that no SRBs or TCBs exist within the enclave and no new SRBs may be scheduled into the enclave, nor may any TCBs join the enclave. Some residual enclave-related CPU time will not be accounted back to the work request whenever active enclave SRBs/TCBs were present at the time IWM4EDEL is invoked. SRBs scheduled to the enclave which have not completed will be converted to ordinary preemptible SRBs. TCBs joined to the enclave which have not completed will be converted to ordinary TCBs.

If IWM4EDEL is invoked for an enclave which is registered, the enclave is considered only logically deleted while all its functionality stays in place. Physical deletion is deferred until all interested parties have deregistered the enclave. The caller does not receive any notice when the physical deletion of the enclave is done.

When an enclave is deleted, the work request is considered to have finished and all related resource accounting will be finalized.

IWM4EDEL cannot be used to delete a foreign enclave. The IWMUIMPT macro must be used instead.

Note: This service was previously called IWMEDEL for 31-bit addressing only (see “IWMEDEL — Delete an enclave” on page 896).

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary or access register (AR)</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held. FRR environments may be established.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded.
from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

6. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.

Restrictions

This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

Input register information

Before issuing the IWM4EDEL macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.
**Syntax**

The syntax of the IWM4EDEL macro is as follows:

```
name IWM4EDEL ETOKEN=etoken ,CPUSERVICE=cpuservice

,SYSPLEXCPUSRV=sysplexcpusrv ,CPUSRV=cputime

,RESPTIME_RATIO=resptime_ratio ,ZAAPSERVICE=zaapservice

,ZAAPTIME=zaaptime ,ZAAPPFACTOR=zaapnfactor ,ZIIPSERVICE=zipservice

,ZIIPTIME=ziiptime ,RETCODE=retcode ,RSNICODE=rsncode

,PLISTVER=IMPLIED_VERSION

,PLISTVER=MAX ,PLISTVER=0 ,PLISTVER=1 ,PLISTVER=2

,MF=S

,MF=(L,list addr,attr,COMPLETE)
```

**Parameters**

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWM4EDEL macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**,CPUSERVICE=cpuservice**

An optional output parameter, which will contain the CPU service accumulated by the enclave on the local system.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

**,CPUTIME=cputime**

An optional output parameter, which will contain the total CPU time accumulated by the enclave on the local system.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

**ETOKEN=etoken**

A required input parameter, which contains the enclave token to be returned.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**,MF=S**

**,MF=(L,list addr)**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of X'0F' to force the parameter list to a word boundary, or X'0D' to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of X'0D'.

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
0, which supports all parameters except those specifically referenced in higher versions.

• 1, which supports the following parameter and those from version 0:

    RESPTIME_RATIO

• 2, which supports the following parameters and those from version 0 and 1:

    ZAAPNFACTOR  ZAAPTIME  ZIPTIME
    ZAAPSERVICE  ZIIPSERVICE

**To code:** Specify one of the following:

• IMPLIED_VERSION

• MAX

• A decimal value of 0, 1, or 2

**RESPTIME_RATIO**=resptime_ratio

An optional output parameter, which contains the response time ratio times 100: act.resp.time / goal * 100 if the enclave has a response time goal (limited to: 1<=RESPTIME_RATIO<=1000) 0 otherwise

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

**RETCODE**=retcode

An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**RSNCODE**=rsncode

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**SYSPLEXCPUSRV**=sysplexcpusrv

An optional output parameter, which will contain the CPU service accumulated by the enclave on the local system and on other systems through the use of the IWMEXPT and IWMIMPT services. If the IWMEXPT and IWMIMPT services were not used, SYSPLEXCPUSRV returns the same value as CPUSERVICE.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

**ZAAPNFACTOR**=zaapnfactor

An optional output parameter, which contains the normalization factor for application assist processors (zAAPs). If zAAPs are running at a different speed, multiply zAAP service and times with this factor and divide the result by 256 to normalize the values to the speed of regular CPUs. Note however, that if there has been a speed change of zAAP processors during the life time of the enclave, this calculation will return imprecise data.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.
,ZAAPSERVICE=*zaapservice
An optional output parameter, which contains the application assist processor (zAAP) service accumulated by the enclave on the local system. The value is not normalized to the speed of regular CPs, but is expressed in zAAP speed which might be different. You may use ZAAPNFACTOR to normalize the value to the speed of regular CPs. Note however, that if the zAAP speed changed during the life time of the enclave, this value cannot be normalized precisely.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

,ZAAPTIME=*zaaptime
An optional output parameter, which contains the total application assist processor (zAAP) time accumulated by the enclave on the local system. The value is not normalized to the speed of regular CPs, but is expressed in zAAP speed which might be different. You may use ZAAPNFACTOR to normalize the value to the speed of regular CPs. Note however, that if the zAAP speed changed during the life time of the enclave, this value cannot be normalized precisely.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

,ZIIPSERVICE=*ziipservice
An optional output parameter, which contains the integrated information processor (zIIP) service accumulated by the enclave on the local system. The service is normalized to standard processor speed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

,ZIIPTIME=*ziiptime
An optional output parameter, which contains the total integrated information processor (zIIP) time accumulated by the enclave on the local system. The time is normalized to standard processor speed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

ABEND codes
None.

Return codes and reason codes
When the IWM4EDEL macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Example

None.
IWM4EQRY — Query an enclave

This service offers three functions:
1. Query the classification attributes for an enclave.
2. Query WLM performance management information for an enclave.
3. Query both the classification attributes and WLM performance management
   information for an enclave.

The output of this service is mapped by macro IWMECDX.

The query macro is provided in list, execute, and standard form. The list form
accepts no variable parameters and is used only to reserve space for the parameter
list. The standard form is provided for use with routines which do not require
reentrant code. The execute form is provided for use with the list format for
reentrant routines.

Note: This service was previously called IWMEQRY for 31-bit addressing only (see
IWMEQRY — Enclave query” on page 904).

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state or program key mask (PKM) allowing keys 0-7.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE
AMODE64=YES before invoking this macro.
ASC mode: Primary or access register (AR)
  If in Access Register ASC mode, specify SYSSTATE ASCENV=AR
  before invoking this macro.
Interrupt status: Enabled for I/O and external interrupts
Locks: No locks may be held.
Control parameters: Control parameters must be in the primary address space.

Programming requirements
1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by
   IWMYCON.
3. Note that the high order halfword of register 0, and the reason code variable
   when specified, may be non-zero and represents diagnostic data which is NOT
   part of the external interface. The high order halfword should thus be excluded
   from comparison with the reason code values described above. The constant,
   IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this
   purpose.

Restrictions
1. This macro may not be used prior to the completion of WLM address space
   initialization.
2. The caller must provide storage for an answer area mapped by macro IWMECDX. This answer area may reside in the caller’s primary address space, or in a dataspace accessible via the current unit of work’s dispatchable unit access list (DUal).

**Input register information**

Before issuing the IWM4EQRY macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None

```

```plaintext
,QUERYLEN=querylen,FUNCTION=CLASSINFO
,FUNCTION=PERFINF,RETCODE=retcode
```
IWM4EQRY

Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4EQRY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ANSAREA=ansarea
A required output parameter, which is to receive the data being returned. The layout of this area is defined by macro IWMECDX.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,ANSLEN=anslen
A required input parameter, variable which contains the length of the area provided to contain the data being returned by IWM4EQRY.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

ETOKEN=etoken
A required input parameter, which contains the Enclave token representing the Enclave of interest.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,FUNCTION=CLASSINFO
,FUNCTION=PERFINfo
,FUNCTION=ALL
A required parameter that indicates the query function to be executed.

,FUNCTION=CLASSINFO
Use this function to query the classification attributes of an enclave. This is the same information as is returned by service IWMECQRY.

,FUNCTION=PERFINfo
Use this function to query the WLM performance management information of an enclave. This data is based on the classification attributes and the active WLM Policy.

,FUNCTION=ALL
Use this function to query both, the classification attributes and the WLM performance management information of an enclave.

,MF=S
IWM4EQRY

\text{MF=(L,} \text{list addr)}
\text{MF=(L,} \text{list addr,} \text{attr)}
\text{MF=(L,} \text{list addr,} 0D)
\text{MF=(E,} \text{list addr)}
\text{MF=(E,} \text{list addr,} \text{COMPLETE)}

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\text{list addr}

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\text{attr}

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code \text{attr}, the system provides a value of 0D.

\text{COMPLETE}

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\text{PLISTVER=IMPLIED\_VERSION}
\text{PLISTVER=MAX}
\text{PLISTVER=0}

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- \text{IMPLIED\_VERSION}, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED\_VERSION is the default.
- \text{MAX}, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- \text{0}, if you use the currently available parameters.
**IWM4EQRY**

**To code:** Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

`QUERYLEN=querylen`

A required output parameter, variable is to receive the number of bytes needed to contain the data being returned by IWM4EQRY. The length of the area needed to contain the data is dependent on the Function being used. If the ANSLEN is less than the QUERYLEN, then no data is returned in the output area specified by ANSAREA and a return code of 4 is issued.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

`RETCODE=retcode`

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

`RSNCODE=rsncode`

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4EQRY macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Action: Consider reporting the problem to IBM. |

#### Examples

None.
The IWM4HLTH service is used to inform WLM about the health state of a server. The health indicator is a number which shows, in percent, how well the server is performing. It can be an integer value between 0 and 100.

**Value**  **Meaning**

100  The server is fully capable to do work without any health problems.

0  The server is not able to do any work.

Any value between 0 and 100  Indicates the level of health of the server.

IWM4HLTH provides two functions: SET and RESET. With the SET function, which is the main intended use and default function, a caller informs WLM about its view of the health state of a server. WLM then sets the server’s health indicator to the minimum number of all the current settings from the different callers of the service since the last RESET.

TheRESET function primarily refers to reliability, availability, and serviceability (RAS) considerations regarding a server’s health state. RESET restarts setting the health indicator by specifying an initial value and discarding any values reported by other callers before.

Callers can identify themselves by a subsystem type and subsystem name. The service uses these parameters to recognize different callers of the service. If no subsystem type is passed, the job name of the caller address space is used instead. This information will then also be available to callers of the IWM4QHLT (Query Server Health Indicators) service.

The health indicator is activated when one of the routing services IWM4SRSC or IWMSRSRS with FUNCTION=SPECIFIC are used to get routing recommendations. The weights are reduced to the percentage given by the health indicator of the server address space.

The health indicator of a server keeps its value until it is modified by resetting it with the IWM4HLTH service, or with the IWMSRSRG service.
Environment

The requirements for the caller are:

Minimum authorization: **FUNCTION=SET:**

Problem state with any PSW key if the address space token specified with STOKEN=stoken equals the address space token of the home address space. That is, the caller provides a health indicator for itself. When providing a health indicator for an address space other than the home address space, the minimum authorization is one of the following:

- Supervisor state.
- Program key mask (PKM) allowing at least one of the keys 0-7.
- The caller has UPDATE authority to the resource IWM.SERVER.HEALTH in the FACILITY class.

**FUNCTION=RESET:**

The minimum authorization is one of the the following:

- Supervisor state.
- Program key mask (PKM) allowing at least one of the key 0-7.
- The caller has CONTROL authority to the resource IWM.SERVER.HEALTH in the FACILITY class.

| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31-bit or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro. |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | The caller may hold locks, but is not required to hold any. FRRs may be established. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
Restrictions

This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information

Before issuing the IWM4HLTH macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWM4HLTH macro is as follows:

```
IWM4HLTH

name

STOKEN=stoken,FUNCTION=SET

FUNCTION=RESET

HEALTH=health

SUBSYS=NO_SUBSYS

SUBSYS=subsys

SUBSYSNM=NO_SUBSYSNM

SUBSYSNM=subsysnm

HEALTHRSN=NO_RSN

HEALTHRSN=healthrsn
```
IWM4HLTH

Parameters

The parameters are explained as follows:

STOKEN
A required input parameter which contains the space token of the server.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

FUNCTION
An optional parameter which indicates the function to perform. The default is FUNCTION=SET.

FUNCTION=SET
Informs WLM about the caller's view of the health state of a server. WLM then sets the server's health indicator to the minimum number of all the current settings from the different callers of the service since the last RESET.

FUNCTION=RESET
Restarts setting the health indicator by specifying an initial value and discarding any values reported by other callers before. RESET primarily refers to reliability, availability, and serviceability (RAS) considerations regarding a server's health state.

HEALTH
A required input parameter, which contains the health indicator associated with the address space. This value is the percentage up to which this address space is capable to handle requests.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

SUBSYS
An optional input parameter which contains the generic name or type of the caller of the service. It is used by WLM together with the SUBSYSNM parameter to recognize different callers of this service. This data is also available to callers of the IWM4QHLT service.

The default is NO_SUBSYS which indicates that no type was passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

SUBSYSNM
An optional input parameter which contains the name of a specific instance of the caller of the service. It is used by WLM together with the SUBSYS
parameter to recognize different callers of this service. This data is also available to callers of the IWM4QHLT service.

The default is NO_SUBSYSNM which indicates that no name was passed.

**To code**: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**HEALTHRSN**

An optional input parameter that allows the caller to pass additional information, such as the reason for changing the health indicator. This data is available to callers of the IWM4QHLT service.

The format is undefined. The default is NO_RSN which indicates that no additional information is passed.

**To code**: Specify the RS-type address or address in register (2)-(12) of an 16-character field.

**RETCODE**

An optional output parameter into which the return code is to be copied from GPR 15.

**To code**: Specify the RS-type address or address in register (2)-(12) of a fullword field.

**RSNCODE**

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code**: Specify the RS-type address or address in register (2)-(12) of a fullword field.

,**PLISTVER=IMPLIED_VERSION**

,**PLISTVER=MAX**

,**PLISTVER=0**

,**PLISTVER=1**

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

**IMPLIED_VERSION**

The lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

**MAX**

Indicates that you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

**0** Indicates to use version 0 of the macro, which supports all parameters except those specifically identified in higher versions.
IWM4HLTH

1  Supports the following parameters and those from version 0:
   FUNCTION
   SUBSYS
   SUBSYSNM
   HEALTHRSN

To code: Specify one of the following:
   • IMPLIED_VERSION
   • MAX
   • A decimal value of 0 or 1

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline
parameter list and generates the macro invocation to transfer control to the
service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter may be coded with the list form of
the macro.

Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
defined by the list form, and generates the macro invocation to transfer control
to the service.

,list addr
   The name of a storage area to contain the parameters. For MF=S and MF=E,
   this can be an RS-type address or an address in register (1)-(12).

,attr
   An optional 1- to 60-character input string that you use to force boundary
   alignment of the parameter list. Use a value of 0F to force the parameter
   list to a word boundary, or 0D to force the parameter list to a doubleword
   boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
   Specifies that the system is to check for required parameters and supply
   defaults for omitted optional parameters.

ABEND codes

None.

Return codes and reason codes

When the IWM4HLTH macro returns control to your program:
   • GPR 15 (and retcode, if you coded RETCODE) contains a return code.
When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

Table 73 identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

### Example

To set the health indication value for a particular server, specify:

```plaintext
IWM4HLTH STOKEN=STKN
    HEALTH=HLTH
    RETCODE=RC,RSNCODE=RSN
```

* Storage areas
  * STKN DS CLB Contains the STOKEN
  * HLTH DS F Field to input the health value
  * RC DS F Return code
  * RSN DS F Reason code
IWM4MABN — Monitor environment abnormal event

The purpose of this service is to indicate that an abnormal event has occurred for the work request represented by the input monitoring environment. This condition will supplement any existing abnormal conditions recorded in the input monitoring environment (multiple conditions may exist).

Note that abnormal conditions are propagated to the parent monitoring environment via IWM4MXFR Function(Return).

Note: This service was previously called IWMABNL for 31-bit addressing only (see “IWMABNL — Record abnormal event” on page 911).

Environment

The requirements for the caller are:

Minimum authorization:
- Either problem state or supervisor state.
- PSW key must either be 0 or match the value supplied on IWM4MCRE for the input monitoring token when MONENKEYP(PSWKEY) is specified.
- MONEnVEyP(VALUE) may only be specified in supervisor state or with PKM authority to the key specified by MONENKEY.
  Note that the key for IWM4MABN is located in bit positions 0-3 (using 0 origin), which is the machine orientation to keeping keys, not the "natural" way of declaring the key value.
- MONENKEYP(UNKNOWN) may only be specified in supervisor state or with PKM authority to key 0.

Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code $SYSTATE AMODE64=YES before invoking this macro.
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: Unlocked
Control parameters: Control parameters must be in the primary address space.

Programming requirements

None.

Restrictions

1. This macro may not be used prior to the completion of WLM address space initialization
2. All parameter areas must reside in current primary.
3. If the key specified on IWM4MCRE for the input environment was a user key (8-F), then either primary OR secondary addressability must exist to the performance block.
4. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the input monitoring environment.
5. Only limited validity checking is done on the input monitoring token.
IWM4MABN

6. Caller is responsible for error recovery.
7. This macro may only be used on z/OS V2R1 or higher.

Input register information

Before issuing the IWM4MABN macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GRI5 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>15</td>
<td>Used as a work register by the macro</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after using a service. If the system changes the contents of registers on which the caller depends, the caller must save them before calling the service, and restore them after the system returns control.

Performance implications

None

Syntax

```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4MABN macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

ABNORMAL=abnormal
A required input parameter, which indicates the abnormal mask to use to reflect the abnormality. Macro IWMYCON contains the defined abnormal masks. The mask variable names begin with IWM4MABN, for example - IWMABNL_SCOPE_LOCALMVS.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

MONENV=NOSWITCH
MONENV=SECONDARY
A required parameter, which describes whether a space switch is needed to access the input monitoring environment.

MONENV=NOSWITCH
indicates that NO space switch is needed to access the input monitoring environment. This would be appropriate if the input monitoring environment was established (by IWM4MCRE) to be used by routines in a specific system key or if it was established to be used in a specific user key in the current primary.

MONENV=SECONDARY
indicates that the input monitoring environment was established in current secondary (for use by a specific user key).

MONENKEY=monenvkey
When MONENKEYP=VALUE is specified, a required input parameter, which contains the key in which the input monitoring environment must be accessed. Use of this keyword value requires that the invoker be in supervisor state or that the caller have PKM authority to the key specified. The leftmost, i.e. high order, 4 bits contain the key value.

Note that this is different from the “natural” way of declaring the key, and uses the machine orientation for keeping the storage key in the high order bits.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8 bit field.

MONENKEYP=VALUE
MONENKEYP=PSWKEY
A required parameter, which describes whether a key switch is needed to access the input monitoring environment.

\texttt{MONENVKEYP=VALUE} indicates that the key is being passed explicitly via \texttt{MONENVKEY}.

\texttt{MONENVKEYP=PSWKEY} indicates that the current PSW key should be used. Use of this keyword value requires that the input monitoring environment was established with the same key as the current PSW.

\texttt{MONENVKEYP=UNKNOWN} indicates that the key associated with the input monitoring environment is unknown. Use of this keyword value requires that the invoker be in supervisor state or that the caller have PKM authority to key 0.

\texttt{MONTKN=} \texttt{montkn} 
A required input parameter which contains the delay monitoring token for the environment affected by the abnormality.

\textbf{To code:} Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\texttt{MONTKN64=} \texttt{montkn64} 
A required input parameter which contains the long delay monitoring token for the environment affected by the abnormality.

\textbf{To code:} Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

\texttt{RETCODE=} \texttt{retcode} 
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

\textbf{To code:} Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

\texttt{RSNCODE=} \texttt{rsncode} 
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

\textbf{To code:} Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

\textbf{ABEND codes}
None.

\textbf{Return codes and reason codes}
When the IWM4MABN macro returns control to your program:
\begin{itemize}
  \item GPR 15 (and \texttt{retcode}, when you code \texttt{RETCODE}) contains a return code.
  \item When the value in GPR 15 is not zero, GPR 0 (and \texttt{rsncode}, when you code \texttt{RSNCODE}) contains a reason code.
\end{itemize}
The following table identifies the hexadecimal return and reason codes. IBM support personnel may request the entire reason code, including the xxxx value.

Table 74. Return and reason codes for the IWM4MABN macro

Examples

None.
IWM4MCHS — Change the state of a work request

The purpose of this service is to reflect in a monitoring environment what the current state of a work request is with respect to delays.

A work unit started by IWM4MSTR is blocked and unblocked automatically. WAITING states, that allow the specification of the ASYNC keyword, block the work unit. All other states unblock the work unit.

Note: This service was previously called IWMMCHST for 31-bit addressing only (see “IWMMCHST — Monitor change state of work unit” on page 915).

Environment

The requirements for the caller are:

Minimum authorization: Problem state. PSW key must either be 0 or match the value supplied on IWM4MCRE.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: Suspend locks are allowed.
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high order halfword of bits 0-31 of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMSNSCODE_MASK CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. Caller is responsible for error recovery
2. Only limited checking is done against the input monitoring token.
3. If the key specified on IWM4MCRE was a user key (8-F), then the primary addressability must exist to the performance block IWM4MCRE obtained. This condition is satisfied by ensuring that current primary matches primary at the time that IWM4MCRE was invoked. If this service is invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.
4. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.
5. This macro may only be used on z/OS R2 or higher levels for the following state/resources
• STATE(ACTIVE_APPL)
• RESOURCE(SSL_THREAD)
• RESOURCE(REG_THREAD)
• RESOURCE(REG_TO_WRKTB)
• RESOURCE(TYPE1)
• RESOURCE(TYPE2)
• RESOURCE(TYPE3)
• RESOURCE(TYPE4)
• RESOURCE(TYPE5)

6. This macro may only be used on z/OS R8 or higher levels for the following resources
   • RESOURCE(BUFFER_POOL_IO)

7. This macro may only be used on z/OS R8 or higher levels for RESTKN keyword.

8. This macro may only be used on z/OS R10 or higher levels for the following state/resources
   • RESOURCE(TYPE6)
   • RESOURCE(TYPE7)
   • RESOURCE(TYPE8)
   • RESOURCE(TYPE9)
   • RESOURCE(TYPE10)
   • RESOURCE(TYPE11)
   • RESOURCE(TYPE12)
   • RESOURCE(TYPE13)
   • RESOURCE(TYPE14)
   • RESOURCE(TYPE15)

9. This macro may only be used on z/OS V2R1 or higher levels for the MONTKN64 keyword.

10. This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

**Input register information**

Before issuing the IWM4MCHS macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

**Register**

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0  Reason code if GR15 return code is non-zero. The reason code is stored in bits 0-31</td>
</tr>
<tr>
<td>1  Used as work registers by the system</td>
</tr>
<tr>
<td>2-13 Unchanged</td>
</tr>
<tr>
<td>14 Used as work registers by the system</td>
</tr>
<tr>
<td>15 Return code stored in bits 0-31</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:
IWM4MCHS

Register

Contents

0-1    Used as work registers by the system
2-13   Unchanged
14-15  Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

main diagram

```
name | IWM4MCHS
```
Parameters

The parameters are explained as follows:

name
    An optional symbol, starting in column 1, that is the name on the IWM4MCHS macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ASYNC=NO
,ASYNC=YES
    When RESOURCE=CONV and STATE=WAITING are specified, an optional parameter, which specifies the blocking type of a work unit started by IWM4MSTR. The default is ASYNC=NO.
        ,ASYNC=NO
        indicates that the blocking type is synchronous.
        ,ASYNC=YES
        indicates that the blocking type is asynchronous.

,ASYNC=NO
,ASYNC=YES
    When RESOURCE=DISTRIB and STATE=WAITING are specified, an optional parameter, which specifies the blocking type of a work unit started by IWM4MSTR. The default is ASYNC=NO.
        ,ASYNC=NO
        indicates that the blocking type is synchronous.
        ,ASYNC=YES
        indicates that the blocking type is asynchronous.

,ASYNC=NO
,ASYNC=YES
    When RESOURCE=SESS_LOCALMVS and STATE=WAITING are specified, an optional parameter, which specifies the blocking type of a work unit started by IWM4MSTR. The default is ASYNC=NO.
        ,ASYNC=NO
        indicates that the blocking type is synchronous.
        ,ASYNC=YES
        indicates that the blocking type is asynchronous.

,ASYNC=NO
,ASYNC=YES
    When RESOURCE=SESS_NETWORK and STATE=WAITING are specified, an optional parameter, which specifies the blocking type of a work unit started by IWM4MSTR. The default is ASYNC=NO.
        ,ASYNC=NO
        indicates that the blocking type is synchronous.
indicates that the blocking type is asynchronous.

ASYNC=NO

indicates that the blocking type is synchronous.

ASYNC=YES

indicates that the blocking type is asynchronous.

ASYNC=NO

When RESOURCE=SESS_SYSPLEX and STATE=WAITING are specified, an optional parameter, which specifies the blocking type of a work unit started by IWM4MSTR. The default is ASYNC=NO.

ASYNC=NO

indicates that the blocking type is synchronous.

ASYNC=YES

indicates that the blocking type is asynchronous.

ASYNC=NO

When RESOURCE=OTHER_PRODUCT and STATE=WAITING are specified, an optional parameter, which specifies the blocking type of a work unit started by IWM4MSTR. The default is ASYNC=NO.

ASYNC=NO

indicates that the blocking type is synchronous.

ASYNC=YES

indicates that the blocking type is asynchronous.

COMPCODE=YES

An optional parameter, which indicates whether completion status for this service is needed. The default is COMPCODE=YES.

COMPCODE=YES

indicates that completion status is needed.

COMPCODE=NO

indicates that completion status is not needed. Registers 0, 15 cannot be used as reason code and return code registers upon completion of the macro expansion. For this reason neither RETCODE NOR RSNCODE may be specified when COMPCODE(NO) is specified.

EWLM=NO

An optional parameter, which indicates if this work manager intents to participate in cross platform Enterprise Workload Management (eWLM). The default is EWLM=NO.

EWLM=NO

The work manager interacts only with WLM and no interaction with eWLM takes place.

MONTKN=montkn

A required input parameter which contains the delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

MONTKN64=montkn64

A required input parameter which contains the long delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

PLISTVER=IMPLIED_VERSION

PLISTVER=MAX
An optional input parameter that specifies the version of the macro. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want to indicate the latest version currently possible.
- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports all parameters except those specifically referenced in higher versions. No parameters correspond to this version number.
- **2**, which supports all parameters except those specifically referenced in higher versions. No parameters correspond to this version number.
- **3**, which supports both the following parameters and those from version 0, 1 and 2:

**MONTKN64**

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0, 1, 2, or 3

,RESOURCE=LATCH,RESOURCE=LOCK,RESOURCE=IO,RESOURCE=CONV,RESOURCE=DISTRIB,RESOURCE=SESS_LOCALMVS,RESOURCE=SESS_NETWORK,RESOURCE=SESS_SYSPLEX,RESOURCE=TIMER,RESOURCE=OTHER_PRODUCT,RESOURCE=MISC,RESOURCE=SSL_THREAD,RESOURCE=REG_THREAD,RESOURCE=REG_TO_WRKTB,RESOURCE=TYPE1,RESOURCE=TYPE2,RESOURCE=TYPE3,RESOURCE=TYPE4,RESOURCE=TYPE5,RESOURCE=TYPE6,RESOURCE=TYPE7,RESOURCE=TYPE8,RESOURCE=TYPE9,RESOURCE=TYPE10,RESOURCE=TYPE11,RESOURCE=TYPE12
When STATE=WAITING is specified, a required parameter, which indicates the resource that the work manager is waiting for on behalf of the work request described by the monitoring environment.

- **RESOURCE=LATCH** indicates that the work manager is waiting on a latch.
- **RESOURCE=LOCK** indicates that the work manager is waiting on a lock.
- **RESOURCE=IO** indicates that the work manager is waiting on an activity related to an I/O request. This may either be an actual I/O operation or some function associated with an IO request that cannot be more precisely determined by the work manager (e.g. locks, buffers, etc.).
- **RESOURCE=CONV** indicates that the work manager is waiting on a conversation. This may be used in conjunction with IWM4MSWC to identify where the target is located.
- **RESOURCE=DISTRIBUT** indicates that the work manager is waiting on a distributed request. This says at a high level that some function or data must be routed prior to resumption of the work request. This is to be contrasted with Waiting on Conversation, which is a low level view of the precise resource that is needed. A distributed request could involve waiting on a conversation as part of its processing.
- **RESOURCE=SESS_LOCALMVS** indicates that the work manager is waiting to establish a session somewhere in the current MVS image.
- **RESOURCE=SESS_NETWORK** indicates that the work manager is waiting to establish a session somewhere in the network.
- **RESOURCE=SESS_SYSPLEX** indicates that the work manager is waiting to establish a session somewhere in the sysplex.
- **RESOURCE=TIMER** indicates that the work request is waiting on a timer.
- **RESOURCE=OTHER_PRODUCT** indicates that the work manager is waiting on another product to complete its function.
- **RESOURCE=MISC** indicates that the work manager is waiting on some unidentified resource, possibly among the previous categories.
- **RESOURCE=SSL_THREAD** indicates that the work manager is waiting on a SSL thread.
- **RESOURCE=REG_THREAD** indicates that the work manager is waiting on a regular processing thread.
indicates that the work manager is waiting for the registration to a worktable.

RESOURCE=TYPE1
indicates that the work manager is waiting for resource type 1.

RESOURCE=TYPE2
indicates that the work manager is waiting for resource type 2.

RESOURCE=TYPE3
indicates that the work manager is waiting for resource type 3.

RESOURCE=TYPE4
indicates that the work manager is waiting for resource type 4.

RESOURCE=TYPE5
indicates that the work manager is waiting for resource type 5.

RESOURCE=TYPE6
indicates that the work manager is waiting for resource type 6.

RESOURCE=TYPE7
indicates that the work manager is waiting for resource type 7.

RESOURCE=TYPE8
indicates that the work manager is waiting for resource type 8.

RESOURCE=TYPE9
indicates that the work manager is waiting for resource type 9.

RESOURCE=TYPE10
indicates that the work manager is waiting for resource type 10.

RESOURCE=TYPE11
indicates that the work manager is waiting for resource type 11.

RESOURCE=TYPE12
indicates that the work manager is waiting for resource type 12.

RESOURCE=TYPE13
indicates that the work manager is waiting for resource type 13.

RESOURCE=TYPE14
indicates that the work manager is waiting for resource type 14.

RESOURCE=TYPE15
indicates that the work manager is waiting for resource type 15.

RESOURCE=BUFFER_POOL_IO
indicates that the work manager is waiting for resource buffer pool IO.

RESTKN=restkn
RESTKN=NORESTKN
An optional input parameter, which contains the token of the managed resource previously registered with Register Resource (IWM4MREG) The default is NORESTKN which indicates that no resource token is provided. NORESTKN will preserve the existing resource token, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

RETCODE=retcode
An optional output parameter into which the return code is to be copied from
GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

\RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0), (REG00), or (R0).

\RUNTIME_VER=SHORT_FORM
\RUNTIME_VER=MINIMAL
An optional parameter, which indicates what level of runtime verification will be performed. The default is RUNTIME_VER=SHORT_FORM.

\RUNTIME_VER=SHORT_FORM
indicates that checking should verify that a monitoring environment is established and passes a short form of verification prior to being used.

\RUNTIME_VER=MINIMAL
indicates that checking will only be done to verify that a monitoring environment may be established, assuming that it would be valid and useable if established.

\STATE=FREE
\STATE=ACTIVE
\STATE=ACTIVE_APPL
\STATE=READY
\STATE=IDLE
\STATE=WAITING
A required parameter, which indicates the current state for the work request.

\STATE=FREE
indicates that the work manager has no work request associated with the monitoring environment.

\STATE=ACTIVE
indicates that there is a program executing on behalf of the work request described by the monitoring environment. This is an indication from the perspective of the work manager using this service, who should not try to factor in MVS decisions in preempting work, etc.

\STATE=ACTIVE_APPL
indicates that there is a application program executing on behalf of the work request described by the monitoring environment. This is an indication from the perspective of the work manager using this service, who should not try to factor in MVS decisions in preempting work, etc. This state represents the application activity in contrast to the active (subsystem) state.

\STATE=READY
indicates that there is a program ready to execute on behalf of the work request described by the monitoring environment, but the work manager has given priority to another work request.

\STATE=IDLE
indicates that the work manager has no work requests that it is allowed to service within the monitoring environment. This represents a delay that is
not under the control of the work manager itself and which it cannot eliminate. This may be caused by limits imposed by the installation or by the nature of the work request itself.

**STATE=WAITING**

indicates that the work manager is waiting for a resource on behalf of the work request described by the monitoring environment. Some resources the work manager is waiting for cause a blocking of the work unit started by IWM4MSTR. The blocking is terminated when the work unit state is changed into a state that does not cause blocking.

### ABEND codes

None.

### Return codes and reason codes

When the IWM4MCHS macro returns control to your program:

- GPR 15 (and `retcode`, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and `rsncode`, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the `xxxx` value.

**Table 75. Return and Reason Codes for the IWM4MCHS Macro**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning and Action</th>
</tr>

</tbody>
</table>

### Examples

None.
The purpose of this service is to create a single delay monitoring environment or a number of delay monitoring environments so that work and resource managers may utilize other delay monitoring services to reflect to MVS the execution states and delays associated with work requests.

There are three types of monitoring environments available: management monitoring environments, report-only monitoring environments, and buffer pool management only environments.

Management monitoring environments
Provide both performance management and performance reporting, including performance management for buffer pools.

Report-only monitoring environments
Can only be used for performance reporting.

Buffer pool management only environments
If you do not use management monitoring environments, buffer pool management only environments can be used to report buffer pool delays to manage buffer pools with enclaves. If used for buffer pool management, they can also be used to report other delays for performance reporting.

Optionally with this macro, you can use the REPORTONLY=YES parameter to specify that the monitoring environment will be used for reporting purposes only.

Optionally with this macro, you can use the BPMGMTONLY=YES parameter to specify that the monitoring environment will be used together with enclaves for buffer pool management.

Note: This service was previously called IWMMCREA for 31-bit addressing only (see “IWMMCREA — Create delay monitoring environment” on page 922).

Environment
The requirements for the caller are:

- **Minimum authorization:** Supervisor state or program key mask (PKM) allowing keys 0-7.
- **Dispatchable unit mode:** Task
- **Cross memory mode:** Non-XMEM or XMEM. Any P.S.H.
- **AMODE:** 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
- **ASC mode:** Primary
- **Interrupt status:** Enabled for I/O and external interrupts No (EUT) FRR established.
- **Locks:** No locks may be held.
- **Control parameters:** Control parameters must be in the primary address space.

Programming requirements
1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

5. All character data, unless otherwise specified, is assumed to be left justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information

Before issuing the IWM4MCRE macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.
Syntax

main diagram

parameters-1

parameters-2
Parameters

The parameters are explained as follows:

*name*

An optional symbol, starting in column 1, that is the name on the IWM4MCRE macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,*ALLOCATEBELOW=NO*

*ALLOCATEBELOW=YES*

When MONTKN64=montkn64 and REQTYPE=SINGLE are specified, an optional parameter, which indicates whether the virtual storage for the delay monitoring environment is to be obtained below 2 gigabytes. This is especially helpful for callers with 31-bit dependencies. The default is ALLOCATEBELOW=NO.

,*ALLOCATEBELOW=NO*

indicates that the delay monitoring environment is to be located as 64-bit virtual storage.

,*ALLOCATEBELOW=YES*

indicates that the virtual storage is to be located below 2 gigabytes.

,*ALLOCATEBELOW=NO*

,*ALLOCATEBELOW=YES*

When MONTKN64_LIST=montkn64_list and REQTYPE=MULTIPLE are specified, an optional parameter, which indicates whether the virtual storage for the delay monitoring environment is to be obtained below 2 gigabytes. This is especially helpful for callers with 31-bit dependencies. The default is ALLOCATEBELOW=NO.

,*ALLOCATEBELOW=NO*

indicates that the delay monitoring environment is to be located as 64-bit virtual storage.

,*ALLOCATEBELOW=YES*

indicates that the virtual storage is to be located below 2 gigabytes.

,*AMOUNT=amount*

When REQTYPE=MULTIPLE is specified, a required input parameter, which specifies the number of delay monitoring environments to be created.

While there is no restriction on the number of delay monitoring environments to be created, caller should only create the minimum number of delay monitoring environments that are needed.

If there are too many unused delay monitoring environments existing in the system, the storage and CPU overheads may be significant.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

,*BPMGMTONLY=NO*
When REPORTONLY=NO is specified, an optional parameter, which indicates whether the monitoring environment is used together with enclaves to manage buffer pools (YES) or (NO). The default is BPMGMTONLY=NO.

BPMGMTONLY=YES
When REPORTONLY=NO is specified, an optional parameter, which indicates whether the monitoring environment is used together with enclaves to manage buffer pools (YES) or (NO). The default is BPMGMTONLY=NO.

BPMGMTONLY=NO
indicates that the monitoring environment is not used together with enclaves to manage buffer pools.

BPMGMTONLY=YES
indicates that the monitoring environment is used together with enclaves to manage buffer pools.

CONNTKN=
When SUBSYSP=CONNECT is specified, a required input parameter, which contains the connect token associated with the subsystem.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

EWLM=NO

EWLM=YES
When SUBSYSP=VALUE is specified, an optional parameter, which indicates if the created monitoring environment is intended to participate in Enterprise Workload Management (EWLM). The default is EWLM=NO.

EWLM=NO
The monitoring environment can not be used to report on ARM work requests.

EWLM=YES
The monitoring environment participates in cross platform Enterprise Workload Management and interacts with EWLM. An ARM application instance will be registered and started using the passed subsystem type (SUBSYS), subsystem name (SUBSYSNM), and the new parameter group name (GROUPNM, GROUPNM_LEN) - an already existing ARM registration for the same address space with identical SUBSYS, SUBSYSNM, GROUPNM and GROUPNM_LEN parameters will be reused. All ARM work requests associated with the created monitoring environment are reported for this ARM application instance.

GROUPNM=
groupnm

GROUPNM=NO

GROUPNM=groupnm
When EWLM=YES and SUBSYSP=VALUE are specified, an optional input parameter, which contains the name of an application group, i.e. a group of similar or cooperating subsystem instances. A group name can be up to 255 characters long. Provision of a data area initialized to all blanks is equivalent to specification of NO_GROUPNM. The default is NO_GROUPNM. indicates that no group name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

GROUPNM_LEN=
groupnm_len
When GROUPNM=groupnm, EWLM=YES and SUBSYSP=VALUE are specified, a required input parameter, which contains the length of the group name. A group name can be up to 255 characters long.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.
When REQTYPE=MULTIPLE is specified, a required input parameter which specifies the length (in bytes) of the area identified by the MONTKN_LIST / MONTKN64_LIST keyword.

Size of this area must be at least the size of one monitoring token (see MONTKN / MONTKN64 keyword) times AMOUNT. If the user specified area is not large enough to return the delay monitoring tokens, a specific return/reason code will be returned and the request will not be processed.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

\[\text{list addr}\]

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\[\text{attr}\]

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code \textit{attr}, the system provides a value of 0D.

\[\text{COMPLETE}\]

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\[\text{MONTKN}=\text{montkn}\]

When REQTYPE=SINGLE is specified, a required output parameter which will receive the delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\[\text{MONTKN_LIST}=\text{montkn_list}\]

When REQTYPE=MULTIPLE is specified, a required input parameter which specifies an area into which a list of delay monitoring tokens will be placed. A single MONTKN has a size of 4 byte.
To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,MONTKN_LISTLEN=montkn_listlen
When REQTYPE=MULTIPLE is specified, a required input parameter
Still supported, but use LISTLEN instead

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

,MONTKNKEY=montknkey
When MONTKNKEYP=VALUE is specified, a required input parameter, which contains the key in which the delay monitoring environment will be invoked subsequently when using the output MONTKN / MONTKN64. The low order 4 bits (bits 4-7) contain the key value. The high order 4 bits (bits 0-3) must be 0.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8 bit field.

,MONTKNKEYP=VALUE
,MONTKNKEYP=PSWKEY
A required parameter, which describes how the input key for the monitoring environment should be obtained.

,MONTKNKEYP=VALUE
indicates that the key is being passed explicitly via MONTKNKEY.

,MONTKNKEYP=PSWKEY
indicates that the current PSW key should be used.

,MONTKN64=montkn64
When REQTYPE=SINGLE is specified, a required output parameter which will receive the long delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

,MONTKN64_LIST=montkn64_list
When REQTYPE=MULTIPLE is specified, a required input parameter which specifies an area into which a list of long delay monitoring tokens will be placed. A single MONTKN64 has a size of 8 byte.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
,PLISTVER=1
,PLISTVER=2
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
IWM4MCRE

- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- 0, which supports all parameters except those specifically referenced in higher versions.
- 1, which supports both the following parameters and those from version 0:
  
  BPMGMTONLY GROUPNM
  EWLM GROUPNM_LEN

- 2, which supports both the following parameters and those from version 0 and 1:
  
  ALLOCATEBELOW LISTLEN MONTKN64_LIST
  MONTKN64

  To code: Specify one of the following:
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0, 1, or 2

,REPORTONLY=NO,REPORTONLY=YES
  An optional parameter, which indicates whether the monitoring environment is for reporting purposes only (YES) or (NO). The default is REPORTONLY=NO.

,REPORTONLY=NO
  indicates that the monitoring environment is for management and reporting purposes.

,REPORTONLY=YES
  indicates that the monitoring environment is for reporting purposes only.

REQTYPE=SINGLE
REQTYPE=MULTIPLE
  An optional parameter that indicates whether the request is to create a single delay monitoring environment or to create multiple delay monitoring environments. The default is REQTYPE=SINGLE.

REQTYPE=SINGLE
  The request is to create a single delay monitoring environment.

REQTYPE=MULTIPLE
  The request is to create a number of delay monitoring environments.
,RETCODE=retcode
   An optional output parameter into which the return code is to be copied from
   GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without
   parentheses), the value will be left in GPR 15.

   To code: Specify the RS-type address of a fullword field, or register (2)-(12) or
   (15), (GPR15), (REG15), or (R15).

,RSNCODE=rsncode
   An optional output parameter into which the reason code is to be copied from
   GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or
   without parentheses), the value will be left in GPR 0.

   To code: Specify the RS-type address of a fullword field, or register (0) or
   (2)-(12), (00), (GPR0), (GPR00), REG0), (REG00), or (R0).

,SUBSYS=subsys
   When SUBSYSP=VALUE is specified, a required input parameter, which
   contains the generic subsystem type (e.g. IMS, CICS, etc.).

   To code: Specify the RS-type address, or address in register (2)-(12), of a
   4-character field.

,SUBSYSNM=subsysnm
   When SUBSYSP=VALUE is specified, a required input parameter, which
   contains the subsystem name.

   To code: Specify the RS-type address, or address in register (2)-(12), of an
   8-character field.

,SUBSYSP=CONNECT
,SUBSYSP=VALUE
   A required parameter, which describes how the calling subsystem is providing
   identification.

   ,SUBSYSP=CONNECT
      indicates that the connect token is being passed.

   ,SUBSYSP=VALUE
      indicates that the subsystem name is being passed directly.

ABEND codes

None.

Return codes and reason codes

When the IWM4MCRE macro returns control to your program:
• GPR 15 (and retcode, when you code RETCODE) contains a return code.
• When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code
   RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the
   equate symbol associated with each reason code. IBM support personnel may
   request the entire reason code, including the xxxx value.
### Table 76. Return and Reason Codes for the IWM4MCRE Macro

### Examples

None.
IWM4MDEL — Delete delay monitoring environment

The purpose of this service is to delete a delay monitoring environment, so that MVS state sampling will no longer monitor for new work requests to be associated with the input monitoring token.

The delete macro is provided in list, execute, and standard form. The list form accepts no variable parameters and is used only to reserve space for the parameter list. The standard form is provided for use with routines which do not require reentrant code. The execute form is provided for use with the list format for reentrant routines. The delete macro is provided in PL/AS and assembler formats.

The parameter list must be in the caller’s primary address space.

Note: This service was previously called IWMMDELE for 31-bit addressing only (see “IWMMDELE — Delete the monitoring environment” on page 932).

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state or program key mask (PKM) allowing keys 0-7.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: Unlocked, but FRRs are allowed.
Control parameters: Control parameters must be in the primary address space.

Programming requirements

None.

Restrictions

1. This macro may not be used prior to the completion of WLM address space initialization
2. If the key specified on IWM4MCRE was a user key (8-F), then the following must ALL be true:
   • Caller must be in non-cross-memory mode (P=S=H). This implies that the current primary must match the primary at the time that IWM4MCRE was invoked. Running in a subspace is not supported.
   • Must be in TCB mode (not SRB).
   • Current TCB must match the TCB at the time that IWM4MCRE was invoked.
3. The caller must serialize to prevent any delay monitoring services from being invoked concurrently or subsequently for the environment represented by the monitoring token
4. This service should not be invoked while in a RTM termination routine (resource manager) for the TCB owning the monitoring environment since MVS
IWM4MDEL

will have its own resource cleanup routine and unpredictable results would occur. It is legitimate to use this service while in a recovery routine, however, or in mainline processing.

5. This macro may only be used on z/OS V2R1 or higher.

Input register information

Before issuing the IWM4MDEL macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>15</td>
<td>Return code'</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>15</td>
<td>Used as a work register by the macro'</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after using a service. If the system changes the contents of registers on which the caller depends, the caller must save them before calling the service, and restore them after the system returns control.

Performance implications

None.

Syntax

main diagram

```
IWM4MDEL

name:Montkn:Montkn64:Retcode
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4MDEL macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

\[MF=S\]
\[MF=(L, list addr)\]
\[MF=(L, list addr, attr)\]
\[MF=(L, list addr, OD)\]
\[MF=(E, list addr)\]
\[MF=(E, list addr, COMPLETE)\]
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.
MONTKN=montkn
A required input parameter which contains the delay monitoring token for the environment to be deleted.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

MONTKN64=montkn64
A required input parameter which contains the long delay monitoring token for the environment to be deleted.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form.

When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 0, if you use the currently available parameters.

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).
ABEND codes

None.

Return codes and reason codes

When the IWM4MDEL macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Meaning and Action</th>
</tr>
</thead>
</table>
| 0           | —           | Equate symbol: IwmRetCodeOk
|             |             | Meaning: Successful completion. |
| 4           | —           | Equate symbol: IwmRetCodeWarning
|             |             | Meaning: Successful completion, unusual conditions noted. |
| 4           | xxxx0402    | Equate symbol: IwmRsnCodeNoMonEnv
|             |             | Meaning: Input monitoring token indicates no monitoring environment was established. |
| 4           | xxxx0403    | Equate symbol: IwmRsnCodeMonEnvNotAlloc
|             |             | Meaning: Input monitoring token does not reflect an allocated monitoring environment owned by the current home address space. |
| 8           | —           | Equate symbol: IwmRetCodeInvocError
|             |             | Meaning: Invalid invocation environment or parameters. |
| 8           | xxxx0802    | Equate symbol: IwmRsnCodeXmemUserKeyTkn
|             |             | Meaning: Caller is in cross-memory mode while the token was obtained in user key. |
| 8           | xxxx0803    | Equate symbol: IwmRsnCodeDisabled
|             |             | Meaning: Caller is disabled. |
| 8           | xxxx0804    | Equate symbol: IwmRsnCodeLocked
|             |             | Meaning: Caller is locked. |
| 8           | xxxx0805    | Equate symbol: IwmRsnCodeMonEnvSwitchCont
|             |             | Meaning: Input monitor token reflects a switch continuation. |
| 8           | xxxx0806    | Equate symbol: IwmRsnCodeMonEnvParent
|             |             | Meaning: Input monitoring token reflects a continuation to a dependent monitoring environment. |
| 8           | xxxx0808    | Equate symbol: IwmRsnCodeMonEnvDepCont
|             |             | Meaning: Input monitoring token reflects a continuation from a parent monitoring environment. |
Table 77. Return and Reason Codes for the IWM4MDEL Macro (continued)

<table>
<thead>
<tr>

**Meaning:** Caller invoked service but was not DAT on Primary ASC mode. |
| 8           | xxxx0826    | **Equate symbol:** IwmRsnCodeTaskTerm  
**Meaning:** Caller invoked service while task termination is in progress for the TCB associated with the owner. |
| 8           | xxxx0827    | **Equate symbol:** IwmRsnCodeRsvdNot0  
**Meaning:** Reserved field in parameter list was non-zero. |
| 8           | xxxx0828    | **Equate symbol:** IwmRsnCodeBadVersion  
**Meaning:** Version number in parameter list is not valid. |
| 8           | xxxx082A    | **Equate symbol:** IwmRsnCodeMonEnvRelated  
**Meaning:** Input monitor token is related to a parent monitoring environment. |
| 10          | —           | **Equate symbol:** IwmRetCodeCompError  
**Meaning:** Component error. |

**Examples**

None.
IWM4MDRG — Deregister a resource from monitoring

The purpose of the IWM4MDRG service is to deregister a resource from monitoring which was previously registered via IWM4MREG. The service allows the caller to identify a resource which is no longer involved in delays to work requests. Thus, the system may no longer alter the size of the resource to balance associated delays.

The system implicitly deregisters a resource due to repetitive errors in calling exits associated with the resource. In this case, the invocation to deregister finds that the associated resource token is invalid and returns with a warning return code. The same return code will be returned in all cases where the resource token is invalid.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state or program key mask (PKM) allowing keys 0-7. |
| Dispatchable unit mode: | Task |
| Cross memory mode: | PASN=HASN=SASN. The current HASN must match the HASN at the time that IWM4MREG was used to register the resource. |
| AMODE: | 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro. |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
4. All character data input is assumed to be left-justified and padded with blanks on the right, as needed, to fill in the specified number of bytes.

Restrictions

1. NO FRRs may be established.
2. This service should not be invoked from an address space resource manager, because those are dispatched from master's address space which will not match the space which invoked the registration service. The system will take care of the resources associated with registration when the owning address space terminates.
Input register information

Before issuing the IWM4MDRG macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWM4MDRG macro is as follows:

```
name(IWM4MDRG) RESOURCE_TKN=resource_tkn,RETCODE=retcode

,PLISTVER=IMPLIED_VERSION  
,RSNCOE=rsncode
,PLISTVER=MAX
,PLISTVER=8
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4MDRG macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

\texttt{MF=S}
\texttt{MF=(L,\textit{list addr})}
\texttt{MF=(L,\textit{list addr},\textit{attr})}
\texttt{MF=(L,\textit{list addr},0D)}
\texttt{MF=(E,\textit{list addr})}
\texttt{MF=(E,\textit{list addr},\texttt{COMPLETE})}

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\texttt{list addr}
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\texttt{attr}
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code \textit{attr}, the system provides a value of 0D.

\texttt{COMPLETE}
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\texttt{PLISTVER=IMPLIED VERSION}
\texttt{PLISTVER=MAX}
\texttt{PLISTVER=0}
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

  To code: Specify one of the following:
  
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0

**RESOURCE_TKN=resource_tkn**

A required input parameter, which contains the associated WLM resource token which is returned by the resource monitoring registration service (IWM4MREG).

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**RETCODE=retcode**

An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

**RSNCODE=rsncode**

An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4MDRG macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.
### Table 78. Return and Reason Codes for the IWM4MDRG Macro

<td>Action: Avoid requesting this function in this environment.</td>
</tr>
</tbody>
</table>
### Example

To deregister a resource from monitoring, specify the following:

```plaintext
IWM4MDRG RESOURCE_TKN=RSCTOKEN, X
    RETCODE=RC, RSN=RSN
*
* Storage areas
*
RSCTOKEN DS CL8 WLM resource token
RC    DS F    Return code
RSN   DS F    Reason code
```
IWM4MGDD — Define descriptions for generic delay states

Using this service, a subsystem can define descriptions for its generic delay states. The term generic delay states in this context is related to service IWM4MCHS. It means the case when STATE=WAITING is specified and the resource that is specified is RESOURCE=TYPEx, where x is a number between 1 and 15.

With this service, descriptions can be defined that might be more intuitive to a human reader than the generic terms. If defined, these descriptions will be accessible to performance monitors in the IWMWRCAA data area as a result of a call to the IWMRCOLL service.

Note, that for a subsystem that allows multiple instances (address spaces) to be active on the same z/OS system, only one set of descriptions can be in effect. If more than one instance of such subsystem defines a set of definitions, the last one defined will be effective.

For a subsystem that allows the customer to run multiple instances at possibly different release levels on the same system, it might be helpful if each instance first checks whether there are already some descriptions defined for that subsystem, before the instance decides whether to define its own descriptions.

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state or program key mask (PKM) allowing keys 0-7.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code SYSSSTATE AMODE64=YES before invoking this macro.
ASC mode: Primary or access register (AR)
Interrupt status: Enabled for I/O and external interrupts
Locks: No locks may be held.
Control parameters: Control parameters must be in the primary address space or, for AR-mode callers, must be in an address/data space that is addressable through a public entry on the caller's dispatchable unit access list (DU-AL).

Programming requirements
1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

None.

Input register information

Before issuing the IWM4MGDD macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

main diagram

```
#define IWM4MGDD
.REQTYPE=DEFINE,DESCRIPTIONS=descriptions
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the
IWM4MGDD macro invocation. The name must conform to the rules for an
ordinary assembler language symbol.

DESCRIPTIONS=descriptions
A required input parameter,
For REQTYPE=DEFINE, the address specifies the input area to the request that
contains descriptions for generic delay states to be defined for a particular
subsystem. The layout of the data area must adhere to the mapping defined by
macro IWMWGDD.

Note: With one DEFINE request, a subsystem defines a set of descriptions for
the generic delay states it uses. A subsequent DEFINE request will override the
currently existing definitions. If IWMGWNUM is set to 0, then the currently
existing definitions are deleted.

Following fields in the data area must be set correctly. For their meaning refer
to the header of macro IWMWGDD directly.
- IWMWGEYE
- IWMWGVER
- IWMWGTYP
- IWMGWNUM
- IWMWGNUM

Following field in the data area must not be set, i.e. it must have a value of
zero. For its meaning refer to the header of macro IWMWGDD directly.
- IWMWGNXT

If any of these fields is not set correctly, the request is terminated with return
code IwmRetCodeInvocError and reason code IwmRsnCodeBadRequestList.
The field in error is identified by setting IWMWGRC appropriately, refer to
macro IWMWGDD for the possible values in IWMWGRC.

For REQTYPE=RETRIEVE, the address specifies the input/output area to the
request. As input to the request the area contains the type of the subsystem for
which the descriptions are to be retrieved. After execution of the request the
area contains the descriptions for generic delay states as they are currently
defined for the input subsystem. The layout of the data area must adhere to
the mapping defined by macro IWMWGDD.
Following fields in the data area must be set correctly. For their meaning refer to the header of macro IWMWGDD directly.

- IWMWGEYE
- IWMWGVER
- IWMWGTYP
- IWMWGNUM

Following field in the data area must not be set
- IWMWGNXT

If any of these fields is not set correctly, the request is terminated with return code IwmRetCodeInvocError and reason code IwmRsnCodeBadRequestList. The field in error is identified by setting IWMWGRC appropriately, refer to macro IWMWGDD for the possible values in IWMWGRC.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

```
, MF=S
, MF=(L, list addr)
, MF=(L, list addr, attr)
, MF=(L, list addr, 0D)
, MF=(E, list addr)
, MF=(E, list addr, COMPLETE)
```

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

```
,list addr
```

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

```
,attr
```

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

```
,COMPLETE
```

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

```
,PLISTVER=IMPLIED VERSION
,PLISTVER=MAX
,PLISTVER=0
```

An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

**REQTYPE=DEFINE**

**REQTYPE=RETRIEVE**

A required parameter that indicates whether the request is to define or to retrieve generic delay state descriptions.

**REQTYPE=DEFINE**

The request is to define the generic delay state descriptions for a particular subsystem.

**REQTYPE=RETRIEVE**

The request is to retrieve the generic delay state descriptions of a particular subsystem.

**RETCODE=retcode**

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

**RSNCODE=rsncode**

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

**ABEND codes**

None.
### IWM4MGDD

**Return codes and reason codes**

When the IWM4MGDD macro returns control to your program:
- GPR 15 (and `retcode`, when you code `RETCODE`) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and `rsncode`, when you code `RSNCODE`) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the `xxxx` value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

**Example**

None.
**IWM4MINI — Monitoring environment initialization**

IWM4MINI allows the caller to supply MVS with some or all of the work request attributes needed for the monitoring environment. The attributes include user ID, transaction name, transaction class, source LU, and LU 6.2 token.

There are three types of monitoring environments available: management monitoring environments, report-only monitoring environments, and buffer pool management only environments. Management monitoring environments provide both performance management and performance reporting. Report-only monitoring environments can be used for performance reporting only. Buffer pool management only environments provide only buffer pool performance management for enclaves.

Use the REPORTONLY=YES parameter to specify the monitoring environment will be used for reporting purposes only.

If you invoke IWM4MINI with the REPORTONLY=YES parameter, you must specify ASSOCIATE=ENCLAVE or ASSOCIATE=ADDRESS_SPACE to associate the monitoring environment with an enclave or an address space.

Use the BPMGMTONLY=YES parameter to specify the monitoring environment will be used for buffer pool management for enclaves only.

If you invoke IWM4MINI with the BPMGMTONLY=YES parameter, you must specify ASSOCIATE=ENCLAVE to associate the monitoring environment with an enclave.

For management monitoring environments, where possible, you should invoke IWM4MINI immediately following IWMCLSFY, and pass the service class for the work request. Without the associated service class in the monitoring environment, delay information cannot be accumulated and reported accurately.

IWM4MINI can be issued multiple times for the same work request. The first time you invoke IWM4MINI for a work request, you must specify MODE=RESET, otherwise the previous work request's attributes are associated with this work request. Any subsequent time you invoke IWM4MINI from the same address space for the same monitoring token for the same work request, specify MODE=RETAIN. If the caller subsystem work manager consists of multiple address spaces (with multiple monitoring tokens), the first time IWM4MINI is invoked in each address space for a given work request must specify MODE=RESET. Any subsequent invocations for the same work request should specify MODE=RETAIN.

If you are invoking IWM4MINI for a management monitoring environment, multiple times for the same work request, only one of the invocations should specify EXSTARTTIME=exstarttime. It is up to you to decide at which point in the subsystem work manager's processing you consider the real execution start time.

Optionally with this macro, you can use the OWNER_TOKEN and OWNER_DATA parameters to specify a token for the user/owner of the monitoring environment for your own use.

Optionally with this macro, you can use the FROM_SUBSYSNM parameter to specify the subsystem name from where a request came in. This allows you to identify an address space as work provider or consumer.
Note: This service was previously called IWMMINIT for 31-bit addressing only (see “IWMMINIT — Initialize monitoring environment” on page 943).

Environment

The requirements for the caller are:

Minimum authorization: Either problem state or supervisor state. PSW key must
either be 0 or match the value supplied on IWM4MCRE.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN If the key specified on
IWM4MCRE was a user key (8-F), then primary
addressability must be the same as when IWM4MCRE was
invoked.
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE
AMODE64=YES before invoking this macro.
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: Locked or unlocked
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by
IWMYCON.
3. Note that the high order halfword of 31-Bit register 0, and the reason code
variable when specified, may be non-zero and represents diagnostic data which
is NOT part of the external interface. The high order halfword should thus be
excluded from comparison with the reason code values described above. The
constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used
for this purpose.
4. For ASSEMBLER programmers an Assembler that supports the new
z/Architecture instructions and the relative Branch (Jxx) instructions (such as
High-Level Assembler Release 4 or higher) is required.

Restrictions

1. All parameter areas must reside in current primary, except that the TCB (if
specified) must reside in current home.
2. Caller is responsible for error recovery.
3. Only limited checking is done against the input monitoring token.
4. If the key specified on IWM4MCRE was a user key (8-F), then the primary
addressability must exist to the performance block IWM4MCRE obtained. This
condition is satisfied by ensuring that current primary matches primary at the
time that IWM4MCRE was invoked. If this service is invoked in a subspace, the
condition may be satisfied by ensuring that the performance block is shared
with the base space.
5. The caller must serialize to prevent any delay monitoring services from being
invoked concurrently for the environment represented by the monitoring token.
6. This macro may only be used on z/OS V1R13 or later levels for FROM_SUBSYSNM
keyword.
7. This macro may only be used on z/OS V2R1 or later levels for the MONTKN64
keyword.
8. This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information

Before issuing the IWM4MINI macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

IWM4MINI

parameters-1

parameters-2
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4MINI macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ARRIVALTIME=arrivaltime
When ARRIVALTIMEP=YES and MODE=RESET are specified, a required input parameter, which contains the work arrival time in STCK format.
To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

,ARRIVALTIMEP=CURRENT
,ARRIVALTIMEP=YES
When MODE=RESET is specified, a required parameter, which indicates whether the work arrival time is passed. This keyword is not applicable for report-only or bufferpool-only monitoring environments.

,ARRIVALTIMEP=CURRENT
indicates that the current time should be supplied by the service.

,ARRIVALTIMEP=YES
indicates that the work arrival time is passed.

,ASID=asid
When ASSOCIATE=ADDRESS_SPACE and REPORTONLY=YES are specified, a required input parameter, which contains the address space ID.
To code: Specify the RS-type address, or address in register (2)-(12), of a 16 bit field.

,ASSOCIATE=ENCLAVE
When BPMGMTONLY=YES and REPORTONLY=NO are specified, a required parameter, which indicates whether the monitoring environment should be associated only to an enclave

,ASSOCIATE=ENCLAVE
indicates that the monitoring environment should be associated to an enclave.

,ASSOCIATE=ENCLAVE
,ASSOCIATE=ADDRESS_SPACE
When REPORTONLY=YES is specified, a required parameter, which indicates whether the monitoring environment should be associated to an enclave or an address space.

,ASSOCIATE=ENCLAVE
indicates that the monitoring environment should be associated to an enclave.

,ASSOCIATE=ADDRESS_SPACE
indicates that the monitoring environment should be associated to an address space.
When REPORTONLY=NO is specified, an optional parameter, which indicates whether the monitoring environment is for bufferpool management purposes only (YES) or not (NO). The default is BPMGMTONLY=NO.

BPMGMTONLY=NO indicates that the monitoring environment is not for bufferpool management purposes only.

BPMGMTONLY=YES indicates that the monitoring environment is for bufferpool management purposes only.

CONTINUEP=YES, CONTINUEP=NO
A required parameter, which indicates whether it is known (YES) or not (NO) that there exists another monitoring environment for this same work request.

CONTINUEP=YES indicates that the existence of a prior monitoring environment for the work request is known.

CONTINUEP=NO indicates that it is not known whether there exists a prior monitoring environment for the work request. If MODE(RESET) is specified, no status is saved. If MODE(RETAIN) is specified, the existing status is preserved.

DISPTYPE=TCB, DISPTYPE=SRB
When MODE=RESET is specified, a required parameter, which describes the nature of the MVS dispatchable units which participate in processing work requests associated with the delay monitoring environment established by this service.

DISPTYPE=TCB indicates that work requests run in TCB mode under a TCB within the current home address space. Note that in cross-memory mode, this may be different from the current primary address space.

DISPTYPE=SRB indicates that work requests run in SRB mode within the current home address space.

DISPTYPE=SAVEDTYPE
When MODE=RETAIN is specified, a required parameter, which describes the nature of the MVS dispatchable units which participate in processing work requests associated with the delay monitoring environment established by this service.

DISPTYPE=SAVEDTYPE indicates that the information saved when MODE(RESET) was used is still applicable.

DISPTYPE=TCB
indicates that work requests run in TCB mode under a TCB within the current home address space. Note that in cross-memory mode, this may be different from the current primary address space.

,DISPTYPE=SRB
indicates that work requests run in SRB mode within the current home address space.

,DURATION=EXECUTION
,DURATION=BEGIN_TO_END
When MODE=RESET is specified, an optional parameter, which indicates the duration of the work request over which the delays are to be represented. The default is DURATION=EXECUTION.

,DURATION=EXECUTION
indicates that the monitoring environment will reflect delays from the point where an application or transaction program is given control, i.e. the execution phase. Typically a monitoring environment with this scope would be passed to IWM4MNTF to pass the execution time for the work request.

,DURATION=BEGIN_TO_END
indicates that the monitoring environment will reflect delays from the arrival of the work request into the MVS sysplex until its completion. Ordinarily use of this option would be in close proximity to the time when the work request is classified. Typically a monitoring environment with this duration would be passed to Iwmrpt to report the total elapsed time for the work request.

,DURATION=PREV_VALUE
,DURATION=EXECUTION
,DURATION=BEGIN_TO_END
When MODE=RETAIN is specified, an optional parameter, which indicates the duration of the work request over which the delays are to be represented. The default is DURATION=PREV_VALUE.

,DURATION=PREV_VALUE
indicates that the duration for delays has been specified on a previous invocation.

,DURATION=EXECUTION
indicates that the monitoring environment will reflect delays from the point where an application or transaction program is given control, i.e. the execution phase. Typically a monitoring environment with this duration would be passed to IWM4MNTF to pass the execution time for the work request.

,DURATION=BEGIN_TO_END
indicates that the monitoring environment will reflect delays from the arrival of the work request into the MVS syplex until its completion. Ordinarily use of this option would be in close proximity to the time when the work request is classified. Typically a monitoring environment with this duration would be passed to Iwmrpt to report the total elapsed time for the work request.

,ENCLAVETOKEN=enclavetoken
When ASSOCIATE=ENCLAVE, BPMGMTONLY=YES and REPORTONLY=NO are specified, a required input parameter, which contains the enclave token.
To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

,ENCLAVETOKEN=enclavetoken

When ASSOCIATE=ENCLAVE and REPORTONLY=YES are specified, a required input parameter, which contains the enclave token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

EWLM=NO

An optional parameter, which indicates if this work manager intends to participate in cross platform Enterprise Workload Management (eWLM). The default is EWLM=NO.

EWLM=NO

The work manager interacts only with WLM and no interaction with eWLM takes place.

,EWLM_PACORR=ewlm_pacorr

,EWLM_PACORR=NO_EWLM_PACORR

When MODE=RESET is specified, an optional input parameter, which contains the cross platform Enterprise Workload Management (EWLM) parent correlator associated with the work request.

Note:

• If EWLM_PACORR is specified and the correlator does not contain a valid ARM correlator, reason code IwmRsnCodeInvalidEWLMCorr is returned to the caller. Refer to Table 80 on page 604 for further information. If the correlator is a valid ARM correlator, but cannot be understood by EWLM (no EWLM format), it is silently ignored.

• Parameters EWLM_PACORR and EWLM_PACTKN are mutually exclusive.

The default is NO_EWLM_PACORR. indicates that no EWLM parent correlator is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,EWLM_PACTKN=ewlm_pactkn

,EWLM_PACTKN=NO_EWLM_PACTKN

When MODE=RESET is specified, an optional input parameter, which contains the cross platform Enterprise Workload Management (EWLM) parent correlator token associated with the work request. If EWLM_PACTKN is specified and the correlator token does not contain a valid correlator token, reason code IwmRsnCodeInvalidEWLMCorr is returned to the caller (see Return Codes section). The default is NO_EWLM_PACTKN. indicates that no EWLM correlator token is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,EXSTARTTIME=exstarttime

When EXSTARTTIME=YES, BPMGMTONLY=NO and REPORTONLY=NO are specified, a required input parameter, which contains the start execution time in STCK format.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

,EXSTARTTIME=NO
When BPMGMTONLY=NO and REPORTONLY=NO are specified, a required parameter, which indicates whether the execution start time value is passed.

,EXSTARTTIMEP=NO
indicates that the execution start time value is not passed.

If MODE(RETAIN) is specified, EXSTARTTIMEP(NO) will preserve the existing execution start time, if any.

,EXSTARTTIMEP=CURRENT
indicates that the current time should be supplied by the service.

,EXSTARTTIMEP=YES
indicates that the start execution time value is passed.

,FROM=NONE
,FROM=LOCALMVS
,FROM=SYSPLEX
,FROM=NETWORK
When CONTINUEP=YES is specified, a required parameter.

,FROM=NONE
indicates that there is no other environment.

,FROM=LOCALMVS
indicates that such an environment should exist on the current MVS.

,FROM=SYSPLEX
indicates that such an environment should exist in the current syplex, but is not expected to be on the current MVS image.

,FROM=NETWORK
indicates that such an environment may exist, but is not expected to be in the current syplex.

,FROM_SUBSYSNM=from_subsysnm
,FROM_SUBSYSNM=NO_SUBSYSNM
An optional input parameter, which contains the subsystem name from where the request came in. The default is NO_SUBSYSNM which indicates that no FROM_SUBSYSNM is provided.

If MODE(RETAIN) is specified, NO_SUBSYSNM will preserve the existing FROM_SUBSYSNM, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,LU62TKN=lu62tkn
,LU62TKN=NO_LU62TKN
An optional input parameter, which contains LU 6.2 token for the work request. This is not a SNA term, but it is comprised of the following fields which are defined by SNA for the FMH5.

- Logical Unit of Work Identifier length byte, in binary, which may have the values 0 or 10-26 decimal (inclusive)
- Logical Unit of Work Identifier
  - Length byte for the network qualified LU name, in binary, which may have the values 1-17 decimal (inclusive)
  - Network qualified LU network name (1-17 bytes)
  - Logical Unit of Work Instance Number, in binary (6 bytes)
Logical Unit of Work Sequence Number, in binary (2 bytes)

• Conversation Correlator Field (0 to 9 bytes)
  - Length byte for the Conversation Correlator, in binary, which may have the values 0-8 decimal (inclusive)
  - Conversation Correlator of the sending transaction (1-8 bytes)

The Conversation Correlator Field (which includes its length byte) may be dropped when its length byte is 0. The default is NO_LU62TKN, indicates that no LU 6.2 token was passed.

If MODE(RETAIN) is specified, NO_LU62TKN will preserve the existing LU6.2 token, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,LU62TKN_FMT=LU_NO_CC_27
,LU62TKN_FMT=FULL_LU_NO_CC_27
,LU62TKN_FMT=FULL_LU_0_CC_28
,LU62TKN_FMT=FULL_LU_CC_36
,LU62TKN_FMT=OTHER

When LU62TKN=lu62tkn is specified, a required parameter, which indicates the format/length of the LU 6.2 token.

,LU62TKN_FMT=LU_NO_CC_27
  indicates that a fixed length token of 27 bytes is provided, with no conversation correlator (not even its length byte). The LU name may be 1-17 bytes. Bytes at the end of the token are padded with hexadecimal zeros, if necessary, to form a full 27 bytes.

,LU62TKN_FMT=FULL_LU_NO_CC_27
  indicates that the fully qualified LU name (17 bytes) is used, but no conversation correlator (not even its length byte) is provided. This format is architected to be 27 bytes long.

,LU62TKN_FMT=FULL_LU_0_CC_28
  indicates that the fully qualified LU name (17 bytes) is used, and the conversation correlator length byte is present and has the value 0. This format is architected to be 28 bytes long.

,LU62TKN_FMT=FULL_LU_CC_36
  indicates that the fully qualified LU name (17 bytes) is used, and the conversation correlator is provided with a length of 8 (maximum allowed). This format is architected to be 36 bytes long.

,LU62TKN_FMT=OTHER
  indicates that the format of the LU 6.2 token is different from those specified by the remaining keywords.

,LU62TKN_LEN=lu62tkn_len

When LU62TKN_FMT=OTHER and LU62TKN=lu62tkn are specified, a required input parameter, which contains the length of the LU62 token. Valid values are in the range 1-36 decimal (inclusive).

To code: Specify the RS-type address, or address in register (2)-(12), of a one-byte field.

,MODE=RESET
A required parameter, which indicates how previous attributes established for a monitoring environment should be treated. This does not refer to (or include) attributes established in IWM4MCRE.

,MODE=RESET
indicates that previous attributes should be discarded.

,MODE=RETAIN
indicates that previous attributes should be retained unless explicitly specified.

,MONTKN=montkn
A required input parameter which contains the delay monitoring token.
To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,MONTKN64=montkn64
A required input parameter which contains the long delay monitoring token.
To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

,OWNER_DATA=owner_data
,OWNER_DATA=NO_OWNER_DATA
An optional input parameter, which contains data maintained by the user/owner of the monitoring environment. The format is undefined to MVS.
The default is NO_OWNER_DATA which indicates that no owner data is provided.
If MODE(RETAIN) is specified, NO_OWNER_DATA will preserve the existing owner data, if any.
To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,OWNER_TOKEN=owner_token
,OWNER_TOKEN=NO_OWNER_TOKEN
An optional input parameter, which contains a token maintained by the user/owner of the monitoring environment. The format is undefined to MVS.
The default is NO_OWNER_TOKEN which indicates that no owner token is provided.
If MODE(RETAIN) is specified, NO_OWNER_TOKEN will preserve the existing owner token, if any.
To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
,PLISTVER=1
,PLISTVER=2
An optional input parameter that specifies the version of the macro. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want to indicate the latest version currently possible.
• 0, which supports all parameters except those specifically referenced in higher versions.
• 1, which supports both the following parameters and those from version 0:
  
  BPMGMTONLY    EWLM_PACORR    EWLM_PACTKN

• 2, which supports both the following parameters and those from version 0 and 1:
  
  FROM_SUBSYSNM    MONTKN64

To code: Specify one of the following:
  • IMPLIED_VERSION
  • MAX
  • A decimal value of 0, 1, or 2

,REPORTONLY=NO  ,REPORTONLY=YES
An optional parameter, which indicates whether the monitoring environment is for reporting purposes only (YES) or not (NO). The default is REPORTONLY=NO.

,REPORTONLY=NO  indicates that the monitoring environment is not for reporting purposes only.

,REPORTONLY=YES  indicates that the monitoring environment is for reporting purposes only.

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0), (REG00), or (R0).

,SCOPE=SHARED    ,SCOPE=SINGLE
A required parameter, which indicates the scope of work passed.

,SCOPE=SHARED    indicates that multiple work requests, possibly from different service classes, could be described.

,SCOPE=SINGLE    indicates that only a single work request is described.

,SERVCLS=servcls
When BPMGMTONLY=NO and REPORTONLY=NO are specified, an optional input parameter, which contains the service class token. The default is NO_SERVCLS. indicates that no service class token was passed.

If MODE(RETAIN) is specified, NO_SERVCLS will preserve the existing service class token, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

An optional input parameter, which contains the LU name associated with the requestor. This may be the fully qualified NETID.LUNAME, i.e. network name (1-8 bytes), followed by a period, followed by the LU name for the requestor (1-8 bytes). It may also be the 1-8 byte local LU name, with no network qualifier. The SOURCELU field may be from 1-17 characters. In the assembler form, the macro will determine the length of the field as follows:

1. if the field is specified by register notation, it will be assumed to be 17 characters (padded with blanks) and a full 17 characters will be copied.
2. if the field is specified using an RS form name, then the length will be determined using the L` assembler function. When the length is less than 17 characters, the macro will pad with blanks. When the length is greater than or equal to 17 characters, the macro will copy the first 17 bytes.

In the PL/AS form, the rules for the PL/AS compiler will determine when to pad with blanks, i.e. less than 17 characters implies padding, 17 or more implies a 17 character copy.

This is intended to be the same value as used in IWMCLSFY, and may be distinct from the LU name contained within the LU 6.2 token. For environments where the LU name may be available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_SOURCELU when MODE(RESET) is specified. Providing an area of all blanks when MODE(RETAIN) is specified will cause that to be used. The default is NO_SOURCELU. indicates that no source LU name was passed.

If MODE(RETAIN) is specified, NO_SOURCELU will preserve the existing source LU name, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

When DISPTYPE=TCB and MODE=RESET are specified, an optional input parameter, which defines the TCB within the current home address space which will serve the work request. Note that this name is not the pointer to the TCB, but the name of the data area containing the TCB. A typical invocation might replace xTCB with TCB.

Ordinarily the input TCB specified should be the TCB under which the work request (e.g. transaction program) runs and under which the delay information is recorded (in spite of the fact that task switches may occur). The default is NO_TCB which indicates that no TCB is currently associated with the monitoring environment for this work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.
When DISPTYPE=TCB and MODE=RETAIN are specified, an optional input parameter, which defines the TCB within the current home address space which will serve the work request. Note that this name is not the pointer to the TCB, but the name of the data area containing the TCB. A typical invocation might replace xTCB with TCB.

Ordinarily the input TCB specified should be the TCB under which the work request (e.g., transaction program) runs and under which the delay information is recorded (in spite of the fact that task switches may occur). The default is NO_TCB which indicates that no TCB is currently associated with the monitoring environment for this work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

An optional input parameter, which contains a class name within a subsystem. For environments where the transaction class is available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_TRXCLASS when MODE(RESET) is specified. Providing an area of all blanks when MODE(RETAIN) is specified will cause that to be used. The default is NO_TRXCLASS. indicates that no class name was passed.

If MODE(RETAIN) is specified, NO_TRXCLASS will preserve the existing transaction class, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

An optional input parameter, which contains the transaction name. For environments where the transaction name is available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_TRXNAME when MODE(RESET) is specified. Providing an area of all blanks when MODE(RETAIN) is specified will cause that to be used. The default is NO_TRXNAME. indicates that no transaction name was passed.

If MODE(RETAIN) is specified, NO_TRXNAME will preserve the existing transaction name, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

An optional input parameter, which contains the transaction trace token. The default is NO_TTRACETOKEN. indicates that no transaction trace token was passed.

If MODE(RETAIN) is specified, NO_TTRACETOKEN will preserve the existing transaction trace token, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.
IWM4MINI

**USERID=NO_USERID**

An optional input parameter, which contains the local userid associated with the work request. For environments where the user id is available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_USERID when MODE(RESET) is specified. Providing an area of all blanks when MODE(RETAIN) is specified will cause that to be used. The default is NO_USERID, indicates that no userid was passed.

If MODE(RETAIN) is specified, NO_USERID will preserve the existing user id, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4MINI macro returns control to your program:

- GPR 15 (and retnode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol and Action</th>
</tr>
</thead>
</table>
| 0           | —           | Equate Symbol: IwmRetCodeOk
|             |             | Meaning: Successful completion. |
| 4           | —           | Equate Symbol: IwmRetCodeWarning
|             |             | Meaning: Successful completion, unusual conditions noted. |
| 4           | xxxx0402    | Equate Symbol: IwmRsnCodeNoMonEnv
|             |             | Meaning: Monitoring token indicates that no monitoring environment exists. |
| 8           | —           | Equate Symbol: IwmRetCodeInvocError: Invalid invocation environment or parameters |
| 8           | xxxx081E    | Equate Symbol: IwmRsnCodeBadLU62TknLen
|             |             | Meaning: The length byte of the LU62 token has an invalid value. Only values 1-36 (decimal) are valid. |
| 8           | xxxx0820    | Equate Symbol: IwmRsnCodeBadMonEnv:
|             |             | Meaning: Monitoring environment does not pass short form verification. |
| 8           | xxxx0894    | Equate Symbol: IwmRsnCodeInvalidEWLMCorr
|             |             | Meaning: Passed correlator information (EWLM_PACORR or EWLM_PACTKN) does not pass validity checking, that means: the architected ARM correlator length field in the first two Bytes of the correlator (token) is either less than 4 ('0004'x) or greater than 512 ('0200'x).
|             |             | Action: Check the specification of the correlator information. |
### Table 80. Return and Reason Codes for the IWM4MINI Macro (continued)

### Example

```plaintext
IWM4MINI MONTKN=(R9),ARRIVALTIMEP=YES,
ARRIVALTIME=(R3),EXSTARTTIMEP=YES,
EXSTARTTIME=(R4),DISPSTATE=TCB,TCB=(R7),
SCOPE=SINGLE,TRXNAME=WLTRXNAME,SOURCELU=SOURCLU,
CONTINUEP=YES,LU62TKN_FMT=OTHER,LU62TKN_LEN=LU62TKNLEN,
LU62TKN=LU62TKN1,MORE=RESET, FROM=NONE,
REPORTONLY=NO,RETCODE=RCODE,RSNCODE=RSN
```
The primary purpose of this service is to notify MVS that the execution phase for a work request that is associated with a monitoring environment just completed. Processor consumption data can also be provided. The execution phase might represent the entire work request or a subset of it.

An indication is also given regarding whether the monitoring environment should be disassociated from the work request. When DISASSOCIATE(YES) is specified, this service renders the information that is associated with the monitoring environment unpredictable. To associate a work request with the monitoring environment after use of DISASSOCIATE(YES), first use Initialize Mode(Reset) or Relate/Transfer.

**Note:** This service was previously called IWMMNTFY for 31 bit addressing only (see "IWMMNTFY — Notify of work execution completion" on page 958).

**Environment**

The requirements for the caller are:

**Minimum authorization:** Supervisor state. PSW key must either be 0 or match the value that is supplied on IWM4CON when a connect token is passed. PSW key must either be 0 or match the value that is supplied on IWM4MCRE. PSW key must be 0-7. See "Restrictions" on page 709.

**Dispatchable unit mode:** Task or SRB

**Cross memory mode:** Any PASN, any HASN, any SASN

**AMODE:** 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.

**ASC mode:** Primary

**Interrupt status:** Enabled for I/O and external interrupts

**Locks:** LOCAL lock is held

**Control parameters:** Control parameters must be in the primary address space.

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. The high-order halfword of register 0, and the reason code variable when specified, might be nonzero and represents diagnostic data that is not part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, can be used for this purpose.

**Restrictions**

1. Caller is responsible for error recovery
2. Though the caller is required to be enabled, this condition is not checked. Violation of this restriction might cause disabled program checks, which would be the responsibility of the caller's recovery to handle.
3. The monitoring environment must contain the information that is saved by IWM4MINI, not IWM4MRLT.

4. The current PSW key must be 0 or match the key that is specified on IWM4MCRE provided the latter is a system key (0-7).

5. IWM4MNTF cannot be used for Report-Only Monitoring Environments.

6. If the key specified on IWM4MCRE was a user key (8-F), then:
   - PSW key must be 0.
   - Current primary must match the primary at the time that IWM4MCRE was invoked. Calling from a subspace is not supported.

7. If a connect token is passed to IWM4MNTF, then:
   - The connect token must be enabled for using the WLM Work Management services (specifying WORK_MANAGER=YES on IWM4CON).
   - If the key specified on IWM4CON was a user key (8-F), then:
     - PSW key must be 0.
     - Current primary must match the primary at the time that IWM4CON was invoked. Calling from a subspace is not supported.

8. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment that is represented by the monitoring token.

9. This macro can be used only on z/OS V2R1 or later.

Input register information

Before issuing the IWM4MNTF macro, the caller must ensure that the following general-purpose registers (GPRs) contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>The address of a 216 byte standard save area in the primary address space</td>
</tr>
</tbody>
</table>

Before issuing the IWM4MNTF macro, the caller does not have to place any information into any AR unless the caller is using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>
IWM4MNTF

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

,PLISTVER=1 ,MF={L=,list addr},COMPLETE
```

Parameters

The parameters are explained as follows:

*name*

An optional symbol, starting in column 1, that is the name on the IWM4MNTF macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

*,COMPLETION=YES*
*,COMPLETION=NO*

A required parameter, which indicates whether the major execution phase or phases are now complete.

*,COMPLETION=YES*

Indicates that execution for an entire phase of processing is now complete. Typically IWM4MNTF Completion(Yes) would be issued as a result of the
completion of the transaction program for the work request. When a work request is composed of several (typically cascaded) transaction programs, each would correspond to an invocation of IWM4MNTF Completion(Yes).

The execution time, as given by the difference between the IWM4MNTF ENDTIME value and the Execution start time (established by the use of IWM4MINI), is added to the running total execution time for the service class. There might still be "output" processing that is left to perform for the work request, which time would be accounted for through the use of Iwmrpt. There might also be operations corresponding to hardening of the database data outside the scope of Notify.

\texttt{,COMPLETION=NO}

Indicates that this invocation of Notify does not correspond to the completion of an entire execution segment. Instead, this invocation of Notify corresponds to the portion of the work request that is represented by the monitoring environment. For example, use Completion(No) when this portion of processing behaves like a subroutine in the execution phase, which is therefore a subset of the execution time passed in another Notify.

The execution time, as given by the difference between the IWM4MNTF ENDTIME value and the Execution start time (established through the use of IWM4MINI), is treated separately from that passed for Completion(Yes), since otherwise there would be double-counting.

\texttt{,CONNTKN=conntkn,CONNTKN=NO_CONNTKN}

An optional input parameter, which is returned by IWM4CON. The default is NO_CONNTKN, which indicates that no connect token is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

\texttt{,CPUTIME=cputime}

An optional input parameter that contains the total CPU time, in STCK format, for the current work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

\texttt{,DISASSOCIATE=NO}

A required parameter, which indicates whether the work request should be disassociated from the monitoring environment or not.

\texttt{,DISASSOCIATE=YES}

Indicates that the work request should be disassociated from the monitoring environment.

\texttt{,DISASSOCIATE=NO}

Indicates that the work request should not be disassociated from the monitoring environment.

\texttt{,ENDTIME=endtime,ENDTIME=CURRENT}

An optional input parameter, which specifies the ending execution time for the transaction in STCK format. The default is CURRENT, which indicates that the current time should be used.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.
An optional parameter, which indicates whether this work manager intends to participate in cross platform Enterprise Workload Management (eWLM). The default is EWLM=NO.

The work manager interacts only with WLM and no interaction with eWLM takes place.

An optional input parameter that specifies the macro form.

*MF=S*
  Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

*MF=L*
  Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter can be coded with the list form of the macro.

*MF=E*
  Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area that is defined by the list form, and generates the macro invocation to transfer control to the service.

*list addr*
  The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

*attr*
  An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code *attr*, the system provides a value of 0D.

*COMPLETE*
  Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

*MONTKN=montkn*
  A required input parameter that contains the delay monitoring token.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

*MONTKN64=montkn64*
  A required input parameter that contains the long delay monitoring token.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.
When CPUTIME is specified, a required input parameter that contains the CPU time on standard CP that was offload eligible, in STCK format, for the current work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

PLISTVER=IMPLIED_VERSION
PLISTVER=MAX
PLISTVER=0
PLISTVER=1

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms that are used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters that are specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 0, which supports all parameters except parameters that are referenced in the description of higher versions.
- 1, which supports the parameters that are supported by 0, and CPUTIME, TIMEONCP, and OFFLOADONCP.

To code: Specify one of the following:
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0 or 1.

RETCODE=retcode

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value is left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

RSNCODE=rsncode

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value is left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

TIMEONCP=timeoncp

When CPUTIME is specified, a required input parameter that contains the CPU time on standard CP, in STCK request format, for the current work.
To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

\texttt{,WORKREQ_STA=workreq_sta}
\texttt{,WORKREQ_STA=IWMEWLMARMSTATUSNONE}

When DISASSOCIATE=YES is specified, an optional input parameter, which contains the completion status code of the work request. Available completion status codes (defined in macro IWMYCON) are:
- IwmEwlmArmStatusGood(0),
- IwmEwlmArmStatusAborted(1),
- IwmEwlmArmStatusFailed(2) or
- IwmEwlmArmStatusUnknown(3)

The codes above correspond to status codes in the OpenGroup ARM 4.0 Standard (for the meaning of the status codes see the ARM 4.0 Standard at http://www.opengroup.org/management/arm). The default is IWMEWLMARMSTATUSNONE, which indicates that the COMPLETION parameter value and internal information in the Monitoring Environment will be examined to determine the status of the work request. If COMPLETION=YES is specified and no abnormal event was recorded for the monitoring environment through the use of the IWM4MABN service, the completion status IwmEwlmArmStatusGood is reported to EWLM. If an abnormal event was reported through the use of IWM4MABN or COMPLETION=NO was specified, the completion status IwmEwlmArmStatusFailed is reported to EWLM.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4MNTF macro returns control to your program:

- GPR 15 (and \texttt{recode}, when you code \texttt{RETCODE}) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and \texttt{rsncode}, when you code \texttt{RSNCODE}) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol that is associated with each reason code. IBM support personnel might request the entire reason code, including the xxxx value.

<table>

| C           | xxxx0C04    | Equate Symbol: IwmRsnCodeNtfyNoWorkElt | **Meaning:** Notify routine invoked, but no work element was available to save the input information.  
**Action:** Invoke the function when the conditions are alleviated. This condition may be due to a common storage shortage condition. |
| C           | xxxx0C06    | Equate Symbol: IwmRsnCodeNoEndTime | **Meaning:** No end time was supplied to the service and STCK gave a nonzero condition code.  
**Action:** No action is required. |

### Example

None.
IWM4MREG — Register a resource for monitoring

The IWM4MREG service registers a resource for delay monitoring. The service allows the caller to identify a resource which may be involved in delays to work requests. The caller's home address space is assumed to be the owner of the resource to be monitored. The system may decide to increase or decrease the size of the resource to balance the associated delays.

The resource to be monitored may require the caller to provide one or more exits to interact with the system. These exits are called in the same system key and non-cross memory environment as the program which registers the resource. The exit always receives control in AMODE31, regardless of the mode in which IWM4MREG was invoked.

The system implicitly deregisters a resource due to repetitive errors in calling exits associated with the resource. In this case, the invocation to deregister finds that the associated resource token is invalid and returns with a warning return code.

The system also cleans up its resources associated with the registration when the address space which owns the resource goes through address space termination. Therefore, no deregistration is required or honored for this case.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th><strong>Minimum authorization:</strong></th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7. The caller's PSW key must be in the range 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dispatchable unit mode:</strong></td>
<td>Task</td>
</tr>
<tr>
<td><strong>Cross-memory mode:</strong></td>
<td>PASN=HASN=SASN</td>
</tr>
<tr>
<td><strong>AMODE:</strong></td>
<td>31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.</td>
</tr>
<tr>
<td><strong>ASC mode:</strong></td>
<td>Primary</td>
</tr>
<tr>
<td><strong>Interrupt status:</strong></td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td><strong>Locks:</strong></td>
<td>No locks may be held.</td>
</tr>
<tr>
<td><strong>Control parameters:</strong></td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is not part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
4. All character data input is assumed to be left-justified and padded with blanks on the right, as needed, to fill in the specified number of bytes.
Restrictions

NO FRRs may be established.

Input register information

Before issuing the IWM4MREG macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWM4MREG macro is as follows:

```
main diagram

name IWM4MREG RESOURCE_NAME=resource_name

 RESOURCE_TYPE=BUFFER_POOL parameters-1 RESOURCE_TKN=resource_tkn
```
Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWM4MREG macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,**MF=S**
,**MF=(L,list addr)**
,**MF=(L,list addr,attr)**
,**MF=(E,list addr,0D)**
,**MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,**list addr**

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,**attr**

An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

\texttt{COMPLETE}

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\texttt{OWNER_TKN=owner_tkn}

When RESOURCE\_TYPE=BUFFER\_POOL is specified, a required input parameter, which contains any data associated with the resource that may be useful later when the resource adjustment exit or the resource data collection exit is called. The format is undefined to MVS.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\texttt{PLISTVER=IMPLIED\_VERSION}

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- \texttt{IMPLIED\_VERSION}, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED\_VERSION is the default.
- \texttt{MAX}, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- 0, if you use the currently available parameters.

To code: Specify one of the following:

- \texttt{IMPLIED\_VERSION}
- \texttt{MAX}
- A decimal value of 0

\texttt{RES\_ADJ\_EXIT@=res\_adj\_exit@}

When RESOURCE\_TYPE=BUFFER\_POOL is specified, a required input parameter that contains the address of the resource adjustment exit to be invoked when the system wishes to rebalance resource usage. This exit is called with the same non cross-memory environment and PSW key as when IWM4MREG is invoked.

To code: Specify the RS-type address, or address in register (2)-(12), of a pointer field.

\texttt{RES\_ADJ\_SIZE=\textit{res}\_adj\_size}

When RESOURCE\_TYPE=BUFFER\_POOL is specified, a required input
parameter, which contains the minimum size (in 4K pages) by which the specified resource can be adjusted. For a bufferpool, this corresponds to a product external or the size of a cell.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,RES_DATA_EXIT=res_data_exit@
When RESOURCE_TYPE=BUFFER_POOL is specified, a required input parameter that contains the address of the resource data collection exit to be invoked when the system checks how physical resources relate to effectiveness of the given resource. This exit is called with the same non cross-memory environment and PSW key as when IWM4MREG is invoked.

To code: Specify the RS-type address, or address in register (2)-(12), of a pointer field.

,RES_MAX_SIZE=res_max_size
When RESOURCE_TYPE=BUFFER_POOL is specified, a required input parameter, which contains the maximum size (in 4K pages) associated with the specified resource.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,RES_MIN_SIZE=res_min_size
When RESOURCE_TYPE=BUFFER_POOL is specified, a required input parameter, which contains the minimum size (in 4K pages) associated with the specified resource.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

RESOURCE_NAME=resource_name
A required input parameter, which contains the resource name associated with the resource to be registered. The value should be padded on the right with blanks for any unused characters.

To code: Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

RESOURCE_TKN=resource_tkn
A required input parameter, which contains the associated WLM resource token which is used, for example, by the change state service (IWMMCHST) and the deregister a resource service (IWM4MDRG).

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,RESOURCE_TYPE=BUFFER_POOL
A required parameter, which indicates the type of resource being registered.

,RESOURCE_TYPE=BUFFER_POOL
indicates that a bufferpool is being registered.

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.
To code: Specify the RS-type address of a fullword field, or register (2)-(12).

ABEND codes

None.

Return codes and reason codes

When the IWM4MREG macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Table 82. Return and Reason Codes for the IWM4MREG Macro

</table>

### Example

To register a resource for delay monitoring, specify the following:

```plaintext
IWM4MREG RESOURCE_NAME=RSCNAME,
RESOURCE_TYPE=BUFFER_POOL,
RES_ADJ_SIZE=RESADJSIZE,
RES_MIN_SIZE=RESMINSIZE,
RES_MAX_SIZE=RESMAXSIZE,
RES_ADJ_EXIT@=ADJEXIT@,
RES_DATA_EXIT@=DATAEXIT@,
OWNER_TKN=OWNERTKN,
X
```
**Storage areas**

- **RSCNAME DS CL16**: Contains the resource name
- **RESADJSIZE DS FL4**: Contains the minimum size by which the specified resource can be adjusted
- **RESMINSIZE DS FL4**: Contains the minimum size associated with the specified resource
- **RESMAXSIZE DS FL4**: Contains the maximum size associated with the specified resource
- **ADJEXIT@ DS AL4**: Contains the address of the Resource Adjustment Exit to be invoked when the system wishes to rebalance resource usage
- **DATAEXIT@ DS AL4**: Contains the address of the Resource Data Collection Exit to be invoked when the system wishes to understand how physical resources relate to effectiveness of the given resource
- **OWNERTKN DS CL8**: Contains data maintained by the user
- **RSCTOKEN DS CL8**: WLM resource token
- **RC DS F**: Return code
- **RSN DS F**: Reason code
IWM4MRLT — Relate monitoring environments (PBs)

The calling subsystem work manager can use IWM4MRLT to relate two different monitoring environments that are associated with the same work request. IWM4MRLT initializes a monitoring environment, called a dependent monitoring environment, and associates it with a previously established monitoring environment, called a parent monitoring environment.

You can use IWM4MRLT when you do not have direct access to the information required by IWM4MINI. If the caller has the monitoring token for a parent environment that is previously established for the same work request, you provide it in the PARENTMONTKN or PARENTMONTKN64 parameter. If the caller does not pass the monitoring token, you can use PARENT=FINDACTIVE to specify that the parent monitoring environment is the active monitoring environment owned by the address space and which is associated with the TCB provided via PARENTTCB.

IWM4MRLT must be used together with IWM4MXFR to ensure that the dependent monitoring environment is a valid representation for the work request.

Optionally with this macro, you can use the OWNER_TOKEN and OWNER_DATA parameters to use the monitoring environment for your own purposes. You can use the token/data to keep your own information.

Note: This service was previously called IWMMRELA for 31-bit addressing only (see “IWMMRELA — Relate monitoring environment service” on page 967).

Environment

The requirements for the caller are:

Minimum authorization: Problem state or supervisor state. PSW key must either be 0 or match the value supplied on IWM4MCRE.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code SYSSSTATE AMODE64=YES before invoking this macro.
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: Unlocked when PARENT=FINDACTIVE is specified, otherwise, no restrictions.
Control parameters: Control parameters must be in the primary address space, except the TCB, if specified, must reside in current home address space.

Programming requirements

1. You must include the IWMYCON mapping macro in the calling program.
2. If the key specified on IWM4MCRE for the input MONTKN / MONTKN64 was a user key (8-F), then the following must be true:
   - If you specify PARENT=F, then:
     - Primary addressability must exist to the performance block IWM4MCRE obtained (represented by the input MONTKN / MONTKN64). You could do this by ensuring that current primary matches primary at the time that
IWM4MRLT was invoked. If this service is invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.

- You cannot specify the list form of this macro. With PARENTP=YES, IWM4MRLT produces an inline expansion rather than an out-of-line service, so you do not need a parameter list. Registers 0, 1, 14, and 15 are not preserved across the expansion.

- If you specify PARENTP=FINDACTIVE, then the caller must be in non-cross-memory mode (PASN=SASN=HASN). That is, the current primary (and home) must match the primary (and home) at the time that IWM4MCRE was invoked.

3. If the key specified on IWM4MCRE for the parent environment was a user key (8-F), then either primary or secondary addressability must exist to the monitoring environment for the parent environment.

4. Both monitoring environments must be established on the same MVS image.

5. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the monitoring environment.

6. When PARENTP=YES, the caller must provide recovery.

Restrictions

This macro may only be used on z/OS V2R1 or later.

Input register information

Before issuing the IWM4MRLT macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

The following general purpose registers (GPRs) have to contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>The address of a 216-byte standard save area in the primary address space.</td>
</tr>
</tbody>
</table>

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>
2-13 Unchanged
14-15 Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications
None.

Syntax

main diagram

Parameters

The parameters are explained as follows:
name
An optional symbol, starting in column 1, that is the name on the IWM4MRLT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,DISPTYPE=TCB
,DISPTYPE=SRB
When FUNCTION=CREATE is specified, a required parameter, which describes the dispatchable units which participate in processing work requests associated with the monitoring environment represented by the monitoring token (MONTKN / MONTKN64).

,DISPTYPE=TCB
indicates that work requests run in TCB mode under a TCB within the current home address space. Note that in cross-memory mode, this may be different from the current primary address space.

,DISPTYPE=SRB
indicates that work requests run in SRB mode within the current home address space.

,EWLM=NO
An optional parameter, which indicates if this work manager intents to participate in cross platform Enterprise Workload Management (eWLM). The default is EWLM=NO.

,EWLM=NO
The work manager interacts only with WLM and no interaction with eWLM takes place.

FUNCTION=CREATE
FUNCTION=DELETE
A required parameter, which indicates whether the relationship is being established or inactivated.

FUNCTION=CREATE
indicates that the relationship is being established.

FUNCTION=DELETE
which indicates that the relationship is being inactivated.

Note that this produces an inline expansion rather than an out-of-line service, so that no parameter list is needed. Thus the MF keyword is not applicable when this option is specified, and is not allowed. Registers 0, 1, 14, and 15 are not preserved across the expansion.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,OD)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\texttt{list addr}

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\texttt{attr}

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

\texttt{COMPLETE}

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\texttt{MONTKN=montkn}

A required input parameter which contains the delay monitoring token for the dependent environment.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\texttt{MONTKN64=montkn64}

A required input parameter which contains the long delay monitoring token for the dependent environment.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

\texttt{OWNER_DATA=owner_data}

\texttt{OWNER_DATA=NO_OWNER_DATA}

When FUNCTION=CREATE is specified, an optional input parameter, which contains data maintained by the user/owner of the monitoring environment. The format is undefined to MVS. The default is NO_OWNER_DATA, which indicates that no owner data is provided.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\texttt{OWNER_TOKEN=owner_token}

\texttt{OWNER_TOKEN=NO_OWNER_TOKEN}

When FUNCTION=CREATE is specified, an optional input parameter, which contains a token maintained by the user/owner of the monitoring environment. The format is undefined to MVS. The default is NO_OWNER_TOKEN, which indicates that no owner token is provided on this service.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\texttt{PARENTENV=NOSWITCH}

\texttt{PARENTENV=SECONDARY}
When **PARENTP**=**YES** and **FUNCTION**=**CREATE** are specified, a required parameter, which describes whether a space switch is needed to access the parent monitoring environment.

**PARENTEVN**=**NOSWITCH**

Indicates that NO space switch is needed to access the parent monitoring environment. This would be appropriate if the parent monitoring environment was established (by IWM4MCRE) to be used by routines in a specific system key or if it was established to be used in a specific user key in the current primary.

**PARENTEVN**=**SECONDARY**

Indicates that the parent monitoring environment was established in current secondary (for use by a specific user key).

**PARENTEVN**=**HOME**

Indicates that the parent monitoring environment was established in current home (for use by a specific user key). Use of this option requires that the program must reside in the MVS common area.

**PARENTMONTKN**=*parentm蒙tkn*

When **PARENTP**=**YES** and **FUNCTION**=**CREATE** are specified, a required input parameter which contains the delay monitoring token for the parent environment, i.e. the monitoring environment which was established earlier and contains the characteristics to be inherited.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

**PARENTMONTKN64**=*parentm蒙tkn64*

When **PARENTP**=**YES** and **FUNCTION**=**CREATE** are specified, a required input parameter which contains the long delay monitoring token for the parent environment, i.e. the monitoring environment which was established earlier and contains the characteristics to be inherited.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

**PARENTP**=**YES**

Indicates that the parent monitoring environment is known.

Note that this produces an inline expansion rather than an out-of-line service, so that no parameter list is needed. Thus the MF keyword is not applicable when this option is specified, and is not allowed. Registers 0, 1, 14, and 15 are not preserved across the expansion.

**PARENTP**=**FINDACTIVE**

Indicates that the parent monitoring environment is unknown, but requests that the input monitoring environment be related to the active monitoring environment owned by the current HOME address space and which is associated with the TCB specified by **PARENTTCB** and which has no further
continuations to other monitoring environments. When no such monitoring environment exists, the input monitoring environment will be related to the current home address space.

,PARENTTCB=parenttcb
When PARENTP=FINDACTIVE and FUNCTION=CREATE are specified, a required input parameter, which defines the TCB owned by the current home address space associated with a monitoring environment via Initialize/Relate Disptype=TCB,TCB=. This TCB need not be the owner of the monitoring environment. Note that this name is not the pointer to the TCB, but the name of the data area containing the TCB. A typical invocation might replace xTCB with TCB.

To code: Specify the RS-type address, or address in register 2)-(12), of a character field.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 0, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register 2)-(12) or (15), (GPR15), (REG15), or (R15).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register 0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).
When DISPTYPE=SRB and FUNCTION=CREATE are specified, a required parameter, which describes whether the dependent monitoring environment associated with MONTKN / MONTKN64 is running under the same dispatchable unit as the parent. In that case, it would behave as a "subroutine" and execute on the same processor (CP, also known as CPU) as the parent environment.

,SAMEDU=YES

Indicates that the work request runs as a subroutine of the parent.

YES may not be specified when PARENT(FINDACTIVE) is coded.

,SAMEDU=NO

Indicates that the work request runs in SRB mode and is independent of the parent dispatchable unit.

,TCB=tcb

When DISPTYPE=TCB and FUNCTION=CREATE are specified, a required input parameter, which defines the TCB within the current home address space which will serve the work request. Note that this name is not the pointer to the TCB, but the name of the data area containing the TCB. A typical invocation might replace xTCB with TCB.

Ordinarily the input TCB specified should be the TCB under which the work request (e.g., transaction program) runs and under which the delay information is recorded (in spite of the fact that task switches may occur).

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

ABEND codes

None.

Return codes and reason codes

When the IWM4MRLT macro returns control to your program:

- GPR 15 (and recode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>

</tr>
</tbody>
</table>

### Example

To relate two monitoring environments where an address space switch is not required, specify:

```plaintext
IWM4MRLT FUNCTION=CREATE,MONTKN64=(R7),PARENT=YES,
PARENTMONTKN64=(R8),PARENTENV=NOSWITCH,
DISPTYPE=SRB,SAMEDU=YES,
RETCODE=RCODE,RSNCODE=RSN
```
IWM4MSTO — Stops a work unit

The purpose of this service is to stop a work unit which has been started by IWM4MSTR. A work unit started by IWM4MINI is not affected by this service. The work unit is unblocked, if it is blocked at the time you issue this macro.

Note: This service was previously called IWMMSTOP for 31-bit addressing only (see “IWMMSTOP — Stop a work unit” on page 976).

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state or program key mask (PKM) allowing keys 0-7.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code $SYSTYPE AMODE64=YES before invoking this macro.
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: No restriction.
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of bits 0-31 of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. This macro may not be used prior to the completion of WLM address space initialization
2. Caller must have issued the IWM4MSTR macro successfully.
3. Caller is responsible for error recovery
4. The current PSW key must be 0 or match the key specified on IWM4MCRE provided the latter is a system key (0-7).
5. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token
6. This macro may only be used on z/OS V2R1 or later.
**IWM4MSTO**

**Input register information**

Before issuing the IWM4MSTO macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

The following general purpose registers (GPRs) have to contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>The address of a 216-byte standard save area in the primary address space.</td>
</tr>
</tbody>
</table>

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if the return code in GPR 15 is not 0, otherwise, used as a work register by the system. The reason code is stored in bits 0-31</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code is stored in bits 0-31</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

`main diagram`

```plaintext
name IWM4MSTO MONTKN=montkn MONTKN64=montkn64 EWLM=NO
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4MSTO macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,AFTER_STRT=NO
,AFTER_STRT=YES
When EWLM_RCVD_CORR=ewlm_rcvd_corr is specified, an optional parameter, which indicates the moment the correlator has been received. The default is AFTER_STRT=NO.

,AFTER_STRT=NO
indicates that the correlator has been received before this work unit has been started by IWM4MSTR.

,AFTER_STRT=YES
indicates that the correlator has arrived within the scope of this work unit that means after issuing IWM4MSTR.

,END_FLOW=NO
,END_FLOW=YES
An optional parameter, which indicates the completion of a message flow. The default is END_FLOW=NO.

,END_FLOW=NO
indicates that a message flow has not completed.

,END_FLOW=YES
indicates that a message flow has completed. Specify END_FLOW=YES, if you know that the running work unit is the last one in a work unit flow. This indication can not be cleared, if it has been set.
An optional parameter, which indicates if this work manager intends to participate in cross platform Enterprise Workload Management (eWLM). The default is EWLM=NO.

The work manager interacts only with WLM and no interaction with eWLM takes place.

An optional input parameter, which contains a cross platform Enterprise Workload Management (EWLM) correlator received from another application. Workflows often have multiple parent work units that must complete before a new work unit can be initiated. You can pass only 1 parent correlator to the IWM4MSTR macro and one additional parent correlator to the IWM4MSTO macro. You have to issue the IWM4MUPD macro, if more than two parent correlators should be assigned to a work unit. This correlator is ignored, if it is an unknown EWLM correlator. The default is NO_EWLM_RCVD_CORR, indicates that parameter EWLM_RCVD_CORR has not been specified.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

An optional input parameter, which contains the number of messages sent to other applications. This value is added to the total messages_sent value of the work unit. The total messages_sent value should not exceed 32767. The default is NO_MESSAGES_SENT, indicates that parameter MESSAGES_SENT has not been specified.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.
LIST ADDR
The name of a storage area to contain the parameters. For MF=S and
MF=E, this can be an RS-type address or an address in register (1)-(12).

ATTR
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code ATTR, the system provides a value of 0D.

COMPLETE
Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

Montkn=montkn
A required input parameter which contains the delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit
field.

Montkn64=montkn64
A required input parameter which contains the long delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit
field.

PLISTVER=IMPLIED_VERSION
PLISTVER=MAX
PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and
with the same value on all of the macro forms. The values are:
• IMPLIED_VERSION, which is the lowest version that allows all parameters
  specified on the request to be processed. If you omit the PLISTVER
  parameter, IMPLIED_VERSION is the default.
• MAX, if you want the parameter list to be the largest size currently possible.
  This size might grow from release to release and affect the amount of
  storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always
  specify PLISTVER=MAX on the list form of the macro. Specifying MAX
  ensures that the list-form parameter list is always long enough to hold all
  the parameters you might specify on the execute form, when both are
  assembled with the same level of the system. In this way, MAX ensures that
  the parameter list does not overwrite nearby storage.
• 0, if you use the currently available parameters.

To code: Specify one of the following:
• IMPLIED_VERSION
• MAX
• A decimal value of 0

RETCODE=retcode
An optional output parameter into which the return code is to be copied from
GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without
parentheses), the value will be left in GPR 15.
IWM4MSTO

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

\[RSNCODE=rsncode\]

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

\[STATUS=status\]

\[STATUS=IWMWLM螳MSTATUSGOOD\]

An optional input parameter, which contains the completion status code of the work unit. Available completion status codes (defined in macro IWMYCON) are: * IwmEwlmArmStatusGood(0), * IwmEwlmArmStatusAborted(1), * IwmEwlmArmStatusFailed(2) or * IwmEwlmArmStatusUnknown(3) The codes above correspond to status codes in the OpenGroup ARM 4.0 Standard (for the meaning of the status codes see the ARM 4.0 Standard at http://www.opengroup.org/management/arm). The default is IWMWLM螳MSTATUSGOOD. indicates that the work unit completed successfully.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4MSTO macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

### Example

None.
IWM4MSTR — Indicate the start of a work unit

The purpose of this service is to indicate that a work unit is beginning execution. The work unit runs under the specified monitoring environment, but is reported to EWLM completely independent from a potentially running transaction on the same monitoring environment that is defined by IWM4MINI and IWM4RPT/IWM4MNTF calls. You can use the set of services IWM4MSTR, IWM4MSTO, IWM4MUPD to provide data for "mini work units" running within a long-running transaction. In addition a work unit started by IWM4MSTR can participate in asynchronous and synchronous work unit flows.

Note: This service was previously called IWMMSTRT for 31-bit addressing only (see “IWMMSTRT — Indicate the start of a work unit” on page 983).

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state or program key mask (PKM) allowing keys 0-7.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: No restriction.
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of bits 0-31 of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. This macro may not be used prior to the completion of WLM address space initialization
2. The caller must have issued the IWM4MCRE macro successfully and the created delay monitoring environment must be enabled for EWLM support. This means the delay monitoring environment must be created by one of the following ways:
   • IWM4CON EWLM=YES ...
   • IWM4MCRE SUBSYS=CONNECT ...
   • IWM4MCRE SUBSYS=VALUE EWLM=YES ...
3. The caller is responsible for error recovery.
4. The current PSW key must be 0 or match the key specified on IWM4MCRE provided the latter is a system key (0-7).
5. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.
6. This macro may only be used on z/OS V2R1 or later.

**Input register information**

Before issuing the IWM4MSTR macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

The following general purpose registers (GPRs) have to contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>The address of a 216-byte standard save area in the primary address space.</td>
</tr>
</tbody>
</table>

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if the return code in GPR 15 is not 0, otherwise, used as a work register by the system. The reason code is stored in bits 0-31</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return Code stored in bits 0-31</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.
Syntax

main diagram

Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4MSTR macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ARRIVALTIME=arrivaltime
,ARRIVALTIME=NO_ARRIVALTIME
An optional input parameter, which contains a timestamp in STCK format. This timestamp is subtracted from the current timestamp and assigned as queued time to the work unit. For example, you may use this parameter, if the work unit is started by receipt of a message from a queue and you know the put time (the timestamp when the message has been put onto the queue). The default is NO_ARRIVALTIME. indicates that parameter ARRIVALTIME has not been specified.

to code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,ENDFLOW=NO
,ENDFLOW=YES
An optional parameter, which indicates the completion of a message flow. The default is ENDFLOW=NO.

,ENDFLOW=NO
indicates that a message flow has not completed.

,ENDFLOW=YES
indicates that a message flow has completed. Specify END_FLOW=YES, if you know that this work unit is the last one in a work unit flow. This indication can not be cleared, if it has been set.

,EWLM=NO
An optional parameter, which indicates if this work manager intends to participate in cross platform Enterprise Workload Management (eWLM). The default is EWLM=NO.

,EWLM=NO
The work manager interacts only with WLM and no interaction with eWLM takes place.

,EWLM_RCVD_CORR=ewlm_rcvd_corr
,EWLM_RCVD_CORR=NO EWLM_RCVD_CORR
When EWLM_S_CURCORR=ewlm_s_curcorr is specified, an optional input parameter, which contains a cross platform Enterprise Workload Management (EWLM) correlator received from another application. Normally this is a received correlator which has the independent flag and the asynchronous flag set. It should not be passed to the EWLM_S_PACORR or the EWLM_S_CURCORR parameter. If you pass this correlator to one of them then the started work unit is not reclassified and runs under the classification of this correlator. When you receive a correlator with the independent flag set then you should:
1. Reclassify the work unit by issuing IWM4CLFY EWLM_CORR=r_corr
   EWLM_CHCORR=c_corr. r_corr is the received correlator and c_corr is the correlator created by IWM4CLFY.
2. Start the work unit by issuing IWM4MSTR EWLM_S_CURCORR=c_corr
   EWLM_RCVD_CORR=r_corr.

The default is NO_EWLM_RCVD_CORR. indicates that parameter EWLM_RCVD_CORR has not been specified.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,EWLM_S_CURCORR=ewlm_s_curcorr
A required input parameter which contains a cross platform Enterprise Workload Management (EWLM) correlator for the current application. The correlator passed to this parameter is used as the current correlator of this work unit. It has usually been created by means of a previous IWM4CLFY call with the EWLM_CHCORR parameter (see below).

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,EWLM_S_PACORR=ewlm_s_pacorr
A required input parameter which contains a cross platform Enterprise Workload Management (EWLM) parent correlator received from another application.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
IWM4MSTR

\[MF= (E, list \ addr, COMPLETE)\]
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\[list \ addr\]
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\[attr\]
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

\[COMPLETE\]
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\[MONTKN= montkn\]
A required input parameter which contains the delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\[MONTKN64= montkn64\]
A required input parameter which contains the long delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

\[MSG\_RECEIVED=NO\], \[MSG\_RECEIVED=YES\]
An optional parameter, which indicates whether this work unit has been started as a result of a receipt of a message. The default is MSG\_RECEIVED=NO.

\[MSG\_RECEIVED=NO\]
indicates that this work unit has not been started by receipt of a message.

\[MSG\_RECEIVED=YES\]
indicates that this work unit has been started as a result of a receipt of a message.

\[PLISTVER=IMPLIED\_VERSION\], \[PLISTVER=MAX\], \[PLISTVER=0\]
An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

**RETCODE=retcode**

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

**RSNCODE=rsncode**

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4MSTR macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.
## Table 85. Return and Reason Codes for the IWM4MSTR Macro

<table>
<thead>
<tr>

<tr>
<td></td>
<td></td>
<td><strong>Action</strong>: Check the format of the passed arrivaltime.</td>
</tr>
</tbody>
</table>
Example

None.
### IWM4MSWC — Monitoring environment switch

The purpose of this service is to reflect that the delay information for a work request may now also reside in another monitoring environment which is not related to the current environment (Continue) or that there is no further information for the current work request beyond the current environment (Return).

The scope of this service is restricted to the input monitoring environment and no other monitoring environments are accessed or otherwise involved.

It is preferable to use IWM4MXFR, where the necessary information is available, and the restrictions can be met, since this gives more specific information to MVS about the status of the work request.

### Environment

The requirements for the caller are:

- **Minimum authorization:** Problem state. PSW key must either be 0 or match the value supplied on IWM4MCRE.
- **Dispatchable unit mode:** Task or SRB
- **Cross memory mode:** Any PASN, any HASN, any SASN
- **AMODE:** 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
- **ASC mode:** Primary
- **Interrupt status:** Enabled for I/O and external interrupts
- **Locks:** Suspend locks are allowed, as are FRRs
- **Control parameters:** Control parameters must be in the primary address space.

### Programming requirements

None.

### Restrictions

1. This macro may not be used prior to the completion of WLM address space initialization.
2. All parameter areas must reside in current primary.
3. Caller is responsible for error recovery.
4. Only limited checking is done against the input monitoring token.
5. If the key specified on IWM4MCRE was a user key (8-F), then the primary addressability must exist to the performance block IWM4MCRE obtained. This condition is satisfied by ensuring that current primary matches primary at the time that IWM4MCRE was invoked. If this service is invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.
6. FUNCTION(CONTINUE) may not be used when there is an outstanding continuation established by use of Transfer Continue.
7. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the input monitoring environment.
8. This macro may only be used on z/OS V2R1 or later.
**Input register information**

Before issuing the IWM4MSWC macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

The following general purpose registers (GPRs) have to contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>The address of a 216-byte standard save area.</td>
</tr>
</tbody>
</table>

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the macro</td>
</tr>
<tr>
<td>15</td>
<td>Used as a work register by the macro</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after using a service. If the system changes the contents of registers on which the caller depends, the caller must save them before calling the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

*main diagram*
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWM4MSWC macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**,COMPCODE=YES**
**,COMPCODE=NO**
An optional parameter, which indicates whether completion status for this service is needed. The default is COMPCODE=YES.

**,COMPCODE=YES**
indicates that completion status is needed.

**,COMPCODE=NO**
indicates that completion status is not needed. Registers 0, 15 cannot be used as reason code and return code registers upon completion of the macro expansion. For this reason neither RETCODE NOR RSNCODE may be specified when COMPCODE(NO) is specified.

**,EWLM=NO**
An optional parameter, which indicates if this work manager intents to participate in cross platform Enterprise Workload Management (eWLM). The default is EWLM=NO.

**,EWLM=NO**
The work manager interacts only with WLM and no interaction with eWLM takes place.

**FUNCTION=CONTINUE**
**FUNCTION=RETURN**
A required parameter, which indicates where there may be one or more other
monitoring environments which represent current information about the work request. This is meant to cover further continuations of the work request, and does not deal with any parent environment that may exist.

**FUNCTION=CONTINUE**
indicates that the current environment is creating only a single continuation elsewhere.

**FUNCTION=RETURN**
indicates that any continuations of the work request have completed. These continuations may have been established through use of Transfer or Switch.

```
,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
```

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,`list addr`
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,`attr`
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

,`COMPLETE`
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,`MONTKN=montkn`
A required input parameter which contains the delay monitoring token for the current environment.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,`MONTKN64=montkn64`
A required input parameter which contains the long delay monitoring token for the current environment.
To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

**PLICVER=IMPLIED_VERSION**
**PLICVER=MAX**
**PLICVER=0**

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

**RETCODE=retcode**

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

**RSNCODE=rsncode**

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

**RUNTIME_VER=SHORT_FORM**

When FUNCTION=CONTINUE is specified, an optional parameter, which indicates what level of runtime verification will be performed. The default is RUNTIME_VER=SHORT_FORM.

**RUNTIME_VER=MINIMAL**

indicates that checking should verify that a monitoring environment is established and passes a short form of verification prior to being used.
indicates that checking will only be done to verify that a monitoring environment may be established, assuming that it would be valid and useable if established.

\textit{RUNTIME\_VER=SHORT\_FORM}\textit{RUNTIME\_VER=MINIMAL}

When FUNCTION=RETURN is specified, an optional parameter, which indicates what level of runtime verification will be performed. The default is RUNTIME\_VER=SHORT\_FORM.

\textit{RUNTIME\_VER=SHORT\_FORM}

indicates that checking should verify that a monitoring environment is established and passes a short form of verification prior to being used.

\textit{RUNTIME\_VER=MINIMAL}

indicates that checking will only be done to verify that a monitoring environment may be established, assuming that it would be valid and useable if established.

\textit{WHERE=LOCALMVS}\textit{WHERE=SYSPLEX}\textit{WHERE=NETWORK}

When FUNCTION=CONTINUE is specified, a required parameter, which indicates where there may be another monitoring environment

\textit{WHERE=LOCALMVS}

indicates that such an environment may exist on the current MVS.

\textit{WHERE=SYSPLEX}

indicates that such an environment may exist in the current syplex, but is not expected to be on the current MVS image.

\textit{WHERE=NETWORK}

indicates that such an environment may exist, but is not expected to be in the current syplex.

\textbf{ABEND codes}

None.

\textbf{Return codes and reason codes}

When the IWM4MSWC macro returns control to your program:

- GPR 15 (and \textit{retcode}, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and \textit{rsncode}, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes. IBM support personnel may request the entire reason code, including the \textit{xxxx} value.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|l|}
\hline
\textbf{Return Code} & \textbf{Reason Code} & \textbf{meaning and Action} \\
\hline
0 & — & \textit{Equate symbol: IwmRetCodeOk} \\
 & & \textit{Meaning: Successful completion.} \\
4 & — & \textit{Equate symbol: IwmRetCodeWarning} \\
 & & \textit{Meaning: Successful completion, unusual conditions noted.} \\
\hline
\end{tabular}
\end{table}

### Example

None.
IWM4MUPD — Update data for a work unit

The purpose of this service is to update data about a work unit which has been started by IWM4MSTR. A work unit started by IWM4MINI is not affected by this service.

Note: This service was previously called IWMMUPD for 31-bit addressing only (see “IWMMUPD — Update data for a work unit” on page 995).

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state or program key mask (PKM) allowing keys 0-7.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: No locks may be held. No restriction.
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of bits 0-31 of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. This macro may not be used prior to the completion of WLM address space initialization
2. Caller must have issued the IWM4MSTR macro successfully
3. Caller is responsible for error recovery
4. The current PSW key must be 0 or match the key specified on IWM4MCRE provided the latter is a system key (0-7)
5. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token
6. This macro may only be used on z/OS V2R1 or later.
Input register information

Before issuing the IWM4MUPD macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

The following general purpose registers (GPRs) have to contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>The address of a 216-byte standard save area in the primary address space.</td>
</tr>
</tbody>
</table>

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if the return code in GPR 15 is not 0, otherwise, used as a work register by the system. The reason code is stored in bits 0-31</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code stored in bits 0-31</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

main diagram

```
+b IWM4MUPD+b MONTKN=montkn MONTKN64=montkn64 ,EWLM=NO
```
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWM4MUPD macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**AFTER_STRT=NO**
**AFTER_STRT=YES**
When EWLM_RCVD_CORR=ewlm_rcvd_corr is specified, an optional parameter, which indicates the moment the correlator has been received. The default is AFTER_STRT=NO.

**AFTER_STRT=NO**
indicates that the correlator has been received before this work unit has been started by IWM4MSTR.

**AFTER_STRT=YES**
indicates that the correlator has arrived within the scope of this work unit that means after issuing IWM4MSTR.

**END_FLOW=NO**
**END_FLOW=YES**
An optional parameter, which indicates the completion of a message flow. The default is END_FLOW=NO.

**END_FLOW=NO**
indicates that a message flow has not completed.

**END_FLOW=YES**
indicates that a message flow has completed. Specify END_FLOW=YES, if you know that the running work unit is the last one in a work unit flow. This indication can not be cleared, if it has been set.
An optional parameter, which indicates if this work manager intends to participate in cross platform Enterprise Workload Management (eWLM). The default is EWLM=NO.

The work manager interacts only with WLM and no interaction with eWLM takes place.

An optional input parameter, which contains a cross platform Enterprise Workload Management (EWLM) correlator received from another application. Workflows often have multiple parent work units that must complete before a new work unit can be initiated. You can pass only 1 parent correlator to the IWM4MSTR macro and one additional parent correlator to the IWM4MSTO macro. You have to issue this macro, if more than two parent correlators should be assigned to a work unit. This correlator is ignored, if it is an unknown EWLM correlator. The default is NO_EWLM_RCVD_CORR. indicates that parameter EWLM_RCVD_CORR has not been specified.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

An optional input parameter, which contains the number of messages sent to other applications. This value is added to the total messages_sent value of the work unit. The total messages_sent value should not exceed 32767. The default is NO_MESSAGES_SENT. indicates that parameter MESSAGES_SEND has not been specified.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.
The name of a storage area to contain the parameters. For MF=S and
MF=E, this can be an RS-type address or an address in register (1)-(12).

attr
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code attr, the system provides a value of 0D.

COMPLETE
Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

montkn=montkn
A required input parameter which contains the delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit
field.

montkn64=montkn64
A required input parameter which contains the long delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit
field.

PLISTVER=IMPLIED_VERSION,
PLISTVER=MAX,
PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and
with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters
  specified on the request to be processed. If you omit the PLISTVER
  parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible.
  This size might grow from release to release and affect the amount of
  storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always
  specify PLISTVER=MAX on the list form of the macro. Specifying MAX
  ensures that the list-form parameter list is always long enough to hold all
  the parameters you might specify on the execute form, when both are
  assembled with the same level of the system. In this way, MAX ensures that
  the parameter list does not overwrite nearby storage.
- 0, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

RETCODE=retcode
An optional output parameter into which the return code is to be copied from
GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without
parentheses), the value will be left in GPR 15.
To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

`RSNCODE=rsncode`
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4MUPD macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>

**Meaning:** No work unit has been started by IWM4MSTR for the specified monitoring environment.  
**Action:** Start a work unit by IWM4MSTR macro, before issuing this macro. |

**Example**

None.
The purpose of this service is to reflect that the delay information for a work request may now also reside in a dependent monitoring environment (CONTINUE) OR that delay information is no longer present in a dependent monitoring environment (RETURN).

The two monitoring environments referred to above must be related by a previous IWM4MRLT invocation. This service requires as input the monitoring token for the dependent environment, which is accessed, but the parent environment must also be updated. This implies that the user must have addressability and update access to the parent monitoring environment. The PARENTKEYP and PARENTENV keywords are provided to accommodate these requirements. These restrictions apply even when the Relate was performed using the FINDACTIVE option, though when the monitoring environment is related to the address space characteristics, no key or addressability requirements exist beyond those for the dependent monitoring environment.

Note: This service was previously called IWMMXFER for 31-bit addressing only (see "IWMMXFER — Transfer monitoring environment" on page 1001).

Environment

The requirements for the caller are:

Minimum authorization:
- Either problem state or supervisor state.
- PSW key must either be 0 or match the value supplied on IWM4MCRE for the (dependent) monitoring token.
- PARENTKEYP(VALUE) may only be specified in supervisor state or with PKM authority to the key specified by PARENTKEY. Note that the key for IWM4MXFR is located in bit positions 0-3 (using 0 origin), which is the machine orientation to keeping keys, not the "natural" way of declaring the key value.
- PARENTKEYP(UNKNOWN) may only be specified in supervisor state or with PKM authority to key 0.
- When PARENTKEYP(PSWKEY) is specified, the PSW key must either be 0 or match the value supplied on IWM4MCRE for the parent monitoring environment.
- If FUNCTION=RETURN is specified and the passed delay monitoring token is associated with an ARM work request (EWLM=YES was specified on IWMCONN and the monitoring environment was created using that CONNTKN), the caller must be in supervisor state or have PKM authority to key 0.

Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: No locks may be held.
Control parameters: Control parameters must be in the primary address space.
Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
4. Note that specification of FUNCTION(CONTINUE) produces an inline expansion rather than an out-of-line service. Registers 0, 1, 14, and 15 are not preserved across the expansion.

Restrictions

1. If the key specified on IWM4MCRE for the dependent monitoring environment was a user key (8-F), then primary addressability must exist to the performance block IWM4MCRE obtained. This condition is satisfied by ensuring that current primary matches primary at the time that IWM4MCRE was invoked. If this service is invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.
2. If the key specified on IWM4MCRE for the parent environment was a user key (8-F), then either primary OR secondary addressability must exist to the performance block for the parent environment.
3. When FUNCTION(CONTINUE|RETURN) are used, the caller is responsible for error recovery
4. When FUNCTION(CONTINUE) is used, the caller is responsible to ensure that the parent monitoring environment does not already have a continuation (via a previous IWM4MXFR or IWM4MSWC) to another (or other) dependent monitoring environment(s).
5. Both monitoring environments must be established on the same MVS image.
6. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the dependent monitoring environment.
7. The caller and/or the owner of the parent environment must ensure that parent environment is not deleted while between the time that IWM4MXFR FUNCTION(CONTINUE) is used and the time that either IWM4MXFR FUNCTION(RETURN) is used against the dependent monitoring environment OR IWM4MSWC FUNCTION(RETURN) is used against the parent monitoring environment.
8. Only limited validity checking is done on the input monitoring tokens.
9. This macro may only be used on z/OS V2R1 or later.

Input register information

Before issuing the IWM4MXFR macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

The following general purpose registers (GPRs) have to contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
</table>

The address of a 216-byte standard save area in the primary address space.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

IWM4MXFR
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWM4MXFR macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**COMPCODE=**
An optional parameter, which indicates whether completion status for this service is needed. The default is COMPCODE=YES.

- **COMPCODE=YES**
  indicates that completion status is needed.

- **COMPCODE=NO**
  indicates that completion status is not needed. Registers 0, 15 cannot be used as reason code and return code registers upon completion of the macro expansion. For this reason neither RETCODE NOR RSNCODE may be specified when COMPCODE(NO) is specified.

**EWLM=**
An optional parameter, which indicates if this work manager intents to participate in cross platform Enterprise Workload Management (eWLM). The default is EWLM=NO.

- **EWLM=NO**
  The work manager interacts only with WLM and no interaction with eWLM takes place.

**FUNCTION=**
A required parameter, which indicates whether the dependent environment is continuing from or returning to the parent environment.

- **FUNCTION=CONTINUE**
  indicates that this is a unique continuation of the work request which is reflected in the dependent monitoring environment.

  Note that the parent environment may continue to be active on behalf of the work request.

  Note that specification of FUNCTION(CONTINUE) produces an inline expansion rather than an out-of-line service. Registers 0, 1, 14, and 15 are not preserved across the expansion.

- **FUNCTION=RETURN**
  indicates that the work request is returning to a previously established parent monitoring environment.

  Use of this option indicates that the dependent environment no longer represents the work request.

  Note that specification of FUNCTION(RETURN) produces an inline expansion rather than an out-of-line service. Registers 0, 1, 14, and 15 are not preserved across the expansion.

**MONTKN**
A required input parameter which contains the delay monitoring token for the dependent environment.
To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

, MONTKN64=montkn64
   A required input parameter which contains the long delay monitoring token for the dependent environment.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

, PARENTENV=NOSWITCH
, PARENTENV=SECONDARY
   A required parameter, which describes whether a space switch is needed to access the parent monitoring environment.

, PARENTENV=NOSWITCH
   indicates that NO space switch is needed to access the parent monitoring environment. This would be appropriate if the parent monitoring environment was established (by IWM4MCRE) to be used by routines in a specific system key or if it was established to be used in a specific user key in the current primary.

, PARENTENV=SECONDARY
   indicates that the parent monitoring environment was established in current secondary (for use by a specific user key).

, PARENTKEY=parentkey
   When PARENTKEYP=VALUE is specified, a required input parameter, which contains the key in which the parent monitoring environment must be accessed. Use of this keyword value requires that the invoker be in supervisor state or that the caller have PKM authority to the key specified. The high order 4 bits (i.e. bits 0-3) contain the key value.

   Note that this is different from the "natural" way of declaring the key, and uses the machine orientation for keeping the storage key in the high order bits.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8 bit field.

, PARENTKEYP=VALUE
, PARENTKEYP=PSWKEY
, PARENTKEYP=UNKNOWN
   A required parameter, which describes whether a key switch is needed to access the parent monitoring environment.

, PARENTKEYP=VALUE
   indicates that the key is being passed explicitly via PARENTKEY.

, PARENTKEYP=PSWKEY
   indicates that the current PSW key should be used. Use of this keyword value requires that the parent monitoring environment was established with the same key as the current PSW.

, PARENTKEYP=UNKNOWN
   indicates that the key associated with the parent monitoring environment is unknown. Use of this keyword value requires that the invoker be in supervisor state or that the caller have PKM authority to key 0.

, RETCODE=retcode
   An optional output parameter into which the return code is to be copied from
GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

\texttt{RSNCODE=rsnco}de

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

\texttt{RUNTIME\_VER=SHORT\_FORM, RUNTIME\_VER=MINIMAL}

When FUNCTION=CONTINUE is specified, an optional parameter, which indicates what level of runtime verification will be performed. The default is \texttt{RUNTIME\_VER=SHORT\_FORM}.

\texttt{RUNTIME\_VER=SHORT\_FORM}

indicates that checking should verify that a monitoring environment is established and passes a short form of verification prior to being used.

\texttt{RUNTIME\_VER=MINIMAL}

indicates that checking will only be done to verify that a monitoring environment may be established, assuming that it would be valid and useable if established.

\texttt{RUNTIME\_VER=SHORT\_FORM, RUNTIME\_VER=MINIMAL}

When FUNCTION=RETURN is specified, an optional parameter, which indicates what level of runtime verification will be performed. The default is \texttt{RUNTIME\_VER=SHORT\_FORM}.

\texttt{RUNTIME\_VER=SHORT\_FORM}

indicates that checking should verify that a monitoring environment is established and passes a short form of verification prior to being used.

\texttt{RUNTIME\_VER=MINIMAL}

indicates that checking will only be done to verify that a monitoring environment may be established, assuming that it would be valid and useable if established.

\texttt{WORKREQ\_STA=workreq\_sta, WORKREQ\_STA=IWM\_EWM\_M\_RM\_ST\_STATUSNONE}

When FUNCTION=RETURN is specified, an optional input parameter, which contains the completion status code of the work request. Available completion status codes (defined in macro IWMYCON) are: * IwmEwmArmStatusGood(0), * IwmEwmArmStatusAborted(1), * IwmEwmArmStatusFailed(2) or * IwmEwmArmStatusUnknown(3) The codes above correspond to status codes in the OpenGroup ARM 4.0 Standard (for the meaning of the status codes see the ARM 4.0 Standard at http://www.opengroup.org/management/arm). The default is IWM\_EWM\_M\_RM\_ST\_STATUSNONE. indicates that internal information in the Monitoring Environment will be examined to determine the status of the work request: if no abnormal event was recorded for the monitoring environment via the IWM4MABN service, the completion status IwmEwmArmStatusGood will be reported to EWLM. If an abnormal event was reported via IWM4MABN, the completion status IwmEwmArmStatusFailed will be reported to EWLM.
**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4MXFR macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol Meaning and Action</th>
</tr>
</thead>
</table>
| 0           |             | **Equate Symbol:** IwmRetCodeOk
|             |             | **Meaning:** Successful completion. |

### Example

None.
The purpose of this service is to extract information about the monitoring environment which was previously passed through IWM4MINI/IWM4MRLT. When IWM4MRLT was invoked for a management monitoring environment, owner token, owner data and abnormal conditions are always available. Arrival time, userid, and transaction name are only available when IWM4MINI was previously invoked. Arrival time, however is only available for management monitoring environments.

When the service class token is requested for a management monitoring environment, the value may represent a token from a prior active policy. Furthermore, when the monitoring environment was established via IWM4MRLT, the token may be zero, which does not represent a valid service class or report class. IWMWQRY may be used to obtain the service and/or report class name, along with other information about these classes. The SERVCLS keyword is not applicable for report-only monitoring environments. The returned token is zero, which does not represent a valid service class.

The Enclave Token and ASID keywords are only applicable for report-only monitoring environments.

The EWLM_S_CURCORR keyword should be specified only, if a work unit has been started by IWM4MSTR.

When no output keywords are specified, the service merely checks whether a monitoring environment was established and passes short form checking.

**Note:** This service was previously called IWMMEXTR for 31-bit addressing only (see “IWMMEXTR — Monitoring environment extract” on page 936).

**Environment**

The requirements for the caller are:

**Minimum authorization:** Either problem state or supervisor state. Any PSW key.

**Dispatchable unit mode:** Task or SRB

**Cross memory mode:** Any PASN, any HASN, any SASN

**AMODE:** 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.

**ASC mode:** Primary

**Interrupt status:** Enabled for I/O and external interrupts

**Locks:** Suspend locks are allowed.

**Control parameters:** Control parameters must be in the primary address space.

**Programming requirements**

1. The macro IWMYCON must be included to use this macro.

2. The macro IWMYPB must be in the library concatenation, since it is included by IWMYCON.

3. Note that the high order halfword of bits 0-31 of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be
excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. Caller is responsible for error recovery
2. Only limited checking is done against the input monitoring token.
3. If the key specified on IWM4MCRE was a user key (8-F), then the primary addressability must exist to the performance block IWM4MCRE obtained. This condition is satisfied by ensuring that current primary matches primary at the time that IWM4MCRE was invoked. If this service is invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.
4. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.
5. This macro may only be used on z/OS V2R1 or later.

Input register information

Before issuing the IWM4MXTR macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

The following general purpose registers (GPRs) have to contain the specified information:

Register  
Contents
13  The address of a 216-byte standard save area in the primary address space.

Output register information

When control returns to the caller, the GPRs contain:

Register  
Contents
0  Reason code if GR15 return code is non-zero. The reason code is stored in bits 0-31
1  Used as work register by the system
2-13  Unchanged
14  Used as work register by the system
15  Return code stored in bits 0-31

When control returns to the caller, the ARs contain:

Register  
Contents
0-1  Used as work registers by the system
2-13  Unchanged
14-15  Used as work registers by the system

Chapter 12. Workload management services  671
Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

```

**Parameters**

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWM4MXTR macro invocation. The name must conform to the rules for an ordinary assembler language symbol.
ABNORMAL_COND=abnormal_cond
An optional output parameter, which contains the current information about
abnormal conditions which were either recorded in the input monitoring
environment or which were propagated to it via IWM4MXFR Function(Return).
Multiple conditions may exist.

The mask, Iwmmabnl_Scope_LocalMVS, may be used to determine whether an
abnormality which only affects work on the current MVS image was recorded.

The mask, Iwmmabnl_Scope_Sysplex, may be used to determine whether an
abnormality which affects work on all MVS images in the sysplex was
recorded.

To determine whether a condition was recorded, merely AND the field
supplied for ABNORMAL_COND with the relevant mask. The result will be
nonzero when the condition is true, zero when the condition is false.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit
field.

ARRIVALTIME=arrivaltime
An optional output parameter, which contains the work arrival time in STCK
format.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit
field.

ASID=asid
An optional output parameter, which contains the address space ID. When the
monitoring environment is not associated with an address space, the output
will be a halfword of binary zeros.

To code: Specify the RS-type address, or address in register (2)-(12), of a 16 bit
field.

ENCLAVE_TOKEN=enclave_token
An optional output parameter, which contains the enclave token. When the
monitoring environment is not associated with an enclave, the output will be a
doubleword of binary zeros.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit
field.

EWLM=NO
An optional parameter, which indicates if this work manager intents to
participate in cross platform Enterprise Workload Management (eWLM). The
default is EWLM=NO.

EWLM=NO
The work manager interacts only with WLM and no interaction with
eWLM takes place.

EWLM_CHCORR=ewlm_chcorr
An optional output parameter, which contains the cross platform Enterprise
Workload Management (EWLM) correlator of the work request created by
IWM4MINI. Normally this correlator is different from the current correlator of
the work unit created by IWM4MSTR.

To code: Specify the RS-type address, or address in register (2)-(12), of a
character field.

EWLM_PACTKN=ewlm_pactkn
An optional output parameter, which contains the cross platform Enterprise
Workload Management (EWLM) parent correlator token of the work request associated with the monitoring environment.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{EWLM\_S\_CURCORR=ewlm\_s\_curcorr}

An optional output parameter, which contains the current correlator of the work unit started by IWM4MSTR. Normally this correlator is different from the child correlator of the work request created by IWM4MINI.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{MONTKN=montkn}

A required input parameter which contains the delay monitoring token.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\texttt{MONTKN64=montkn64}

A required input parameter which contains the long delay monitoring token.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

\texttt{OMONTKN=omontkn}

An optional output parameter, which is to receive the delay monitoring token. This option can be used to convert a long delay monitoring token into the short form.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\texttt{OMONTKN64=omontkn64}

An optional output parameter, which is to receive the long delay monitoring token. This option can be used to convert a short delay monitoring token into the long form.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

\texttt{OWNER\_DATA=owner\_data}

An optional output parameter, which is to receive the data established by the user/owner of the monitoring environment. The format is undefined to MVS. When the monitoring environment is not associated with an OWNER_TOKEN value, the output will be a word of binary zeros.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\texttt{OWNER\_TOKEN=owner\_token}

An optional output parameter, which is to receive the token established by the user/owner of the monitoring environment. The format is undefined to MVS. When the monitoring environment is not associated with an OWNER_TOKEN value, the output will be a word of binary zeros.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\texttt{RETCODE=retcode}

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.
**To code:** Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

_,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0), (REG00), or (R0).

_,SERVCLS=servcls
An optional output parameter, which contains the service class token. When the monitoring environment is not associated with a service class token, the output will be a word of binary zeros.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

_,TRXNAME=trxname
An optional output parameter, which contains the transaction name. The field will be all blanks when NO_TRXNAME was specified on IWM4MINI.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

_,TTRACETOKEN=ttracetoken
An optional output parameter, which contains the transaction trace token associated with the work request. The field will be all zero when NO_TTRACETOKEN was specified on IWM4MINI.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

_,USERID=userid
An optional output parameter, which contains the local userid associated with the work request. The field will be all blanks when NO_USERID was specified on IWM4MINI.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**
None.

**Return codes and reason codes**

When the IWM4MXTR macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.
### Table 89. Return and Reason Codes for the IWM4MXTR Macro

<td>Start a work unit by IWM4MSTR macro, before specifying the EWLM_S_CURCORR parameter.</td>
</tr>
</tbody>
</table>

### Example

None.
IWM4OPTQ — Query IEAOPTxx parameters

The IWM4OPTQ service queries the current IEAOPTxx settings in the system and returns a list of the IEAOPTxx parameters, including the actual value, unit, default value, and description.

The caller of IWM4OPTQ must provide storage to contain all of the parameter information. This storage area must reside in the caller’s primary address space.

It is possible that the storage required by IWM4OPTQ can change such that multiple calls to IWM4OPTQ are required to obtain data. Users of IWM4OPTQ should take this into consideration when obtaining an amount of storage for the IWM4OPTQ service to use.

If the caller does not provide enough storage to contain all of the parameter information, the IWM4OPTQ service returns a return code and reason code pair to indicate that the storage area specified by the OPTINFO_BLOCK input parameter is too small. The QUERYLEN output parameter will be set to the required size for the storage area specified by OPTINFO_BLOCK. No IEAOPTxx parameter information is returned.

Applications that monitor the current system environment can use this service to display the SRM and WLM parameter settings.

The output of the IWM4OPTQ service is a data area mapped by the IWMWOPTI macro and provides a point-in-time snapshot of the parameter settings on the current system.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Minimum authorization</strong></td>
<td>Problem state, any PSW key.</td>
</tr>
<tr>
<td><strong>Dispatchable unit mode</strong></td>

</tr>
<tr>
<td><strong>Cross memory mode</strong></td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td><strong>AMODE</strong></td>
<td>31-bit or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE=YES before invoking this macro.</td>
</tr>
<tr>
<td><strong>ASC mode</strong></td>
<td>Primary or access register (AR)</td>
</tr>
<tr>
<td><strong>Interrupt status</strong></td>
<td>Enabled for I/O and external interrupts.</td>
</tr>
<tr>
<td><strong>Locks</strong></td>
<td>No locks may be held.</td>
</tr>
<tr>
<td><strong>Control parameters</strong></td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro. The macro IWMYCON must be included to use this macro.

   **Note:** The high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
Restrictions

None.

Input register information

Before issuing the IWM4OPTQ macro, the caller does not have to place any
information into any register unless using it in register notation for a particular
parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after
issuing a service. If the system changes the contents of registers on which the caller
depends, the caller must save them before issuing the service, and restore them
after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWM4OPTQ macro is as follows:

```plaintext
IWM4OPTQ
    name
    OPTINFO_BLOCK=optinfo_block
    ANSLEN=anslen
    QUERYLEN=querylen
    RETCODE=retcode
    RSNCODE=rsncode
    PLISTVER=IMPLIED_VERSION
    PLISTVER=MAX
    PLISTVER=1
```
Parameters

The parameters are explained as follows:

name
   An optional symbol, starting in column 1, that is the name on the IWM4OPTQ
   macro invocation. The name must conform to the rules for an ordinary
   assembler language symbol.

,ANSLEN=anslen
   A required input parameter that contains the length of the OPTINFO_BLOCK
   storage area, in bytes.
   To code: Specify the RS-type address or address in register (2)-(12) of a
   fullword field.

,MF=S
    Use MF=S to specify the standard form of the macro, which builds an inline
    parameter list and generates the macro invocation to transfer control to the
    service. MF=S is the default.

,MF=L
   Use MF=L to specify the list form of the macro. Use the list form together with
   the execute form of the macro for applications that require reentrant code. The
   list form defines an area of storage that the execute form uses to store the
   parameters. Only the PLISTVER parameter may be coded with the list form of
   the macro.

,MF=E
    Use MF=E to specify the execute form of the macro. Use the execute form
    together with the list form of the macro for applications that require reentrant
    code. The execute form of the macro stores the parameters into the storage area
    defined by the list form, and generates the macro invocation to transfer control
to the service.

,list addr
    The name of a storage area to contain the parameters. For MF=S and MF=E,
    this can be an RS-type address or an address in register (1)-(12).

,attr
    An optional 1- to 60-character input string that you use to force boundary
    alignment of the parameter list. Use a value of 0F to force the parameter
    list to a word boundary, or 0D to force the parameter list to a doubleword
    boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
    Specifies that the system is to check for required parameters and supply
    defaults for omitted optional parameters.
**OPTINFO_BLOCK=optinfo_block**
Is the name (RS-type), or address in register (2)-(12), of a required character input of an output area to contain information provided by this service. The format of this area is mapped by IWMWOPTI and should only be considered valid upon return code zero from this service.

OPTINFO_BLOCK is not the address of a pointer but the address of the output area.

**,PLISTVER=IMPLIED_VERSION**
**,PLISTVER=MAX**
**,PLISTVER=1**
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms that are used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 1, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 1

**,QUERYLEN=querylen**
A required output parameter variable which contains the output area size that must be provided by the caller to contain all of the active system's IEAOPTxx parameter descriptions (that is, the amount of data returned by the IWM4OPTQ service).

To code: Specify the RS-type address or address in register (2)-(12) of a fullword field.

**,RETCODE=retcode**
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

**,RSNRCODE=rscncode**
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**

None.
Return codes and reason codes

When the IWM4OPTQ macro returns control to your program:
- GPR 15 (and _retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and _rsncode, if you coded RSNCODE) contains reason code.

Table 90 identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the _xxxx value.

</tbody>
</table>
IWM4QDE — Delete a request from the queue for an execution address space

This service deletes a work request that was previously inserted using the IWM4QIN service, if it has not been selected using the IWM4SSL service.

Note: This service was previously called IWMQDEL for 31-bit addressing only (see “IWMQDEL — Delete a request from the queue for an execution address space” on page 1009).

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state or program key mask (PKM) allowing keys 0-7. |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any HASN, any SASN. PASN must be the address space which connected to WLM (i.e. the address space that was home when IWM4CON was issued for Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue). |
| AMODE: | 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro. |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

None.

Input register information

Before issuing the IWM4QDE macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
### Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

### Performance implications

None.

### Syntax

The syntax of the IWM4QDE macro is as follows:

```
IWM4QDE
  CONNTKN=connktn,WLMWUTKN=wlmwutkn
  RETCODE=retcode
```

### Parameters

The parameters are explained as follows:
An optional symbol, starting in column 1, that is the name on the IWM4QDE macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**CONNTKN=conntkn**

A required input parameter, which contains the connect token associated with the use of WLM Work Queuing services as returned by IWM4CON (specifying Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue).

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

- **MF=S**
  - **MF=(L,list addr)**
  - **MF=(L,list addr,attr)**
  - **MF=(L,list addr,0D)**
  - **MF=(E,list addr)**
  - **MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

- **list addr**
  - The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

- **attr**
  - An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

- **COMPLETE**
  - Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

- **PLISTVER=IMPLIED_VERSION**
- **PLISTVER=MAX**
- **PLISTVER=0**

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form.

When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
**IWM4QDE**

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

  **To code:** Specify one of the following:
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0

  
  **RETCODE=retcode**
  
  An optional output parameter into which the return code is to be copied from GPR 15.

  **To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

  
  **RSNCODE=rsncode**
  
  An optional output parameter into which the reason code is to be copied from GPR 0.

  **To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

  
  **WLMWUTKN=wlmwutkn**
  
  A required input parameter, specifying the work unit to be deleted. This token must be a token that was returned on a prior IWM4QIN request.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4QDE macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.
### Table 91. Return and Reason Codes for the IWM4QDE Macro

**Meaning:** Primary address space does not own the passed connect token.  
**Action:** Avoid requesting this function while primary address space does not own the connect token. |
| 8           | xxxx0840    | **Equate Symbol:** IwmRsnCodeServiceNotEnabled  
**Meaning:** Caller's space connection is not enabled for this service.  
**Action:** Make sure that Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue is specified on the IWM4CON request to enable this service. |
| 8           | xxxx0848    | **Equate Symbol:** IwmRsnCodeBadWorkUnitToken  
**Meaning:** The work unit token is not valid.  
**Action:** Check the specification of the WLMWUTKN parameter. |
| 10          | —           | **Equate Symbol:** IwmRetCodeCompError  
**Meaning:** Component error.  
**Action:** Contact your system programmer. |

### Example

To delete a work request from the WLM queue manager queues, specify:

```plaintext
IWM4QDE CONNTKN=CONNTOKEN, X
WLMWUTKN=WLMWUTKN, RETCODE=RC, RSNCODE=RSN
```

* Storage areas

* **CONNTOKEN** DS FL4  
  Contains the connect token  
  associated with the use of WLM  
  Queuing services as returned by  
  IWM4CON  
  *(specifying QUEUE_MANAGER=YES  
  or SERVER_MANAGER=YES  
  or SERVER_TYPE=QUEUE)*

**WLMWUTKN** DS CL16  
  Work unit token

**RC** DS F  
  Return code

**RSN** DS F  
  Reason code
The IWM4QHLT service provides information about health indicators that were set for server address spaces via the IWM4HLTH or IWMSRSRG services. IWM4QHLT allows the caller to obtain the health information for:

- All address spaces for which health indicators were provided
- A list of particular address spaces

The caller must provide an area of storage in the ANSAREA parameter and the length of that area in the ANSLEN parameter for IWM4QHLT to place the health information. IWM4QHLT returns the actual length of the information in the QUERYLEN parameter.

If a caller does not know the size of the answer area that is required by the service, it should issue IWM4QHLT with ANSLEN set to zero. The length of the answer area is placed in QUERYLEN.

The answer area is mapped by the IWMWQHAA data area, which is described in z/OS MVS Data Areas, Volume 4.

The returned information is not serialized upon return to the caller, so it might be outdated due to a change in health indicators.

Environment

The requirements for the caller are:

**Minimum authorization:** Supervisor state or program key mask (PKM) allowing keys 0-7

**Dispatchable unit mode:** Task

**Cross memory mode:** Any PASN, any HASN, any SASN

**AMODE:** 31-bit or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.

**ASC mode:** Primary or access register (AR). If in AR mode, specify SYSSTATE ASCENV=AR before invoking this macro.

**Interrupt status:** Enabled for I/O and external interrupts

**Locks:** No locks can be held. FRR environments can be established.

**Control parameters:** The caller of IWM4QHLT must provide storage for an answer area that is mapped by IWMWQHAA. This answer area might reside in the caller’s primary address space or in a dataspace accessible via the current unit of work’s dispatchable unit access list (DUAL).

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. The high-order halfword of register 0, and the reason code variable when specified, might be non-zero and represents diagnostic data that is NOT part of the external interface. The high-order halfword should thus be excluded from
comparison with the reason code values that are described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

5. All character data, unless otherwise specified, is assumed to be left-aligned and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

None.

Input register information

Before issuing the IWM4QHLT macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWM4QHLT macro is as follows:

```
IWM4QHLT [ASID_LIST=NO ASID_LIST, ASID_LIST=asid_list, ASID_NUM=asid_num, ANSAREA=ansarea] name
```
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWM4QHLT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**ANSAREA=ansarea**
A required output parameter that specifies an answer area, ansarea, to contain the data that is returned by the query service. The area is mapped by the IWMWQHAA mapping macro. If the length of ansarea is insufficient to hold all of the data to be returned, no data is returned.

To code: Specify an RS-type address or address in register (2)-(12) of a character field.

**ANSLEN=anslen**
A required input parameter that contains the length of the answer area (ansarea).

To code: Specify the RS-type address or address in register (2)-(12) of a fullword field.

**ASID_LIST=NO_ASID_LIST**

**ASID_LIST=asid_list**
An optional input parameter that specifies an area for the list of ASIDs for which health information should be returned. Each entry (ASID) is a halfword field in hexadecimal format. A maximum number of 100 entries in the list is supported. The default value is NO_ASID_LIST, which indicates that no ASID list was passed and health information for all address spaces for which health indicators was provided should be returned.

To code: Specify the RS-type name or address in register (2)-(12) of a field specifying the area for the list of ASIDs.

**ASID_NUM=asid_num**
A required input parameter for ASID_LIST=asid_list that contains the number of ASIDs in asid_list.

To code: Specify the RS-type address or address in register (2)-(12) of a fullword field.

**MF=S**
**MF=(L,list addr)**
**MF=(L,list addr,attr)**
**MF=(L,list addr,0D)**
**MF=(E,list addr)**
MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.
Use MF=S to specify the standard form of the macro, which builds an inline
parameter list and generates the macro invocation to transfer control to the
service. MF=S is the default.
Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter can be coded with the list form of
the macro.
Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
that is defined by the list form, and generates the macro invocation to transfer
control to the service.
list addr
The name of a storage area to contain the parameters. For MF=S and MF=E,
this can be an RS-type address or an address in register (1)-(12).
attr
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code attr, the system provides a value of 0D.
COMPLETE
Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.
PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an optional
input parameter on all forms of the macro, including the list form. When using
PLISTVER, specify it on all macro forms that are used for a request and with the
same value on all of the macro forms. The values are:
IMPLIED_VERSION
The lowest version that allows all parameters that are specified on the
request to be processed. If you omit the PLISTVER parameter,
IMPLIED_VERSION is the default.
MAX
Indicates that you want the parameter list to be the largest size currently
possible. This size might grow from release to release and affect the
amount of storage that your program needs.
If you can tolerate the size change, IBM recommends that you always
specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures
that the list-form parameter list is always long enough to hold all the
parameters you might specify on the execute form, when both are
assembled with the same level of the system. In this way, MAX ensures that
the parameter list does not overwrite nearby storage.
0 Indicates to use the currently available parameters.
To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

\texttt{QUERYLEN=querylen}

A required output parameter that contains the length of the storage area that is required by the IWM4QHLT service. The length of the area might change between invocations.

To code: Specify the RS-type address or address in register (2)-(12) of a fullword field.

\texttt{RETCODE=retcode}

An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address or address in register (2)-(12) of a fullword field.

\texttt{RSNCODE=rsncode}

An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address or address in register (2)-(12) of a fullword field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4QHLT macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains a reason code.

Table 92. Identifies the hexadecimal return and reason codes and the equate symbol that is associated with each reason code. IBM support personnel might request the entire reason code, including the xxxx value.

Example

To query server health indicators, specify:

```
IWM4QHLT ASID_LIST=ASLST,ASID_NUM=ASNUM,  
ANSAREA=AAREA,  
ANSLEN=ALEN,  
QUERYLEN=QLEN,  
RETCODE=RC,RSNCODE=RSN
```

* Storage areas
  * ASLST DS Cxx List of server ASIDs to query
  * ASNUM DS F Number of ASIDs in list
  * AAREA DS CLxx Answer area
  * ALEN DS F Length of answer area
  * QLEN DS F Length of returned data
  * RC DS F Return code
  * RSN DS F Reason code
IWM4QIN — Insert a request onto the queue for an execution address space

The IWM4QIN service inserts a work request onto workload management queues so its execution in a server address space can be managed by WLM.

Before using this service, the caller must connect to WLM using the IWM4CON service, specifying Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue.

The IWM4QIN service requires the use of enclaves to manage the performance goals and reporting of work. It requires the use of application environments to associate types of work requests with servers capable of processing them.

Note: This service was previously called IWMQINS for 31-bit addressing only (see “IWMQINS — Insert a request onto the queue for an execution address space” on page 1016).

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any HASN, any SASN. PASN must be the address space which connected to WLM (i.e. the address space that was home when IWM4CON was issued for Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue).</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
Restrictions

None.

Input register information

Before issuing the IWM4QIN macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWM4QIN macro is as follows:

```
IWM4QIN conntkn=conntkn,etoken=etoken,userdata=userdata
```

```
APPLENV=applenv,DEPENDENT=no,DYNAMIC=咁
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWM4QIN macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

APPLENV=applenv
A required input parameter, which contains an application environment name. An application environment is defined in the workload manager service definition and instructs WLM how to create a server address space.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

CONNTKN=conntkn
A required input parameter, which contains the connect token returned by the IWM4CON macro.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

DEPENDENT=NO
DEPENDENT=YES
An optional parameter indicating whether the insert is for a dependent or a standard request. The default is DEPENDENT=NO.

DEPENDENT=NO
The request is for an independent (standard) work request (default).

DEPENDENT=YES
The insert is for a dependent work request which is required by already active server tasks to complete their processing. The request is prioritized above requests which are not marked as dependent.

DYNAMIC=NO
DYNAMIC=YES
An optional parameter indicating whether the insert is for a dynamic or static application environment. The default is DYNAMIC=NO.

DYNAMIC=NO
The server manager connects to a static application environment according to the WLM service definition. This is the default.

DYNAMIC=YES
The server manager connects to a dynamic application environment according to a prior definition via IWM4AEDF service.

ETOKEN=etoken
A required input parameter, which contains the enclave token associated with the work request. An enclave token is obtained using either the IWM4ECRE or IWMESQRY macro.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

MF=S
MF=(L,list addr)
MF=(L,list addr,attr)
MF=(L,list addr,0D)
MF=(E,list addr)
MF=(E,list addr,COMPLETE)
MF=(E,list addr,NOCHECK)
MF=(M,list addr)
MF=(M,list addr,COMPLETE)
MF=(M,list addr,NOCHECK)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

Use MF=M together with the list and execute forms of the macro for service routines that need to provide different options according to user-provided input. Use the list form to define a storage area; use the modify form to set the appropriate options; then use the execute form to call the service.

IBM recommends that you use the modify and execute forms of IWM4QIN in the following order:

- Use IWM4QIN ...MF=(M,list-addr,COMPLETE) specifying appropriate parameters, including all required ones.
- Use IWM4QIN ...MF=(M,list-addr,NOCHECK), specifying the parameters that you want to change.
• Use IWM4QIN ...MF=(E,list-addr,NOCHECK) to execute the macro.

,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

IMPLIED_VERSION
The lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

MAX
if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

0 Supports all parameters except those specifically referenced in higher versions.

To code: Specify one of the following:
• IMPLIED_VERSION
• MAX
• A decimal value of 0

,REGION_TOKEN=region_token
,REGION_TOKEN=0
An optional input parameter, which contains a region token returned by the IWM4CON and IWM4SSL macro. Use REGION_TOKEN to queue a work request to a specific server region. Such a work request is considered to be part of a set of work requests which all need access to the same status information which is kept in the virtual storage of the server region.

The following qualifications apply when specifying a region token:
The application is responsible for passing the region token to the queueing manager so that it can insert the work request to the region.

WLM has to know that temporal affinities for work requests to a specific server region exist in order not to stop the server region. The application must use the IWM4TAF macro to tell WLM when a temporal affinity starts and when it ends.

Coding REGION_TOKEN=0 is equivalent to omitting the REGION_TOKEN keyword. The default is 0.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

\[\text{RET}CODE=\text{retcode}\]

An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

\[\text{RSN}CODE=\text{rsn}code\]

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

\[\text{SECUSER}=\text{NO}\]

An optional parameter, which specifies whether the security environment of the user should be associated with the request at run time. The default is SECUSER=NO.

\[\text{SECUSER}=\text{YES}\]

Use the specified user ID to establish a security environment.

\[\text{SERVER}_TOKEN=\text{server}_token\]

An optional input parameter, which contains a server token returned by the IWM4SSL macro. Use SERVER_TOKEN to queue a secondary work request to the same server task that selected a prior work request. A secondary work request is considered to be an extension of the prior work request.

The following qualifications apply when specifying a server token:

- The server task is responsible for passing the server token to the queueing manager so that it can insert a secondary work request.
- Coordination is required between the queueing manager and the server task so that the server task knows when to expect secondary work requests. The server task uses the IWM4SSM macro to select secondary work requests. It must select all secondary work requests before it can resume normal selection using IWM4SSL.
- The same application environment and enclave token passed for the original work request must be passed for each secondary work request.
- A secondary work request cannot be deleted using the IWM4QDE macro. IWM4QIN does not return a work unit token (WLMWUTKN).
- The SECUSER keyword is ignored.

Coding SERVER_TOKEN=0 is equivalent to omitting the SERVER_TOKEN keyword. The default is 0.
**IWM4QIN**

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,**USERDATA=userdata**
A required input parameter, which contains data to pass to the server address space. This user data is returned to the caller of the IWM4SSL or IWM4SSM macro. The format is undefined to MVS.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

,**USERID=userid**
When SECUSER=YES is specified, a required input parameter, which contains the requester's user ID.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,**WLMWUTKN=wlmwutkn**
An optional output parameter, which will receive the work unit token. This token can be passed to the IWM4QDE service to delete the work request.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

**ABEND codes**
None.

**Return codes and reason codes**

When the IWM4QIN macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

</table>
| C xxxx0C16  |             | **Equate Symbol**: IwmRsnCodeServerUnavail  
**Meaning**: A server cannot be started to process the work request. This is probably caused by one of the following:
1. An error in the JCL procedure used to start the server address space.
2. Repeated, unexpected terminations of the server address space.

In either of these cases, workload management stops the application environment. A **DISPLAY WLM** command shows this state as **INTERNALLY STOPPED**.

**Action**: Look at the system log to determine what caused the error:
1. If it is a JCL error, correct the error in the procedure.
2. If it is repeated terminations of the server address space, correct the application error causing the termination.

In either case, the server environment can then be resumed using the **VARY** operator command: `V WLM,APPLENV=nnn,RESUME` where `nnn` is the applicable application environment name.

**Note**: A re-IPL of some or all of the systems in the sysplex does not reset the stopped state of the application environment. The **VARY** command is the only way to resume the environment. |
| C xxxx0C1A  |             | **Equate Symbol**: IwmRsnCodeApplNotDefined  
**Meaning**: The application environment name is not defined in the active WLM policy.

**Action**: Check whether the correct application environment name is being used. If so, a service administrator must define the application environment in the WLM service definition. |
| C xxxx0C1B  |             | **Equate Symbol**: IwmRsnCodeApplNotSST  
**Meaning**: The application environment name is defined for use by a different subsystem type in the active WLM policy.

**Action**: Check whether the correct application environment name is being used. If so, a service administrator must change the application environment in the WLM service definition to specify the correct subsystem type. |
| C xxxx0C1D  |             | **Equate Symbol**: IwmRsnCodeQMgrNotActive  
**Meaning**: The required Queue Manager is not active.

**Action**: The Queue Manager with the same subsystem type and name as the server must be started and connected to workload management before the request can be honored. |
| C xxxx0C22  |             | **Equate Symbol**: IwmRsnCodeApplEnvQuiesced  
**Meaning**: For server applications connecting to WLM with subsystem type IWEB only: The application environment has been quiesced. The work request is not inserted to the WLM work queue.

**Action**: Resume the application environment. |
Table 93. Return and Reason Codes for the IWM4QIN Macro (continued)

Example

To insert a work request onto the WLM queue manager queues, specify the following:

```plaintext
IWM4QIN CONNTKN=CONNTOKEN,ETOKEN=ENCOKEN, X
  USERDATA=USERDATA,APPLENV=APPLENV,SECUSER=NO, X
  WLMWUTKN=WLMWUTKN,RETCODE=RC,RSNCODE=RSN
```
Storage areas

- **CONNTOKEN DS FL4**
  - Contains the connect token
  - associated with the use of WLM
  - Queuing services as returned by
  - IWM4CON
  - (specifying QUEUE_MANAGER=YES
  - or SERVER_MANAGER=YES
  - SERVER_TYPE=QUEUE

- **ENCTOKEN DS CL8**
  - Contains the enclave token
  - associated with the work
  - request as returned by IWM4ECRE

- **USERDATA DS CL16**
  - Contains data maintained by the
  - user

- **APPLENV DS CL32**
  - Contains the application
  - environment name

- **WLMWUTKN DS CL16**
  - Work unit token

- **RC DS F**
  - Return code

- **RSN DS F**
  - Reason code
IWM4RPT — Report response time

The primary purpose of this service is to allow MVS to obtain the total response time for a completed work request and its corresponding service class and (when customer specified) its report class. Processor consumption data can also be provided.

The secondary purpose of this service is to allow MVS to know which address spaces were involved in serving the service class.

When a monitoring token is provided, the third purpose of this service is to allow MVS to know that the monitoring environment should no longer be associated with the now completed work request. The use of this service renders the information that is associated with the monitoring environment unpredictable. To associate a work request with the monitoring environment after use of Report, first use Initialize Mode(Reset) or Relate/Transfer.

**Note:** This service was previously called IWMRPT for 31 bit addressing only (see “IWMRPT — Report on work request completion” on page 1028).

**Environment**

The requirements for the caller are:

- **Minimum authorization:** Supervisor state. PSW key must either be 0 or match the value that is supplied on IWM4CON. PSW key must either be 0 or match the value that is supplied on IWM4MCRE when a monitoring token is passed. PSW key must be 0-7. See “Restrictions” on page 709.
- **Dispatchable unit mode:** Task or SRB
- **Cross memory mode:** Any PASN, any HASN, any SASN
- **AMODE:** 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
- **ASC mode:** Primary
- **Interrupt status:** Enabled for I/O and external interrupts
- **Locks:** LOCAL lock is held
- **Control parameters:** Control parameters must be in the primary address space.

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. The high-order halfword of register 0, and the reason code variable when specified, might be non-zero and represents diagnostic data that is NOT part of the external interface. The high-order halfword should be excluded from comparison with the reason code values described above. The constant IWMRSNCODE_MASK_CONST defined in IWMYCON, might be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-aligned and padded with blanks on the right, as needed, to occupy the specified number of bytes.
Restrictions
1. Caller is responsible for error recovery
2. Though the caller is required to be enabled, this requirement is not checked. Violation of this restriction might cause disabled program checks, which would be the responsibility of the caller's recovery to handle.
3. If a delay monitoring token is provided, then
   - The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment that is represented by the monitoring token.
   - The monitoring environment must contain the information that is saved by IWM4MINI, not IWM4MRLT.
   - If the key specified on IWM4MCRE was a system key (0-7), then the current PSW key must be 0 or match the key that is specified on IWM4MCRE.
   - If the key specified on IWM4MCRE was a user key (8-F), then:
     - PSW key must be 0.
     - Current primary must match the primary at the time that IWM4MCRE was invoked. Calling from a subspace is not supported.
4. If the key specified on IWM4CON for the input connect token was a user key (8-F), then:
   - PSW key must be 0.
   - Current primary must match the primary at the time that IWM4CON was invoked. Calling from a subspace is not supported.
5. This macro can be used only on z/OS V2R1 or higher.

Input register information
Before issuing the IWM4RPT macro, the caller must ensure that the following general-purpose registers (GPRs) contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>The address of a 216 byte standard save area in the primary address space.</td>
</tr>
</tbody>
</table>

Before issuing the IWM4RPT macro, the caller does not have to place any information into any AR unless using it in register notation for a particular parameter, or using it as a base register.

Output register information
When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>
2-13  Unchanged
14-15  Used as work registers by the system.

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

parameters-1

ARRIVALTIME=arrivaltime
    EXSTARTTIMEP=NO
    EXSTARTTIMEP=YES,, EXSTARTTIME=exstarttime
```
Parameters

The parameters are explained as follows:

`name`
An optional symbol, starting in column 1, that is the name on the IWM4RPT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`,`ARRIVALTIME=arrivaltime`
When MONTKNI=NO is specified, a required input parameter, which contains the arrival time for the work unit in STCK format.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

`,`BLOCK_TIME=block_time`
When MONTKNI=NO is specified, an optional input parameter, which contains the duration where the work request has been blocked. The format of the field is STCK. A work request is blocked, when the transaction processing is waiting on an external transaction processing or some other event to complete. The default is NO_BLOCK_TIME, which indicates that no block time is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

`,`CONNTKN=conntkn`
A required input parameter, which is returned by IWM4CON.

If a monitoring token is passed (MONTKNI(YES)), AND this monitoring token was obtained by using a connect token on IWM4MCRE, then the latter connect token is expected to be the same as that specified for IWM4RPT.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

`,`CPUTIME=cputime`
An optional input parameter that contains the total CPU time, in STCK format, for the current work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.
,ENDTIME=endtime

An optional input parameter, which specifies the ending time for the
transaction (typically, when the output is sent or available to be sent) in STCK
format. The default is CURRENT, which indicates that the current time should
be used.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit
field.

,EWLM=NO

An optional parameter, which indicates whether this work manager intends to
participate in cross platform Enterprise Workload Management (eWLM). The
default is EWLM=NO.

,EWLM=NO

The work manager interacts only with WLM and no interaction with
eWLM takes place.

,EWLM_Chcorr=ewlm_chcorr

When MONTKNI=NO is specified, an optional input parameter, which
contains the cross platform Enterprise Workload Management (EWLM)
correlator that is associated with the work request.

Note: If this correlator is not a valid ARM correlator, return code 8 and reason
code IwmRsncdlnvalidEwlmCcorr is returned to the caller (see return code
section below). If the correlator is valid, but cannot be understood by EWLM
(no EWLM format), the correlator is silently ignored and the work request is
not reported to EWLM.

Parameter EWLM_Chcorr and EWLM_Chctkn are mutually exclusive.

The default is NO_EWLM_Chcorr, which indicates that no EWLM correlator
is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a
character field.

,EWLM_Chctkn=ewlm_chctkn

When MONTKNI=NO is specified, an optional input parameter, which
contains the cross platform Enterprise Workload Management (EWLM)
correlator token that is associated with the work request. Parameter
EWLM_Chcorr and EWLM_Chctkn are mutually exclusive. The default is
NO_EWLM_Chctkn, which indicates that no EWLM correlator token is
passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a
character field.

,EWLM_Pacorr=ewlm_pacorr

When EWLM_Chcorr=ewlm_chcorr and MONTKNI=NO are specified, an
optional input parameter, which contains the cross platform Enterprise
Workload Management (EWLM) parent correlator that is associated with the
work request. The default is NO_EWLM_Pacorr, which indicates that no
EWLM parent correlator is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a
character field.
When EXSTARTTIMEP=YES and MONTKNI=NO are specified, a required input parameter, which contains the start execution time in STCK format. This should be used only when IWM4MNTF was NOT used to pass the execution time for this work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

EXSTARTTIMEP=NO
EXSTARTTIMEP=YES

When MONTKNI=NO is specified, a required parameter, which indicates whether the start execution time value is passed.

EXSTARTTIMEP=NO
Indicates that the start execution time value is not passed.

EXSTARTTIMEP=YES
Indicates that the start execution time value is passed. This should be used only when IWM4MNTF was NOT used to pass the execution time for this work request.

MF=S
MF=(L,list addr)
MF=(L,list addr,attr)
MF=(L,list addr,0D)
MF=(E,list addr)
MF=(E,list addr,COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter can be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area that is defined by the list form, and generates the macro invocation to transfer control to the service.

list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.
When MONTKNI=YES is specified, a required input parameter that contains the delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

When MONTKNI=YES is specified, a required input parameter that contains the long delay monitoring token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

When CPU TIME is specified, a required input parameter that contains the CPU time on standard CP that was offload eligible, in STCK format, for the current work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

When STATUS=NORMAL_LE_VAL is specified, a required input parameter, which contains the threshold value at which the work request is considered to have ended normally.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

When STATUS=NORMAL_GE_VAL is specified, a required input parameter, which contains the threshold value at which the work request is considered to have ended normally.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms that are used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters that are specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
• MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

• 0, which supports all parameters except parameters referenced in the description of higher versions.

• 1, which supports the parameters that are supported by 0, as well as CPUTIME, TIMEONCP, and OFFLOADONCP.

To code: Specify one of the following:

• IMPLIED_VERSION

• MAX

• A decimal value of 0 or 1.

\texttt{PSWKEY=pswkey}

When PSWKEYP=VALUE is specified, a required input parameter, which contains the current PSW key. The low order 4 bits (bits 4-7) contain the key value. The high order 4 bits (bits 0-3) contain zeros.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-bit field.

\texttt{PSWKEYP=CURRENT}

\texttt{PSWKEYP=VALUE}

An optional parameter, which describes how to determine the current PSW key. The default is PSWKEYP=CURRENT.

\texttt{PSWKEYP=CURRENT}

Indicates that the current PSW key should be determined.

\texttt{PSWKEYP=VALUE}

Indicates that the key is being passed explicitly via PSWKEY.

\texttt{RETCODE=retcode}

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value is left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

\texttt{RSNCODE=rsncode}

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value is left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

\texttt{SERVCLS=servecls}

When MONTKNI=NO is specified, a required input parameter, which contains the service class token.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.
An optional parameter, which indicates whether the portion of the work request that is associated with the Report call has completed normally or not. The default is STATUS=NORMAL.

- **STATUS=NORMAL** indicates that work request execution that is associated with the Report call has completed normally.

- **STATUS=ABNORMAL** indicates that work request execution that is associated with the Report call has completed abnormally.

- **STATUS=NORMAL_LE_VAL** indicates that work request execution that is associated with the Report call has completed normally PROVIDED the work completion code is below or at (<=) the threshold value that is given by OK_THRESHOLD.

- **STATUS=NORMAL_GE_VAL** indicates that work request execution that is associated with the Report call has completed normally PROVIDED the work completion code is above or at (>=) the threshold value that is given by OK_THRESHOLD.

**TIMEONCP=timeoncp**

When CPUTIME is specified, a required input parameter that contains the CPU time on standard CP, in STCK request format, for the current work.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

**WORK_AREA=work_area**

- **WORK_AREA=NO_WORK_AREA**

  When MONTKNI=NO is specified, an optional input parameter, which is used as a work area by WLM when MONTKNI(NO) is specified and either EWLM_CHCORR or EWLM_CHTKN is specified on the IWM4RPT invocation (in these cases WORK_AREA is required). The work area must begin on a doubleword boundary and must be accessible in the current PSW key when the macro is invoked. The default is NO_WORK_AREA, which indicates that no work area is passed.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a 512-character field.

- **WORK_COMPCD=work_compcd**

  When STATUS=NORMAL is specified, an optional input parameter, which contains the completion/return code for the work request execution that is associated with the Report call. The default is NO_WORK_COMPCD, which indicates that NO completion/return code is passed.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

- **WORK_COMPCD=work_compcd**

  When STATUS=ABNORMAL is specified, an optional input parameter, which contains the completion/return code for the work request execution that is
associated with the Report call. The default is NO_WORK_COMPCD, indicates
that NO completion/return code is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a
fullword field, or specify a literal decimal value.

\[\text{,WORK_COMPCD=} \text{work_compcd} \]

When STATUS=NORMAL_LE_VAL is specified, a required input parameter,
which contains the completion/return code for the work request execution that
is associated with the Report call.

To code: Specify the RS-type address, or address in register (2)-(12), of a
fullword field, or specify a literal decimal value.

\[\text{,WORK_COMPCD=} \text{work_compcd} \]

When STATUS=NORMAL_GE_VAL is specified, a required input parameter,
which contains the completion/return code for the work request execution that
is associated with the Report call.

To code: Specify the RS-type address, or address in register (2)-(12), of a
fullword field, or specify a literal decimal value.

\[\text{,WORKREQ_STA=} \text{workreq_sta} \]

An optional input parameter, which contains the completion status code of the
work request. Available completion status codes (defined in macro IWMYCON)
are: * IwmEwlmArmStatusGood(0), * IwmEwlmArmStatusAborted(1), *
IwmEwlmArmStatusFailed(2) or * IwmEwlmArmStatusUnknown(3) The codes
above correspond to status codes in the OpenGroup ARM 4.0 Standard (for the
meaning of the status codes see the ARM 4.0 Standard at http://
www.opengroup.org/management/arm). The default is
IWMEWLMARMSSTATUSNONE, which indicates that work request completion
status should be derived from the passed STATUS parameter value.

To code: Specify the RS-type address, or address in register (2)-(12), of a
fullword field, or specify a literal decimal value.

\[\text{,WORKREQ_STA=} \text{IWMEWLMARMSTATUSNONE} \]

ABEND codes

None.

Return codes and reason codes

When the IWM4RPT macro returns control to your program:
• GPR 15 (and retcode, when you code RETCODE) contains a return code.
• When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code
  RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the
equate symbol that is associated with each reason code. IBM support personnel
might request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>

</tr>
</tbody>
</table>
### Table 94. Return and Reason Codes for the IWM4RPT Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning and Action</th>
</tr>
</thead>
</table>
| 4           | —           | **Equate Symbol:** IwmRetCodeWarning  
               **Meaning:** Successful completion, unusual conditions noted. |
| 4           | xxxx0405    | **Equate Symbol:** IwmRsnCodeGoalNoMonEnv  
               **Meaning:** System is in goal mode but the input monitoring token indicates that no monitoring environment was established, hence MVS did not receive the information.  
               **Action:** None required. |
| 4           | xxxx0409    | **Equate Symbol:** IwmRsnCodeNoConn  
               **Meaning:** Connect token does not reflect a successful Connect. The system did not receive the information.  
               **Action:** None required. |
| 8           | —           | **Equate Symbol:** IwmRetCodeInvocError  
               **Meaning:** Invalid invocation environment or parameters. |
| 8           | xxxx080C    | **Equate Symbol:** IwmRsnCodeMonEnvLacksData  
               **Meaning:** Input monitoring environment does not contain the necessary information.  
               **Action:** Ensure that the monitoring environment was established with the necessary information. |
| 8           | xxxx080E    | **Equate Symbol:** IwmRsnCodeArrTimeGTEndTime  
               **Meaning:** Input arrival time later than end time.  
               **Action:** Check for possible storage overlay of the parameter list or variable. |
| 8           | xxxx0820    | **Equate Symbol:** IwmRsnCodeBadMonEnv  
               **Meaning:** Input monitoring environment does not pass short form validity checking.  
               **Action:** Check for possible storage overlay. |
| 8           | xxxx0821    | **Equate Symbol:** IwmRsnCodeBadConn  
               **Meaning:** Input connect token does not pass validity checking.  
               **Action:** Check for possible storage overlay. |
| 8           | xxxx082D    | **Equate Symbol:** IwmRsnCodeExStTimeGTEndTime  
               **Meaning:** Execution start time greater than execution end time  
               **Action:** Check for possible storage overlay of the parameter list or variable. |
| 8           | xxxx0840    | **Equate Symbol:** IwmRsnCodeServiceNotEnabled  
               **Meaning:** Caller’s space connection is not enabled for this service.  
               **Action:** Avoid requesting this function under the input connection. IWM4CON options must be specified previously to enable this service. |
### Table 94. Return and Reason Codes for the IWM4RPT Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>xxxx087E</td>
<td>IwmRsnCodeRoMonEnv</td>
<td><strong>Meaning:</strong> Input monitoring environment is report-only checking. &lt;br&gt;<strong>Action:</strong> Avoid calling this function for report-only monitoring environments.</td>
</tr>
<tr>
<td>8</td>
<td>xxxx0894</td>
<td>IwmRsnCodeInvalidEWLMCorr</td>
<td><strong>Meaning:</strong> Passed correlator information (EWLM_CHCORR, EWLM_PACORR, or EWLM_CHCTKN) did not pass validity checking, that means the architected ARM correlator length field in the first two Bytes of the correlator (token) is either less than 4 ('0004'x) or greater than 512 ('0200'x). &lt;br&gt;<strong>Action:</strong> Check the specification of the correlator information.</td>
</tr>
<tr>
<td>8</td>
<td>xxxx0895</td>
<td>IwmRsnCodeEWLMServNotEnabled</td>
<td><strong>Meaning:</strong> Service is not enabled because caller invoked the IWMCONN service with EWLM=NO. &lt;br&gt;<strong>Action:</strong> Specify the parameter EWLM_CHCORR, EWLM_PACORR, EWLM_CHCTKN, or WORKREQ_STA only when connected with EWLM=YES.</td>
</tr>

</tr>
<tr>
<td>C</td>
<td>xxxx0C06</td>
<td>IwmRsnCodeNoEndTime</td>
<td><strong>Meaning:</strong> No end time was supplied to the service and STCK gave a nonzero condition code. &lt;br&gt;<strong>Action:</strong> No action required.</td>
</tr>
</tbody>
</table>

**Example**

None.
IWM4SLI — Application environment limit service

The IWM4SLI service should be used to tell WLM the total number of server instances which are supported by the application. WLM will ensure that no more server instances will be started in the system.

In addition the caller can define a minimum number of servers which should be made available by WLM regardless of whether work is available to execute or not. The user can decide if an additional server will be started before previously started servers have connected to WLM, or if WLM needs to wait until all previously started servers have connected before an additional server will be started. If the user defines multiple service classes to give the work of the application different service goals, the caller can define that the minimum number of servers is spread across these service classes to ensure that servers are available for all work executed by the application.

The caller must have previously connected to WLM using the IWM4CON service specifying `SERVER_MANAGER=YES` and `SERVER_TYPE=QUEUE`. It is recommended to use the IWM4SLI service directly after IWM4CON. If any server uses this service to define limits, the limits apply for all servers of the application environment regardless of whether other servers use the service or not.

If a server defines new limits during execution, WLM attempts to meet the new limit definitions as soon as possible. If the maximum limit for servers is reduced during execution it is not predictable when WLM is able to meet the new maximum definition. This depends highly on the execution time of the running work requests. Therefore changing the limits during execution should be used very carefully and primarily during times of low application utilization.

**Note:** This service was previously called IWMSLIM for 31-bit addressing only (see “IWMSLIM — Application environment limit service” on page 1040).

**Environment**

The requirements for the caller are:

| Minimum authorization: | Problem state. Any PSW key |
| Dispatchable unit mode: | Task |
| Cross memory mode: | PASN=HASN=SASN |
| AMODE: | 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro. |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

**Programming requirements**

1. Make sure no EUT FRRs are established.
2. The macro CVT must be included to use this macro.
3. The macro IWMYCON must be included to use this macro.
4. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.

5. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

1. This macro may not be used during task/address space termination.

2. Only a single invocation is allowed to be active for a given address space at any given time.

3. Before using this macro the caller must connect to WLM via IWM4CON
   
   Server_Manager=YES, Server_Type=Queue.

4. The macro must be used directly after using IWM4CON.

**Input register information**

Before issuing the IWM4SLI macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.
Syntax

The syntax of the IWM4SLI macro is as follows:

```
/*SM590000*/
IWM4SLI

name

,AE_SERVERMAX=ae_servermax

,AE_SERVERMIN=ae_servermin

,AE_SPREADMIN=NO

,START_MINIMUM=SERIAL

,AE_SPREADMIN=YES

,START_MINIMUM=PARALLEL

,RETCODE=retcode

,RSCALLCODE=rsncode

,PLISTVER=IMPLIED_VERSION

,PLISTVER=MAX

,PLISTVER=0

,MF=(L,list addr,attr)

,MF=(E,list addr,attr)

,MF=S

,0D

,MF=(L,list addr,attr)

,MF=(E,list addr,attr)

,*SM590000*
```

Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWM4SLI macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**AE_SERVERMAX=ae_servermax**

An optional input parameter, which indicates the architectural limit for the total number of server instances which can run concurrently across the application environment for a given subsystem type and subsystem name.

This parameter represents a physical limit, such as the maximum number of available connections to a back-end subsystem. WLM will not start more than this number of server instances, even if goals cannot be met because of the limit. This value should be an integral multiple of the PARALLEL_EU value defined on the IWM4CON service. If AE_SERVERMAX is not an even multiple of PARALLEL_EU, WLM will round this value down to the next integral multiple.

The maximum limit and the number of service classes to execute work requests should be defined carefully. If the number of service classes exceeds the quotient of AE_SERVERMAX divided by PARALLEL_EU WLM cannot start enough server address spaces to execute the work requests for all service classes. The default is 0, indicating that no maximum limit has been specified.

**To code:** Specify the RS-type address of a halfword field.

**AE_SERVERMIN=ae_servermin**

An optional input parameter, which indicates the minimum number of servers which should be up and running at all times.

This parameter can be used to tell WLM that a certain amount of server tasks should always be kept available to select work. This value should be an
integral multiple of the PARALLEL_EU value defined on IWM4CON service. If
AE_SERVERMIN is not an even multiple of PARALLEL_EU, WLM will round
this value down to the next integral multiple. The default is 0, which indicates
that no limit has been specified.

To code: Specify the RS-type address of a halfword field.

,AE_SPREADMIN=NO
,AE_SPREADMIN=YES

When AE_SERVERMIN=ae_servermin is specified, an optional parameter, which
indicates whether WLM will distribute the minimum number of servers as
evenly as possible across the service classes being used to process the work
requests. The default is AE_SPREADMIN=NO.

,AE_SPREADMIN=NO

The server tasks specified in AE_SERVERMIN will be distributed to service
classes as needed in order to meet goals.

,AE_SPREADMIN=YES

The server tasks specified in AE_SERVERMIN will be distributed as evenly
as possible to all service classes being used to execute work requests.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline
parameter list and generates the macro invocation to transfer control to the
service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter may be coded with the list form of
the macro.

Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
defined by the list form, and generates the macro invocation to transfer control
to the service.

,list addr

The name of a storage area to contain the parameters. For MF=S and
MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr

An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE

Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 0, if you use the currently available parameters.

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

START_MINIMUM=SERIAL
START_MINIMUM=PARALLEL
When AE_SERVERMIN=ae_servermin is specified, an optional parameter, which indicates whether WLM will start the minimum number of servers one by one or in parallel. The default is START_MINIMUM=SERIAL.

START_MINIMUM=SERIAL
The server tasks specified in AE_SERVERMIN will be started one by one. This means the next server will only be started if the previous server has connected to WLM.

START_MINIMUM=PARALLEL
The server tasks specified in AE_SERVERMIN will be started in parallel. This means WLM will start additional servers even when the previous servers have not connected to WLM.

ABEND codes

None.
Return codes and reason codes

When the IWM4SLI macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 0           | —           | Equate Symbol: IwmRetCodeOk  
Meaning: Successful completion.  
Action: None required. |
| 8           | —           | Equate Symbol: IwmRetCodeInvocError  
Meaning: Invalid invocation environment or parameters. |
| 8           | xxxx0801    | Equate Symbol: IwmRsnCodeSrbMode  
Meaning: The caller is in SRB mode.  
Action: Avoid requesting this function while in SRB mode. |
| 8           | xxxx0803    | Equate Symbol: IwmRsnCodeDisabled  
Meaning: Caller is disabled.  
Action: Avoid requesting this function while disabled. |
| 8           | xxxx0804    | Equate Symbol: IwmRsnCodeLocked  
Meaning: The caller is locked.  
Action: Avoid requesting this function while locked. |
| 8           | xxxx080B    | Equate Symbol: IwmRsnCodeBadPl  
Meaning: Error accessing parameter list.  
Action: Check for possible storage overlay. |
| 8           | xxxx0824    | Equate Symbol: IwmRsnCodeAmode24  
Meaning: The caller invoked the service but was in 24-bit addressing mode.  
Action: Request this function only when you are in 31-bit addressing mode. |
| 8           | xxxx0825    | Equate Symbol: IwmRsnCodeAscModeNotPrimary  
Meaning: The caller invoked the service but was not in primary ASC mode.  
Action: Avoid requesting this function in this environment. |
| 8           | xxxx0827    | Equate Symbol: IwmRsnCodeRsvdNot0  
Meaning: Reserved field in parameter list was not zero.  
Action: Check for use of keywords that are not supported by the MVS release on which the program is running. |
### Table 95. Return and Reason Codes for the IWM4SLI Macro (continued)

<table>
<thead>

</tbody>
</table>
IWM4SRSC — Obtain server-specific routing information

The IWM4SRSC service provides information about how well a server is suitable to receive work from a WLM point-of-view. The IWM4SRSC service allows to check a specific server before routing work to it from WLM. Thus, the information obtained can be used for making balanced routing decisions.

The input to the IWM4SRSC service is the STOKEN of an address space. The output is an indicator, of how well the address space itself, the transactions or enclaves—if it is a registered transaction server, an enclave server, or an enclave owner—are performing relative to their WLM goal and to the displaceable capacity for its WLM importance on that system.

The service returns an indicator that can be used for load balancing by comparing it to calls of this service for other servers.

The indicator output is a weight. WLM provides two methods for computing the weight, which can be selected with the optional input parameter METHOD. The default method is PROPORTIONAL, the other one is EQUICPU.

- With PROPORTIONAL, the weight is calculated based on six factors: it is a combination of the three processor weights (CPU weight, ZAAP weight, and ZIIP weight) and their respective consumed service units repartition.
- With EQUICPU, WLM computes the weight by trying to simulate a 100% usage of the system capacity, and determining the capacity of a CPU-only system having equivalent resource consumption.

The CPU, ZAAP, and ZIIP weights are each computed based on the following four factors:

- The first factor is how well this server, or the transactions or enclaves it is related to, fulfill their goals.
- The second factor is the abnormal termination factor. This depends on the ratio of abnormal terminations to normal terminations as reported by the IWMRPT service. If no terminations were reported by IWM4RPT, this factor is neutral (=1).
- The third factor is the health factor of this server. It is dependent on the health indicator which was reported to WLM for this server by the IWM4HLTH service or by IWMSRSRG. If no health indicator was reported, this factor is also neutral.
- The fourth factor is how much other work with lower importance can be displaced, if it receives more work to handle on this system. With the optional IL_WEIGHTING parameter, the caller can set the relative balance between the lower and the higher importance levels.

These four factors are combined to create the output processor WEIGHT as a number.

To make it easier for the caller to determine, how far the weights were influenced by the abnormal terminations and health factors, those values can also be output through the optional parameters ABNORM_COUNT and HEALTH.

The processor weights are returned through the optional CPUWEIGHT, ZAAPWEIGHT and ZIIPWEIGHT parameters. The respective parts of these weights in the WEIGHT are returned through the optional parameters CPUPROPORTION, ZAAPPROPORTION, and ZIIPPROPORTION.
If there are pre-V1R9 systems in the sysplex, the zAAP and zIIP weights and proportions are automatically set to 0, because pre-V1R9 systems do not have such weights and could not be compared to V1R9 systems. For the same reason, if there are pre-V1R11 systems in the sysplex, only \texttt{METHOD=PROPORTIONAL} will be used, even if \texttt{METHOD=EQUICPU} is specified.

The \texttt{WEIGHT} is equal to the sum of these three proportion fields. As WLM computes the values with higher precision, and rounds them before output, the \texttt{WEIGHT} actually returned is probably greater than the sum of the returned proportion fields by one or two units.

A scenario where TCP/IP communicates on each system with WLM to obtain information about the servers which receive work is described in the following.

TCP/IP recognizes the server address spaces when they open a port. It invokes the IWM4SRSC service to WLM with an identification of the address space (STOKEN). WLM then finds out whether that address space is a registered WLM server address space or whether it creates WLM transactions which can execute in other server address spaces. The following possibilities are considered:

- The address space does not create any enclaves and is not a server address space registered to WLM. The FTP daemon is such an address space, for example. In this case WLM uses the service class the address space has been classified to.
- The address space is not a registered server address space but it creates independent enclaves which are processed by other address spaces on that system. In this case WLM has to use the service classes for the enclaves which are owned by this address space.

\textbf{Note:} There can be multiple service classes which are associated with enclaves. In this case the service class with the highest transaction rate is used.

- The address space is a server address space from the point-of-view of WLM. In this case it is either an enclave or a transaction server, for example, CICS or IMS. In this case WLM uses the service classes the enclaves or CICS or IMS transactions are classified to.

\section*{Environment}

The requirements for the caller are:

\begin{itemize}
  \item \textbf{Minimum authorization:} Problem state. Any PSW key
  \item \textbf{Dispatchable unit mode:} Task or SRB
  \item \textbf{Cross memory mode:} Any PASN, any HASN, any SASN
  \item \textbf{AMODE:} 31- or 64-bit. If in 64-bit addressing mode, code \texttt{SYSSTATE AMODE64=YES} before invoking this macro.
  \item \textbf{ASC mode:} Primary
  \item \textbf{Interrupt status:} Enabled for I/O and external interrupts
  \item \textbf{Locks:} No locks may be held. FRRs may be established.
  \item \textbf{Control parameters:} Control parameters must be in the primary address space.
\end{itemize}

\section*{Programming requirements}

1. The macro \texttt{CVT} must be included to use this macro.
2. The macro \texttt{IWMYCON} must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

**Restrictions**
- This macro may only be used on systems running z/OS V1R7 or later.
- This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

**Input register information**
Before issuing the IWM4SRSC macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**
When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**
None.
Syntax

The syntax of the IWM4SRSC macro is as follows:

```
name IWM4SRSC WEIGHT=weight,STOKEN=stoken,ABNORM_COUNT=abnorm_count

,HEALTH=health,CPUWEIGHT=cpuweight,ZAAPWEIGHT=zaapweight

,ZIIPWEIGHT=ziipweight,CUPROPORTION=cpuproportion

,ZAAPPORPOTION=zaapproportion,ZIIPPROPORTION=ziipproportion

,MAXSRVUNITS=maxsrvunits,METHOD=PROPORTIONAL

,COST_ZAAP_ON_CP=1,COST_ZIIP_ON_CP=1

,COST_ZAAP_ON_CP=cost_zaab_on_cp,COST_ZIIP_ON_CP=cost_ziip_on_cp

,MAXEQUIVUNITS=maxequvunits,IL_WEIGHTING=il_weighting,RETCODE=retcode

,RSNCODE=rsncode,PLISTVER=IMPLIED_VERSION

,MF=S

,MF=(L,list addr,attr,COMPLETE)
```

Parameters

The parameters are explained as follows:

`name`
An optional symbol, starting in column 1, that is the name on the IWM4SRSC macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`ABNORM_COUNT=abnorm_count`
An optional output parameter, which contains the number of abnormal terminations per 1000 total terminations, if available. If no abnormal terminations were reported to WLM, this value is zero. This is independent of
the reason why no report was issued - whether no abnormal terminations occurred or whether the subsystem of the server is not enabled to report them to WLM.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

\,\text{COST\_ZAAP\_ON\_CP} = \text{cost\_zaap\_on\_cp}
\,\text{COST\_ZAAP\_ON\_CP} = 1

An optional input parameter, which is used in conjunction with \text{METHOD=EOUCPU}. It describes how much more it costs to execute zAAP-eligible work on a CPU instead of on a zAAP processor.

To use the full system capacity, independently of the cost, specify \text{COST\_ZAAP\_ON\_CP}=1. With high values of this cost parameter, WLM considers that a system having used up its whole free zAAP capacity should offload less work to the CPU, and gives this system a smaller output weight.

This cost parameter must be in the range from 1 to 100. If the passed value is outside of this range, WLM will instead use the nearest valid integer (1 or 100) as cost parameter. The default is 1.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

\,\text{COST\_ZIIP\_ON\_CP} = \text{cost\_ziip\_on\_cp}
\,\text{COST\_ZIIP\_ON\_CP} = 1

An optional input parameter, which is used in conjunction with \text{METHOD=EOUCPU}. It describes how much more it costs to execute zIIP-eligible work on a CPU instead of on a zIIP processor.

To use the whole system capacity, independently of the cost, specify \text{COST\_ZIIP\_ON\_CP}=1. With high values of this cost parameter, WLM considers that a system having used up its whole free zIIP capacity should offload less work to the CPU, and gives this system a smaller output weight.

This cost parameter must be in the range from 1 to 100. If the passed value is outside of this range, WLM will use the nearest valid integer (1 or 100) as cost parameter. The default is 1.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

\,\text{CPUPROPORTION} = \text{cpuproportion}

An optional output parameter, which contains the CPU weight part in the calculation of the weight.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

\,\text{CPUWEIGHT} = \text{cpuweight}

An optional output parameter, which contains the weight of how well the server is doing on the CPU.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

\,\text{HEALTH} = \text{health}

An optional output parameter, which contains the health indicator of this server. This is a value between 0 and 100, which was reported to WLM either by the IWM4HLTH or the IWMSRSRG service. If no health indicator was reported, the value is 100.
To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,IL_WEIGHTING=il_weighting

An optional input parameter, which controls how WLM evaluates available capacity at importance levels (ILs) lower than the currently selected one. The value of IL_WEIGHTING should be in the range from 0 to 3. If the passed value is out of this range, WLM will use the nearest valid integer (0 or 3) as IL_WEIGHTING instead.

When this parameter is set to 0 (the default value), all free capacities used by levels less important than the current one are evaluated the same. This means that the free capacity below current level is considered to be totally free, and this is equivalent to what WLM did prior to V1R11.

When this parameter is set to 1, free capacity at the lowest ILs is evaluated higher than the current IL, with a weighting growing proportionally to the square root of the IL difference + 1. For example, with a selected IL of 1, free capacity at IL 5 is weighted about 2.236 times more than free capacity at IL 1.

When this parameter is set to 2, free capacity at the lowest ILs is evaluated higher than the current IL, with a weighting growing proportionally to the IL difference + 1. For example, with a selected IL of 1, free capacity at IL 5 is weighted 5 times more than free capacity at IL 1.

When this parameter is set to 3, free capacity at the lowest ILs is weighted more than the current IL, with a weighting growing proportionally to the square of the IL difference + 1. For example, with a selected IL of 1, free capacity at IL 5 is weighted 25 times more than free capacity at IL 1. The default is 0.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

,MAXEQUIVUNITS=maxequivunits

An optional output parameter, which contains the maximum equivalent service units across all processing resources used to calculate the mixed weight output.

If METHOD=PROPORTIONAL is specified, MAXEQUIVUNITS is automatically set to 0, since WLM does not compute equivalent CPU service units in this case.

If METHOD=EQUIPCPU is specified, MAXEQUIVUNITS is always a number in the range from 1 to MAXSRVUNITS. MAXEQUIVUNITS then relates to the mixed weight output only, and MAXSRVUNITS to the CPU, ZAAP and ZIIP weight outputs only.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,MAXSRVUNITS=maxsrvunits

An optional output parameter, which contains the maximum service units across all processing resources used to calculate the weights.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,METHOD=PROPORTIONAL
,METHOD=EQUIPCPU

An optional parameter, which selects the method for computing the output weights. The default is METHOD=PROPORTIONAL.
METHOD=PROPORTIONAL

Computes the output weights as a proportion of the three processor type weights.

METHOD=EQUICPU

Computes a CPU equivalent of the systems before computing the output weights.

To specify METHOD=EQUICPU, all systems in the sysplex must run z/OS V1R11, or higher. Otherwise WLM automatically switches back to METHOD=PROPORTIONAL.

, MF=S
, MF=(L, list addr)
, MF=(L, list addr, attr)
, MF=(L, list addr, 0D)
, MF=(E, list addr)
, MF=(E, list addr, COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

, list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

, attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

, COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

, PLISTVER=IMPLIED_VERSION
, PLISTVER=MAX
, PLISTVER=0
, PLISTVER=1
, PLISTVER=2
, PLISTVER=3
, PLISTVER=4

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, which supports all parameters except those specifically referenced in higher versions.

- **1**, which supports the following parameters and those from version 0:
  - ABNORM_COUNT
  - HEALTH

- **2**, which supports the following parameters and those from version 0 and 1:
  - CPU_PROPORTION
  - CPU_WEIGHT
  - ZAAP_PROPORTION
  - ZAAP_WEIGHT
  - ZIIP_PROPORTION
  - ZIIP_WEIGHT

- **3**, which supports the following parameter and those from version 0, 1, and 2:
  - MAXSRVUNITS

- **4**, which supports the following parameters and those from version 0, 1, 2, and 3:
  - COST_ZAAP_ON_CP
  - COST_ZIIP_ON_CP
  - IL_WEIGHTING
  - MAX_EQUIVUNITS
  - METHOD

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0, 1, 2, 3, or 4

```
,RetCode=retcode
```

An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

```
,RSNCode=rsncode
```

An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

```
,SToken=stoken
```

A required input parameter, which contains the space token of the server.
To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

**WEIGHT=weight**
A required output parameter, which contains the weight of how well the server is performing.
To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,**ZAAPPROPORTION=zaapproportion**
An optional output parameter, which contains the ZAAP weight part in the calculation of the WEIGHT.
To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,**ZAAPWEIGHT=zaapweight**
An optional output parameter, which contains the weight of how well the server is doing on the ZAAP.
To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,**ZIIPPROPORTION=ziipproportion**
An optional output parameter, which contains the ZIIP weight part in the calculation of the WEIGHT.
To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,**ZIIPWEIGHT=ziipweight**
An optional output parameter, which contains the weight of how well the server is doing on the ZIIP.
To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4SRSC macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

Example

To get the recommended values for a particular server, specify:

```
IWM4SRSC STOKEN=STKN,
  WEIGHT=WGHT,
  ABNORM_COUNT=ABCNT,
  HEALTH=HLTH,
  RETCODE=RC,RSNCODE=RSN
```

* Storage areas
* STKN DS CL8 Contains the STOKEN associated with the address
* WGHT DS F Field to receive the weight
* ABCNT DS F Field to receive the Abnormal Count
* HLTH DS F Field to receive the Health Indicator
* RC DS F Return code
* RSN DS F Reason code
IWM4SSL — Select a request from a caller's work manager queue

The IWM4SSL service selects the next work request from the queue associated with the caller's application environment. The caller must have previously connected to WLM using the IWM4CON service specifying SERVER_MANAGER=YES.

If there are no queued work requests waiting for selection the calling task will be suspended, pending arrival of work to do. The caller cannot rely upon asynchronous exits receiving control while the task is suspended.

After a work request is selected, the caller uses the IWM4STBG and IWM4STEN services to indicate the start and end of processing of the request.

Note: This service was previously called IWMSSEL for 31-bit addressing only (see "IWMSSEL — Select a request from a caller's work manager queue" on page 1047).

Environment

The requirements for the caller are:

| Minimum authorization:       | Problem state. Any PSW key              |
| Dispatchable unit mode:      | Task                                      |
| Cross memory mode:           | PASN=HASN=SASN                            |
| AMODE:                       | 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro. |
| ASC mode:                    | Primary                                   |
| Interrupt status:            | Enabled for I/O and external interrupts   |
| Locks:                       | No locks may be held.                     |
| Control parameters:          | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

None.
Input register information

Before issuing the IWM4SSL macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWM4SSL macro is as follows:

```
name       IWM4SSL=USERDATA=userid=WLMEXITNL=wlmeutkn
,SERVER_TOKEN=server_token,REGION_TOKEN=region_token,RETCODE=retcode
,PLISTVER=IMPLIED_VERSION,PLISTVER=MAX,PLISTVER=0
```
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWM4SSL macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**MF=S**
**MF=(L,list addr)**
**MF=(L,list addr,attr)**
**MF=(L,list addr,0D)**
**MF=(E,list addr)**
**MF=(E,list addr,COMPLETE)**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**list addr**
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

**COMPLETE**
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

**PLISTVER=IMPLIED_VERSION**
**PLISTVER=MAX**
**PLISTVER=0**
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, which supports all parameters except those specifically referenced in higher versions.

**To code:** Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

**REGION_TOKEN=region_token**

An optional output parameter, which contains a region token. A queueing manager can use the region token to queue work requests to a specific server region. These work requests are considered to belong to a set of work requests all needing access to same status information which exists only in the virtual storage of the server region. They are selected using the IWM4SSL macro. It is assumed that the application uses the service IWM4TAF to tell WLM when the temporary affinity to the defined server region begins and ends.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**RETCODE=retcode**

An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**RSNCODE=rsncode**

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a

**SERVER_TOKEN=server_token**

An optional output parameter, which contains a server token. A queueing manager can use the server token to queue secondary work requests to this server task. Secondary work requests are considered to be extensions of the work request selected by IWM4SSL. They are selected using the IWM4SSM macro. See the IWM4SSM macro for more information.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

**USERDATA=userdata**

A required output parameter, which contains the user data previously passed to WLM via IWM4QIN.
To code: Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

wlmeutkn

A required output parameter, which will receive the execution unit token. This token must be passed on subsequent IWM4STBG and IWM4STEN requests.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4SSL macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

### Example

To select a work request from the WLM queue manager queues, specify:

```plaintext
IWM4SSL USERDATA=USERDATA, X
WLMEUTKN=WLMEUTKN, RETCODE=RC, RSNCODE=RSN

* Storage areas
* USERDATA DS CL16 Contains the user-defined data that was passed to IWM4QIN
  WLMETK=WLMEUTKN, RETCODE=RC, RSNCODE=RSN
  * RC DS F Returns code
  RSN DS F Reason code
```
IWM4SSM — WLM server select secondary service

The IWM4SSM service selects the next secondary work request from the queue associated with the caller's server task.

If there are no queued secondary work requests waiting for selection the calling task will be suspended, pending arrival of work to do. The caller cannot rely upon asynchronous exits receiving control while the task is suspended.

Secondary work requests are considered to be extensions of an original work request selected using IWM4SSL. The caller must invoke WLM services in the following sequence:

1. The caller invokes the IWM4SSL macro to select an initial work request. IWM4SSL returns a token identifying the server task. The caller is responsible for passing the server token to the queueing manager so that it can insert secondary work requests.
2. The caller invokes the IWM4STBG macro to establish an environment for processing the work request selected using IWM4SSL. This environment also covers all secondary work requests.
3. The caller invokes the IWM4SSM macro to select each secondary work request. The queueing manager is responsible for indicating the last secondary work request so that the server task knows when not to try to select another one.
4. After the last secondary work request has been processed, the caller invokes the IWM4STEN macro to remove the environment created by IWM4STBG.
5. The caller invokes IWM4SSL to select a new primary work request, and repeats the above flow.

In the above flow, IWM4SSL, IWM4STBG, IWM4SSM, and IWM4STEN must be invoked from the same task.

**Note:** This service was previously called IWSMSEM for 31-bit addressing only (see "IWSMSEM — WLM server select secondary service" on page 1055).

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state. Any PSW key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>PASN=HASN=SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>
Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

None.

Input register information

Before issuing the IWM4SSM macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.
IWM4SSM

Syntax

The syntax of the IWM4SSM macro is as follows:

```
/IWM4SSM USERDATA=userdata RETCODE=retcode RSNCODE=rsncode
```

Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWM4SSM macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**MF=S**

An optional input parameter that specifies the macro form. Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**list addr**

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code **attr**, the system provides a value of 0D.
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

**PLISTVER**

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

**RETCODE**

An optional output parameter into which the return code is to be copied from GPR 15.

**RSNCODE**

An optional output parameter into which the reason code is to be copied from GPR 0.

**USERDATA**

A required output parameter, which contains the user data previously passed to WLM via IWM4QIN.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWM4SSM macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
• When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Table 98. Return and Reason Codes for the IWM4SSM Macro

<tr>
<td>RSN DS</td>
<td>F</td>
<td>Reason code</td>
</tr>
</tbody>
</table>
IWM4STBG — WLM begin server transaction service

IWM4STBG establishes the environment to process a work request that was previously selected using IWM4SSL. The caller must invoke IWM4STBG from the task in the server address space that will process the request. IWM4STBG establishes a business unit-of-work relationship by joining the caller's task to the enclave associated with the request. IWM4STBG creates a security environment if there is a userid associated with the request previously selected.

Use IWM4STBG together with IWM4STEN to begin and end the processing of a work request. A task can process only one work request at a time.

Note that a task may only join an enclave if it is not already part of an enclave. In particular, a subtask which inherited the enclave attribute from its mother task (which may happen either as a result of the mother task issuing IWMEJOIN or IWM4STBG) is not allowed to use IWMEJOIN to explicitly join an enclave. This restriction is independent of whether the specified enclave is the same enclave as it is in, or a different enclave from the one it is in. Such a subtask which inherited the enclave attribute is also not allowed to use IWMELEAV to explicitly leave the enclave. The subtask would only leave the enclave upon its own (task) termination or when the enclave is deleted (IWM4EDEL). Also, a task which successfully establishes a Begin environment (IWM4STBG) may not invoke enclave Join, nor is the task allowed to use enclave Leave while this Begin environment exists.

Note: This service was previously called IWMSTBGN for 31-bit addressing only (see “IWMSTBGN — Begin a request from a caller's work manager queue” on page 1062).

Environment

The requirements for the caller are:

- **Minimum authorization:** Problem state. Any PSW key
- **Dispatchable unit mode:** Task
- **Cross memory mode:** PASN=HASN=SASN
- **AMODE:** 31- or 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.
- **ASC mode:** Primary
- **Interrupt status:** Enabled for I/O and external interrupts
- **Locks:** No locks may be held.
- **Control parameters:** Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
Restrictions

The caller cannot have an EUT FRR established.

Input register information

Before issuing the IWM4STBG macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

main diagram

```
>>> b.IWM4STBG b.WLMEUTKN=wlmeutkn.,ETOKEN=etoken-

,SUBTASKS=NO

,SUBTASKS=YES

,RETCODE=retcode

,RSNCODE=rsncode
```
IWM4STBG

Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWM4STBG macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**ETOKEN=etoken**

An optional output parameter, which will receive the enclave token.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**MF=S**

**MF=(L,list addr)**

**MF=(L,list addr,attr)**

**MF=(L,list addr,0D)**

**MF=(E,list addr)**

**MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**list addr**

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code *attr*, the system provides a value of 0D.

**COMPLETE**

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

An optional parameter, which specifies if subtasks of the requesting task are also to be processed. The default is SUBTASKS=NO.

**SUBTASKS=NO** specifies that subtasks of the requesting task are not to be processed.

**SUBTASKS=YES** specifies that subtasks of the requesting task that are not already joined to an enclave are to be joined to the enclave identified by this invocation's ETOKEN parameter. When a currently-dispatched subtask is joined to the enclave, its CPU time for that dispatch is associated with the enclave rather than the address space. When the subtask is removed from the enclave, if
IWM4STBG

it is currently dispatched, its CPU time for that dispatch is associated with
the address space rather than the enclave.

If SYSEVENT REQSRMST does not indicate, via bit SRMSTSTS being on,
that this function is available, this is treated as SUBTASKS=NO.

When SUBTASKS=YES is in effect, this task’s corresponding IWM4STEN
will also perform leave processing upon any subtasks that are implicitly
associated with the enclave. This includes subtasks that were joined to the
enclave due to this task’s IWM4STBG processing as well as subtasks that
were joined to the enclave by ATTACH processing.

WLMEUTKN=wlmeutkn
A required input parameter, execution unit token that was returned by a prior
invocation of IWM4SSL.

To code: Specify the RS-type address, or address in register (2)-(12), of an
8-character field.

ABEND codes

None.

Return codes and reason codes

When the IWM4STBG macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code
  RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the
equate symbol associated with each reason code. IBM support personnel may
request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>

### Table 99. Return and Reason Codes for the IWM4STBG Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol Meaning and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0840    | **Equate Symbol**: IwmRsnCodeServiceNotEnabled  
Meaning: Caller's space connection is not enabled for this service  
Action: Make sure that SERVER_MANAGER=YES is specified on the IWM4CON request to enable this service. |
| 8           | xxxx0841    | **Equate Symbol**: IwmRsnCodeXmemMode  
Meaning: Caller is in cross-memory mode.  
Action: Request this function only when you are not in cross-memory mode. |
| 8           | xxxx0842    | **Equate Symbol**: IwmRsnCodeNoWLMConnect  
Meaning: Caller's space is not connected to WLM.  
Action: Invoke the IWM4CON macro before invoking this macro. |
| 8           | xxxx0850    | **Equate Symbol**: IwmRsnCodeBeginEnvOutstanding  
Meaning: Caller is already operating under an outstanding Begin environment.  
Action: Avoid requesting this function in this environment. |
| 8           | xxxx0851    | **Equate Symbol**: IwmRsnCodeSecEnvOutstanding  
Meaning: Caller is already operating under an outstanding security environment.  
Action: Avoid requesting this function while there is a TCB level security environment outstanding. |
| 8           | xxxx0852    | **Equate Symbol**: IwmRsnCodeExecTokenNotCorrect  
Meaning: The execution unit token does not identify a previously selected work unit.  
Action: Verify that you have coded the WLMEUTKN parameter correctly. |
| 8           | xxxx0857    | **Equate Symbol**: IwmRsnCodeAlreadyInEnclave  
Meaning: Current dispatchable workunit is already in an enclave.  
Action: Avoid requesting this function while the caller is already in an enclave. |
| 8           | xxxx085A    | **Equate Symbol**: IwmRsnCodeSelectedWorkActive  
Meaning: The selected work element associated with the input execution unit token is already in execution.  
Action: You may have invoked IWM4STBG from multiple tasks in the server address space passing the same WLMEUTKN. Avoid requesting this function in this environment. |
| C           | —           | **Equate Symbol**: IwmRetCodeEnvError  
Meaning: Environmental error. |
Table 99. Return and Reason Codes for the IWM4STBG Macro (continued)

<table>
<thead>

<td></td>
<td><strong>Action</strong>: Contact your system programmer.</td>
</tr>
</tbody>
</table>

**Example**

Suppose a work request was selected using IWM4SSL and the execution unit token returned by IWM4SSL is WLMEUTKN.

To establish the environment to process the work request:

```plaintext
IWM4STBG WLMEUTKN=WLMEUTKN,RETCODE=RC,RSNCODE=RSN
```

* Storage areas

```plaintext
WLMEUTKN DS CL8 Contains the execution unit token that was returned by IWM4SSL
RC DS F Return code
RSN DS F Reason code
```
IWM4STEN — End a request from a caller's work manager queue

IWM4STEN removes the environment which was previously established using IWM4STBG to process a work request. The caller must invoke IWM4STEN from the same task that invoked IWM4STBG. IWM4STEN removes the caller's task from the enclave associated with the request. IWM4STEN deletes the security environment if one was previously established by IWM4STBG.

Note: This service was previously called IWMSTEND for 31-bit addressing only (see "IWMSTEND — End a request from a caller's work manager queue" on page 1070).

Environment

The requirements for the caller are:

| Minimum authorization: | Problem state. Any PSW key |
| Dispatchable unit mode: | Task |
| Cross memory mode: | PASN=HASN=SASN |
| AMODE: | 31- and 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro. |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

The caller cannot have an EUT FRR established.

Input register information

Before issuing the IWM4STEN macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWM4STEN macro is as follows:

```
{name} IWM4STEN MLMEUTKN=wlmeutkn ,RETCODE=retcode ,RSNCODE=rsncode ,PLISTVER=IMPLIED_VERSION ,PLISTVER=MAX ,PLISTVER=0 ,MF=S ,MF=(L,list addr ,attr ,COMPLETE )
```

Parameters

The parameters are explained as follows:

`name`

An optional symbol, starting in column 1, that is the name on the IWM4STEN macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`,MF=S`
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

`list addr`

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

`attr`

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

`COMPLETE`

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

`PLISTVER=IMPLIED_VERSION`
`PLISTVER=MAX`
`PLISTVER=0`

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form.

When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (with or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (with or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0), (REG00), or (R0).

WLMEUTKN=wlmeutkn
A required input parameter, execution unit token that was specified on the prior invocation of IWM4STBG.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

ABEND codes
None.

Return codes and reason codes

When the IWM4STEN macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Return Code</th>
<th>Equate Symbol, Meaning, and Action</th>

### Table 100. Return and Reason Codes for the IWM4STEN Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Return Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 4           | xxxx041F    | Equate Symbol: IwmRsnCodeExecEnvChanged  
Meaning: The execution environment has changed while the requested function is in progress.  
Action: None required. |
| 4           | xxxx042F    | Equate Symbol: IwmRsnCodeSecondaryWorkDeleted  
Meaning: There were secondary work requests queued to this server task. The caller was expected to process them using IWM4SSM before calling IWM4STEN. The secondary work requests were deleted.  
Action: Select all secondary work requests before issuing IWM4STEN. |
| 8           | —           | Equate Symbol: IwmRetCodeInvocError  
Meaning: Invalid invocation environment or parameters. |
| 8           | xxxx0801    | Equate Symbol: IwmRsnCodeSrbMode  
Meaning: Caller is in SRB mode.  
Action: Avoid requesting this function while in SRB mode. |
| 8           | xxxx0803    | Equate Symbol: IwmRsnCodeDisabled  
Meaning: Caller is disabled.  
Action: Avoid requesting this function while disabled. |
| 8           | xxxx0804    | Equate Symbol: IwmRsnCodeLocked  
Meaning: The caller is locked.  
Action: Avoid requesting this function while locked. |
| 8           | xxxx080B    | Equate Symbol: IwmRsnCodeBadPl  
Meaning: Error accessing parameter list.  
Action: Check for possible storage overlay. |
| 8           | xxxx0810    | Equate Symbol: IwmRsnCodeEutFrr  
Meaning: The caller has EUT FRR established.  
Action: Avoid requesting this function with an EUT FRR set. |
| 8           | xxxx0823    | Equate Symbol: IwmRsnCodeDatoff  
Meaning: The caller invoked the service while DATOFF  
Action: Avoid requesting this function in this environment. |
| 8           | xxxx0824    | Equate Symbol: IwmRsnCodeAmode24  
Meaning: The caller invoked the service but was in 24-bit addressing mode.  
Action: Request this function only when you are in 31-bit addressing mode. |
| 8           | xxxx0825    | Equate Symbol: IwmRsnCodeAscModeNotPrimary  
Meaning: The caller invoked the service but was not DAT on Primary ASC mode.  
Action: Avoid requesting this function in this environment. |
Table 100. Return and Reason Codes for the IWM4STEN Macro (continued)

</tbody>
</table>

Example

To remove the environment which was previously established using IWM4STBG, specify:

```
IWM4STEN WLMEUTKN=WLMEUTKN,RETCODE=RC,RSNCODE=RSN
*  
* Storage areas
*  
WLMEUTKN DS CL8 Contains the execution unit
*  
* token that was specified on
*  
the prior invocation of
*  
IWM4STBG
RC DS F Return code
RSN DS F Reason code
```
IWM4TAF — WLM temporal affinity service

The IWM4TAF service should be used to inform WLM when a temporal affinity for a specific server region starts and when it ends. WLM will ensure that server regions will not be terminated as long as temporal affinities exist.

The caller must have previously connected to WLM using the IWM4CON as server or as queue manager.

**Note:** This service was previously called IWMTAFF for 31-bit addressing only (see “IWMTAFF — WLM temporal affinity service” on page 1076).

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Requirement details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum authorization</td>
<td>Problem state. Any PSW key</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>PASN=HASN=SASN</td>
</tr>
<tr>
<td>AMODE</td>
<td>31- and 64-bit. If in 64-bit addressing mode, code SYSSTATE AMODE64=YES before invoking this macro.</td>
</tr>
<tr>
<td>ASC mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. Make sure no EUT FRRs are established.
2. The macro CVT must be included to use this macro.
3. The macro IWMYCON must be included to use this macro.
4. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
5. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

1. This macro may not be used during task/address space termination.
2. Before using this macro the caller must connect to WLM via IWM4CON
   
   Server_Manager=YES, Server_Type=Queue or IWM4CON Queue_Manager=YES.

**Input register information**

Before issuing the IWM4TAF macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
### Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

### Performance implications

None.

### Syntax

The syntax of the IWM4TAF macro is as follows:

```
IWM4TAF
  AFFINITY=YES
  AFFINITY=NO
  REGION_TOKEN=REGION_TOKEN
  ,REGION_TOKEN=region_token
  ,RETCODE=retcode
  ,RSNCODE=rsncode
  ,PLISTVER=IMPLIED_VERSION
  ,PLISTVER=MAX
  ,PLISTVER=0
  ,MF=S
  ,MF=(L ,list addr)
  ,MF=(E ,list addr)
  ,MF=(attr)
  ,COMPLETE
```

### Parameters

The parameters are explained as follows:
name
An optional symbol, starting in column 1, that is the name on the IWM4TAF
macro invocation. The name must conform to the rules for an ordinary
assembler language symbol.

AFFINITY=YES
AFFINITY=NO
A required parameter indicating whether a temporal affinity begins or ends

AFFINITY=YES
A new temporal affinity for the server region begins. WLM will ensure that
the server regions is not terminated before all temporal affinity have ended.

AFFINITY=NO
A temporal affinity for the server region has ended. WLM will start to
terminate server regions if all temporal affinities have ended.

, MF=S
, MF=(L, list addr)
, MF=(L, list addr, attr)
, MF=(L, list addr, 0D)
, MF=(E, list addr)
, MF=(E, list addr, COMPLETE)
An optional input parameter that specifies the macro form.
Use MF=S to specify the standard form of the macro, which builds an inline
parameter list and generates the macro invocation to transfer control to the
service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter may be coded with the list form of
the macro.

Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
defined by the list form, and generates the macro invocation to transfer control
to the service.

, list addr
The name of a storage area to contain the parameters. For MF=S and
MF=E, this can be an RS-type address or an address in register (1)-(12).

, attr
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code attr, the system provides a value of 0D.

, COMPLETE
Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

, PLISTVER=IMPLIED_VERSION
, PLISTVER=MAX
, PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0

\[REGION_TOKEN=region\_token\]

An optional input parameter, which contains the region token. The region token is not required if the macro is invoked from the server region for which the temporal affinity should be started or stopped. The region token must be used if the services is used from the queueing manager. The region token is returned by the IWM4CON and IWM4SSL macro.

The caller must be supervisor state or have PSW key mask 0-7 authority to use this service with the REGION_TOKEN parameter.

Coding REGION_TOKEN=0 is equivalent to omitting the REGION_TOKEN keyword. The default is 0.

To code: Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

\[RETCODE=retcode\]

An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

\[RSNCODE=rsncode\]

An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

### ABEND codes

None.
Return codes and reason codes

When the IWM4TAF macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning</th>
<th>Action</th>
</tr>
</thead>
</table>
| 0           | —           | Equate Symbol: IwmRetCodeOk  
Meaning: Successful completion.  
Action: None required. |
| 4           | —           | Equate Symbol: IwmRetCodeWarning  
Meaning: Successful completion, unusual conditions noted.  
Action: None required. |
| 4           | xxxx0439    | Equate Symbol: IwmRsnCodeNoAffinityFound  
Meaning: The service has been invoked to tell WLM that an existing server region affinity has been terminated but WLM has no affinity defined for this server region.  
Action: If region token was not specified make sure to use the service properly at the beginning and end of each affinity. If the region token has been defined make sure that it is used for the correct server region. |
| 4           | xxxx043A    | Equate Symbol: IwmRsnCodeRegionNotFound  
Meaning: The region token does not identify a valid server region.  
Action: Please specify the correct region token. |
| 8           | —           | Equate Symbol: IwmRetCodeInvocError  
Meaning: Invalid invocation environment or parameters. |
| 8           | xxxx0801    | Equate Symbol: IwmRsnCodeSrbMode  
Meaning: Caller is in SRB mode.  
Action: Avoid requesting this function while in SRB mode. |
| 8           | xxxx0803    | Equate Symbol: IwmRsnCodeDisabled  
Meaning: Caller is disabled.  
Action: Avoid requesting this function while disabled. |
| 8           | xxxx0804    | Equate Symbol: IwmRsnCodeLocked  
Meaning: Caller is locked.  
Action: Avoid requesting this function while locked. |
| 8           | xxxx080B    | Equate Symbol: IwmRsnCodeBadPl  
Meaning: Error accessing parameter list.  
Action: Check for possible storage overlay. |
### Table 101. Return and Reason Codes for the IWM4TAF Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0824    | **Equate Symbol:** IwmRsnCodeAmode24  
**Meaning:** The caller invoked the service but was in 24-bit addressing mode.  
**Action:** Request this function only when you are in 31-bit addressing mode. |
| 8           | xxxx0825    | **Equate Symbol:** IwmRsnCodeAscModeNotPrimary  
**Meaning:** The caller invoked the service but was not in primary ASC mode.  
**Action:** Avoid requesting this function in this environment. |
| 8           | xxxx0827    | **Equate Symbol:** IwmRsnCodeRsvdNot0  
**Meaning:** Reserved field in parameter list was not zero.  
**Action:** Check for use of keywords that are not supported by the MVS release on which the program is running. |
| 8           | xxxx0828    | **Equate Symbol:** IwmRsnCodeBadVersion  
**Meaning:** Version number in parameter list is not valid.  
**Action:** Check for possible storage overlay of the parameter list. |
| 8           | xxxx0840    | **Equate Symbol:** IwmRsnCodeServiceNotEnabled  
**Meaning:** The caller's space connection is not enabled for this service  
**Action:** Make sure that SERVER_MANAGER=YES and SERVER_TYPE=QUEUE is specified on the IWM4CON request to enable this service. |
| 8           | xxxx0841    | **Equate Symbol:** IwmRsnCodeXmemMode  
**Meaning:** Caller is in cross-memory mode.  
**Action:** Request this function only when you are not in cross-memory mode. |
| 8           | xxxx0842    | **Equate Symbol:** IwmRsnCodeNoWLMConnect  
**Meaning:** The caller's space is not connected to WLM.  
**Action:** Invoke the IWM4CON macro before invoking this macro. |
| 8           | xxxx084D    | **Equate Symbol:** IwmRsnCodeNotAuthConnect  
**Meaning:** The caller must be supervisor state or have PSW key mask 0-7 authority to use the requested WLM service. This applies only if the caller provides a region token for a server address space for which it wants to set the affinity.  
**Action:** Avoid requesting this function in this environment. |
| 8           | xxxx08B1    | **Equate Symbol:** IwmRsnCodeTooManyTempAff  
**Meaning:** No more than 2 GB temporal affinities supported.  
**Action:** Avoid requesting more than 2 GB temporal affinities to an address space. |
### Table 101. Return and Reason Codes for the IWM4TAF Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>

Appendix C. Structure of the XML service definition (DTD)

This section describes the following:
- The structure of the XML output of IWMDEXTR
- The layout of the XML service definition (DTD) that can be passed to IWMDINST

To obtain XML output, specify the TYPE=XML parameter for the IWMDEXTR service.

To install such an XML service definition with the IWMDINST service, also specify the TYPE=XML parameter.

The following DTD defines the structure of an XML service definition:

```xml
<!ATTLIST ServiceDefinition

### Interfaces for sysplex routing services

Table 106 on page 825 shows the C language interfaces that can be used to access WLM sysplex routing services.
Note: You need to include the header file IWMWDNSH before invoking these functions.

Table 106. C language interfaces for WLM sysplex routing services

</table>

Interface for querying a virtual server

Products can use the query virtual server interface to obtain a virtual server’s ID and capacity. The C interface for this query is IWMQVS, and the assembler interface is SYSEVENT QVS. Both forms of this query return a QVS structure which maps the returned identification and capacity information. See z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO for more information.
Appendix E. WLM services supporting 31-bit addressing only

The following WLM services support 31-bit addressing only.

The equivalent form of these services that support both 31-bit and 64-bit addressing are described in Chapter 12, “Workload management services,” on page 143.
The IWMAEDEF service defines dynamic application environments to WLM. The service can be used by queue manager address spaces to add new application environments after they connected to WLM and to delete the dynamic application environments before they disconnect from WLM.

Furthermore, the service can be used to define the method how server spaces should be resumed for static and dynamic application environments.

Before using this service, the caller must connect to WLM using the IWM4CON service, specifying Work_Manager=Yes, and Queue_Manager=Yes.

A queueing manager must not insert requests for a dynamic and static application environment with the same application environment name concurrently.

Note: It is recommended to use the equivalent service, IWM4AEDF, which also supports 64-bit addressing. For more information, see “IWM4AEDF — WLM define dynamic application environments” on page 454.

Environment

The requirements for the caller are:

- **Minimum authorization:** Supervisor state or program key mask (PKM) allowing keys 0-7.
- **Dispatchable unit mode:** Task or SRB
- **Cross memory mode:** Any HASN, any SASN. PASN must be the address space which connected to WLM (i.e. the address space that was home when IWM4CON was issued for Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue).
- **AMODE:** 31-bit
- **ASC mode:** Primary
- **Interrupt status:** Enabled for I/O and external interrupts
- **Locks:** No locks may be held.
- **Control parameters:** Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
IWMAEDEF

Restrictions

This macro supports multiple versions. Some keywords are unique to certain versions. Refer to the description of the PLISTVER parameter for further information.

Input register information

Before issuing the IWMAEDEF macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMAEDEF macro is as follows:

```
main diagram
```

---
Parameters

The parameters are explained as follows:

name
   An optional symbol, starting in column 1, that is the name on the IWMAEDEF macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,APPLENV=applenv
   When FUNC=ADD is specified, a required input parameter, which contains the name of the static or dynamic application environment.
   To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,CONNTKN=conntkn
   A required input parameter, which contains the connect token returned by the IWM4CON macro.
   To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,DISTRIBUTE_WORK=FIRST_AVAILABLE
,DISTRIBUTE_WORK=ROUND_ROBIN
   When FUNC=ADD is specified, an optional parameter that controls how Workload Management resumes bound server spaces that are waiting for work
   The default is DISTRIBUTE_WORK=FIRST_AVAILABLE.

   Workload Management wakes up the server space that has been suspended first (default).
Workload Management wakes up the server space that has the smallest number of affinities. If there are several server spaces with the same number of affinities, workload management will start the server space with the smallest number of active server tasks.

 FUNC=ADD
 FUNC=DELETE
 FUNC=MODIFY
 A required parameter that indicates how the caller uses the service

 FUNC=ADD
 indicates that the caller wants to add a dynamic application environment to WLM.

 FUNC=DELETE
 indicates that the caller wants to delete its interest in the dynamic application environment.

 FUNC=MODIFY
 indicates that the caller wants to redefine the method how server spaces should be resumed for static and dynamic application environments.

 JCLPARMS=jclparms
 JCLPARMS=0
 When FUNC=ADD is specified, an optional input parameter, which contains the parameters which are passed to the start procedure of the server manager address spaces by WLM. The default is 0.

 To code: Specify the RS-type address, or address in register (2)-(12), of a 115-character field.

 JCLPROC=jclproc
 When FUNC=ADD is specified, a required input parameter, which contains the name of the start procedure which is used by WLM to start server manager address spaces for the application environment.

 To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

 MF=S
 MF=(L,list addr)
 MF=(L,list addr,attr)
 MF=(L,list addr,0D)
 MF=(E,list addr)
 MF=(E,list addr,COMPLETE)
 An optional input parameter that specifies the macro form.

 Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

 Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

 Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code.
code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\texttt{,list addr}

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\texttt{,attr}

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code \texttt{attr}, the system provides a value of 0D.

\texttt{,COMPLETE}

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\texttt{,PLISTVER=IMPLIED\_VERSION, PLISTVER=MAX, PLISTVER=0, PLISTVER=1}

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- \texttt{IMPLIED\_VERSION}, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED\_VERSION is the default.

- \texttt{MAX}, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- \texttt{0}, which supports all parameters except those specifically referenced in higher versions.

- \texttt{1}, which supports the following parameters and those from version 0:

\texttt{DISTRIBUTE\_WORK}

\texttt{STATIC}

To code: Specify one of the following:

- \texttt{IMPLIED\_VERSION}

- \texttt{MAX}

- A decimal value of 0, or 1

\texttt{,RETCODE=retcode}

An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).
,RSNCODE=rsn code

An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,SELECT_POLICY=select_policy

,SELECT_POLICY=0

When FUNC=ADD is specified, an optional input parameter, which tells WLM how to select work if work requests are directly routed to the server address space. Only 0,1 and 2 are valid select policies. 0 is the default which is also selected if an invalid policy is specified.

The select policy options 0,1 and 2 have the following meaning:

- 0 Default, the oldest request on either the service class or server address space queue is selected first.
- 1 The request on the server address space queue (if present) is selected first independently of the times the requests have been inserted.
- 2 The request on the service class queue is always selected first.

The default is 0.

To code: Specify the RS-type address, or address in register (2)-(12), of an one-byte field.

,SINGLE_SERVER=NO

,SINGLE_SERVER=YES

When FUNC=ADD is specified, an optional parameter indicating whether one or multiple server spaces should be started for the application environment. The default is SINGLE_SERVER=NO.

,SINGLE_SERVER=NO

Multiple server spaces should be started for the application environment (default).

,SINGLE_SERVER=YES

Only one server space should be started for the application environment.

,STATIC=NO

,STATIC=YES

When FUNC=MODIFY is specified, an optional parameter that controls whether a static or dynamic application environment should be updated. The default is STATIC=NO.

,STATIC=NO

indicates that the caller wants to modify a dynamic application environment (default).

,STATIC=YES

indicates that the caller wants to modify a static application environment.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMAEDEF macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Table 107. Return and Reason Codes for the IWMAEDEF Macro

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 0           |             | Equate Symbol: IwmRetCodeOk  
Meaning: Successful completion.  
Action: None required. |
| 8           |             | Equate Symbol: IwmRetCodeInvocError  
Meaning: Invalid invocation environment or parameters. |
| 8 xxxx0803  |             | Equate Symbol: IwmRsnCodeDisabled  
Meaning: Caller is disabled.  
Action: Avoid requesting this function while disabled. |
| 8 xxxx0804  |             | Equate Symbol: IwmRsnCodeLocked  
Meaning: Caller is locked.  
Action: Avoid requesting this function while locked. |
| 8 xxxx080B  |             | Equate Symbol: IwmRsnCodeBadPl  
Meaning: Error accessing parameter list.  
Action: Check for possible storage overlay. |
| 8 xxxx0821  |             | Equate Symbol: IwmRsnCodeBadConn  
Meaning: Input connect token does not pass validity checking.  
Action: Make sure to use the connect token returned by the IWM4CON service requesting Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue. |
| 8 xxxx0823  |             | Equate Symbol: IwmRsnCodeDatoff  
Meaning: The caller invoked the service while DATOFF  
Action: Avoid requesting this function in this environment. |
| 8 xxxx0824  |             | Equate Symbol: IwmRsnCodeAmode24  
Meaning: Caller invoked the service but was in 24-bit addressing mode.  
Action: Request this function only when you are in 31-bit addressing mode. |
| 8 xxxx0825  |             | Equate Symbol: IwmRsnCodeAscModeNotPrimary  
Meaning: Caller invoked service but was not in primary ASC mode.  
Action: Avoid requesting this function in this environment. |
**Table 107. Return and Reason Codes for the IWMAEDEF Macro (continued)**

Example

To add a dynamic application environment:

IWMAEDEF CONNTKN=CONNTOKEN, X
  FUNC=ADD, X
  APPLENV=APPLENV X
  JCLPROC=JCLPROC X
  RETCODE=RC,RSNCODE=RSN

* Storage areas
  CONNTOKEN DS FL4 Contains the connect token
  associated with the use of WLM
  Queuing services as returned by
  IWM4CON
  APPLENV DS CL32 Contains the application
  environment name
  JCLPROC DS CL8 Contains the name of the
  start procedure
  RC DS F Return code
  RSN DS F Reason code
IWMCLSﻔY — Classify work request

The purpose of this service is to factor in available information about an arriving work request in order to associate a service class and possibly a report class with it.

Environment

The requirements for the caller are:

Minimum authorization: Either problem state or supervisor state. PSW key must either be 0 or match the value supplied on IWM4CON.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31-bit
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: Unlocked or locked.
Control parameters: Control parameters must be in the primary address space.

Programming requirements
1. The macro IWMYCON must be included to use this macro.
2. Caller is responsible for error recovery.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions
• This macro may only be used on MVS/ESA (version 3 or higher), NOT versions 1 or 2 of MVS.
• FRRs are allowed.
• This macro may not be used during task/address space termination for the connect owner.
• If the key specified on IWM4CON was a user key (8-F), then current primary must equal primary at the time that IWM4CON was invoked.
• Only limited checking is done of the connect token obtained from IWM4CON.
• SOURCELU is mutually exclusive with NETID/LUNAME.
• This macro supports multiple versions. Some keywords are unique to certain versions. See the PLISTVER parameter description.

Input register information

Before issuing the IWMCLSﻔY macro, the caller must ensure that the following general purpose registers (GPRs) contain the specified information:
IWMCLSFY

Register

Contents

13 The address of a 72-byte standard save area in the primary address space

Output register information

When control returns to the caller, the GPRs contain:

Register

Contents

0 Reason code if GR15 return code is non-zero
1 Used as work registers by the system
2-13 Unchanged
14 Used as work registers by the system
15 Return code

When control returns to the caller, the ARs contain:

Register

Contents

0-1 Used as work registers by the system
2-13 Unchanged
14-15 Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

SRMTOKEN=srtoken

SERVCLS=sercls
Parameters

The parameters are explained as follows:

`name`
An optional symbol, starting in column 1, that is the name on the IWMCLSFY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`ACCTINFL=acctinfl`
When ACCTINFO=acctinfo is specified, a required input parameter, which contains the length of the accounting information field. The maximum value supported is 143.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

`ACCTINFO=acctinfo`
`ACCTINFO=NO_ACCTINFO`
An optional input parameter, which contains the accounting information. For environments where accounting information is available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_ACCTINFO. The default is NO_ACCTINFO. indicates that no accounting information was passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

`COLLECTION=collection`
`COLLECTION=NO_COLLECTION`
An optional input parameter, which contains the customer defined name for a
group of associated packages. For environments where the collection name may be available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_COLLECTION. The default is NO_COLLECTION. indicates that no COLLECTION name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

, COLLECTION_LEN=collection_len
When COLLECTION=collection is specified, a required input parameter, which contains the length of the collection name. There is no restriction on the length of data passed, but all storage between the start and end must be allocated (getmained).

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

, CONNECTION=connection
, CONNECTION=NO_CONNECTION
An optional input parameter, which contains the name associated with the environment creating the work request, which may reside anywhere within the network. For environments where the connection name may be available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_CONNECTION. The default is NO_CONNECTION. indicates that no CONNECTION name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

, CONNTKN=conntkn
A required input parameter, which is returned by IWMCONN for use by the classify routine.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

, CORR_LEN=corr_len
When CORRELATION=correlation is specified, a required input parameter, which contains the length of the correlation identifier. There is no restriction on the length of data passed, but all storage between the start and end must be allocated (getmained).

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

, CORRELATION=correlation
, CORRELATION=NO_CORRELATION
An optional input parameter, which contains the name associated with the user/program creating the work request, which may reside anywhere within the network. For environments where the correlation name may be available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_CORRELATION. The default is NO_CORRELATION. indicates that no CORRELATION name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

, EWLM_CHCORR=ewlm_chcorr
An optional output parameter, which contains the cross platform Enterprise Workload Management (EWLM) child correlator associated with the instantiated sub work request. Specification of this parameter indicates that a sub work request will be created.
**Notes:**

- Currently (z/OS V1R6) only uses the first 64 Bytes of the EWLM_CHCORR field.
- Parameters EWLM_OUTCORR, EWLM_CHCORR and EWLM_CHCTKN are all mutually exclusive.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 512-character field.

- **EWLM_CHCTKN=ewlm_chctkn**
  An optional output parameter, which contains the cross platform Enterprise Workload Management (EWLM) child correlator token associated with the instantiated sub work request. Specification of this parameter indicates that a sub work request will be created. A EWLM child correlator token must not be passed outside of the EWLM Management Domain.

Parameters EWLM_OUTCORR, EWLM_CHCORR and EWLM_CHCTKN are all mutually exclusive.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64-character field.

- **EWLM_CLTOKEN=ewlm_cltoken**
  An optional input parameter, which contains internal EWLM classification information to be passed from EWLM to WLM. This parameter is internally used by WLM and must not be used by application programs. The default is NO_EWLM_CLTOKEN. indicates that no EWLM classification information was passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 40-character field.

- **EWLM_CORR=ewlm_corr**
  An optional input parameter, which contains the cross platform Enterprise Workload Management (EWLM) correlator associated with the work request. If this parameter is specified and a valid EWLM correlator is passed, the EWLM transaction class can be used for WLM classification purposes. Moreover the EWLM correlator serves as the input correlator for the EWLM_CHCORR, EWLM_CHTKN, EWLM_OUTCORR parameters.

Note, that the architected length field of an ARM correlator in the first two bytes must contain a value between 4 (’0004’X) and 512 (’0200’X).

For environments where the EWLM correlator may be available on some, but not all flows, provision of a data area with the first four bytes set to binary zeroes is equivalent to the specification of NO_EWLM_CORR.

The default is NO_EWLM_CORR. indicates that no EWLM correlator is passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

- **EWLM_OUTCORR=ewlm_outcorr**
  An optional output parameter, which will receive a validated EWLM correlator on return. The execution form of IWMCLSFY will validate the passed correlator in EWLM_CORR and provide a valid EWLM correlator in EWLM_OUTCORR as follows:
If the EWLM_CORR parameter is specified and the correlator in EWLM_CORR is a valid ARM correlator in EWLM format, it will be copied to EWLM_OUTCORR.

If the correlator in EWLM_CORR is not a valid EWLM ARM correlator or the EWLM_CORR parameter is omitted, a new classify correlator will be returned within the EWLM_OUTCORR field.

Notes:
- The specification of EWLM_OUTCORR (unlike EWLM_CHCORR or EWLM_CHCTKN) does not indicate the beginning of an sub work request.
- Currently (z/OS V1R6) only uses the first 64 Bytes of the EWLM_OUTCORR field.
- The application may specify the same parameter for both EWLM_CORR and EWLM_OUTCORR, which means that the EWLM correlator can be validated/replaced in place.
- Parameters EWLM_OUTCORR, EWLM_CHCORR and EWLM_CHCTKN are all mutually exclusive.

To code: Specify the RS-type address, or address in register (2)-(12), of a 512-character field.

\[,LUNAME=luname\]
\[,LUNAME=NO_LUNAME\]
An optional input parameter, which contains the local LU name associated with the requestor. For environments where the local LU name may be available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_LUNAME.

SOURCELU is mutually exclusive with LUNAME. The default is NO_LUNAME. indicates that no local LU name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\[,MF=S\]
\[,MF=(L,list addr)\]
\[,MF=(L,list addr,attr)\]
\[,MF=(L,list addr,0D)\]
\[,MF=(E,list addr)\]
\[,MF=(E,list addr,COMPLETE)\]
\[,MF=(E,list addr,NOCHECK)\]
\[,MF=(M,list addr)\]
\[,MF=(M,list addr,COMPLETE)\]
\[,MF=(M,list addr,NOCHECK)\]
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
deﬁned by the list form, and generates the macro invocation to transfer control
to the service.

Use MF=M together with the list and execute forms of the macro for service
routines that need to provide different options according to user-provided
input. Use the list form to deﬁne a storage area; use the modify form to set the
appropriate options; then use the execute form to call the service.

IBM recommends that you use the modify and execute forms of IWMCLSFY in
the following order:

• Use IWMCLSFY ...MF=(M,list-addr,COMPLETE) specifying appropriate
  parameters, including all required ones.
• Use IWMCLSFY ...MF=(M,list-addr,NOCHECK), specifying the parameters
  that you want to change.
• Use IWMCLSFY ...MF=(E,list-addr,NOCHECK), to execute the macro.

list addr
The name of a storage area to contain the parameters. For MF=S, MF=E,
and MF=M, this can be an RS-type address or an address in register
(1)-(12).

attr
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code attr, the system provides a value of 0D.

COMPLETE
Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

NOCHECK
Specifies that the system is not to check for required parameters and is not
to supply defaults for omitted optional parameters.

NETID=netid
NETID=NO_NETID
An optional input parameter, which contains the network identifier associated
with the requestor. For environments where the network identifier may be
available on some, but not all flows, provision of a data area initialized to all
blanks is equivalent to speciﬁcation of NO_NETID.

SOURCELU is mutually exclusive with NETID. The default is NO_NETID.
indicates that no network identifier is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an
8-character field.

PACKAGE=package
PACKAGE=NO_PACKAGE
An optional input parameter, which contains the package name for a set of
associated SQL statements. Products using this attribute must chose a speciﬁc
package name to be associated with the work request, e.g. the ﬁrst package
name used in the unit of work. Individual product documentation will
describe how this choice is made to allow the installation to use the WLM
administrative application. For environments where the package name may be
available on some, but not all ﬂows, provision of a data area initialized to all
blanks is equivalent to speciﬁcation of NO_PACKAGE The default is
NO_PACKAGE. indicates that no PACKAGE name is passed.
To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\textbf{PERFORM=perform}  
\textbf{PERFORM=NO\_PERFORM}

An optional input parameter, which contains the performance group number (PGN) associated with the work request. If specified, the performance group number value must be within the range of 1-999, represented as character data, left justified and padded with blanks on the right. For environments where the perform value may be available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO\_PERFORM. The default is NO\_PERFORM. indicates that no PERFORM value is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\textbf{PLAN=plan}  
\textbf{PLAN=NO\_PLAN}

An optional input parameter, which contains the access plan name for a set of associated SQL statements. For environments where the plan name may be available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO\_PLAN The default is NO\_PLAN. indicates that no PLAN name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\textbf{PLISTVER=IMPLIED\_VERSION}  
\textbf{PLISTVER=MAX}  
\textbf{PLISTVER=0}  
\textbf{PLISTVER=1}  
\textbf{PLISTVER=2}  
\textbf{PLISTVER=3}  
\textbf{PLISTVER=4}  
\textbf{PLISTVER=5}  
\textbf{PLISTVER=6}  
\textbf{PLISTVER=7}  
\textbf{PLISTVER=8}

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- \textbf{IMPLIED\_VERSION}, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED\_VERSION is the default.
- \textbf{MAX}, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
  
  - 0, which supports all parameters except those specifically referenced in higher versions.
IWMCLSFY

- 1, which supports both the following parameters and those from version 0:

PERFORM  
PRCNAME  
PRCNAME_LEN

- 2, which supports both the following parameters and those from version 0 and 1:

PRIORITY

- 3, which supports both the following parameters and those from version 1 and 2:

PROCESSNAME  
PROCESSNM_LEN

- 4, which supports both the following parameters and those from version 0,1,2 and 3:

TTRACETOKEN

- 5, which supports both the following parameters and those from version 0,1,2,3 and 4:

SCHEDENV  
SCHEDENV_LEN  
SRM_TOKEN

- 6, which supports both the following parameters and those from version 0,1,2,3,4 and 5:

EWLM_CORR

- 7, which supports both the following parameters and those from version 0,1,2,3,4,5 and 6:

EWLM_CHCORR  
EWLM_CHCTKN  
EWLM_OUTCORR

- 8, which supports both the following parameters and those from version 0,1,2,3,4,5,6 and 7:

EWLM_CLTOKEN
To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0, 1, 2, 3, 4, 5, 6, 7, or 8

,PRCNAME=prcname,PRCNAME=NO_PRCNAME
An optional input parameter, which contains the DB2 Stored SQL Procedure name associated with the work request. For environments where the SQL procedure name may be available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_PRCNAME. The default is NO_PRCNAME. indicates that no PRCNAME value is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 18-character field.

,PRCNAME_LEN=prcname_len
When PRCNAME=prcname is specified, a required input parameter, which contains the length of the procedure name. There is no restriction on the length of data passed, but all storage between the start and end must be allocated (getmained).

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

,PRIORITY=priority,PRIORITY=NO_PRIORITY
An optional input parameter, which contains the priority associated with the work request. For environments where the priority value may be available on some, but not all flows, provision of a data area initialized to hexadecimal 80000000 (the largest negative integer) is equivalent to specification of NO_PRIORITY. The default is NO_PRIORITY. indicates that no PRIORITY value is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

,PROCESSNAME=processname,PROCESSNAME=NOPROCESSNAME
An optional input parameter, which contains the process name associated with the work request. The default is NOPROCESSNAME. indicates that no PROCESSNAME value is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,PROCESSNM_LEN=processnm_len
When PROCESSNAME=processname is specified, a required input parameter, which contains the length of the process name. There is no restriction on the length of data passed, but all storage between the start and end must be allocated (getmained).

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.
To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

\( \text{,RPTCLSNM=\textit{rptclsnm}} \)

An optional output parameter, which is to receive the output report class name.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\( \text{,RSNCODE=\textit{rsncode}} \)

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), (REG0), (REG00), or (R0).

\( \text{,SCHEDENV=\textit{schedenv}} \)

\( \text{SCHEDENV=NO\_SCHEDENV} \)

An optional input parameter, which contains the scheduling environment value associated with the work request. The default is NO\_SCHEDENV. indicates that no scheduling environment value is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

\( \text{,SCHEDENV\_LEN=\textit{schedenv\_len}} \)

\( \text{SCHEDENV\_LEN=16} \)

When SCHEDENV=\textit{schedenv} is specified, an optional input parameter, which contains the length of the scheduling environment. There is no restriction on the length of data passed, but all storage between the start and end must be allocated (getmained). The default is 16.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

\( \text{,SERVCLS=\textit{servcls}} \)

A required output parameter, which is to receive the output token which represents the service and report class for the work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\( \text{,SOURCELU=\textit{sourcelu}} \)

\( \text{SOURCELU=NO\_SOURCELU} \)

An optional input parameter, which contains the LU name associated with the requestor. This may be the fully qualified NETID.LUNAME, e.g. network name (1-8 bytes), followed by a period, followed by the LU name for the requestor (1-8 bytes). It may also be the 1-8 byte local LU name, with no network qualifier. The SOURCELU field may be from 1-17 characters. In the assembler form, the macro will determine the length of the field as follows:

1. if the field is specified by register notation, it will be assumed to be 17 characters (padded with blanks).
2. if the field is specified using an RS form name, then the length will be determined using the L' assembler function.

In the PL/AS form, the rules for the PL/AS compiler will determine the length. The product using IWMCLSFY is responsible for documenting which form is used so that the customer may specify the correct format.
IWMCLSFY

For environments where the LU name may be available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_SOURCELU.

SOURCELU is mutually exclusive with NETID/LUNAME. The default is NO_SOURCELU. indicates that no source LU name was passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,SRMTOKEN=srmtoken
   An optional output parameter, token for SRM internal use only.

   To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,SRCVCLSNM=srvclsnm
   An optional output parameter, which is to receive the output service class name.

   To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,SSPMLEN=sspmlen
   When SUBSYS=ssyspm is specified, a required input parameter, which contains the length of the data passed by the work manager. There is no restriction on the length of data passed, but all storage between the start and end must be allocated (getmained).

   To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

,SUBCOLN=subcoln
,SUBCOLN=NO_SUBCOLN
   An optional input parameter, which contains the subsystem collection name associated with the work request. The default is NO_SUBCOLN. indicates that no subsystem collection name is passed.

   To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,SUBSYS=ssyspm
,SUBSYS=NO_SUBSYS
   An optional input parameter, which contains character data related to the work request which is passed by the work manager for use in classification. The nature of the contents of this data must be documented for customer use. For environments where the subsystem parameter is available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_SUBSYS. The default is NO_SUBSYS. indicates that no parameter was passed.

   To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,TRXCLASS=trxclass
,TRXCLASS=NO_TRXCLASS
   An optional input parameter, which contains a class name within the subsystem. This can be any meaningful value that the installation can recognize and specify to match the value presented by the work manager. For environments where the transaction class is available on some, but not all
flows, provision of a data area initialized to all blanks is equivalent to specification of NO_TRXCLASS. The default is NO_TRXCLASS. indicates that no transaction class was passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**TRXNAME=trxname**

An optional input parameter, which contains the transaction name for the work request, as known by the work manager. For environments where the transaction name is available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_TRXNAME. The default is NO_TRXNAME. indicates that no transaction name is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**TTRACETOKEN=ttracetoken**

An optional output parameter, which is to receive the output transaction trace token associated with the work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

**USERID=userid**

An optional input parameter, which contains the userid associated with the work request. For environments where the user id is available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_USERID. The default is NO_USERID. indicates that no userid is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

### ABEND codes

None.

### Return codes and reason codes

When the IWMCLSFY macro returns control to your program:

- GPR 15 (and recode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol Meaning and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>—</td>
<td><strong>Equate Symbol</strong>: IwmRetCodeOk</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Meaning</strong>: Successful completion.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Action</strong>: None required.</td>
</tr>
<tr>

<tr>
<td></td>
<td></td>
<td><strong>Action</strong>: No action required. The function may be successful if invoked again.</td>
</tr>
</tbody>
</table>
Example

Suppose the transactions processed by a subsystem work manager have the following qualifiers:

- User ID
- Transaction name
- Transaction class

To get the service class associated with an incoming work request, specify:

```
IWMCLSFY USERID=AUSERID,TRXCLASS=ATRXCLS,TRXNAME=ATRXNM,
      CONNTKN=(R7),SERVCLS=(R9),
      RETCODE=RETCODE,RSNCODE=RSNCODE
```

Where the following are declared:

```
AUSERID  DS  CL8
ATRXCLS  DS  CL8
ATRXNM   DS  CL8
```
The purpose of this service is to connect a calling address space to WLM. This service returns a token which is needed to invoke other services. This service can be used to:

- Request that WLM Work Management services be available to the connecting address space and optionally to pass topology information to WLM.
- Request that WLM Work Queuing services be available to the connecting address space.
- Request that WLM Work Execution services be available to the connecting address space.
- Request that WLM Work Balancing services be available to the connecting address space.
- Request that WLM export and import services be available to the connecting address space.

Note that:

- The space which is connected is the current home address space.
- Only a single connection is allowed to be active for a given address space at any given time.
- For each connected task/space, WLM will establish a dynamic resource manager (RESMGR) to be associated with the current task/space. When it receives control, it will free any accumulated resources and delete any enclaves associated with the connect token. This implies that the resource manager will logically perform the disconnect function and the connect token can no longer be passed to WLM services.

**Note:** It is recommended to use the equivalent service, IWM4CON, which also supports 64-bit addressing. For more information, see "IWM4CON — Connect to workload management" on page 480.

### Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization</th>
<th>For WORK_MANAGER=YES or ROUTER=YES, QUEUE_MANAGER=YES or EXPTIMPT=YES, supervisor state or program key mask (PKM) allowing keys 0-7. For SERVER_MANAGER=YES, problem state with any PSW key.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>Non-XMEM when input key is a user key or SERVER_MANAGER = YES, otherwise XMEM, any P,S,H.</td>
</tr>
<tr>
<td>AMODE</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>
Programming requirements

1. Make sure no EUT FRRs are established.
2. The macro CVT must be included to use this macro.
3. The macro IWMYCON must be included to use this macro.
4. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
5. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
6. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

1. This macro may not be used during task/address space termination.
2. Only a single connection is allowed to be active for a given address space at any given time.
3. Specification of both Queue_Manager=Yes, and Server_Manager=Yes requires that Server_Type=Queue. Specification of Server_Type=Routing is rejected.
4. Specification of both Router=Yes, and Server_Manager=Yes requires that Server_Type=Routing. Specification of Server_Type=Queue is rejected.
5. If the callers recovery routine should get control as a result of requesting this service, the function cannot be guaranteed to be complete. It is possible that a token has been saved in the parameter list where the connect token would reside upon successful completion. This token may be passed to IWMDISC to prevent the address space from being disabled from future IWMCONN requests, but the token should not be used for other services. IWMDISC in these circumstances may give a warning return code indicating that no connection was established, however.
6. If the key specified on IWMCONN is a user key (8-F) or SERVER_MANAGER=YES was specified, then the caller must be in non-cross-memory mode (P=S=H).
7. While not a restriction for IWMCONN, it should be noted that when the key specified is a user key (8-F), the Connect token may only be passed to IWMCLSFY, IWMRPT, or IWMMNTFY services, when the current primary matches primary at the time IWMCONN is invoked.

Input register information

Before issuing the IWMCONN macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
</tbody>
</table>
1 Used as work registers by the system
2-13 Unchanged
14 Used as work registers by the system
15 Return code

When control returns to the caller, the ARs contain:

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
</tr>
<tr>
<td>2-13</td>
</tr>
<tr>
<td>14-15</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMCONN macro is as follows:

main diagram

```
IWMCONN
  WORK_MANAGER=YES parameters-1
  WORK_MANAGER=NO
  ROUTER=NO
  ROUTER=YES
  SERVER_MANAGER=NO
  SERVER_MANAGER=YES
  SUBSYS=subsys
  SUBSYSNM=subsysnm
  NODENM=NO
  NODENM=nodenm
  GROUPNM=NO
  GROUPNM=groupnm
  GROUPNM_LEN=groupnm_len
  QMGR_EXIT@=qmgr_exit@
  QMGR_EXIT=NO
  QMGR_EXIT=QMGR_EXIT
  EXPTIMPT=NO
  EXPTIMPT=YES
  CONNTKN=conntkn
```

Appendix E. WLM services supporting 31-bit addressing only
IWMCONN

Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMCONN macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,APPLENV=applenv
When SERVER_MANAGER=YES is specified, a required input parameter, which contains the application environment under which work requests are served.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,CONNTKN=conntkn
A required output parameter, which will receive the connect token.
**IWMCONN**

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,**CONNTKNKEY=conntknkey**
When **CONNTKNKEYP=VALUE** and **WORK_MANAGER=YES** are specified, a required input parameter, which contains the key for which the various branch entry services using the CONNTKN returned by IWMCONN must have PSW update authority. These other services include Classify (IWMCLSFY), Report (IWMRPT), Notify (IWMMNFTFY). Create (IWMMCREA) is a PC interface and hence is excluded. The low order 4 bits (bits 4-7) contain the key value. The high-order 4 bits (bits 0-3) must be zeros.

Note however that there are other services that use the connect token, for which the CONNTKNKEY does not relate to PSW update authority but instead must be a system key (0-7) rather than a user key (8-15).

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8 bit field.

,**CONNTKNKEYP=VALUE**
,**CONNTKNKEYP=PSWKEY**
When **WORK_MANAGER=YES** is specified, a required parameter, which describes how the input key should be obtained.

,**CONNTKNKEYP=VALUE**
indicates that the key is being passed explicitly via CONNTKNKEY.

,**CONNTKNKEYP=PSWKEY**
indicates that the current PSW key should be used.

,**DYNAMIC=NO**
,**DYNAMIC=YES**
When **SERVER_MANAGER=YES** is specified, an optional parameter indicating whether the server manager connects to a dynamic or static application environment. The default is DYNAMIC=NO.

,**DYNAMIC=NO**
The server manager connects to a static application environment. This is the default.

,**DYNAMIC=YES**
The server manager connects to a dynamic application environment.

,**EWLM=NO**
,**EWLM=YES**
When **WORK_MANAGER=YES** is specified, an optional parameter, which indicates if this work manager intends to participate in cross-platform enterprise workload management (EWLM). The default is EWLM=NO.

,**EWLM=NO**
The work manager interacts only with WLM and no interaction with EWLM takes place. This is the default.

,**EWLM=YES**
The work manager participates in cross-platform enterprise workload management and interacts with EWLM.

,**EXPTIMPT=NO**
,**EXPTIMPT=YES**
An optional parameter indicating whether the space needs access to the export and import services (IWMEXPT, IWMUEXPT, IWMMPT, IWMUIMPT). The default is EXPTIMPT=NO.
IWMCONN

,EXPTIMPT=NO
  The connecting address space will not use the export and import services.

,EXPTIMPT=YES
  The connecting address space will use the export and import services.

,GROUPNM=groupnm
,GROUPNM=NO_GROUPNM
  An optional input parameter, which contains the name of an application group,
  for example, a group of similar or cooperating subsystem instances. A group
  name can be up to 255 characters long. Provision of a data area initialized to
  all blanks is equivalent to specification of NO_GROUPNM. The default is
  NO_GROUPNM. This indicates that no group name is passed.

  To code: Specify the RS-type address, or address in register (2)-(12), of a
character field.

,GROUPNM_LEN=groupnm_len
  When GROUPNM=groupnm is specified, a required input parameter, which
  contains the length of the group name. A group name can be up to 255
  characters long.

  To code: Specify the RS-type address, or address in register (2)-(12), of a
  fullword field.

,MANAGE_TASKS=NO
,MANAGE_TASKS=YES
  When SERVER_TYPE=QUEUE and SERVER_MANAGER=YES are specified, an
  optional parameter indicating that WLM will manage the server instances
  (tasks), selecting work from a work queue.

  If YES is specified the caller must use service IWMSINF to obtain the number
  of server instances to start from WLM.

  The meaning of PARALLEL_EU changes in this case. PARALLEL_EU is only
  used to determine the number of tasks to start if the application environment
  cannot be managed by WLM. Otherwise PARALLEL_EU can be used to limit
  the number of server tasks to start initially.

  The server can define the SERVER_LIMIT parameter to specify a limit for the
  number of server tasks supported by the application.

,MANAGE_TASKS=NO
  The connecting address space starts the number of server instances as
  provided with PARALLEL_EU.

,MANAGE_TASKS=YES
  The connecting address space uses IWMSINF to obtain the number of
  server instances to start from WLM.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
  An optional input parameter that specifies the macro form.

  Use MF=S to specify the standard form of the macro, which builds an inline
  parameter list and generates the macro invocation to transfer control to the
  service. MF=S is the default.
IWMCONN

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,, list addr
   The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,, attr
   An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of X'0F' to force the parameter list to a word boundary, or X'0D' to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of X'0D'.

,, COMPLETE
   Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,, NODENM=nodenum
   An optional input parameter, which contains the node name to be used for classifying work requests when Work_Manager=Yes is specified or taken as default. The node name identifies a specific subcomponent of the generic subsystem type.

   When Server_Manager=Yes and Server_Type=Queue is specified, the node name should match the node name specified on the corresponding Connect for the Queue_Manager, for example, all servers associated with the Queue_Manager have identical node names.

   If a product chooses to use both Work_Manager=Yes and Server_Manager=Yes on a single invocation of IWMCONN for a space, then the rules for Server_Manager apply, for example, the node name refers to the node name of the space playing the role of Queue_Manager.

   If the caller connects to the WLM work queueing services, the combination of the subsystem type, node name and the subsystem name must be unique to that MVS system. Node name can be omitted. The default is NO_NODENM.

   To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,, NUMBERASCB=numberascb
   When TOPOLOGY=topology and WORK_MANAGER=YES are specified, a required input parameter, which contains the number of ASCBs in the list passed via xTOPOLOGY. While there is no restriction on the number of entries in the list, the current support will only look at the first 10 entries. The number specified must be positive (hence also non-zero).

   To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.
When `SERVER_MANAGER=YES` is specified, a required input parameter which contains the maximum number of tasks (TCBs) within the address space which will be used to concurrently process distinct work requests if `MANAGE_TASKS=YES` is not in effect. When `Select (IWMSSEL)` is used to obtain a work request, which might then be passed to another task (TCB) for processing under a `Begin (IWMSTBGN)` environment, this count represents the number of tasks (TCBs) which can be running concurrently against these work requests, i.e. the number of concurrent `Begin` environments. It is important that this count represent the actual number of tasks (TCBs) which can be utilized, and not merely some approximate upper bound, as this value will influence system algorithms.

If `MANAGE_TASKS=YES` is in effect, the application environment managed by `WLM PARALLEL_EU` is not used. In this case the parameter is only used as described above if no procedure name was defined for the application environment.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

An optional input parameter that specifies the version of the macro. `PLISTVER` determines which parameter list the system generates. `PLISTVER` is an optional input parameter on all forms of the macro, including the list form. When using `PLISTVER`, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the `PLISTVER` parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify `PLISTVER=MAX` on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, which supports all parameters except those specifically referenced in higher versions.

- **1**, which supports the following parameters and those from version 0:

  - `PARALLEL_EU`
  - `QUEUE_MANAGER`
  - `SERVER_TYPE`
  - `EXPTIMPT`
  - `ROUTER`
  - `SRV_MGR_EXIT@`
  - `PARALLEL_EU`
  - `SERVER_DATA`
  - `WORK_MANAGER`
  - `QMGR_EXIT@`
  - `SERVER_MANAGER`

- **2**, which supports the following parameters and those from version 0 and 1:
MANAGE_TASKS SERVER_LIMIT GROUPNM_LEN

- 3, which supports the following parameters and those from version 0, 1, and 2:

DYNAMIC NODENM

- 4, which supports the following parameters and those from version 0, 1, 2, and 3:

EWLM GROUPNM GROUPNM_LEN

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0, 1, 2, 3, or 4

QMGR_EXIT@=qmgr_exit@
QMGR_EXIT@=NO_QMGR_EXIT@

When QUEUE_MANAGER=YES and ROUTER=NO are specified, an optional input parameter that contains the address of the Queue Manager Connect Exit to be invoked when the system wishes to inform the queue manager of actions it should perform. The exit will be called in enabled, unlocked TCB mode with no FRRs set, but may be called in a cross-memory environment. The mapping of the parameter list for the exit and its invocation environment is given by the list form of the IWMQCXIT macro.

The system may chose to discontinue calling the exit upon repetitive abnormal completions, i.e. where the system recovery routine is percolated to from an error within the exit. The exit must be callable from any address space and remain available after the queue manager disconnects or terminates. The default is NO_QMGR_EXIT@, which indicates that no queue manager exit is provided.

To code: Specify the RS-type address, or address in register (2)-(12), of a pointer field.

,QUEUE_MANAGER=NO

,QUEUE_MANAGER=YES

When ROUTER=NO is specified, an optional parameter indicating that WLM Work Queuing services be available to the connecting address space. For example:
- Insert (IWMQINS)
- Delete (IWMQDEL)

If YES is specified, the combination of the subsystem type and the subsystem name must be unique to that MVS system. The default is QUEUE_MANAGER=NO.

,QUEUE_MANAGER=NO

The connecting address space will not use the WLM Work Queuing services.
 QUEUE_MANAGER=YES
The connecting address space will be using the WLM Work Queuing services.

RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

ROUTER=NO
ROUTER=YES
An optional parameter, which describes whether recommendations for sysplex routing to servers associated with the same subsystem type and name are requested. The default is ROUTER=NO.

ROUTER=NO
indicates that recommendations for sysplex routing via IWMSRFSV are not required.

ROUTER=YES
indicates that recommendations for sysplex routing via IWMSRFSV is required. Note that only server spaces which have the same Subsystem type and name AND which specified Server_Type=Routing are considered when IWMSRFSV is invoked.

If YES is specified, the combination of the subsystem type and the subsystem name must be unique to that MVS system.

RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

SERVER_DATA=server_data
When SERVER_TYPE=ROUTING and SERVER_MANAGER=YES are specified, a required input parameter, which contains whatever data is needed to uniquely identify the server when recommended by MVS through use of the IWMSRFSV interface. The structure of this data is undefined to MVS, and will be returned to the program invoking IWMSRFSV when the server is returned.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

SERVER_LIMIT=server_limit
SERVER_LIMIT=1000
When MANAGE_TASKS=YES, SERVER_TYPE=QUEUE and SERVER_MANAGER=YES are specified, an optional input parameter indicating the architectural limit of the application for the number of server instances which can be supported.

This parameter can be used to tell WLM the upper limit up to which WLM will recommend to start server instances. If the parameter is omitted or is set higher than 1000, WLM will use 1000 as upper limit instead. The default is 1000.

To code: Specify the RS-type address of a fullword field.

SERVER_MANAGER=NO
SERVER_MANAGER=YES
An optional parameter indicating whether the space needs access to a family of services specified by SERVER_TYPE. The default is SERVER_MANAGER=NO.
IWMCONN

,SERVER_MANAGER=NO
The connecting address space will not use any of the various server related
WLM services documented under SERVER_TYPE.

,SERVER_MANAGER=YES
The connecting address space will be acting in the role of a server and
needs access to the family of services specified by SERVER_TYPE.

Specification of both Queue_Manager=Yes, and Server_Manager=Yes
requires that Server_Type=Queue. Specification of Server_Type=Routing is
rejected.

Specification of both Router=Yes, and Server_Manager=Yes requires that
Server_Type=Routing. Specification of Server_Type=Queue is rejected.

,SERVER_TYPE=QUEUE
,SERVER_TYPE=ROUTING
When SERVER_MANAGER=YES is specified, an optional parameter, which
describes what type of services are used by the server. The default is
SERVER_TYPE=QUEUE.

,SERVER_TYPE=QUEUE
indicates that the server selects work from a queue, and thus requests that
WLM Work Execution services be available to the connecting address
space. For example:
• Select (IWMssel)
• Begin (IWMSstbgn)
• End (IWMSstend)

The server also has the WLM Work Queuing services available to the
connecting address space when the corresponding Queue Manager with
the same subsystem type and name is active on the same MVS image (see
following macros for macro specific restrictions). For example:
• Insert (IWMQins)
• Delete (IWMQdel)

,SERVER_TYPE=ROUTING
indicates that the server receives work by way of routing, and may be
selected by the IWMSRFSV (Find Server) macro interface. Note that the
space which invokes the IWMSRFSV service must Connect with
Router=Yes.

Termination of the router with the same subsystem type and name on the
same MVS image will not cause notification to the server to terminate. This
coordination, if required, must be handled through a different protocol
than use of Connect.

,SRV_MGR_EXIT@=srv_mgr_exit@
When SERVER_TYPE=ROUTING and SERVER_MANAGER=YES are specified,
a required input parameter that is to contain the address of the Server
Manager Connect Exit to be invoked when the system wishes to inform the
server of actions it should perform. This exit will be called in SRB mode, with
a non cross-memory environment, where HASN=SASN=PASN=HASN at the
time IWMCONN was invoked. The mapping of the parameter list for the exit
and its invocation environment is given by the list form of the IWMSCEXIT
macro.

Note that it may be possible for the exit to be called before the caller has
received control back from IWMCONN. The exit or any program it drives
(synchronously or asynchronously) must synchronize with the program issuing
IWMCONN to ensure that IWMCONN has returned a connect token prior to issuing IWMDISC (disconnect) or any other services that need the connect token.

The system may cause the space to become ineligible to be recommended by IWMSRFSV upon repetitive errors in calling the exit specified. The exit must be callable from the server address space and remain available after the server manager disconnects or the connecting server TCB terminates. The exit need not persist upon memory termination of the server.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a pointer field.

**,SUBSYS=subsys**
A required input parameter, which contains the generic subsystem type (e.g. IMS, CICS, etc.). When WORK_MANAGER=YES is specified, this is the primary category under which classification rules are grouped.

If the caller connects to the WLM work queueing services by specifying QUEUE_MANAGER=YES, or requests sysplex routing by specifying ROUTER=YES, the combination of the subsystem type and the subsystem name must be unique to that MVS system.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 4-character field.

**,SUBSYSSN=subsysnm**
A required input parameter, which contains the subsystem name to be used for classifying work requests when Work_Manager=Yes is specified or taken as default. The subsystem name identifies a specific instance of the generic subsystem type.

When Server_Manager=Yes and Server_Type=Queue is specified, the subsystem name should match the subsystem name specified on the corresponding Connect for the Queue_Manager, i.e. all servers associated with the Queue_Manager have identical subsystem names.

When Server_Manager=Yes and Server_Type=Routing is specified, the subsystem name should match the subsystem name specified on the corresponding Connect for Router=Yes, i.e. all servers associated with the Router have identical subsystem names.

If a product choses to use both Work_Manager=Yes and Server_Manager=Yes on a single invocation of IWMCONN for a space, then the rules for Server_Manager apply, i.e. the subsystem name refers to the subsystem name of the space playing the role of Queue_Manager or Router.

If the caller connects to the WLM work queueing services, or to sysplex routing services, the combination of the subsystem type and the subsystem name must be unique to that MVS system.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**,TOPOLOGY=topology**
**,TOPOLOGY=NO_TOPOLOGY**
When WORK_MANAGER=YES is specified, an optional input parameter, which represents a list of ASCB addresses for the address spaces which comprise the subsystem. This list should ONLY include address spaces which do NOT surface as the current home address space when IWMMINIT or IWMMRELA are used to establish the delay monitoring environments, but that may participate as dispatchable units (TCBs or SRBs) in serving work requests.
If the current primary or home space is a space not surfacing in a monitoring environment and its execution can affect the response time of work flowing through the subsystem, then it should appear in the list. Neither current primary nor current home are defaults. While there are no limits on the number of address spaces, this information is less precise than that provided by monitoring environments. The default is NO_TOPOLOGY, which indicates that no topology information was passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

**WORK_MANAGER=**

**WORK_MANAGER=YES**

An optional parameter indicating that WLM Work Management services be available to the connecting address space. For example:

- Classify (IWMCLSFY)
- Report (IWMRPT)
- Notify (IWMMNTFY)
- Enclave Create (IWMECREA)
- Modify Connect (IWWMCON)

If NO is specified, the above services cannot be used, except for the form of Notify that does not pass an input connect token. The default is WORK_MANAGER=YES.

**WORK_MANAGER=**

**WORK_MANAGER=YES**

The connecting address space will be using the WLM Work Management services.

**WORK_MANAGER=**

**WORK_MANAGER=NO**

The connecting address space will not use the WLM Work Management services. Specifying this keyword may reduce the use of system resources.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMCONN macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

**Table 109. Return and Reason Codes for the IWMCONN Macro**

<table>
<thead>

**Meaning**: NUMBERASCB variable is not a positive value.  
**Action**: Check for possible storage overlay of the parameter list or variable. |
| 8           | xxxx082E    | **Equate Symbol**: IwmRsnCodeConnectExists  
**Meaning**: Connect has already been established for the current home address space.  
**Action**: Avoid requesting this function when a connection already exists. |
| 8           | xxxx0840    | **Equate Symbol**: IwmRsnCodeServiceNotEnabled  
**Meaning**: Requested connection type cannot be established in the current execution environment. This occurs when SERVER_MANAGER=YES is specified and the program is run as a batch job in a WLM-managed job class.  
**Action**: Run the program as a started task. |
| 8           | xxxx0841    | **Equate Symbol**: IwmRsnCodeXMemMode  
**Meaning**: Caller is in cross memory mode.  
**Action**: Invoke the function in non-cross memory mode. |
<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0847    | **Equate Symbol**: IwmRsnCodeOtherSpaceConnected  
**Meaning**: Another address space with the same subsystem type and name is connected to WLM on the MVS image and has the role of queue manager or router.  
**Action**: Avoid requesting this function with duplicate values. |
| 8           | xxxx0849    | **Equate Symbol**: IwmRsnCodeWLMServBadAPPL  
**Meaning**: The application environment name (APPLENV=) specified is not the same as the one used by WLM to start the server.  
**Action**: Verify that the start parameters for the application environment are coded correctly in the WLM ISPF application, and that those parameters are used by the started JCL procedure. |
| 8           | xxxx084A    | **Equate Symbol**: IwmRsnCodeWLMServBadSSN  
**Meaning**: The subsystem name (SUBSYSNM=) specified is not the same as the one used by WLM to start the server.  
**Action**: Verify that the start parameters for the application environment are coded correctly in the WLM ISPF application, and that those parameters are used by the started JCL procedure. |
| 8           | xxxx084B    | **Equate Symbol**: IwmRsnCodeWLMServBadSST  
**Meaning**: The subsystem type (SUBSYS=) specified is not the same as the one used by WLM to start the server.  
**Action**: Verify that the start parameters for the application environment are coded correctly in the WLM ISPF application, and that those parameters are used by the started JCL procedure. |
| 8           | xxxx084D    | **Equate Symbol**: IwmRsnCodeNotAuthConnect  
**Meaning**: The caller must be supervisor state or have PSW key mask 0-7 authority to connect to the requested WLM services.  
**Action**: Avoid requesting this function in this environment. |
| 8           | xxxx084E    | **Equate Symbol**: IwmRsnCodeWlmServBadType  
**Meaning**: For WLM started servers, the SERVER_TYPE= is not the one used to start the server.  
**Action**: Specify the correct SERVER_TYPE. |
| 8           | xxxx0853    | **Equate Symbol**: IwmRsnCodeWlmQmBadType  
**Meaning**: There is a queue manager or router environment of the specified subsystem name, but of a different type than that specified by the caller.  
**Action**: Verify that the option for queue manager/router is specified correctly on IWMCONN. If the option is correct, then server address spaces for a different Server_Type exist and must terminate before the current space may connect as a queue manager or router. |
Table 109. Return and Reason Codes for the IWMCONN Macro (continued)

| 8 xxxx0855  | IwmRsnCodeBadNumEUMax | Equate Symbol: IwmRsnCodeBadNumEUMax  
Meaning: PARALLEL_EU variable is greater than the maximum of 1000.  
Action: Specify a value between 1 and 1000. |
| 8 xxxx0856  | IwmRsnCodeBadNumEUMin | Equate Symbol: IwmRsnCodeBadNumEUMin  
Meaning: PARALLEL_EU variable is less than the minimum of 1.  
Action: Specify a value between 1 and 1000. |
| 8 xxxx085C  | IwmRsnCodeWrongNumEU | Equate Symbol: IwmRsnCodeWrongNumEU  
Meaning: Caller invoked service with a PARALLEL_EU value which is different from the PARALLEL_EU of existing servers in the application environment  
Action: Ensure that all servers in the application environment specify the same PARALLEL_EU value. |
| 8 xxxx0873  | IwmRsnCodeWrongSrvLmt | Equate Symbol: IwmRsnCodeWrongSrvLmt  
Meaning: Caller invoked service with a SERVER_LIMIT parameter setting which is different from the SERVER_LIMIT of existing servers in the application environment  
Action: Ensure that all servers in the application environment specify the same SERVER_LIMIT value. |
| 8 xxxx0874  | IwmRsnCodeWrongMngTsk | Equate Symbol: IwmRsnCodeWrongMngTsk  
Meaning: Caller invoked service with a MANAGE_TASKS parameter setting which is different from the MANAGE_TASKS of existing servers in the application environment  
Action: Ensure that all servers in the application environment specify the same MANAGE_TASKS value. |
| 8 xxxx0878  | IwmRsnCodeBadNumLimitMax | Equate Symbol: IwmRsnCodeBadNumLimitMax  
Meaning: Caller invoked service with a SERVER_LIMIT parameter setting which exceeds the maximum number of tasks which can be started in a server address space.  
Action: Correct number or do not specify SERVER_LIMIT parameter in order to use the default. |
| 8 xxxx0879  | IwmRsnCodeBadNumLimitMin | Equate Symbol: IwmRsnCodeBadNumLimitMin  
Meaning: Caller invoked service with a SERVER_LIMIT parameter setting which is less than what has been defined on the PARALLEL_EU parameter.  
Action: Ensure that SERVER_LIMIT is always greater or equal to PARALLEL_EU. |
| 8 xxxx087A  | IwmRsnCodeNoQServer | Equate Symbol: IwmRsnCodeNoQServer  
Meaning: The MANAGE_TASKS parameter is not allowed when QUEUE_SERVER=YES has been specified.  
Action: Ensure to use the parameters correctly. |
### Table 109. Return and Reason Codes for the IWMCONN Macro (continued)

<table>
<thead>

</tr>
</thead>
</table>
| 8           | xxxx088E     | **Equate Symbol**: IwmRsnCodeWlmServBadSSND  
**Meaning**: For WLM started servers, the NODENM= is not the one used to start the server.  
**Action**: Specify the correct NODENM. |
| 8           | xxxx088F     | **Equate Symbol**: IwmRsnCodeApplNotSSN  
**Meaning**: The application environment name is defined for use by a different subsystem node.  
**Action**: Check whether the correct application environment name is being used. |
| 8           | xxxx089E     | **Equate Symbol**: IwmRsnCodeServiceAModeMismatch  
**Meaning**: The caller is in 64-bit address mode and tried to invoke a service macro that is only enabled for a 31-bit environment.  
**Action**: Use the 64-bit enabled service macro (IWM4CON) or change the address mode of the caller to 31-bit. |
| C           | —            | **Equate Symbol**: IwmRetCodeEnvError  
**Meaning**: Environmental error. |
| C           | xxxx0C01     | **Equate Symbol**: IwmRsnCodeNoStg  
**Meaning**: Storage is not available for the request.  
**Action**: There is a storage shortage. The function may work successfully at a later time. |
| C           | xxxx0C09     | **Equate Symbol**: IwmRsnCodeNoResmgr  
**Meaning**: Resource manager could not be established.  
**Action**: No action required. This condition may be due to a storage shortage condition. |
| C           | xxxx0C14     | **Equate Symbol**: IwmRsnCodeNoWorkShutDown  
**Meaning**: No work selected. Caller is to shutdown.  
**Action**: The server should shut down (terminate). |
| C           | xxxx0C19     | **Equate Symbol**: IwmRsnCodeNotSecAuthConnect  
**Meaning**: The caller is not authorized by SAF to connect to WLM with SERVER_MANAGER=YES.  
**Action**: The security administrator must grant access to the appropriate resource. |
| C           | xxxx0C1A     | **Equate Symbol**: IwmRsnCodeApplNotDefined  
**Meaning**: The application environment name is not defined in the active WLM policy.  
**Action**: Check whether the correct application environment name is being used. If so, a service administrator must define the application environment in the WLM service definition. |
Table 109. Return and Reason Codes for the IWMCONN Macro (continued)

</tbody>
</table>

Example

To connect to workload management specifying: a key value of 8, and a list of 7 address spaces involved in processing work, specify:

```
IWMCONN SUBSYS=GENSUB,SUBSYSNM=SUBNAME,
TOPOLOGY=LISTASCBS,NUMBERASCBC=NUMSPACE
CONNTKN=CTKN,CONNTKNNKEYP=VALUE,CONNTKNNKEY=KEY,
RETCODE=RC,RSNCODE=RSN,
```

Where the following are declared:

- `GENSUB` DS CL4 Generic subsystem type
- `SUBNAME` DS CL8 Subsystem name
- `LISTASCBS` DS CL28 List of 7 address spaces
- `NUMSPACE` DC F'7' Number of ASCBs
- `CTKN` DS FL4 Connect token
- `KEY` DS XL1 Key value
IWMDISC allows the caller to disconnect from the workload management services. This means that the input connect token can no longer be passed to workload management macros such as IWMCLSFY and IWMRPT. When a program disconnects, any enclaves associated with the input connect token are deleted from the system. Any SRBs running in the enclave are run as preemptible SRBs at the priority of the home address space. Any enclave TCBs are converted to ordinary TCBs.

You should issue this macro once during shutdown of the connecting address space.

**Note:** It is recommended to use the equivalent service, IWM4DIS, which also supports 64-bit addressing. For more information, see “IWM4DIS — Disconnect from workload management” on page 499.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>When the corresponding Connect (IWMCONN) invocation specified WORK_MANAGER=YES or QUEUE_MANAGER=YES, ROUTER=YES, or EXPTIMPT=YES, supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When the corresponding Connect (IWMCONN) invocation specified WORK_MANAGER=NO, QUEUE_MANAGER=NO, ROUTER=NO, EXPTIMPT=NO, and SERVER_MANAGER=YES, problem state with any PSW key.</td>
</tr>
<tr>
<td>Disappendable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td></td>
<td>When the corresponding Connect (IWMCONN) invocation specified SERVER_MANAGER=YES, task mode.</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>The current Home address space must be the same as Home when the corresponding Connect was invoked. Any PASN, any SASN.</td>
</tr>
<tr>
<td></td>
<td>When the corresponding Connect (IWMCONN) invocation specified SERVER_MANAGER=YES, non-cross memory mode, P=S=H.</td>
</tr>
<tr>
<td><strong>AMODE:</strong></td>
<td><strong>31-bit</strong></td>
</tr>
<tr>
<td><strong>ASC mode:</strong></td>
<td>Primary</td>
</tr>
<tr>
<td><strong>Interrupt status:</strong></td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td><strong>Locks:</strong></td>
<td>No locks may be held.</td>
</tr>
<tr>
<td></td>
<td>When the corresponding Connect (IWMCONN) invocation specified SERVER_MANAGER=YES, SERVER_TYPE=ROUTING, NO FRRs may be set.</td>
</tr>
<tr>
<td><strong>Control parameters:</strong></td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>
**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSCON_CODE_MASK CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

1. No FRRs may be set when calling to disconnect a space which is connected as a server manager with server type = routing.
2. If the key specified on IWMCN was a user key (8-F), then the following must ALL be true:
   - caller must be in non-cross-memory mode (P=S=H). This implies that the current primary must match the primary at the time that IWMCN was invoked. Running in a subspace is not supported.
   - must be in TCB mode (not SRB)
   - current TCB must match the TCB at the time that IWMCN was invoked.
3. This service should not be invoked while in a RTM termination routine (resource manager) for the TCB owning the connect token since MVS will have its own resource cleanup routine and unpredictable results would occur. It is legitimate to use this service while in a recovery routine, however, or in mainline processing.

**Input register information**

Before issuing the IWMDISC macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
</tbody>
</table>
14-15 Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMDISC macro is as follows:

```
IWMDISC CONNTKN=conntkn,RETCODE=retcode,RSNCODE=rsncode
```

Parameters

The parameters are explained as follows:

name

An optional symbol, starting in column 1, that is the name on the IWMDISC macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

CONNTKN=conntkn

A required input parameter, which contains the connect token for the environment to be disconnected.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,MF=S

,MF=(L,list addr)

,MF=(L,list addr,attr)

,MF=(L,list addr,0D)

,MF=(E,list addr)

,MF=(E,list addr,COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.
Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

`list addr`
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

`attr`
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code `attr`, the system provides a value of 0D.

`COMPLETE`
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

`,PLISTVER=IMPLIED_VERSION`
`,PLISTVER=MAX`
`,PLISTVER=0`
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- `IMPLIED_VERSION`, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- `MAX`, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
- `0`, if you use the currently available parameters.

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

`,RETCODE=retcode`
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

`,RSNCODE=rsncode`
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).
ABEND codes

None.

Return codes and reason codes

When the IWMDISC macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>

Meaning: Version number in parameter list is not valid.  
Action: Check for possible storage overlay of the parameter list. |
| 8           | xxxx082F    | Equate Symbol: IwmRsnCodeWrongHome  
Meaning: The caller invoked the service from the wrong home address space.  
Action: Invoke the function with the correct home address space. |
| 8           | xxxx0841    | Equate Symbol: IwmRsnCodeXMemMode  
Meaning: Caller is in cross-memory mode.  
Action: Invoke the function in non-cross memory mode. |
| 8           | xxxx084D    | Equate Symbol: IwmRsnCodeNotAuthConnect  
Meaning: The caller must be supervisor state or have PSW key mask 0-7 authority to disconnect from the requested WLM services.  
Action: Avoid requesting this function in this environment. |
| 8           | xxxx089E    | Equate Symbol: IwmRsnCodeServiceAModeMismatch  
Meaning: The caller is in 64-bit address mode and tried to invoke a service macro that is only enabled for a 31-bit environment.  
Action: Use the 64-bit enabled service macro (IWM4DIS) or change the address mode of the caller to 31-bit. |
| 10          | —           | Equate Symbol: IwmRetCodeCompError  
Meaning: Component error.  
Action: No action required. The function may be successful if invoked again. |
IWMECQRY — Query enclave classification attributes

The purpose of this service is to query the classification attributes of an enclave. The output is mapped by IWMEDC.

The Query macro is provided in list, execute, and standard form. The list form accepts no variable parameters and is used only to reserve space for the parameter list. The standard form is provided for use with routines which do not require reentrant code. The execute form is provided for use with the list format for reentrant routines.

Note: It is recommended to use the enhanced service, IWM4EQRY, which also supports 64-bit addressing. For more information, see "IWM4EQRY — Query an enclave" on page 528.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary or access register (AR) Any P,S,H.</td>
</tr>

<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Reason code and return code constants are defined within IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above.
   The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. This macro may not be used prior to the completion of WLM address space initialization
2. All parameter areas must reside in current primary or be addressable by the dispatchable unit access list.
The caller must provide storage for an answer area mapped by IWMECD. This answer area may reside in the caller’s primary address space, or in a dataspace accessible via the current unit of work’s dispatchable unit access list (DUal).

**Input register information**

Before issuing the IWMECQRY macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMECQRY macro is as follows:

```plaintext
IWMECQRY name=IWMECQRY,ETOKEN=etoken,ANSAREA=ansarea,ANSLEN=anslen,

QUERYLEN=querylen,RETCODE=retcode,

PLISTVER=IMPLIED_VERSION,PLISTVER=MAX,PLISTVER=0
```
Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMECQRY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**ANSAREA=ansarea**

A required output parameter, which specifies an area to contain the data being returned. The answer area is defined by the IWMECPE macro.

_To code:_ Specify the RS-type address, or address in register (2)-(12), of a character field.

**ANSLEN=anslen**

A required input parameter, variable which contains the length of the area provided to contain the data being returned by IWMECQRY.

_To code:_ Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**ETOKEN=etoken**

A required input parameter, which contains the enclave token representing the enclave of interest.

_To code:_ Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**MF=S**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.
The name of a storage area to contain the parameters. For MF=S and
MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code \texttt{attr}, the system provides a value of 0D.

Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and
with the same value on all of the macro forms. The values are:

- \texttt{IMPLIED\_VERSION}, which is the lowest version that allows all parameters
specified on the request to be processed. If you omit the PLISTVER
parameter, IMPLIED\_VERSION is the default.
- \texttt{MAX}, if you want the parameter list to be the largest size currently possible.
This size might grow from release to release and affect the amount of
storage that your program needs.
  If you can tolerate the size change, IBM recommends that you always
specify PLISTVER\_MAX on the list form of the macro. Specifying MAX
ensures that the list-form parameter list is always long enough to hold all
the parameters you might specify on the execute form; in this way, MAX
ensures that the parameter list does not overwrite nearby storage.
- 0, if you use the currently available parameters.

To code: Specify one of the following:

- \texttt{IMPLIED\_VERSION}
- \texttt{MAX}
- A decimal value of 0

A required output parameter, variable which contains the number of bytes
needed to contain the classification attributes being returned by IWMECQRY.
The length of the area needed to contain the data is dependent on the MVS
release. If the ANSLEN is less than the QUERYLEN, then no data is returned
in the output area specified by ANSAREA.

To code: Specify the RS-type address, or address in register (2)-(12), of a
fullword field.

An optional output parameter into which the return code is to be copied from
GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).
ABEND codes

None.

Return codes and reason codes

When the IWMECQRY macro returns control to your program, GPR 15 (and retcode, if you coded RETCODE) contains a return code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>

<td>Action: No action required. The function may be successful if invoked again.</td>
</tr>
</tbody>
</table>
The purpose of this service is to create an enclave where possibly multiple SRBs and/or TCBs may be simultaneously executing or scheduled. For the duration of each enclave, all SRBs and TCBs associated with the enclave are treated as part of a single work request. All SRBs and/or TCBs associated with the enclave accumulate service as a single entity and are managed as a single entity. The address spaces where enclave SRBs are dispatched, as defined by the ENV= parameter of IEAMSCHD, should be non-swappable.

For more information about managing address spaces with enclaves, see “Performance management of address spaces with enclaves” on page 46.

**Note:** An address space must be non-swappable if it has enclave SRBs dispatched and SYSEVENT ENCASSOC has not been issued.

For TYPE=INDEPENDENT enclaves, a new work business unit of work is created and classified according to the input Connect token's subsystem type and subsystem name, along with whatever other attributes are passed via the Classify parameter list. The current home address space is considered the owner.

For TYPE=DEPENDENT enclaves, SRM considers the enclave to be part of the current home address space's transaction, which then becomes the owning space. This space need not be connected to WLM via IWMCONN.

For TYPE=MONENV enclaves, SRM considers the enclave to be part of the address space's transaction which is delayed according to the input monitoring environment, as set when IWMMINIT or IWMMRELA was used. This space becomes the owning space. This space need not be connected to WLM via IWMCONN.

For both TYPE=MONENV and TYPE=DEPENDENT enclaves, SRM will change the enclave to TYPE=INDEPENDENT if the owning address space's transaction ends.

For both TYPE=MONENV and TYPE=DEPENDENT enclaves, SRM will check the enclave for period switch when the owning address space is swapped in. If the owning address space is swapped out SRM will continue to accumulate service for any enclaves owned by the space, but will not check the address space and any owned enclave for period switch until the address space is swapped in again. The presence of enclaves does not make the address space appear to be ready from an SRM point of view.

Enclaves are deleted if the owning address space terminates.

TYPE=INDEPENDENT enclaves are deleted if the owning address space disconnects or the TCB which connected terminates.

Enclaves should only be created when this environment is ready for execution, and should not be used when prolonged queueing effects are possible prior to the scheduling of the first SRB (IEAMSCHD) or the first task join (IWMEJOIN). "Prolonged" would certainly include times measured in seconds. The service allows the caller to pass the queueing time prior to creation of the enclave so that this may be separately reported.
IWMECREA

Note: It is recommended to use the equivalent service, IWM4ECRE, which also supports 64-bit addressing. For more information, see "IWM4ECRE — Create an enclave" on page 506.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Requirement Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum authorization</td>
<td>Supervisor state or program key mask (PKM) allowing keys 0-7.</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode</td>
<td>Primary or access register (AR)</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro CVT must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSCNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

1. The Connect token from the input classify parameter list must be owned by the current home address space and must be associated with a system key (0-7), as specified on IWMCNON. The Classify parameter list and hence the Connect token is only relevant for TYPE=INDEPENDENT enclaves.
2. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.
3. The variable length fields associated with the classify parameter list (the classify parameter list is only relevant for certain options) given by the CLSFY keyword have the following limitations in addition to those documented in IWMCLSFY:
   - SUBSYSOM is limited to 255 bytes
   - COLLECTION is limited to 18 bytes
   - CORRELATION is limited to 12 bytes
4. When TYPE(MONENV) is specified the following apply:
   - If the key specified on IWMMMCREA was a user key (8-F), then primary or home addressability must exist to the performance block IWMMMCREA.
obtained. This condition is satisfied by ensuring that the current primary or home address space matches primary (=home) at the time that IWMMCREA was invoked.

- The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.
- Only limited checking is done against the input monitoring token.
- TYPE=MONENV enclaves cannot be created for report-only monitoring environments.

5. This macro may only be used on z/OS R2 or higher levels for EXSTARTDEFER keyword.

Input register information

Before issuing the IWMECREA macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMECREA macro is as follows:
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMECREA macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ACCESS=PRIMARY
,ACCESS=HOME
When TYPE=MONENV is specified, a required parameter, which describes how to access the monitoring environment.

,ACCESS=PRIMARY
indicates that the monitoring environment can be accessed in the caller's primary address space. This would be appropriate if the monitoring environment was established (by IWMMCREA) to be used by routines in a specific system key or if it was established to be used in a specific user key in the current primary.

,ACCESS=HOME
indicates that the monitoring environment must be accessed in the home address space, which is not the caller's primary address space. This would be appropriate if the monitoring environment was established (by IWMMCREA) for use by a specific user key.

,ARRIVALTIME=arrivaltime
When TYPE=INDEPENDENT is specified, a required input parameter, which
contains the work arrival time in STCK format. This is the time at which the business work request is considered to have arrived and from which point the system evaluates elapsed time for the work request.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

,CLSFY=clsfy

When TYPE=INDEPENDENT is specified, a required input parameter, which contains the classification information in the format of the parameter list for IWMCLSFY. Note that this name is the data area name, not its pointer. IWMCLSFY MP(M) should be used to initialize the area prior to invocation of IWMECREA.

Note that the variable length fields associated with the classify parameter list given by the CLSFY keyword have the following limitations in addition to those documented in IWMCLSFY:

- SUBSYSMP is limited to 255 bytes
- COLLECTION is limited to 18 bytes
- CORRELATION is limited to 12 bytes

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

,ESTRT=IMPLIED
,ESTRT=EXPLICIT
,ESTRT=EXPLICIT_SINGLE
,ESTRT=NEVER

When TYPE=INDEPENDENT is specified, an optional parameter, which denotes how the work manager indicates the start and end point of an EWLM work request when participating in cross-platform enterprise workload management (EWLM). The default is ESTRT=IMPLIED.

,ESTRT=IMPLIED

If the work manager previously connected to WLM with IWMCONN EWLM=YES, a work request is started implicitly when the enclave is created. If IWMESTOP was not invoked before, the work request will be stopped implicitly when the enclave is deleted.

,ESTRT=EXPLICIT

The work manager indicates the start and end point of an EWLM work request by invoking the services IWMESTRT and IWMESTOP. Note that this option is only meaningful, if the work manager previously connected to WLM with IWMCONN EWLM=YES.

,ESTRT=EXPLICIT_SINGLE

Indicates the same as option ESTRT=EXPLICIT and, in addition, the application ensures that only one work request is active. No nested calls to IWMESTR are allowed. If this option is specified the CPU consumption on all EWLM enclave services (IWMEGCOR, IWMESTR, IWMESTOP, IWMEBLK, IWMEUBLK) will be reduced. If ESTRT=EXPLICIT_SINGLE is specified on IWMECREA, the application must also add the EWLMMODE=EXPLICIT_SINGLE parameter on all calls to IWMEGCOR, IWMESTR, IWMESTOP, IWMEBLK and IWMEUBLK. If this parameter is used, the application has some restrictions on all calls to IWMEGCOR, IWMESTR, IWMESTOP, IWMEBLK and IWMEUBLK. Refer to the corresponding macro descriptions for details.

,ESTRT=NEVER

Indicates that this enclave will never use any EWLM-related enclave
services (IWMEGCOR, IWMESTRT, IWMESTOP, IWMEDBLK, and IWMEUBLK) after the enclave has been created, even if the work manager
has registered (IWM4CON or IWMCNN) with EWLM=YES. Moreover
IWMECREA will not start an EWLM work request on the enclave and will
not do any EWLM-related processing.

,ETOKEN=etoken
A required output parameter, which will receive the enclave token.

To code: Specify the RS-type address, or address in register (2)-(12), of an
8-character field.

,EXSTARTDEFER=NO
,EXSTARTDEFER=YES
When TYPE=INDEPENDENT is specified, an optional parameter, which
indicates whether the enclave execution start time should begin when the first
IWMSTBGN or IWMEJOIN is executed. The time between enclave create and
the first IWMSTBGN or IWMEJOIN is assumed to be the queue time. The
default is EXSTARTDEFER=NO

,EXSTARTDEFER=NO
indicates that the enclave execution start time should not begin when the
first IWMSTBGN or IWMEJOIN is executed.

,EXSTARTDEFER=YES
indicates that the enclave execution start time should begin when the first
IWMSTBGN or IWMEJOIN is executed.

,FUNCTION_NAME=function_name
When TYPE=INDEPENDENT is specified, a required input parameter, which
contains the descriptive name for the function for which the enclave was
created.

To code: Specify the RS-type address, or address in register (2)-(12), of an
8-character field.

,MF=S
,MF={L,list addr}
,MF={L,list addr,attr}
,MF={L,list addr,0D}
,MF={E,list addr}
,MF={E,list addr,COMPLETE}
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline
parameter list and generates the macro invocation to transfer control to the
service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter may be coded with the list form of
the macro.

Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
defined by the list form, and generates the macro invocation to transfer control
to the service.
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

When TYPE=MONENV is specified, a required input parameter, which contains the delay monitoring token which describes the current business unit of work. If the monitoring environment is related to an address space, then it must be the current home address space.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- 0, which supports all parameters except those specifically referenced in higher versions.
- 1, which supports the following parameters and those from version 0:

  ACCESS  MONTKN  TYPE

  - 2, which supports the following parameter and those from version 0 and 1:

  EXSTARTDEFER
IWMECREA

- 3, which supports the following parameters and those from version 0, 1, and 2:

  ESTRT
  WORKREQ_HDL

  To code: Specify one of the following:
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0, 1, 2, or 3

  ,RETCODE=retcode
  An optional output parameter into which the return code is to be copied from GPR 15.
  To code: Specify the RS-type address of a fullword field, or register (2)-(12).

  ,RSNCODE=rsncode
  An optional output parameter into which the reason code is to be copied from GPR 0.
  To code: Specify the RS-type address of a fullword field, or register (2)-(12).

  TYPE=INDEPENDENT
  TYPE=DEPENDENT
  TYPE=MONENV
  An optional parameter, which indicates the type of enclave being created. The default is TYPE=INDEPENDENT.

  TYPE=INDEPENDENT
  indicates that the enclave represents a new business unit of work with its own business objectives.

  TYPE=DEPENDENT
  indicates that the enclave represents a continuation of the business unit of work represented by the current home address space.

  TYPE=MONENV
  indicates that the enclave represents a continuation of the business unit of work represented by the input monitoring environment.

  ,WORKREQ_HDL=workreq_hdl
  When ESTRT=IMPLIED and TYPE=INDEPENDENT are specified, an optional output parameter that will receive the handle which represents the work request. The application must pass this handle to the other work request services IWMESTOP, IWMEBLK, IWMEUBLK, and IWMEGCOR.
  To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

ABEND codes

None.

Return codes and reason codes

When the IWMECREA macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.
The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

**Table 112. Return and Reason Codes for the IWMECREA Macro**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 0           | —           | Equate Symbol: IwmRetCodeOk  
Meaning: Successful completion.  
Action: None required. |
| 8           | —           | Equate Symbol: IwmRetCodeInvocError  
Meaning: Invalid invocation environment or parameters. |

Meaning: Caller is disabled.  
Action: Avoid requesting this function while disabled. |
| 8 xxxx0804  | —           | Equate Symbol: IwmRsnCodeLocked  
Meaning: Caller is locked.  
Action: Avoid requesting this function while locked. |
| 8 xxxx080B  | —           | Equate Symbol: IwmRsnCodeBadPl  
Meaning: Error accessing parameter list.  
Action: Check for possible storage overlay. Also check if you call this macro in 64-bit address mode. Refer to the description of xxxx089E for further information. |
| 8 xxxx0820  | —           | Equate Symbol: IwmRsnCodeBadMonEnv  
Meaning: Monitoring environment does not pass short form verification.  
Action: Check for possible storage overlay. |
| 8 xxxx0821  | —           | Equate Symbol: IwmRsnCodeBadConn  
Meaning: Connect token from the input classify parameter list does not pass validity checking.  
Action: Check for possible storage overlay. |
| 8 xxxx0824  | —           | Equate Symbol: IwmRsnCodeAmode24  
Meaning: Caller invoked service but was in 24 bit addressing mode.  
Action: Request this function only when you are in 31 bit addressing mode. |
| 8 xxxx0828  | —           | Equate Symbol: IwmRsnCodeBadVersion  
Meaning: Version number in parameter list is not valid.  
Action: Check for possible storage overlay of the parameter list. |
| 8 xxxx0836  | —           | Equate Symbol: IwmRsnCodeMaxEnclave  
Meaning: Enclave could not be created because the enclave limit has been reached.  
Action: Check for possible problems wherein enclaves are not being deleted as expected or excessive numbers of enclaves are being created in a loop. |
Table 112. Return and Reason Codes for the IWMCREA Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0837    | **Equate Symbol**: IwmRsnCodeUserKeyConnToken  
**Meaning**: Connect token from the input classify parameter list is associated with a user key.  
**Action**: Invoke the function with a token associated with a system key. |
| 8           | xxxx0838    | **Equate Symbol**: IwmRsnCodeClsfyAreaTooBig  
**Meaning**: Input area associated with classification information is larger than supported.  
**Action**: Invoke the function with an area of the proper size. Check for possible storage overlay. |
| 8           | xxxx0839    | **Equate Symbol**: IwmRsnCodeClsfyPlTooSmall  
**Meaning**: Input Classify parameter list is too small.  
**Action**: Invoke the function with an area of the proper size. Check for possible storage overlay. |
| 8           | xxxx083B    | **Equate Symbol**: IwmRsnCodeHomeNotOwnConn  
**Meaning**: Home address space does not own the connect token from the input classify parameter list.  
**Action**: Invoke the function with the correct home address space. |
| 8           | xxxx0840    | **Equate Symbol**: IwmRsnCodeServiceNotEnabled  
**Meaning**: Caller's space connection is not enabled for this service.  
**Action**: Avoid requesting this function under the input connection. IWMCONN options must be specified previously to enable this service. |
| 8           | xxxx085D    | **Equate Symbol**: IwmRsnCodeMonenvNotHome  
**Meaning**: The input monitoring environment is related to an address space other than home.  
**Action**: None required. |
| 8           | xxxx0892    | **Equate Symbol**: IwmRsnCodeEWLMCorrNotAllowed  
**Meaning**: Passed classification information must not contain an EWLM correlator (EWLM_CORR).  
**Action**: Do not pass an EWLM correlator within the classification information when invoking the service with ESTRT=EXPLICIT. |
| 8           | xxxx0894    | **Equate Symbol**: IwmRsnCodeInvalidEWLMCorr  
**Meaning**: Passed classification information contains an ARM correlator (EWLM_CORR) that does not pass validity checking. The architected ARM correlator length field in the first two bytes of the EWLM_CORR is either less than 4 (X'0004') or greater than 512 (X'200').  
**Action**: Check the specification of the EWLM correlator in the classification information. |
### Table 112. Return and Reason Codes for the IWMECREA Macro (continued)

<table>
<thead>

</tr>
</tbody>
</table>
IWMEDELE

IWMEDELE — Delete an enclave

The purpose of this service is to delete an enclave, so that no SRBs or TCBs exist within the enclave and no new SRBs may be scheduled into the enclave, nor may any TCBs join the enclave. Some residual enclave related CPU time will not be accounted back to the work request whenever active enclave SRBs/TCBs were present at the time IWMEDLE is invoked. SRBs scheduled to the enclave which have not completed will be converted to ordinary preemptable SRBs. TCBs joined to the enclave which have not completed will be converted to ordinary TCBs.

If IWMEDELE is invoked for an enclave which is registered, the enclave is considered only logically deleted while all its functionality stays in place. Physical deletion is deferred until all interested parties have deregistered the enclave. The caller does not receive any notice when the physical deletion of the enclave is done.

When an enclave is deleted, the work request is considered to have finished and all related resource accounting will be finalized.

IWMEDELE cannot be used to delete a foreign enclave. The IWMUIMPT macro must be used instead.

Note: It is recommended to use the equivalent service, IWM4EDEL, which also supports 64-bit addressing. For more information, see "IWM4EDEL — Delete an enclave” on page 520.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state or program key mask (PKM) allowing keys 0-7. |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary or access register (AR) |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. FRR environments may be established. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded
from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

6. Since this service may only be used by system-like code, some validity checking on the parameter list is not performed. These checks would only be needed if the macro were not used to invoke the service routine.

**Restrictions**

This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

**Input register information**

Before issuing the IWMEDELE macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.
Syntax

The syntax of the IWM4EDEL macro is as follows:

```
{name} IWM4EDEL ETOKEN=etoken,CPUSERVICE=cpuservice
```

```
,SYSPLEXCPUSRV=syplexcpusrv,CPUTIME=cputime
```

```
,RESPTIME_RATIO=resptime_ratio,ZAAPSERVICE=zaapservice
```

```
,ZAAPTIME=zaaptime,ZAAPNFACOR=zaapnfactor,ZIIPSERVICE=zipservice
```

```
,ZIIPTIME=ziiptime,RETCODE=retcode,RSNCODE=rsncode
```

```
,PLISTVER=IMPLIED_VERSION
```

```
,PLISTVER=MAX
```

```
,PLISTVER=0
```

```
,PLISTVER=1
```

```
,PLISTVER=2
```

```
,MF=S
```

```
,PLISTVER=MAX
```

```
,PLISTVER=0
```

```
,PLISTVER=1
```

```
,PLISTVER=2
```

```
,MF=(L,list addr)
```

```
,MF=(E,list addr)
```

```
,PLISTVER=0
```

```
,PLISTVER=1
```

```
,PLISTVER=2
```

```
,MF=(L,list addr)
```

```
,MF=(E,list addr)
```

```
,PlISTVER=0
```

```
,PlISTVER=1
```

```
,PlISTVER=2
```

```
,MF=(L,list addr)
```

```
,MF=(E,list addr)
```

Parameters

The parameters are explained as follows:

`name`
An optional symbol, starting in column 1, that is the name on the IWM4EDEL macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`CPUSERVICE=cpuservice`
An optional output parameter, which will contain the CPU service accumulated by the enclave on the local system.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

`CPUTIME=cputime`
An optional output parameter, which will contain the total CPU time accumulated by the enclave on the local system.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

`ETOKEN=etoken`
A required input parameter, which contains the enclave token to be returned.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

`MF=S`
`MF=(L,list addr)`
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

, list addr
   The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

, attr
   An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

, COMPLETE
   Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

, PLISTVER=IMPLIED_VERSION
, PLISTVER=MAX
, PLISTVER=0
, PLISTVER=1
, PLISTVER=2
   An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
   • IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
   • MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
   If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
0, which supports all parameters except those specifically referenced in higher versions.

1, which supports the following parameter and those from version 0:

\[ \text{RESPTIME\_RATIO} \]

2, which supports the following parameters and those from version 0 and 1:

\[ \text{ZAAPNFACTOR} \quad \text{ZAAPTIME} \quad \text{ZIIPTIME} \]

\[ \text{ZAAPSERVICE} \quad \text{ZIIPSERVICE} \]

To code:

Specify one of the following:

- \text{IMPLIED\_VERSION}
- \text{MAX}
- A decimal value of 0, 1, or 2

\[ \text{RESPTIME\_RATIO=}\ \text{resptime\_ratio} \]

An optional output parameter, which contains the response time ratio times 100: \( \frac{\text{act.resp.time}}{\text{goal}} \times 100 \) if the enclave has a response time goal (limited to: \( 1 \leq \text{RESPTIME\_RATIO} \leq 1000 \)) 0 otherwise

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

\[ \text{RETCODE=}\ \text{retcode} \]

An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

\[ \text{RSNCODE=}\ \text{rsncode} \]

An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

\[ \text{SYSPLEXCPUSRV=}\ \text{sysplexcpusrv} \]

An optional output parameter, which will contain the CPU service accumulated by the enclave on the local system and on other systems through the use of the IWMEXPT and IWMIMPT services. If the IWMEXPT and IWMIMPT services were not used, SYSPLEXCPUSRV returns the same value as CPUSERVICE.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

\[ \text{ZAAPNFACTOR=}\ \text{zaapnfactor} \]

An optional output parameter, which contains the normalization factor for application assist processors (zAAPs). If zAAPs are running at a different speed, multiply zAAP service and times with this factor and divide the result by 256 to normalize the values to the speed of regular CPs. Note however, that if there has been a speed change of zAAP processors during the life time of the enclave, this calculation will return incorrect data.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.
,ZAAPSERVICE=zaapservice
An optional output parameter, which contains the application assist processor (zAAP) service accumulated by the enclave on the local system. The value is not normalized to the speed of regular CPs, but is expressed in zAAP speed which might be different. You may use ZAAPNFACtor to normalize the value to the speed of regular CPs. Note however, that if the zAAP speed changed during the life time of the enclave, this value cannot be normalized correctly.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

,ZAAPTIME=zaaptime
An optional output parameter, which contains the total application assist processor (zAAP) time accumulated by the enclave on the local system. The value is not normalized to the speed of regular CPs, but is expressed in zAAP speed which might be different. You may use ZAAPNFACtor to normalize the value to the speed of regular CPs. Note however, that if the zAAP speed changed during the life time of the enclave, this value cannot be normalized correctly.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

,ZIIPSERVICE=ziipservice
An optional output parameter, which contains the integrated information processor (zIIP) service accumulated by the enclave on the local system. The service is normalized to standard processor speed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

,ZIIPTIME=ziiptime
An optional output parameter, which contains the total integrated information processor (zIIP) time accumulated by the enclave on the local system. The time is normalized to standard processor speed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

ABEND codes

None.

Return codes and reason codes

When the IWMEDELE macro returns control to your program:
• GPR 15 (and retcode, if you coded RETCODE) contains a return code.
• When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.
### Table 113. Return and Reason Codes for the IWM4EDEL Macro

<tr>
<td></td>
<td></td>
<td>Meaning: Component error.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Action: No action required. The function may be successful if invoked again.</td>
</tr>
</tbody>
</table>

Example

To allow the current task to join an enclave:

```plaintext
IWMEDELE ETOKEN=ENCTOKEN,RETCODE=RC,RSNCODE=RSN
```

* Storage areas

```
ENCTOKEN DS CL8          Contains the enclave token
RC     DS F               Return code
RSN    DS F               Reason code
```
IWMEQRY — Enclave query

This service extends service IWMECQRY, it offers three functions:
1. query the classification attributes of an enclave,
2. query WLM performance management information of an enclave,
3. both of the above.

The output of this service is mapped by macro IWMECDX.

The Query macro is provided in list, execute, and standard form. The list form accepts no variable parameters and is used only to reserve space for the parameter list. The standard form is provided for use with routines which do not require reentrant code. The execute form is provided for use with the list format for reentrant routines.

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state or program key mask (PKM) allowing keys 0-7.
Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31-bit
ASC mode: Primary or access register (AR)
   If in Access Register ASC mode, specify SYSSTATE ASCENV=AR before invoking this macro.
Interrupt status: Enabled for I/O and external interrupts
Locks: No locks may be held.
Control parameters: Control parameters must be in the primary address space.

Programming requirements
1. This macro may only be used on z/OS V1.R10 (HBB7750) or higher with APAR OA35822 applied.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high order halfword should thus be excluded from comparison with the reason code values described above.

The constant, IWMRSNCODE_MASK CONST defined in IWMYCON, may be used for this purpose.

Restrictions
1. This macro may not be used prior to the completion of WLM address space initialization
2. The caller must provide storage for an answer area mapped by macro IWMECDX. This answer area may reside in the caller's primary address space, or in a dataspace accessible via the current unit of work's dispatchable unit access list (DUal).

**Input register information**

Before issuing the IWMEQRY macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

\  QUERYLEN=querylen,FUNCTION=CLASSINFO
  \  FUNCTION=PERFINFO
  \  FUNCTION=ALL
  \_RETCODE=retcode
```
Parameters

The parameters are explained as follows:

name
   An optional symbol, starting in column 1, that is the name on the IWMEQRY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,ANSAREA=ansarea
   A required output parameter, which is to receive the data being returned. The layout of this area is defined by macro IWMECDX.

      To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

,ANSLEN=anslen
   A required input parameter, variable which contains the length of the area provided to contain the data being returned by IWME4EQRY.

      To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field, or specify a literal decimal value.

ETOKEN=etoken
   A required input parameter, which contains the Enclave token representing the Enclave of interest.

      To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,FUNCTION=CLASSINFO
,FUNCTION=PERFINFO
,FUNCTION=ALL
   A required parameter that indicates the query function to be executed.

      ,FUNCTION=CLASSINFO
         Use this function to query the classification attributes of an enclave. This is the same information as is returned by service IWMECQRY.

      ,FUNCTION=PERFINFO
         Use this function to query the WLM performance management information of an enclave. This data is based on the classification attributes and the active WLM Policy.

      ,FUNCTION=ALL
         Use this function to query both, the classification attributes and the WLM performance management information of an enclave.
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,list addr

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

• IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
• MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
• 0, if you use the currently available parameters.
IWMEQRY

To code: Specify one of the following:
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0

\texttt{querylen}

A required output parameter, variable is to receive the number of bytes needed to contain the data being returned by IWMEQRY. The length of the area needed to contain the data is dependent on the Function being used. If the ANSLEN is less than the QUERYLEN, then no data is returned in the output area specified by ANSAREA and a return code of 4 is issued.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

\texttt{retcode}

An optional output parameter into which the return code is to be copied from GPR 15. If you specify 15, GPR15, REG15, or R15 (within or without parentheses), the value will be left in GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12) or (15), (GPR15), (REG15), or (R15).

\texttt{rsncode}

An optional output parameter into which the reason code is to be copied from GPR 0. If you specify 0, 00, GPR0, GPR00, REG0, REG00, or R0 (within or without parentheses), the value will be left in GPR 0.

To code: Specify the RS-type address of a fullword field, or register (0) or (2)-(12), (00), (GPR0), (GPR00), REG0, (REG00), or (R0).

ABEND codes

None.

Return codes and reason codes

When the IWMEQRY macro returns control to your program:
  - GPR 15 (and \texttt{retcode}, when you code RETCODE) contains a return code.
  - When the value in GPR 15 is not zero, GPR 0 (and \texttt{rsncode}, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol Meaning and Action</th>
</tr>
</thead>
</table>
| 0           | —           | \textbf{Equate Symbol}: IwmRetCodeOk  
  \textbf{Meaning}: Successful completion.  
  \textbf{Action}: None required. |
| 4           | —           | \textbf{Equate Symbol}: IwmRetCodeWarning  
  \textbf{Meaning}: Successful completion, unusual conditions noted. |
<table>
<thead>
<tr>
<th>Return Code</th>

</tbody>
</table>

**Example**

None.
IWMMABNL — Record abnormal event

You can use IWMMABNL to record an abnormal event that has occurred for work requests. The information is kept in the input monitoring environment. The abnormal condition supplements any existing abnormal conditions recorded in the input monitoring environment.

The abnormal events are transferred (with all other information) to any parent monitoring environment with the IWMMXFER FUNCTION=RETURN parameter. These abnormal events are recorded in the monitoring environment so that the caller can get an indication that further requests might fail due to some abnormal situation. This supplements any information a caller receives from the return code.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state, or problem state. PSW key must either be 0 or match the value supplied on IWM4MCRE for the input monitoring token when MONENVKEYP=PSWKEY is specified.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary mode</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled</td>
</tr>
<tr>
<td>Locks:</td>
<td>Unlocked</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

- You must include the IWMYCON mapping macro in the calling program.
- If the key specified on IWM4MCRE was a user key, then either primary or secondary addressability must exist to the performance block IWM4MCRE obtained.
- If you specify MONENVKEYP=VALUE, then the caller must be in supervisor state or have PKM authority to the key specified by MONENVKEY.
- If you specify MONENVKEYP=UNKNOWN, then the caller must be in supervisor state or have PKM authority to key 0.
- The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.
- Only limited validity checking is done on the input monitoring token.
- The caller is responsible for error recovery.

Restrictions

None.
**Input register information**

Before issuing the IWMMABNL macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if the return code in GPR 15 is not 0, otherwise, used as a work register by the system.</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14 - 15</td>
<td>Used as a work register by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMMABNL macro is as follows:

```
IWMMABNL ABNORMAL=abnormal,MONTKN=montkn
```

```
MONENVKEY=value,MONENVKEY=monenvkey,MONENV=NOSWITCH
```

```
RETCODE=retcode,RSNCODE=rsncode
```

**Parameters**

The parameters are explained as follows:
Abnormal

Required input parameter specifying the abnormal mask reflecting the abnormality. Macro IWMYCON contains the defined abnormal masks. The mask variable names begin with IWMMABNL, for example - IWMMABNL_SCOPE_LOCALMVS.

To code: Specify the name (RS-type), or address in register (2)-(12) of a 32-bit field containing the abnormal mask.

Monk

Required input parameter specifying the monitoring token for the environment affected by the abnormality.

To code: Specify the name (RS-type), or address in register (2)-(12) of a 32 bit field containing the monitoring token.

Monenvkeyp=value

Required input parameter that specifies whether a key switch is needed to access the input monitoring environment.

Use MONENVKEYP=VALUE to indicate that the key is being passed explicitly in MONENVKEY.

Use MONENVKEYP=PSWKEY to indicate that the current PSW key should be used. If you use this parameter, the input monitoring environment must have been created with the same key as the current PSW key.

Use MONENVKEYP=UNKNOWN to indicate that the key associated with the input monitoring environment is unknown. If you use this parameter, the caller must be in supervisor state or have PKM authority to key 0.

Monenvkey=monenvkey

Required input parameter for MONENVKEYP=VALUE that specifies the key in which the input monitoring environment must be accessed. If you use this parameter, the caller must be in supervisor state or have PKM authority to the key specified.

To code: Specify an 8 bit name (RS-type), or address in register (2)-(12), of the monitoring environment key. The leftmost (high order) 4 bits contain the key value. Note that this uses the machine orientation for keeping the storage key in the high-order bits.

Monenv=noswitch

Required keyword input which describes whether an address space switch is needed to access the input monitoring environment.

Use MONENV=NOSWITCH to indicate that no space switch is needed to access the input monitoring environment. This is appropriate if the input monitoring environment was established (by IWM4MCRE) to be used by routines in a specific system key or if it was established to be used in a specific user key in the current primary.

Use MONENV=SECONDARY to indicate that the input monitoring environment was established in current secondary (for use by a specific user key).
IWMMABNL

To code: Specify the name (RS-type) or address (using a register from 2 to 12) of a fullword to contain the return code.

\texttt{RSNCODE=rsncode addr}

Optional output parameter that specifies where the system is to store the reason code. The reason code is also in GPR 0.

To code: Specify the name (RS-type) or address (using a register from 2 to 12) of a fullword to contain the reason code (if any).

ABEND codes

None.

Return codes and reason codes

When IWMMABNL macro returns control to your program, GPR 15 contains a return code. When the return code is non-zero, then GPR 0 contains a reason code.

<table>
<thead>
<tr>
<th>Hexadecimal Return Code</th>
<th>Hexadecimal Reason Code</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| 00                      |                         | Meaning: Successful completion.  
Action: None. |
| 04 0402                 |                         | Meaning: Warning. Input monitoring token indicates no monitoring environment was established.  
Action: None. |
| 08 0820                 |                         | Meaning: Program error. The monitoring environment does not pass short form verification. |

Example

To record an abnormal event that has occurred for a work request associated with a monitoring token defined in the field MONTKN1, specify:

\texttt{IWMMABNL ABNORMAL=(R7),  
MONTKN=MONTKN1,  
MONENVKEY=PSWKEY,  
MONENV=NOSWITCH,  
RETCODE=RCODE, RSNCODE=RSN}

No address space switch is required, so you can specify \texttt{MONENV=NOSWITCH}. 
IWMMCHST — Monitor change state of work unit

The purpose of this service is to reflect in a monitoring environment what the current state of a work request is with respect to delays.

**Note:** It is recommended to use the equivalent service, IW4MCHS, which also supports 64-bit addressing. For more information, see “IW4MCHS — Change the state of a work request” on page 548.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state. PSW key must either be 0 or match the value supplied on IWMMCREA.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>Suspend locks are allowed.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

1. Caller is responsible for error recovery
2. Only limited checking is done against the input monitoring token.
3. If the key specified on IWMMCREA was a user key (8-F), then the primary addressability must exist to the performance block IWMMCREA obtained. This condition is satisfied by ensuring that current primary matches primary at the time that IWMMCREA was invoked. If this service is invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.
4. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.
5. This macro may only be used on z/OS R2 or higher levels for the following state/resources:
   - STATE(ACTIVE_APPL)
   - RESOURCE(SSL_THREAD)
IWMMCHST

- RESOURCE(REG_THREAD)
- RESOURCE(REG_TO_WRKTB)
- RESOURCE(TYPE1)
- RESOURCE(TYPE2)
- RESOURCE(TYPE3)
- RESOURCE(TYPE4)
- RESOURCE(TYPE5)

6. This macro may only be used on z/OS R8 or higher versions for the following resources:
   - RESOURCE(BUFFER_POOL_IO)

7. This macro may only be used on z/OS R8 or higher versions for RESTKN keyword.

**Input register information**

Before issuing the IWMMCHST macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.
Syntax

The syntax of the IWMMCHST macro is as follows:

```
IWMMCHST
  STATE=FREE
  STATE=ACTIVE
  STATE=ACTIVE_APPL
  STATE=READY
  STATE=IDLE
  STATE=WAITING
    RESOURCE=LATCH
    RESOURCE=LOCK
    RESOURCE=IO
    RESOURCE=CONV
    RESOURCE=DISTRIBUT
    RESOURCE=SESS_LOCALMVS
    RESOURCE=SESS_NETWORK
    RESOURCE=SESS_SYSPLEX
    RESOURCE=TIMER
    RESOURCE=OTHER_PRODUCT
    RESOURCE=MISC
    RESOURCE=SSL_THREAD
    RESOURCE=REG_THREAD
    RESOURCE=REG_TO_WRKTB
    RESOURCE=TYPE1
    RESOURCE=TYPE2
    RESOURCE=TYPE3
    RESOURCE=TYPE4
    RESOURCE=TYPE5
  ,MONTKN=montkn

  ,RESTKN=NORESTKN
  ,RESTKN=restkn
  ,RUNTIME_VER=SHORT_FORM,COMPCODE=YES
  ,RUNTIME_VER=MINIMAL,COMPCODE=NO

  ,RETCODE=retcode
  ,RSNCODE=rsncode
  ,MF=(M,,list addr,COMPLETE)
  ,NOCHECK
```

Parameters

The parameters are explained as follows:

`name`
An optional symbol, starting in column 1, that is the name on the IWMMCHST macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

`COMPCODE=YES`, `COMPCODE=NO`
An optional parameter, which indicates whether completion status for this service is needed. The default is COMPCODE=YES.

`COMPCODE=YES`
indicates that completion status is needed.

`COMPCODE=NO`
indicates that completion status is not needed. Registers 0, 15 cannot be used as reason code and return code registers upon completion of the macro expansion. For this reason neither RETCODE NOR RSNCODE may be specified when COMPCODE(NO) is specified.

`MONTKN=montkn`
A required input parameter, which contains the delay monitoring token.
To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

When STATE=WAITING is specified, a required parameter, which indicates the resource that the work manager is waiting for on behalf of the work request described by the monitoring environment.

- RESOURCE=LATCH
  indicates that the work manager is waiting on a latch.

- RESOURCE=LOCK
  indicates that the work manager is waiting on a lock.

- RESOURCE=IO
  indicates that the work manager is waiting on an activity related to an I/O request. This may either be an actual I/O operation or some function associated with an I/O request that cannot be more precisely determined by the work manager, for example, locks, buffers, etc.

- RESOURCE=CONV
  indicates that the work manager is waiting on a conversation. This may be used in conjunction with IWMMMSWCH to identify where the target is located.

- RESOURCE=DISTRIBUT
  indicates that the work manager is waiting on a distributed request. This says at a high level that some function or data must be routed prior to resumption of the work request. This is to be contrasted with Waiting on Conversation, which is a low level view of the precise resource that is needed. A distributed request could involve waiting on a conversation as part of its processing.

- RESOURCE=SESS_LOCALMVS
  indicates that the work manager is waiting to establish a session somewhere in the current MVS image.

- RESOURCE=SESS_NETWORK
  indicates that the work manager is waiting to establish a session somewhere in the network.
indicates that the work manager is waiting to establish a session somewhere in the sysplex.

@Resource=Timer
indicates that the work request is waiting on a timer.

@Resource=Other_Product
indicates that the work manager is waiting on another product to complete its function.

@Resource=Misc
indicates that the work manager is waiting on some unidentified resource, possibly among the previous categories.

@Resource=Ssl_Thread
indicates that the work manager is waiting on an SSL thread.

@Resource=Reg_Thread
indicates that the work manager is waiting on a regular processing thread.

@Resource=Reg_To_Wrktb
indicates that the work manager is waiting for the registration to a worktable.

@Resource=Type1
indicates that the work manager is waiting for resource type 1.

@Resource=Type2
indicates that the work manager is waiting for resource type 2.

@Resource=Type3
indicates that the work manager is waiting for resource type 3.

@Resource=Type4
indicates that the work manager is waiting for resource type 4.

@Resource=Type5
indicates that the work manager is waiting for resource type 5.

Restkn=restkn
Restkn=Norestkn
An optional input parameter, which contains the token of the managed resource previously registered with register resource (IWMMREG). The default is Norestkn, which indicates that no resource token is provided.

Norestkn preserves the existing resource token, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

Retcode=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

Rsncode=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

Runtime Ver=Short Form
,RUNTIME_VER=MINIMAL
  An optional parameter, which indicates what level of runtime verification will be performed. The default is RUNTIME_VER=SHORT_FORM.

,RUNTIME_VER=SHORT_FORM
  indicates that checking should verify that a monitoring environment is established and passes a short form of verification prior to being used.

,RUNTIME_VER=MINIMAL
  indicates that checking will only be done to verify that a monitoring environment may be established, assuming that it would be valid and useable if established.

STATE=FREE
STATE=ACTIVE
STATE=ACTIVE_APPL
STATE=READY
STATE=IDLE
STATE=WAITING
  A required parameter, which indicates the current state for the work request.

STATE=FREE
  indicates that the work manager has no work request associated with the monitoring environment.

STATE=ACTIVE
  indicates that there is a program executing on behalf of the work request described by the monitoring environment. This is an indication from the perspective of the work manager using this service, who should not try to factor in MVS decisions in preempting work, etc.

STATE=ACTIVE_APPL
  indicates that there is an application program executing on behalf of the work request described by the monitoring environment. This is an indication from the perspective of the work manager using this service, who should not try to factor in MVS decisions in preempting work. This state represents the application activity in contrast to the active (subsystem) state.

STATE=READY
  indicates that there is a program ready to execute on behalf of the work request described by the monitoring environment, but the work manager has given priority to another work request.

STATE=IDLE
  indicates that the work manager has no work requests that it is allowed to service within the monitoring environment. This represents a delay that is not under the control of the work manager itself and which it cannot eliminate. This may be caused by limits imposed by the installation or by the nature of the work request itself.

STATE=WAITING
  indicates that the work manager is waiting for a resource on behalf of the work request described by the monitoring environment.

ABEND codes

None.
Return codes and reason codes

When the IWMMCHST macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

</tbody>
</table>
IWMMCREA — Create delay monitoring environment

The purpose of this service is to create a single delay monitoring environment or a number of delay monitoring environments so that work and resource managers may utilize other delay monitoring services to reflect to MVS the execution states and delays associated with work requests.

There are three types of monitoring environments available, management monitoring environments, report-only monitoring environments and buffer pool management only environments. Management monitoring environments provide both, performance management and performance reporting. Report-only monitoring environments can be used for performance reporting only. Buffer pool management only monitoring environments provide only buffer pool performance management for enclaves.

Optionally, if you specify REPORTONLY=YES the monitoring environment is used for reporting purposes only.

Furthermore, if you specify BPMGMTONLY=YES, the monitoring environment is used for buffer pool management for enclaves only.

**Note:** It is recommended to use the equivalent service, IWM4MCRE, which also supports 64-bit addressing. For more information, see “IWM4MCRE — Create delay monitoring environment” on page 559.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum authorization</td>
<td>Supervisor state or program key mask (PKM) allowing keys 0-7.</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>Non-XMEM or XMEM. Any P.S.H.</td>
</tr>
<tr>
<td>AMODE</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for I/O and external interrupts No (EUT) FRR established.</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded.
IWMMCREA

from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions
1. This macro may not be used during task/address space termination.
2. If the key specified on IWMMCREA is a user key (8-F), then the caller must be in non-cross-memory mode (P=S=H)
3. While not a restriction for IWMMCREA, it should be noted that when the key specified is a user key (8-F), the delay monitoring token may only be passed (to any service whatsoever), when primary addressability exists to the performance block obtained by IWMMCREA. This condition may be satisfied by ensuring that the then current primary matches primary at the time that IWMMCREA was invoked. If these other services are invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.
4. This service provides a task and address space resource managers to clean up any resources obtained during task and address space terminations. Once the calling task or address space terminates, the monitoring token returned by IWMMCREA must not be used for any services.
5. This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

Input register information

Before issuing the IWMMCREA macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>
Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMMCREA macro is as follows:

main diagram

```
name IWMMCREA
```

```
REQTYPE=SINGLE, MONTKN=montkn
```

```
REQTYPE=MULTIPLE, AMOUNT=amount
```

```
REPORTONLY=NO, BPMGMTONLY=NO
```

```
REPORTONLY=YES, BPMGMTONLY=YES
```

```
MONTKNKEY=VALUE, MONTKNKEY=montknkey
```

```
MONTKNKEY=PSWKEY
```

```
PLISTVER=IMPLIED_VERSION
```

```
PLISTVER=MAX
```

```
PLISTVER=0
```

```
PLISTVER=1

```

```
MF=(E, list addr)
```

parameters-1

```
SUBSYS=subsys, SUBSYSNM=subsysnm
```

```
EWLM=NO
```

```
EWLM=YES
```

```
GROUPNM=NO_GROUPNM, GROUPNM_LEN=groupnm_len
```

```
GROUPNM=groupnm
```

Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMMCREA macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**AMOUNT=amount**

When REQTYPE=MULTIPLE is specified, a required input parameter, which specifies the number of delay monitoring environments to be created.
While there is no restriction on the number of delay monitoring environments to be created, caller should only create the minimum number of delay monitoring environments that are needed.

If there are too many unused delay monitoring environments existing in the system, the storage and CPU overheads may be significant.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

,BPMGMTONLY=NO
,BPMGMTONLY=YES

When REPORTONLY=NO is specified, an optional parameter, which indicates whether the monitoring environment is for buffer pool management purposes only (YES) or (NO). The default is BPMGMTONLY=NO.

,BPMGMTONLY=NO
  indicates that the monitoring environment is not for buffer pool management purposes.

,BPMGMTONLY=YES
  indicates that the monitoring environment is for buffer pool management purposes only.

,CONNTKN=conntkn

When SUBSYSP=CONNECT is specified, a required input parameter, which contains the connect token associated with the subsystem.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,EWLM=NO
,EWLM=YES

IF SUBSYSP=CONNECT is specified, this parameter is not allowed. In this case the EWLM=YES/NO specification is inherited from the IWMMCON (or IWMMCONN) EWLM=YES/NO specification. When SUBSYSP=VALUE is specified, an optional parameter, which indicates if the created monitoring environment is intended to participate in Enterprise Workload Management (EWLM). The default is EWLM=NO.

,EWLM=NO
  The monitoring environment cannot be used to report on ARM work requests.

,EWLM=YES
  The monitoring environment participates in cross-platform Enterprise Workload Management and interacts with EWLM. An ARM application instance will be registered and started using the passed subsystem type (SUBSYS), subsystem name (SUBSYSNM), and the new parameter group name (GROUPNM, GROUPNM_LEN) - an already existing ARM registration for the same address space with identical SUBSYS, SUBSYSNM, GROUPNM and GROUPNM_LEN parameters will be reused. All ARM work requests associated with the created monitoring environment are reported for this ARM application instance.

,GROUPNM=groupnm
,GROUPNM=NO_GROUPNM

When EWLM=YES and SUBSYSP=VALUE are specified, an optional input parameter, which contains the name of an application group, for example, a group of similar or cooperating subsystem instances. A group name can be up to 255 characters long. Provision of a data area initialized to all blanks is
equivalent to specification of NO_GROUPNM. NO_GROUPNM indicates that no group name is passed. This is the default.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

**GROUPNM_LEN=groupnm_len**

When GROUPNM=groupnm, EWLM=YES and SUBSYS=VALUE are specified, a required input parameter, which contains the length of the group name. A group name can be up to 255 characters long.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**MF=S**

**MF={(L,list_addr)**

**MF={(L,list_addr,attr)**

**MF={(L,list_addr,0D)**

**MF={(E,list_addr)**

**MF={(E,list_addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**list_addr**

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

**COMPLETE**

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

**MONTKN=montkn**

When REQTYPE=SINGLE is specified, a required output parameter, which will receive the delay monitoring token.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

**MONTKN_LIST=montkn_list**

When REQTYPE=MULTIPLE is specified, a required input parameter, which specifies an area into which a list of delay monitoring tokens will be placed.
To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{,MONTKN\_LISTLEN=montkn\_listlen}

When \texttt{REQTYPE=MULTIPLE} is specified, a required input parameter, which specifies the length (in bytes) of the area identified by the \texttt{MONTKN\_LIST} keyword.

Size of this area must be at least the size of \texttt{MONTKN} (see \texttt{MONTKN} keyword) times \texttt{AMOUNT}. If the user specified area is not large enough to return the delay monitoring tokens, a specific return/reason code will be returned and the request will not be processed.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

\texttt{,MONTKNKEY=montknkey}

When \texttt{MONTKNKEYP=VALUE} is specified, a required input parameter, which contains the key in which the delay monitoring services will be invoked subsequently when using the output \texttt{MONTKN}. The low order 4 bits (bits 4-7) contain the key value. The high-order 4 bits (bits 0-3) must be 0.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8 bit field.

\texttt{,MONTKNKEYP=VALUE}

\texttt{,MONTKNKEYP=PSWKEY}

A required parameter, which describes how the input key should be obtained.

\texttt{,MONTKNKEYP=VALUE}

indicates that the key is being passed explicitly via \texttt{MONTKNKEY}.

\texttt{,MONTKNKEYP=PSWKEY}

indicates that the current PSW key should be used.

\texttt{,PLISTVER=IMPLIED\_VERSION}

\texttt{,PLISTVER=MAX}

\texttt{,PLISTVER=0}

\texttt{,PLISTVER=1}

An optional input parameter that specifies the version of the macro. \texttt{PLISTVER} determines which parameter list the system generates. \texttt{PLISTVER} is an optional input parameter on all forms of the macro, including the list form. When using \texttt{PLISTVER}, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- \texttt{IMPLIED\_VERSION}, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the \texttt{PLISTVER} parameter, \texttt{IMPLIED\_VERSION} is the default.

- \texttt{MAX}, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify \texttt{PLISTVER=MAX} on the list form of the macro. Specifying \texttt{MAX} ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, \texttt{MAX} ensures that the parameter list does not overwrite nearby storage.

- \texttt{0}, which supports all parameters except those specifically referenced in higher versions.

- \texttt{1}, which supports the following parameters and those from version 0:
BPMGMTONLY  GROUPNM

EWLM  GROUPNM_LEN

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0, or 1

,REPORTONLY=NO,REPORTONLY=YES
An optional parameter, which indicates whether the monitoring environment is for reporting purposes only (YES) or (NO). The default is REPORTONLY=NO.

,REPORTONLY=NO
indicates that the monitoring environment is for management and reporting purposes.

,REPORTONLY=YES
indicates that the monitoring environment is for reporting purposes only.

REQTYPE=SINGLE
REQTYPE=MULTIPLE
An optional parameter that indicates whether the request is to create a single delay monitoring environment or to create multiple delay monitoring environments. The default is REQTYPE=SINGLE.

REQTYPE=SINGLE
The request is to create a single delay monitoring environment.

REQTYPE=MULTIPLE
The request is to create a number of delay monitoring environments.

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,SUBSYS=subsys
When SUBSYSP=VALUE is specified, a required input parameter, which contains the generic subsystem type (e.g. IMS, CICS, etc.).

To code: Specify the RS-type address, or address in register (2)-(12), of a 4-character field.

, SUBSYSNM=subsysnm
When SUBSYSP=VALUE is specified, a required input parameter, which contains the subsystem name.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,SUBSYSP=CONNECT
A required parameter, which describes how the calling subsystem is providing identification.

indicates that the connect token is being passed.

indicates that the subsystem name is being passed directly.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMMCREA macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>

**Meaning**: Component error.  
**Action**: No action required. The function may be successful if invoked again. |
IWMMDELE

IWMMDELE — Delete the monitoring environment

Use this macro to delete the monitoring environment. You should invoke IWMMDELE during address space shutdown processing.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state, or program key mask (PKM) allowing keys 0 - 7. |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any PASN, any SASN. HASN must match the HASN when IWMM4MCRE was invoked. |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled |
| Locks: | Unlocked, but FRRs may be established. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. You must include the CVT and IWMYCON mapping macros in the calling program.
2. The caller must serialize to prevent any delay monitoring services from being invoked concurrently or subsequently for the environment represented by the monitoring token.
3. Do not invoke IWMMDELE while in a RTM termination routine (resource manager) for the task owning the monitoring environment since MVS will have its own resource cleanup routine and unpredictable results would occur. It is legitimate to use this service while in a recovery routine, however, or in mainline processing.

Restrictions

1. If the key specified on IWMM4MCRE was a user key (8-F), then all of the following must be true:
   • Caller must be in non-cross-memory mode (PASN=SASN=HASN). This implies that the current primary must match the primary at the time that IWMM4MCRE was invoked.
   • Must be in task mode (not SRB)
   • Current task must match the task at the time that IWMM4MCRE was invoked.

Input register information

Before issuing the IWMMDELE macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:
Register

Contents

0 Reason code if the return code in GPR 15 is not 0, otherwise, used as a
work register by the system.

1 Used as a work register by the system.

2 - 13 Unchanged

14 Used as a work register by the system.

15 Return code

When control returns to the caller, the ARs contain:

Register

Contents

0 - 1 Used as a work register by the system.

2 - 13 Unchanged

14 - 15 Used as a work register by the system.

Some callers depend on register contents remaining the same before and after
issuing a service. If the system changes the contents of registers on which the caller
depends, the caller must save them before issuing the service, and restore them
after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMMDELE macro is as follows:

```
IWMMDELE MONTKN=montkn,RETCODE=retcode,RSNCODE=rncode
```

Parameters

The parameters are explained as follows:

```
,MONTKN=montkn
```
Required input parameter that specifies the monitoring token obtained from
IWM4MCRE.

**To code**: Specify the name (RS-type) or address (using a register from 2 to 12)
of a 32-bit field containing the monitoring token.
**IWMMDELE**

\[ \text{RETCODE=} \text{retcode addr} \]
Optional output parameter that specifies where the system is to store the return code. The return code is also in GPR 15.

**To code:** Specify the name (RS-type) or address (using a register from 2 to 12) of a fullword to contain the return code.

\[ \text{RSNCODE=} \text{rsncode addr} \]
Optional output parameter that specifies where the system is to store the reason code. The reason code is also in GPR 0.

**To code:** Specify the name (RS-type) or address (using a register from 2 to 12) of a fullword to contain the reason code (if any).

\[ \text{MF=}S \]
\[ \text{MF=} (L, \text{mfctrl}, \text{mfattr}) \]
\[ \text{MF=} (E, \text{mfctrl}, \text{COMPLETE}) \]
Use MF=S to specify the standard form, which places parameters into an inline parameter list and invokes the IWM4CON macro service.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require re-entrant code. The list form defines an area of storage that the execute form uses to store the parameters.

Use MF=E to specify the execute form of the macro. Use the execute form with the list form of the macro for applications that require re-entrant code. The execute form stores the parameters into the storage area defined by the list form and generates the macro invocation to transfer control to the service.

\[ \text{mfctrl} \]
Use this output parameter to specify the name of the storage area to contain the parameters.

**To code:** Specify the name (RS-type) or address (using a register from 2 to 12) of the storage area containing the parameter list.

\[ \text{mfattr} \]
Use this input parameter to specify the name of a 1 to 60 character storage area that can contain any value that is valid on an assembler DS pseudo-op. You can use this parameter to force boundary alignment of the parameter list. If you do not code \text{mfattr} the system provides a value of 0D, which forces the parameter on a doubleword boundary.

\[ \text{COMPLETE} \]
Use this input parameter to specify that the system check for required parameters and supply defaults for omitted optional parameter.

**ABEND codes**

None.

**Return codes and reason codes**

When IWMMDELE macro returns control to your program, GPR 15 contains a return code. When the return code is non-zero, then GPR 0 contains a reason code.

<table>
<thead>
<tr>
<th>Hexadecimal Return Code</th>
<th>Hexadecimal Reason Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td></td>
<td><strong>Meaning:</strong> Successful completion.</td>

<tr>
<td>08 0828</td>
<td></td>
<td>Program error. Version number in parameter list is not valid.</td>
</tr>
<tr>
<td>08 082A</td>
<td></td>
<td>Program error. Input monitor token is related to a parent monitoring environment.</td>
</tr>
</tbody>
</table>

### Example

To delete a monitoring environment, where the monitoring token is in register 7, specify:

```plaintext
IWMMDELE MONTKN=(R7), RETCODE=RCODE, RSNCODE=RSN
```
The purpose of this service is to extract information about the monitoring environment which was previously passed through IWM4MINI/IWMMRELA. When IWMMRELA was invoked for a management monitoring environment, owner token, owner data and abnormal conditions are always available. Arrival time, user ID and transaction name are only available when IWM4MINI was previously invoked. Arrival time, however, is only available for management monitoring environments.

When the service class token is requested for a management monitoring environment, the value may represent a token from a prior active policy. Furthermore, when the monitoring environment was established via IWMMRELA, the token may be zero, which does not represent a valid service class or report class. IWMWQRY may be used to obtain the service and/or report class name, along with other information about these classes. The SERVCLS keyword is not applicable for report-only monitoring environments. The returned token is zero, which does not represent a valid service class.

The ENCLAVE_TOKEN and ASID keywords are only applicable for report-only monitoring environments.

The EWLM_S_CURCORR keyword should only be specified, if a work unit has been started by IWMMSTRT.

When no output keywords are specified, the service merely checks whether a monitoring environment was established and passes short form checking.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Either problem state or supervisor state. Any PSW key.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>Suspend locks are allowed.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded.
IWMMEXTR

from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions
1. The caller is responsible for error recovery
2. Only limited checking is done against the input monitoring token.
3. If the key specified on IWM4MCRE was a user key (8-F), then the primary addressability must exist to the performance block IWM4MCRE obtained. This condition is satisfied by ensuring that current primary matches primary at the time that IWM4MCRE was invoked. If this service is invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.
4. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.
5. This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

Input register information

Before issuing the IWMMEXTR macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.
Performance implications

None.

Syntax

The syntax of the IWMMEXTR macro is as follows:

```
IWMMEXTR
  name
  , MONTKN=montkn
  , OWNER_TOKEN=owner_token
  , OWNER_DATA=owner_data
  , ARRIVALTIME=arrivaltime
  , TRXNAME=trxname
  , USERID=userid
  , SERVCLS=servcls
  , ASID=asid
  , ENCLAVE_TOKEN=enclave_token
  , TTRACETOKEN=ttracetoken
  , ABNORMAL_COND=abnormal_cond
  , EWLM_CHCORR=ewlm_chcorr
  , EWLM_PACTKN=ewlm_pactkn
  , EWLM_S_CURCORR=ewlm_s_curcorr
  , RETCODE=retcode
  , RSNCODE=rsncode
  , PLISTVER=IMPLIED_VERSION
  , MF=(M,list addr)
  , COMPLETE
  , NOCHECK
```

Parameters

The parameters are explained as follows:

```
name
  An optional symbol, starting in column 1, that is the name on the IWMMEXTR
  macro invocation. The name must conform to the rules for an ordinary
  assembler language symbol.

,ABNORMAL_COND=abnormal_cond
  An optional output parameter, which contains the current information about
  abnormal conditions which were either recorded in the input monitoring
  environment or which were propagated to it via IWMMXFER
  Function(Return). Multiple conditions may exist.

  The mask, Iwmabnl_Scope_LocalMVS, may be used to determine whether an
  abnormality which only affects work on the current MVS image was recorded.

  The mask, Iwmabnl_Scope_Sysplex, may be used to determine whether an
  abnormality which affects work on all MVS images in the sysplex was
  recorded.
```
To determine whether a condition was recorded, merely AND the field supplied for ABNORMAL_COND with the relevant mask. The result will be nonzero when the condition is true, zero when the condition is false.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,**ARRIVALTIME=arrivaltime**
An optional output parameter, which contains the work arrival time in STCK format.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

,**ASID=asid**
An optional output parameter, which contains the address space ID. When the monitoring environment is not associated with an address space, the output will be a halfword of binary zeros.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 16-bit field.

,**ENCLAVE_TOKEN=enclave_token**
An optional output parameter, which contains the enclave token. When the monitoring environment is not associated with an enclave, the output will be a doubleword of binary zeros.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

,**EWLM_CHCORR=ewlm_chcorr**
An optional output parameter, which contains the cross-platform Enterprise Workload Management (EWLM) correlator of the work request associated with the monitoring environment.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

,**EWLM_PACTKN=ewlm_pactkn**
An optional output parameter, which contains the cross-platform Enterprise Workload Management (EWLM) parent correlator token of the work request associated with the monitoring environment.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

,**EWLM_S_CURCORR=ewlm_s_curcorr**
An optional output parameter, which contains the current correlator of the work unit started by IWMMSTRT. Normally this correlator is different from the child correlator of the work request created by IWM4MINI.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

,**MONTKN=montkn**
A required input parameter, which contains the delay monitoring token

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,**OWNER_DATA=owner_data**
An optional output parameter, which is to receive the data established by the user/owner of the monitoring environment. The format is undefined to MVS.
When the monitoring environment is not associated with an OWNER_TOKEN value, the output will be a word of binary zeros.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,OWNER_TOKEN=owner_token
An optional output parameter, which is to receive the token established by the user/owner of the monitoring environment. The format is undefined to MVS. When the monitoring environment is not associated with an OWNER_TOKEN value, the output will be a word of binary zeros.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
,PLISTVER=1
,PLISTVER=3
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

- 0, which supports all parameters except those specifically referenced in higher versions.

- 1, which supports the following parameter and those from version 0:

  TTRACETOKEN

- 2, which supports the following parameters and those from version 0 and 1:

  ASID
  ENCLAVE_TOKEN

- 3, which supports the following parameters and those from version 0, 1, and 2:

  EWLM_CHCORR
  EWLM_PACTKN

- 4, which supports the following parameter and those from version 0, 1, 2, and 3:

  EWLM_S_CURCORR

To code: Specify one of the following:
IWMMEXTR

- IMPLIED_VERSION
- MAX
- A decimal value of 0, 1, 2, 3, or 4

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,SERVCLS=servcls
An optional output parameter, which contains the service class token. When the monitoring environment is not associated with a service class token, the output will be a word of binary zeros.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,TRXNAME=trxname
An optional output parameter, which contains the transaction name. The field will be all blanks when NO_TRXNAME was specified on IWM4MINI.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,TTRACETOKEN=ttracetoken
An optional output parameter, which contains the transaction trace token associated with the work request. The field will be all zero when NO_TTRACETOKEN was specified on IWM4MINI.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,USERID=userid
An optional output parameter, which contains the local user ID associated with the work request. The field will be all blanks when NO_USERID was specified on IWM4MINI.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMMEXTR macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.
<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Equates symbol, meaning, and action</th>

</tr>
</tbody>
</table>
IWMMINIT — Initialize monitoring environment

IWMMINIT allows the caller to supply MVS with some or all of the work request attributes needed for the monitoring environment. The attributes include user ID, transaction name, transaction class, source LU, and LU 6.2 token.

There are two types of monitoring environments available, management monitoring environments and report-only monitoring environments. Management monitoring environments provide both performance management and performance reporting. Report-only monitoring environments can be used for performance reporting only.

Use the REPORTONLY=YES parameter to specify the monitoring environment will be used for reporting purposes only.

If you are invoking IWMMINIT with the REPORTONLY=YES parameter, ASSOCIATE=ENCLAVE or ASSOCIATE=ADDRESS_SPACE must be specified to associate the monitoring environment with an enclave or an address space.

For management monitoring environments, if possible, invoke IWMMINIT immediately following IWMCLSFY, and pass the service class for the work request. Without the associated service class in the monitoring environment, delay information cannot be accumulated and reported accurately.

IWMMINIT can be issued multiple times for the same work request. The first time you invoke IWMMINIT for a work request, you must specify MODE=RESET, otherwise the previous work request's attributes are associated with this work request. Any subsequent time you invoke IWMMINIT from the same address space for the same monitoring token for the same work request, specify MODE=RETAIN. If the caller subsystem work manager consists of multiple address spaces (with multiple monitoring tokens), the first time IWMMINIT is invoked in each address space for a given work request must specify MODE=RESET. Any subsequent invocations for the same work request should specify MODE=RETAIN.

If you are invoking IWMMINIT multiple times for the same work request, only one of the invocations should specify EXSTARTTIME=exstarttime. It is up to you to decide at which point in the subsystem work manager's processing you consider the real execution start time.

Optionally, with this macro, you can use the OWNER_TOKEN and OWNER_DATA parameters to specify a token for the user/owner of the monitoring environment for your own use.

Note: It is recommended to use the equivalent service, IWMM4MINI, which also supports 64-bit addressing. For more information, see "IWMM4MINI — Monitoring environment initialization" on page 590.

Environment

The requirements for the caller are:

Minimum authorization: Either problem state or supervisor state. PSW key must either be 0 or match the value supplied on IWMMCREA.
IWMMINIT

<table>
<thead>
<tr>
<th>Dispatchable unit mode:</th>
<th>Task or SRB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN. If the key specified on IWMMCREA was a user key (8-F), then primary addressability must be the same as when IWMMCREA was invoked.</td>
</tr>
<tr>

</tr>
<tr>
<td>Locks:</td>
<td>Locked or unlocked</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements
1. The macro IWMYCON must be included to use this macro.
2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions
1. All parameter areas must reside in current primary, except that the TCB (if specified) must reside in current home.
2. Caller is responsible for error recovery.
3. Only limited checking is done against the input monitoring token.
4. If the key specified on IWMMCREA was a user key (8-F), then the primary addressability must exist to the performance block IWMMCREA obtained. This condition is satisfied by ensuring that current primary matches primary at the time that IWMMCREA was invoked. If this service is invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.
5. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.
6. This macro may only be used on z/OS R2 or higher levels for REPORTONLY and ASSOCIATE keywords.
7. The BPMGMTONLY keyword may only be used on systems running z/OS R8 or higher.
8. This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

Input register information
Before issuing the IWMMINIT macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMMINIT macro is as follows:

```
main diagram
```

```
/IWMMINIT
    /MONTKN=montkn
    /MODE=RESET
    /PARAMETERS-1
    /DURATION=PREV_VALUE
    /DISTYPE=SAVEDTYPE

    /OWNER_TOKEN=owner_token
```

Appendix E. WLM services supporting 31-bit addressing only 945
IWMMINIT

**Parameters**

The parameters are explained as follows:
**IWMMINIT**

*name*

An optional symbol, starting in column 1, that is the name on the IWMMINIT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,**ARRIVALTIME=arrivaltime**

When ARRIVALTIME=YES and MODE=RESET are specified, a required input parameter, which contains the work arrival time in STCK format.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

,**ARRIVALTIME=CURRENT**

When MODE=RESET is specified, a required parameter, which indicates whether the work arrival time is passed.

,**ARRIVALTIME=CUR**

indicates that the current time should be supplied by the service.

,**ARRIVALTIME=YES**

indicates that the work arrival time is passed.

,**ASID=asid**

When ASSOCIATE=ADDRESS_SPACE and REPORTONLY=YES are specified, a required input parameter which contains the address space ID.

To code: Specify the RS-type address, or address in register (2)-(12), of a 16-bit field.

,**ASSOCIATE=ENCLAVE**

,**ASSOCIATE=ADDRESS_SPACE**

When REPORTONLY=YES is specified, a required parameter, which indicates whether the monitoring environment should be associated to an enclave or an address space.

,**ASSOCIATE=ENCLAVE**

indicates that the monitoring environment should be associated to an enclave.

,**ASSOCIATE=ADDRESS_SPACE**

indicates that the monitoring environment should be associated to an address space.

,**ASSOCIATE=ENCLAVE**

When BPMGMTONLY=YES and REPORTONLY=NO are specified, a required parameter, which indicates whether the monitoring environment should be associated only to an enclave.

,**ASSOCIATE=ENCLAVE**

indicates that the monitoring environment should be associated to an enclave.

,**BPMGMTONLY=NO**

,**BPMGMTONLY=YES**

When REPORTONLY=NO is specified, an optional parameter, which indicates whether the monitoring environment is for bufferpool management purposes only (YES) or not (NO). The default is BPMGMTONLY=NO.

,**BPMGMTONLY=NO**

indicates that the monitoring environment is not for bufferpool management purposes only.
indicates that the monitoring environment is for bufferpool management purposes only.

CONTINUEP=YES
CONTINUEP=NO
A required parameter, which indicates whether it is known (YES) or not (NO) that there exists another monitoring environment for this same work request.

CONTINUEP=YES
indicating that the existence of a prior monitoring environment for the work request is known.

CONTINUEP=NO
indicates that it is not known whether there exists a prior monitoring environment for the work request. If MODE(RESET) is specified, no status is saved. If MODE(RETAIN) is specified, the existing status is preserved.

DISPTYPE=TCB
DISPTYPE=SRB
When MODE=RESET is specified, a required parameter, which describes the nature of the MVS dispatchable units which participate in processing work requests associated with the delay monitoring environment established by this service.

DISPTYPE=TCB
indicates that work requests run in TCB mode under a TCB within the current home address space. Note that in cross-memory mode, this may be different from the current primary address space.

DISPTYPE=SRB
indicates that work requests run in SRB mode within the current home address space.

DISPTYPE=SAVEDTYPE
DISPTYPE=TCB
DISPTYPE=SRB
When MODE=RETAIN is specified, a required parameter, which describes the nature of the MVS dispatchable units which participate in processing work requests associated with the delay monitoring environment established by this service.

DISPTYPE=SAVEDTYPE
indicates that the information saved when MODE(RESET) was used is still applicable.

DISPTYPE=TCB
indicates that work requests run in TCB mode under a TCB within the current home address space. Note that in cross-memory mode, this may be different from the current primary address space.

DISPTYPE=SRB
indicates that work requests run in SRB mode within the current home address space.

DURATION=EXECUTION
DURATION=BEGIN_TO_END
When MODE=RESET is specified, an optional parameter, which indicates the duration of the work request over which the delays are to be represented. The default is DURATION=EXECUTION.
indicates that the monitoring environment will reflect delays from the point where an application or transaction program is given control, i.e. the execution phase. Typically a monitoring environment with this scope would be passed to IWMMNTFY to pass the execution time for the work request.

\textbf{DURATION=BEGIN\_TO\_END}

indicates that the monitoring environment will reflect delays from the arrival of the work request into the MVS sysplex until its completion. Ordinarily use of this option would be in close proximity to the time when the work request is classified. Typically a monitoring environment with this duration would be passed to IWMRPT to report the total elapsed time for the work request.

\textbf{DURATION=PREV\_VALUE}

indicates that the duration for delays has been specified on a previous invocation.

\textbf{DURATION=EXECUTION}

indicates that the monitoring environment will reflect delays from the point where an application or transaction program is given control, for example, the execution phase. Typically a monitoring environment with this duration would be passed to IWMMNTFY to pass the execution time for the work request.

\textbf{DURATION=BEGIN\_TO\_END}

indicates that the monitoring environment will reflect delays from the arrival of the work request into the MVS sysplex until its completion. Ordinarily use of this option would be in close proximity to the time when the work request is classified. Typically, a monitoring environment with this duration is passed to IWMRPT to report the total elapsed time for the work request.

\textbf{ENCLAVETOKEN=enclatetoken}

When ASSOCIATE=ENCLAVE and REPORTONLY=YES are specified, a required input parameter, which contains the enclave token.

\textbf{To code:} Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

\textbf{EWLM\_PACORR=ewlm\_pacorr, EWLM\_PACORR=NO\_EWLM\_PACORR}

When MODE=RESET is specified, an optional input parameter, which contains the cross-platform enterprise workload management (EWLM) parent correlator associated with the work request.

\textbf{Note:}

- If EWLM\_PACORR is specified and the correlator does not contain a valid ARM correlator, reason code IwmRsnCodeInvalidEWLMCorr is returned to the caller. Refer to Table 80 on page 604 for further information. If the correlator is a valid ARM correlator, but cannot be understood by EWLM (no EWLM format), it is ignored.
- The parameters EWLM_PACORR and EWLM_PACTKN are mutually exclusive.

The default is NO_EWLM_PACORR. It indicates that no EWLM parent correlator is passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

**,EWLM_PACTKN=ewlm_pactkn**

**,EWLM_PACTKN=NO_EWLM_PACTKN**

When MODE=RESET is specified, an optional input parameter, which contains the cross-platform Enterprise Workload Management (EWLM) parent correlator token associated with the work request.

If EWLM_PACTKN is specified and the correlator token does not contain a valid correlator token, **reason code IwmRsnCodeInvalidEWLMCorr** is returned to the caller. Refer to Table 80 on page 604 for further information. The default is NO_EWLM_PACTKN. It indicates that no EWLM correlator token is passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

**,EXSTARTTIME=exstarttime**

When EXSTARTTIMEP=YES, BPMGMTONLY=NO and REPORTONLY=NO are specified, a required input parameter, which contains the start execution time in STCK format.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

**,EXSTARTTIMEP=NO**

**,EXSTARTTIMEP=CURRENT**

**,EXSTARTTIMEP=YES**

When BPMGMTONLY=NO and REPORTONLY=NO are specified, a required parameter, which indicates whether the execution start time value is passed.

**,EXSTARTTIMEP=NO**

indicates that the execution start time value is not passed.

If MODE(RETAIN) is specified, EXSTARTTIMEP(NO) preserves the existing execution start time, if any.

**,EXSTARTTIMEP=CURRENT**

indicates that the current time should be supplied by the service.

**,EXSTARTTIMEP=YES**

indicates that the start execution time value is passed.

**,FROM=NONE**

**,FROM=LOCALMVS**

**,FROM=SYSPLEX**

**,FROMNETWORK**

When CONTINUEP=YES is specified, a required parameter.

**,FROM=NONE**

indicates that there is no other environment.

**,FROM=LOCALMVS**

indicates that such an environment should exist on the current MVS.

**,FROM=SYSPLEX**

indicates that such an environment should exist in the current sysplex, but is not expected to be on the current MVS image.
indicates that such an environment may exist, but is not expected to be in the current sysplex.

\texttt{\textcolor{red}{,LU62TKN=lu62tkn}}
\texttt{\textcolor{red}{,LU62TKN=NO\_LU62TKN}}

An optional input parameter, which contains LU 6.2 token for the work request. This is not an SNA term, but it is comprised of the following fields which are defined by SNA for the FMH5.

- Logical Unit of Work Identifier length byte, in binary, which may have the values 0 or 10-26 decimal (inclusive)
- Logical Unit of Work Identifier
  - Length byte for the network qualified LU name, in binary, which may have the values 1-17 decimal (inclusive)
  - Network qualified LU network name (1-17 bytes)
  - Logical Unit of Work Instance Number, in binary (6 bytes)
  - Logical Unit of Work Sequence Number, in binary (2 bytes)
- Conversation Correlator Field (0 to 9 bytes)
  - Length byte for the Conversation Correlator, in binary, which may have the values 0-8 decimal (inclusive)
  - Conversation Correlator of the sending transaction (1-8 bytes)

The Conversation Correlator Field (which includes its length byte) may be dropped when its length byte is 0. The default is NO\_LU62TKN, which indicates that no LU 6.2 token was passed.

If \texttt{MODE(RETAIN)} is specified, NO\_LU62TKN will preserve the existing LU6.2 token, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{\textcolor{red}{,LU62TKN\_FMT=LU\_NO\_CC\_27}}
\texttt{\textcolor{red}{,LU62TKN\_FMT=FULL\_LU\_NO\_CC\_27}}
\texttt{\textcolor{red}{,LU62TKN\_FMT=FULL\_LU\_0\_CC\_28}}
\texttt{\textcolor{red}{,LU62TKN\_FMT=FULL\_LU\_CC\_36}}
\texttt{\textcolor{red}{,LU62TKN\_FMT=OTHER}}

When \texttt{LU62TKN=lu62tkn} is specified, a required parameter, which indicates the format/length of the LU 6.2 token.

\texttt{\textcolor{red}{,LU62TKN\_FMT=LU\_NO\_CC\_27}}

indicates that a fixed length token of 27 bytes is provided, with no conversation correlator (not even its length byte). The LU name may be 1-17 bytes. Bytes at the end of the token are padded with hexadecimal zeros, if necessary, to form a full 27 bytes.

\texttt{\textcolor{red}{,LU62TKN\_FMT=FULL\_LU\_NO\_CC\_27}}

indicates that the fully qualified LU name (17 bytes) is used, but no conversation correlator (not even its length byte) is provided. This format is architected to be 27 bytes long.

\texttt{\textcolor{red}{,LU62TKN\_FMT=FULL\_LU\_0\_CC\_28}}

indicates that the fully qualified LU name (17 bytes) is used, and the conversation correlator length byte is present and has the value 0. This format is architected to be 28 bytes long.

\texttt{\textcolor{red}{,LU62TKN\_FMT=FULL\_LU\_CC\_36}}

indicates that the fully qualified LU name (17 bytes) is used, and the
A required parameter, which indicates how previous attributes established for a monitoring environment should be treated. This does not refer to (or include) attributes established in IWMMCREA.

`MODE=RESET` indicates that previous attributes should be discarded.

`MODE=RETAIN` indicates that previous attributes should be retained unless explicitly specified.

MONTKN=montkn
A required input parameter, which contains the delay monitoring token

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

OWNER_DATA=owner_data

An optional input parameter, which contains data maintained by the user/owner of the monitoring environment. The format is undefined to MVS. The default is NO_OWNER_DATA which indicates that no owner data is provided.

If MODE(RETAIN) is specified, NO_OWNER_DATA will preserve the existing owner data, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

OWNER_TOKEN=owner_token

An optional input parameter, which contains a token maintained by the user or owner of the monitoring environment. The format is undefined to MVS. The default is NO_OWNER_TOKEN which indicates that no owner token is provided.

If MODE(RETAIN) is specified, NO_OWNER_TOKEN preserves the existing owner token, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

PLISTVER=IMPLIED_VERSION
PLISTVER=MAX
PLISTVER=0
An optional input parameter that specifies the version of the macro. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want to indicate the latest version currently possible.
- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports the following parameters and those from version 0:
  - BPMGMTONLY
  - EWLM_PACORR
  - EWLM_PACTKN

**To code**: Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0, or 1

**REPORTONLY=NO**

An optional parameter, which indicates whether the monitoring environment is for reporting purposes only (YES) or not (NO). The default is REPORTONLY=NO.

**REPORTONLY=YES**

indicates that the monitoring environment is not for reporting purposes only.

indicates that the monitoring environment is for reporting purposes only.

**RETCODE=retcode**

An optional output parameter into which the return code is to be copied from GPR 15.

**RSNCODE=rsncode**

An optional output parameter into which the reason code is to be copied from GPR 0.

**SCOPE=SHARED**

A required parameter, which indicates the scope of work passed.

**SCOPE=SINGLE**

indicates that multiple work requests, possibly from different service classes, could be described.

indicates that only a single work request is described.

**SERVCLS=SERVCLS**

When BPMGMTONLY=NO and REPORTONLY=NO are specified, an optional
IWMMINIT

input parameter, which contains the service class token. The default is NO_SERVCLS which indicates that no service class token was passed.

If MODE(RETAIN) is specified, NO_SERVCLS preserves the existing service class token, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

\texttt{\textbackslash SOURCELU=source	extbackslash u}
\texttt{\textbackslash SOURCELU=NO\_SOURCELU}

An optional input parameter, which contains the LU name associated with the requestor. This may be the fully qualified NETID.LUNAME, for example, network name (1-8 bytes), followed by a period, followed by the LU name for the requestor (1-8 bytes). It may also be the 1-8 byte local LU name, with no network qualifier. The SOURCELU field may be from 1-17 characters. In the assembler form, the macro determines the length of the field as follows:

1. If the field is specified by register notation, it will be assumed to be 17 characters (padded with blanks) and a full 17 characters will be copied.
2. If the field is specified using an RS form name, then the length will be determined using the L' assembler function. When the length is less than 17 characters, the macro will pad with blanks. When the length is greater than or equal to 17 characters, the macro copies the first 17 bytes.

In the PL/AS form, the rules for the PL/AS compiler determines when to pad with blanks, for example, less than 17 characters implies padding, 17 or more implies a 17 character copy.

This is intended to be the same value as used in IWMCLSFY, and may be distinct from the LU name contained within the LU 6.2 token. For environments where the LU name may be available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_SOURCELU when MODE(RESET) is specified. Providing an area of all blanks when MODE(RETAIN) is specified will cause that to be used. The default is NO_SOURCELU which indicates that no source LU name was passed.

If MODE(RETAIN) is specified, NO_SOURCELU preserves the existing source LU name, if any.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{\textbackslash TCB=tcb}
\texttt{\textbackslash TCB=NO\_TCB}

When DISPTYPE=TCB and MODE=RESET are specified, an optional input parameter, which defines the TCB within the current home address space which will serve the work request. Note that this name is not the pointer to the TCB, but the name of the data area containing the TCB. A typical invocation might replace xTCB with TCB.

Generally, the input TCB specified should be the TCB under which the work request (for example, a transaction program) runs and under which the delay information is recorded (in spite of the fact that task switches may occur). The default is NO_TCB which indicates that no TCB is currently associated with the monitoring environment for this work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{\textbackslash TCB=tcb}
When DISPTYPE=TCB and MODE=RETAIN are specified, an optional input parameter, which defines the TCB within the current home address space which will serve the work request. Note that this name is not the pointer to the TCB, but the name of the data area containing the TCB. A typical invocation might replace xTCB with TCB.

Ordinarily the input TCB specified should be the TCB under which the work request (e.g. transaction program) runs and under which the delay information is recorded (in spite of the fact that task switches may occur). The default is NO_TCB which indicates that no TCB is currently associated with the monitoring environment for this work request.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

,TRXCLASS=trxclass
,TRXCLASS=NO_TRXCLASS

An optional input parameter, which contains a class name within a subsystem. For environments where the transaction class is available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_TRXCLASS when MODE(RESET) is specified. Providing an area of all blanks when MODE(RETAIN) is specified will cause that to be used. The default is NO_TRXCLASS, which indicates that no class name was passed.

If MODE(RETAIN) is specified, NO_TRXCLASS will preserve the existing transaction class, if any.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,TRXNAME=trxname
,TRXNAME=NO_TRXNAME

An optional input parameter, which contains the transaction name. For environments where the transaction name is available on some, but not all flows, provision of a data area initialized to all blanks is equivalent to specification of NO_TRXNAME when MODE(RESET) is specified. Providing an area of all blanks when MODE(RETAIN) is specified will cause that to be used. The default is NO_TRXNAME, which indicates that no transaction name was passed.

If MODE(RETAIN) is specified, NO_TRXNAME will preserve the existing transaction name, if any.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,TTRACETOKEN=ttracetoken
,TTRACETOKEN=NO_TTRACETOKEN

An optional input parameter, which contains the transaction trace token. The default is NO_TTRACETOKEN which indicates that no transaction trace token was passed.

If MODE(RETAIN) is specified, NO_TTRACETOKEN preserves the existing transaction trace token, if any.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,USERID=userid
,USERID=NO_USERID

An optional input parameter, which contains the local user ID associated with
the work request. For environments where the user id is available on some, but
not all flows, provision of a data area initialized to all blanks is equivalent to
specification of NO_USERID when MODE(RESET) is specified. Providing an
area of all blanks when MODE(RETAIN) is specified will cause that to be used.
The default is NO_USERID, which indicates that no user ID was passed.

If MODE(RETAIN) is specified, NO_USERID preserves the existing user ID, if
any.

To code: Specify the RS-type address, or address in register (2)-(12), of an
8-character field.

ABEND codes

None.

Return codes and reason codes

When the IWMMINIT macro returns control to your program:
• GPR 15 (and retcode, when you code RETCODE) contains a return code.
• When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code
RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the
equate symbol associated with each reason code. IBM support personnel may
request the entire reason code, including the xxxx value.

Table 118. Return and Reason Codes for the IWMMINIT Macro

### Example

IWMMINIT MONTKN=(R9),ARRIVALTIME=YES,  
ARRIVALTIME=(R3),EXSTARSTARTIME=YES,  
EXSTARSTARTIME=(R4),DISPTYPE=TCB,TCB=(R7),  
SCOPE=SINGLE,TRXNAME=WLTRXNAME,SOURCELU=SOURCELU,  
CONTINUEP=YES,LU62TKN_FMT=OTHER,LU62TKN_LEN=LU62TKNLEN,  
LU62TKN=LU62TKN1,MODE=RESET,FROM=NONE,  
REPORTONLY=NO,RETCODE=RCODE,RSNCODE=RSN
IWMMNTFY — Notify of work execution completion

The primary purpose of this service is to notify MVS that the execution phase for a work request associated with a monitoring environment has just completed. This may represent the entire work request OR merely a subset of it. An indication is also given as to whether the monitoring environment should be disassociated from the work request or not. When DISASSOCIATE(YES) is specified, this service will render the information associated with the monitoring environment unpredictable. To associate a work request with the monitoring environment following use of DISASSOCIATE(YES), first use Initialize Mode(Reset) or Relate/Transfer.

Environment

The requirements for the caller are:

Minimum authorization: Supervisor state. PSW key must either be 0 or match the value supplied on IWM4CON when a connect token is passed. PSW key must either be 0 or match the value supplied on IWM4MCRE. PSW key must be 0-7. See restrictions below.

Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31-bit
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: LOCAL lock held
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. Caller is responsible for error recovery
2. Though the caller is required to be enabled, this is not checked. Violation of this restriction may cause disabled program checks which would be the responsibility of the caller’s recovery to handle.
3. The monitoring environment must contain the information saved by IWM4MINI, not IWM4MCRE
4. The current PSW key must be 0 or match the key specified on IWM4MCRE provided the latter is a system key (0-7).
5. This service cannot be used for Report-Only Monitoring Environments

6. If the key specified on IWM4MCRE was a user key (8-F), then:
   - PSW key must be 0
   - Current primary must match the primary at the time that IWM4MCRE was invoked. Calling from a subspace is not supported.

7. If a connect token is passed to IWMMNTFY, then:
   - The connect token must be enabled for using the WLM Work Management services (specifying WORK_MANAGER=YES on IWM4CON).
   - If the key specified on IWM4CON was a user key (8-F), then:
     - PSW key must be 0
     - Current primary must match the primary at the time that IWM4CON was invoked. Calling from a subspace is not supported.

8. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.

9. This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

**Input register information**

Before issuing the IWMMNTFY macro, the caller must ensure that the following general purpose registers (GPRs) contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>The address of a 72-byte standard save area in the primary address space</td>
</tr>
</tbody>
</table>

Before issuing the IWMMNTFY macro, the caller does not have to place any information into any AR unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller
IWMMNTFY

depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMMNTFY macro is as follows:

```
IWMMNTFY

name

TRAXFRPT=NO

TRAXFRPT=YES,SYSEVPL=sysevpl

MONTKN=montkn

COMPLETION=YES

COMPLETION=NO

DISASSOCIATE=YES

DISASSOCIATE=NO

WORKREQ_STA=IMNEWLMARMSTATUSNONE

WORKREQ_STA=workreq_sta

CONNTKN=CONNTKN

CONNTKN=conntkn

ENDTIME=CURRENT

ENDTIME=endtime

RETCODE=retcode

RSNCODE=rsncole

PLISTVER=IMPLIED_VERSION

PLISTVER=MAX

PLISTVER=0

PLISTVER=1

MF=S

MF=(L-,list addr)

MF=(E-,list addr)

attr

COMPLETE

COMPLETE
```

Parameters

The parameters are explained as follows:

name

An optional symbol, starting in column 1, that is the name on the IWMMNTFY macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,COMPLETION=YES

,COMPLETION=NO

A required parameter, which indicates whether the (or possibly one of several) major execution phase(s) is(are) now complete.

,COMPLETION=YES

indicates that execution for an entire phase of processing has now completed. Typically IWMMNTFY Completion(Yes) would be issued as a result of the completion of the transaction program for the work request. When a work request is comprised of several (typically cascaded) transaction programs, each would correspond to an invocation of IWMMNTFY Completion(Yes).
The execution time, as given by the difference between the IWMMNTFY ENDTIME value and the Execution start time (established via IWM4MINI), will be added to the running total execution time for the service class. There may still be 'output' processing left to perform for the work request, which time would be accounted for via IWMRPT. There may also be operations corresponding to hardening of the database data outside the scope of NOTIFY.

COMPLETION=NO indicates that this invocation of Notify does not correspond to the completion of an entire execution segment. Instead this invocation of Notify corresponds to the portion of the work request represented by the monitoring environment. For example, use Completion(No) when this portion of processing behaves like a subroutine in the execution phase, which is therefore a subset of the execution time passed in another NOTIFY.

The execution time, as given by the difference between the IWMMNTFY ENDTIME value and the Execution start time (established via IWM4MINI), will be treated separately from that passed for Completion(Yes), since otherwise there would be double-counting.

CONNTKN=CONNTKN
CONNTKN=NO_CONNTKN
An optional input parameter, which is returned by IWM4CON. The default is NO_CONNTKN, which indicates that no connect token is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

DISASSOCIATE=YES, DISASSOCIATE=NO
A required parameter, which indicates whether the work request should be disassociated from the monitoring environment or not.

DISASSOCIATE=YES
indicates that the work request should be disassociated from the monitoring environment.

DISASSOCIATE=NO
indicates that the work request should not be disassociated from the monitoring environment.

ENDTIME=endtime, ENDTIME=CURRENT
An optional input parameter, which specifies the ending execution time for the transaction in STCK format. The default is CURRENT, which indicates that the current time should be used.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

MF=S
MF=(L,list addr)
MF=(L,list addr,attr)
MF=(L,list addr,0D)
MF=(E,list addr)
MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.
Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

\,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

\,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

\,COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\,MONTKN=montkn
A required input parameter, which contains the delay monitoring token

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

\,PLISTVER=IMPLIED_VERSION
\,PLISTVER=MAX
\,PLISTVER=0
\,PLISTVER=1
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.

  • **0**, which supports all parameters except those specifically referenced in higher versions.

  • **1**, which supports the following parameter and those from version 0:
WORKREQ_STA

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0, or 1

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.
To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.
To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,SYSEVPL=sysevpl
When TRAXFRPT=YES is specified, a required input parameter, which is the fully initialized SYSEVENT parameter list, as mapped by IHATRBPL.
To code: Specify the RS-type address, or address in register (2)-(12), of a 40-character field.

TRAXFRPT=NO
TRAXFRPT=YES

An optional parameter, which indicated prior to z/OS R3 whether a SYSEVENT TRAXFRPT should be issued when the system was in compatibility mode. This has become irrelevant. However, for compatibility reasons TRAXFRPT can still be set but has no effect. The default is TRAXFRPT=NO.

TRAXFRPT=NO
indicates that no SYSEVENT TRAXFRPT should be issued.

TRAXFRPT=YES
indicated prior to z/OS R3 that a SYSEVENT TRAXFRPT should be issued when the system was in compatibility mode. This has become irrelevant. However, for compatibility reasons TRAXFRPT can still be set but has no effect.

,WORKREQ_STA=workreq_sta
,WORKREQ_STA=IWMEWLMARMSSTATUSNONE
When DISASSOCIATE=YES is specified, an optional input parameter, which contains the completion status code of the work request. Available completion status codes (defined in macro IWMYCON) are the following:
- IwmEwlmArmStatusGood(0)
- IwmEwlmArmStatusAborted(1)
- IwmEwlmArmStatusFailed(2)
- IwmEwlmArmStatusUnknown(3)

These codes correspond to status codes in the OpenGroup ARM 4.0 Standard. For further information about the meaning of the status codes, refer to the ARM 4.0 Standard at http://www.opengroup.org/management/arm. The default is IWMEWLMARMSSTATUSNONE. This indicates that the COMPLETION parameter value and internal information in the monitoring environment are examined to determine the status of the work request. If COMPLETION=YES is specified and no abnormal event was recorded for the
monitoring environment with the IWMMABNL service, the completion status IwmEwlmArmStatusGood is reported to EWLM. If an abnormal event was reported via IWMMABNL or COMPLETION=NO was specified, the completion status IwmEwlmArmStatusFailed is reported to EWLM.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMMNTFY macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>

</tbody>
</table>
IWMMRELAL—Relate monitoring environment service

The calling subsystem work manager can use IWMMRELAL to relate two different monitoring environments that are associated with the same work request. IWMMRELAL initializes a monitoring environment, called a dependent monitoring environment, and associates it with a previously established monitoring environment, called a parent monitoring environment.

You can use IWMMRELAL when you do not have direct access to the information required by IWM4MINI. If the caller has the monitoring token for a parent monitoring environment that is previously established for the same work request, you should provide it in the PARENTMONTKN parameter. If the caller does not pass the parent monitoring token, you can use PARENTP=FINDACTIVE to specify that the parent monitoring environment is the active monitoring environment owned by the home address space and which is associated with the TCB provided via PARENTTCB.

IWMMRELAL must be used together with IWMMXFER to ensure that the dependent monitoring environment is a valid representation for the work request.

Optionally, with this macro, you can use the OWNER_TOKEN and OWNER_DATA parameters to use the monitoring environment for your own purposes. You could use the token/data to keep your own information.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state, or supervisor state. PSW key must either be 0, or match the value specified on IWM4MCRE.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>Unlocked when PARENT=FINDACTIVE is specified, otherwise, no restrictions.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space, except the TCB, if specified, must reside in current home address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. You must include the IWMYCON mapping macro in the calling program.
2. If the key specified on IWM4MCRE for the input MONTKN was a user key (8-F), then the following must be true:
   • If you specify PARENTP=YES, then:
     – Primary addressability must exist to the performance block IWM4MCRE obtained (represented by the input MONTKN). You could do this by ensuring that current primary matches primary at the time that
IWM4MCRE was invoked. If this service is invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.

- You cannot specify the list form of this macro. With PARENTP=YES, IWMMRELA produces an inline expansion rather than an out-of-line service, so you do not need a parameter list. Registers 0, 1, 14, and 15 are not preserved across the expansion.

- If you specify PARENTP=FINDACTIVE, then the caller must be in non-cross-memory mode (PASN=SASN=HASN). That is, the current primary (and home) must match the primary (and home) at the time that IWM4MCRE was invoked.

3. If the key specified on IWM4MCRE for the parent environment was a user key (8-F), then either primary or secondary addressability must exist to the monitoring environment for the parent environment.

4. Both monitoring environments must be established on the same MVS image.

5. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the monitoring environment.

6. When PARENTP=YES, the caller must provide recovery.

**Restrictions**

None.

**Input register information**

Before issuing the IWMMRELA macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR 15 return code is non-zero.</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14 - 15</td>
<td>Used as a work register by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller
depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

**main diagram**

```

  SAMEDU=NO

PARENTP=YES
  PARENTMONTKN=parentmontkn
  PARENTENV=SECONDARY
  PARENTENV=HOME

PARENTP=FINDACTIVE
  PARENTTCB=parenttcb
```

**Parameters**

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMMRELA macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**DISPTYPE=TCB**

**DISPTYPE=SRB**

When FUNCTION=CREATE is specified, a required parameter, which describes the dispatchable units which participate in processing work requests associated with the monitoring environment represented by the monitoring token (MONTKN).
indicates that work requests run in TCB mode under a TCB within the current home address space. Note that in cross-memory mode, this may be different from the current primary address space.

,DISPTYPE=SRB
indicates that work requests run in SRB mode within the current home address space.

FUNCTION=CREATE
FUNCTION=DELETE
A required parameter, which indicates whether the relationship is being established or inactivated.

FUNCTION=CREATE
indicates that the relationship is being established.

FUNCTION=DELETE
which indicates that the relationship is being inactivated.

Note that this produces an inline expansion rather than an out-of-line service, so that no parameter list is needed. Therefore, the MF keyword is not supported when this option is specified. Registers 0, 1, 14, and 15 are not preserved across the expansion.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

,MONTKN=montkn
A required input parameter, which contains the delay monitoring token for the dependent environment.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

,OWNER_DATA=owner_data

,OWNER_DATA=NO_OWNER_DATA
When FUNCTION=CREATE is specified, an optional input parameter, which contains data maintained by the user or owner of the monitoring environment. The format is undefined to MVS. The default is NO_OWNER_DATA which indicates that no owner data is provided.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

,OWNER_TOKEN=owner_token

,OWNER_TOKEN=NO_OWNER_TOKEN
When FUNCTION=CREATE is specified, an optional input parameter, which contains a token maintained by the user or owner of the monitoring environment. The format is undefined to MVS. The default is NO_OWNER_TOKEN which indicates that no owner token is provided on this service.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

,PARENTENV=NOSWITCH

,PARENTENV=SECONDARY

,PARENTENV=HOME
When PARENTP=YES and FUNCTION=CREATE are specified, a required parameter, which describes whether a space switch is needed to access the parent monitoring environment.

,PARENTENV=NOSWITCH
indicates that NO space switch is needed to access the parent monitoring environment. This would be appropriate if the parent monitoring environment was established (by IWM4MCRE) to be used by routines in a specific system key or if it was established to be used in a specific user key in the current primary.

,PARENTENV=SECONDARY
indicates that the parent monitoring environment was established in current secondary (for use by a specific user key).

,PARENTENV=HOME
indicates that the parent monitoring environment was established in current home (for use by a specific user key). Use of this option requires that the program must reside in the MVS common area.

,PARENTMONTKN=parentmontkn
When PARENTP=YES and FUNCTION=CREATE are specified, a required input parameter, which contains the delay monitoring token for the parent environment, for example, the monitoring environment which was established earlier and contains the characteristics to be inherited.
To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

\texttt{\textbf{\texttt{PARENTP=YES}}}  \\
\texttt{\textbf{\texttt{PARENTP=FINDACTIVE}}}  \\
When \texttt{FUNCTION=CREATE} is specified, a required parameter, which describes whether the parent monitoring environment is known or not.

\texttt{\textbf{\texttt{PARENTP=YES}}}  \\
indicates that the parent monitoring environment is known.

Note, that this produces an inline expansion rather than an out-of-line service, so that no parameter list is needed. Therefore, the MF keyword is not supported when this option is specified. Registers 0, 1, 14, and 15 are not preserved across the expansion.

\texttt{\textbf{\texttt{PARENTP=FINDACTIVE}}}  \\
indicates that the parent monitoring environment is unknown, but requests that the input monitoring environment be related to the active monitoring environment owned by the current HOME address space and which is associated with the TCB specified by \texttt{PARENTTCB} and which has no further continuations to other monitoring environments. When no such monitoring environment exists, the input monitoring environment will be related to the current home address space.

\texttt{\textbf{\texttt{PARENTTCB=parenttcb}}}  \\
When \texttt{PARENTP=FINDACTIVE} and \texttt{FUNCTION=CREATE} are specified, a required input parameter, which defines the TCB owned by the current home address space associated with a monitoring environment via Initialize/Relate Disptype=TCB,TCB=. This TCB need not be the owner of the monitoring environment. Note that this name is not the pointer to the TCB, but the name of the data area containing the TCB. A typical invocation might replace xTCB with TCB.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\texttt{\textbf{\texttt{PLISTVER=IMPLIED\_VERSION}}}  \\
\texttt{\textbf{\texttt{PLISTVER=MAX}}}  \\
\texttt{\textbf{\texttt{PLISTVER=0}}}  \\
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED\_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED\_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
0, if you use the currently available parameters.

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

\texttt{,RETCODE=retcode}
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

\texttt{,RSNCODE=rsncode}
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

\texttt{,SAMEDU=YES}
\texttt{,SAMEDU=NO}
When DISPTYPE=SRB and FUNCTION=CREATE are specified, a required parameter, which describes whether the dependent monitoring environment associated with MONTKN is running under the same dispatchable unit as the parent. In that case, it would behave as a "subroutine" and execute on the same processor (CP, a.k.a. CPU) as the parent environment.

\texttt{,SAMEDU=YES}
indicates that the work request runs as a subroutine of the parent.
YES may not be specified when PARENTP(FINDACTIVE) is coded.

\texttt{,SAMEDU=NO}
indicates that the work request runs in SRB mode and is independent of the parent dispatchable unit.

\texttt{,TCB=tcb}
When DISPTYPE=TCB and FUNCTION=CREATE are specified, a required input parameter, which defines the TCB within the current home address space which will serve the work request. Note that this name is not the pointer to the TCB, but the name of the data area containing the TCB. A typical invocation might replace xTCB with TCB.

Generally, the input TCB specified should be the TCB under which the work request (e.g. transaction program) runs and under which the delay information is recorded (in spite of the fact that task switches may occur).

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.

\textbf{ABEND codes}

None.

\textbf{Return codes and reason codes}

When the IWMMRELA macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.
The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

### Table 120. Return and Reason Codes for the IWMMRELA Macro

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning</th>
<th>Action</th>
</tr>
</thead>
</table>
| 0           | —           | Equate Symbol: IwmRetCodeOk  
             |             | Meaning: Successful completion. |         |        |
| 4           | —           | Equate Symbol: IwmRetCodeWarning  
             |             | Meaning: Successful completion, unusual conditions noted. |         |        |
| 4           | xxxx0402    | Equate Symbol: IwmRsncodeNoMonEnv  
             |             | Meaning: Input monitoring token indicates no monitoring environment was established. |         |        |
| 4           | xxxx0406    | Equate Symbol: IwmRsncodeNoParEnv  
             |             | Meaning: No parent monitoring environment was established. The input dependent monitoring environment is now related to the Home address space. |         |        |
| 8           | —           | Equate Symbol: IwmRetCodeInvocError  
             |             | Meaning: Invalid invocation environment or parameters. |         |        |
| 8           | xxxx0802    | Equate Symbol: IwmRsncodeXmemUserKeyTkn  
             |             | Meaning: The caller is in cross-memory mode while the token was obtained in user key. |         |        |
| 8           | xxxx0803    | Equate Symbol: IwmRsncodeDisabled  
             |             | Meaning: Caller is disabled. |         |        |
| 8           | xxxx0804    | Equate Symbol: IwmRsncodeLocked  
             |             | Meaning: The caller is locked. |         |        |
| 8           | xxxx080B    | Equate Symbol: IwmRsncodeBadPl  
             |             | Meaning: Error accessing parameter list. |         |        |
| 8           | xxxx081A    | Equate Symbol: IwmRsncodeCallerNotAuthDepEnv  
             |             | Meaning: The caller is not authorized to update the dependent monitoring environment. |         |        |
| 8           | xxxx0820    | Equate Symbol: IwmRsncodeBadMonEnv  
             |             | Meaning: Monitoring environment does not pass verification. |         |        |
| 8           | xxxx0822    | Equate Symbol: IwmRsncodeBadParEnv  
             |             | Meaning: Parent monitoring environment does not pass verification. |         |        |
| 8           | xxxx0823    | Equate Symbol: IwmRsncodeDatoff  
             |             | Meaning: The caller invoked the service while DATOFF. |         |        |
| 8           | xxxx0824    | Equate Symbol: IwmRsncodeAmode24  
             |             | Meaning: The caller invoked the service but was in 24-bit addressing mode. |         |        |
| 8           | xxxx0825    | Equate Symbol: IwmRsncodeAscModeNotPrimary  
             |             | Meaning: The caller invoked the service but was not DAT on Primary ASC mod. |         |        |
### Table 120. Return and Reason Codes for the IWMMRELA Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>xxxx0827</td>
<td>Equate Symbol: IwmRsnCodeRsvdNot0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Reserved field in parameter list was non-zero</td>
</tr>
<tr>
<td>8</td>
<td>xxxx0828</td>
<td>Equate Symbol: IwmRsnCodeBadVersion</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Parent monitoring environment is report only.</td>
</tr>
<tr>
<td>8</td>
<td>xxxx08A4</td>
<td>Equate Symbol: IwmRsnCodeBPParEnv</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Parent monitoring environment is buffer pool management only.</td>
</tr>
<tr>
<td>10</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeCompError:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Meaning: Component error</td>
</tr>
</tbody>
</table>

### Example

To relate two monitoring environments where an address space switch is not required, specify:

```
IWMMRELA FUNCTION=CREATE,MONTKN=(R7),PARENT=YES,
             PARENTMONTKN=(R8),PARENTENV=NOSWITCH,
             DISPTYPE=SRB,SAMEDU=YES,
             RETCODE=RCODE,RSNCODE=RSN
```
The IWMMSTOP service allows to stop a work unit which has been started by IWMMSTRT. A work unit started by IWM4MINI is not affected by this service. The work unit is unblocked, if it is blocked at the time you issue this macro.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No restrictions.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of bits 0-31 of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

• This macro may not be used before the completion of WLM address space initialization
• The caller must have issued the IWMMSTRT macro successfully.
• The caller is responsible for error recovery.
• The current PSW key must be 0 or match the key specified on IWM4MCRE provided the latter is a system key (0-7).
• The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.

Input register information

Before issuing the IWMMSTOP macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if the return code in GPR 15 is not 0, otherwise, used as a work register by the system. The reason code is stored in bits 0-31.</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged.</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>15</td>
<td>Return code is stored in bits 0-31.</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged.</td>
</tr>
<tr>
<td>14 - 15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMMSTOP macro is as follows:

```
IWMMSTOP name

MESSAGES_SENT=NO_MESSAGES_SENT
MESSAGES_SENT=messages_sent

EWLM_RCVD_CORR=NO_EWLM_RCVD_CORR
EWLM_RCVD_CORR=ewlm_rcvd_corr

AFTER_STRT=NO
AFTER_STRT=YES

STATUS=IWMEWLMARMSSTATUSGOOD
STATUS=status

RETCODE=rcode
RSNCODE=rsncode
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMMSTOP macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

AFTER_STRT=NO
AFTER_STRT=YES
When EWLM_RCVD_CORR=ewlm_rcvd_corr is specified, an optional parameter, which indicates the moment the correlator has been received. The default is AFTER_STRT=NO.

AFTER_STRT=NO
indicates that the correlator has been received before this work unit has been started by IWMMSTRT.

AFTER_STRT=YES
indicates that the correlator has arrived within the scope of this work unit that means after issuing IWMMSTRT.

END_FLOW=NO
END_FLOW=YES
An optional parameter, which indicates the completion of a message flow. The default is END_FLOW=NO.

END_FLOW=NO
indicates that a message flow has not completed.

END_FLOW=YES
indicates that a message flow has completed. Specify END_FLOW=YES, if you know that the running work unit is the last one in a work unit flow. This indication cannot be cleared, if it has been set.

EWLM_RCVD_CORR=ewlm_rcvd_corr
EWLM_RCVD_CORR=NO_EWLM_RCVD_CORR
An optional input parameter, which contains a cross-platform Enterprise Workload Management (EWLM) correlator received from another application. Workflows often have multiple parent work units that must complete before a new work unit can be initiated. You can pass only one parent correlator to the IWMMSTRT macro and one additional parent correlator to the IWMMSTOP macro. You have to issue the IWMMPUPD macro, if more than two parent correlators should be assigned to a work unit. This correlator is ignored, if it is an unknown EWLM correlator. The default is NO_EWLM_RCVD_CORR, which indicates that parameter EWLM_RCVD_CORR has not been specified.

To code: Specify the RS-type address, or address in register (2)-(12), of a character field.
MESSAGES_SENT=messages_sent
MESSAGES_SENT=NO_MESSAGES_SENT

An optional input parameter, which contains the number of messages sent to other applications. This value is added to the total messages_sent value of the work unit. The total messages_sent value should not exceed 32767. The default is NO_MESSAGES_SENT, which indicates that parameter MESSAGES_SEND has not been specified.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

MF=S
MF=(L,list addr)
MF=(L,list addr,attr)
MF=(L,list addr,0D)
MF=(E,list addr)
MF=(E,list addr,COMPLETE)

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

MONTKN=montkn
A required input parameter, which contains the delay monitoring token

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

PLISTVER=IMPLIED_VERSION
PLISTVER=MAX
PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:

- **IMPLIED_VERSION**
- **MAX**
- A decimal value of 0

`RETCODE=retcode`

An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

`RSNCODE=rsncode`

An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

`STATUS=status`

An optional input parameter, which contains the completion status code of the work unit. Available completion status codes (defined in macro IWMYCON) are:

- *IwmEwlmArmStatusGood(0)*
- *IwmEwlmArmStatusAborted(1)*
- *IwmEwlmArmStatusFailed(2)*
- *IwmEwlmArmStatusUnknown(3)*

The codes above correspond to status codes in the OpenGroup ARM 4.0 Standard. For an explanation of the status codes, refer to the ARM 4.0 Standard at http://www.opengroup.org/management/arm. The default is IWMEWMARMSTATUSGOOD, which indicates that the work unit completed successfully.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**ABEND codes**

None.
Return codes and reason codes

When the IWMMSTOP macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

</table>
### Table 121. Return and Reason Codes for the IWMMSTOP Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>xxxx0897</td>
<td><strong>Equate Symbol</strong>: IwmRsnCodeTranStatusInvalid</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Meaning</strong>: An unsupported value has been passed to the STATUS parameter.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Action</strong>: Specify a supported value.</td>
</tr>
<tr>
<td>8</td>
<td>xxxx08AC</td>
<td><strong>Equate Symbol</strong>: IwmRsnCodeTranNotStarted</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Meaning</strong>: No work unit has been started by IWMMSTRT for the specified monitoring environment.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Action</strong>: Start a work unit by IWMMSTRT macro, before issuing this macro.</td>
</tr>
</tbody>
</table>
IWMMSTRT — Indicate the start of a work unit

This service indicates that a work unit is beginning execution. The work unit runs under the specified monitoring environment, but is reported to EWLM completely independently from a potentially running transaction on the same monitoring environment that is defined by IWM4MINI and IWMRPT/IWMNTFY calls. You can use the set of services IWMMSTRT, IWMMSTOP, IWMMUPD to provide data for "mini work units" running within a long-running transaction. In addition, a work unit started by IWMMSTRT can participate in asynchronous and synchronous work unit flows.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th><strong>Minimum authorization:</strong></th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dispatchable unit mode:</strong></td>
<td>Task or SRB</td>
</tr>
<tr>
<td><strong>Cross memory mode:</strong></td>
<td>Any PASN, any HASN, any SASN</td>
</tr>
<tr>
<td><strong>AMODE:</strong></td>
<td>31-bit</td>
</tr>
<tr>
<td><strong>ASC mode:</strong></td>
<td>Primary</td>
</tr>
<tr>
<td><strong>Interrupt status:</strong></td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td><strong>Locks:</strong></td>
<td>No restrictions.</td>
</tr>
<tr>
<td><strong>Control parameters:</strong></td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. You must include the IWMYCON and CVT mapping macros in the calling program.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of bits 0-31 of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. This macro may not be used before the completion of WLM address space initialization.
2. The caller must have issued the IWM4MCRE macro successfully and the created delay monitoring environment must be enabled for EWLM support. This means the delay monitoring environment must be created by one of the following ways:
   • IWM4CON EWLM=YES ... and IWM4MCRE SUBSYSP=CONNECT ... OR
   • IWM4MCRE SUBSYSP=VALUE EWLM=YES ...
3. The caller is responsible for error recovery.
4. The current PSW key must be 0 or match the key specified on IWM4MCRE provided the latter is a system key (0-7).
5. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.

**Input register information**

Before issuing the IWMSTRT macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if the return code in GPR 15 is not 0, otherwise, used as a work register by the system. The reason code is stored in bits 0-31.</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system.</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>15</td>
<td>Return code stored in bits 0-31</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system.</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMSTRT macro is as follows:

```
IWMSTRT name=MONTKN=montkn,END_FLOW=NO,MSG_RECEIVED=NO,ARRIVALTIME=NO_ARRIVALTIME
```

```
IWMSTRT name=MONTKN=montkn,END_FLOW=YES,MSG_RECEIVED=NO,ARRIVALTIME=arrivaltime
```

```
IWMSTRT name=MONTKN=montkn,END_FLOW=NO,MSG_RECEIVED=YES,ARRIVALTIME=NO_ARRIVALTIME
```

```
IWMSTRT name=MONTKN=montkn,END_FLOW=YES,MSG_RECEIVED=YES,ARRIVALTIME=arrivaltime
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMMSTRT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

, ARRIVALTIME=arrivaltime
, ARRIVALTIME=NO_ARRIVALTIME
, ARRIVALTIME=NO

An optional input parameter, which contains a timestamp in STCK format. This timestamp is subtracted from the current timestamp and assigned as queued time to the work unit. For example, you may use this parameter, if the work unit is started by receipt of a message from a queue and you know the put time (the timestamp when the message has been put onto the queue). The default is NO_ARRIVALTIME which indicates that parameter ARRIVALTIME has not been specified.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

, END_FLOW=NO
, END_FLOW=YES

An optional parameter, which indicates the completion of a message flow. The default is END_FLOW=NO.

, END_FLOW=NO

indicates that a message flow has not completed.

, END_FLOW=YES

indicates that a message flow has completed. Specify END_FLOW=YES, if you know that this work unit is the last one in a work unit flow. This indication cannot be cleared, if it has been set.

, EWLM_RCVD_CORR=ewlm_rcvd_corr
, EWLM_RCVD_CORR=NO_EWLM_RCVD_CORR

When EWLM_S_CURCORR=ewlm_s_curcorr is specified, an optional input parameter, which contains a cross platform Enterprise Workload Management (EWLM) correlator received from another application. Normally this is a received correlator which has the independent flag and the asynchronous flag
IWMMSTRT

set. It should not be passed to the EWLM_S_PACORR or the
EWLM_S_CURCORR parameter. If you pass this correlator to one of them then
the started work unit is not reclassified and runs under the classification of this
correlator. When you receive a correlator with the independent flag set, you
should:

1. Reclassify the work unit by issuing IWM4CLSY EWLM_CORR=r_corr
   EWLM_CHCORR=c_corr. r_corr is the received correlator and c_corr is the
correlator created by IWM4CLSY.

2. Start the work unit by issuing IWMMSTRT EWLM_S_CURCORR=c_corr
   EWLM_RCVD_CORR=r_corr.

The default is NO_EWLM_RCVD_CORR which indicates that parameter
EWLM_RCVD_CORR has not been specified.

To code: Specify the RS-type address, or address in register (2)-(12), of a
character field.

,EWLM_S_CURCORR=ewlm_s_curcorr
   A required input parameter which contains a cross-platform Enterprise
   Workload Management (EWLM) correlator for the current application. The
correlator passed to this parameter is used as the current correlator of this
work unit. It has usually been created by means of a previous IWM4CLSY call
with the EWLM_CHCORR parameter.

To code: Specify the RS-type address, or address in register (2)-(12), of a
character field.

,EWLM_S_PACORR=ewlm_s_pacorr
   A required input parameter which contains a cross-platform Enterprise
   Workload Management (EWLM) parent correlator received from another
application.

To code: Specify the RS-type address, or address in register (2)-(12), of a
character field.

,MF=S
,MF=(L,list addr)
,MF=(L,list addr,attr)
,MF=(L,list addr,0D)
,MF=(E,list addr)
,MF=(E,list addr,COMPLETE)
   An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline
parameter list and generates the macro invocation to transfer control to the
service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter may be coded with the list form of
the macro.

Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
defined by the list form, and generates the macro invocation to transfer control
to the service.
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

A required input parameter, which contains the delay monitoring token. To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit field.

An optional parameter, which indicates whether this work unit has been started as a result of a receipt of a message. The default is MSG_RECEIVED=NO.

indicates that this work unit has not been started by receipt of a message.

indicates that this work unit has been started as a result of a receipt of a message.

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 0, if you use the currently available parameters.

To code: Specify one of the following:
- IMPLIED_VERSION
- MAX
IWMMSTRT

- A decimal value of 0

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

ABEND codes
None.

Return codes and reason codes

When the IWMMSTRT macro returns control to your program:
- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>

</tbody>
</table>

**Example**

To indicate that the current monitoring environment continues only once elsewhere in the sysplex, specify:

```plaintext
IWMMSTRT FUNCTION=CONTINUE,WHERE=SYSPLEX,MONTKN=(R7),
RETCODE=RCODE,RSNCODE=RSN
```
IWMMSWCH — Switch monitoring environment

The IWMMSWCH macro allows the caller to indicate that the delay information for a work request may now also reside in another monitoring environment which is not related (via IWMMRELA) to the current environment. You can also use IWMMSWCH to indicate that there is no further information for the current work request beyond the current monitoring environment.

The scope of this service is restricted to the input monitoring environment; no other monitoring environments are accessed or otherwise involved.

Environment

The requirements for the caller are:

| Minimum authorization: | Problem state, or supervisor state. PSW key must either be 0, or match the value specified on IWM4MCRE. |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | Suspend locks are allowed, as are FRRs |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. You must include the IWMYCON and CVT mapping macros in the calling program.
2. The caller is responsible for error recovery.
3. If you specify FUNCTION=CONTINUE, you cannot specify the list form of this macro. With FUNCTION=CONTINUE, IWMMSWCH produces an inline expansion rather than an out-of-line service, so you do not need a parameter list. Registers 0, 1, 14, and 15 are not preserved across the expansion.
4. If the key specified on IWM4MCRE was a user key (8 - F) then primary addressability must exist to the monitoring environment IWM4MCRE obtained. You could do this by making sure the primary address space matches the primary at the time IWM4MCRE was invoked.
5. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the monitoring environment.

Restrictions

You cannot use FUNCTION=CONTINUE when there is an outstanding continuation established by the IWMMXFER macro FUNCTION=CONTINUE.

Input register information

Before issuing the IWMMSWCH macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2 - 13</td>
</tr>
<tr>
<td>14</td>
</tr>
<tr>
<td>15</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
</tr>
<tr>
<td>2 - 13</td>
</tr>
<tr>
<td>14 - 15</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMMSWCH macro is as follows:

**main diagram**
Parameters

The parameters are explained as follows:

,FUNCTION=CONTINUE
,FUNCTION=RETURN

Required input parameter that specifies where there may be one or more monitoring environments which represent current information about the work request. FUNCTION indicates further continuations, and does not deal with any parent environment that may exist.

Use FUNCTION=CONTINUE to indicate that the current monitoring environment continues elsewhere.

If you specify FUNCTION=CONTINUE, you cannot specify the MF keyword. With FUNCTION=CONTINUE, IWMMSWCH produces an inline expansion rather than an out-of-line service, so that you do not need a parameter list. Registers 0, 1, 14, and 15 are not preserved across the expansion.

Use FUNCTION=RETURN to indicate that continuations of the current monitoring environment have completed. Registers 0, 1, 14, and 15 are not preserved across the expansion.

,RUNTIME_VER=SHORT_FORM
,RUNTIME_VER=MINIMAL

Optional parameter that specifies what level of runtime verification will be performed.

RUNTIME_VER=SHORT_FORM indicates that checking should verify that a monitoring environment is established and passes a short form of verification prior to being used.

RUNTIME_VER=MINIMAL indicates that checking should assume that if a monitoring environment is created, it is valid and useable.

,WHERE=LOCALMVS
,WHERE=SYSPLEX
,WHERE=NETWORK

Required input parameter for FUNCTION=CONTINUE that specifies where there may be another monitoring environment.

Use WHERE=LOCALMVS to indicate that another monitoring environment may exist on the current MVS.

Use WHERE=SYSPLEX to indicate that another monitoring environment may exist in the current sysplex, but is not expected to be on the current MVS image.

Use WHERE=NETWORK to indicate that another monitoring environment may exist, but is not expected to be in the current MVS sysplex.

,MONTKN=montkn

Required input parameter that specifies the monitoring token.

To code: Specify the RS-type name or address (using a register from 2 to 12) of a 32 bit field containing the monitoring token.
,COMPCODE=NO
,COMPCODE=YES

Optional input parameter that specifies whether you need completion status for IWMMSWCH.

COMPCODE=NO specifies that you do not need completion status. Registers 0, 15 cannot be used as reason code and return code registers upon completion of the macro expansion. If you specify COMPCODE=NO, you cannot specify RETCODE nor RSNCODE.

COMPCODE=YES specifies that you need completion status.

,RETCODE=retcode addr
Optional output parameter that specifies where the system is to store the return code. The return code is also in GPR 15.

To code: Specify the name (RS-type) or address (using a register from 2 to 12) of a fullword to contain the return code.

,RSNCODE=rsncode addr
Optional output parameter that specifies where the system is to store the reason code. The reason code is also in GPR 0.

To code: Specify the name (RS-type) or address (using a register from 2 to 12) of a fullword to contain the reason code (if any).

,MF=S
MF=(L,mfctrl,mfattr)
MF=(E,mfctrl,COMPLETE)

Use MF=S to specify the standard form, which places parameters into an inline parameter list and invokes the IWM4CON macro service.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require re-entrant code. The list form defines an area of storage that the execute form uses to store the parameters.

Use MF=E to specify the execute form of the macro. Use the execute form with the list form of the macro for applications that require re-entrant code. The execute form stores the parameters into the storage area defined by the list form and generates the macro invocation to transfer control to the service.

,mfctrl
Use this output parameter to specify the name of the storage area to contain the parameters.

To code: Specify the name (RS-type) or address (using a register from 2 to 12) of the storage area containing the parameter list.

,mfattr
Use this input parameter to specify the name of a 1 to 60 character storage area that can contain any value that is valid on an assembler DS pseudo-op. You can use this parameter to force boundary alignment of the parameter list. If you do not code ,mfattr the system provides a value of 0D, which forces the parameter on a doubleword boundary.

,COMPLETE
Use this input parameter to specify that the system check for required parameters and supply defaults for omitted optional parameter.
ABEND codes

None.

Return codes and reason codes

When IWMMSWCH macro returns control to your program, GPR 15 contains a return code. When the return code is non-zero, then GPR 0 contains a reason code.

<table>
<thead>
<tr>
<th>Hexadecimal Return Code</th>
<th>Hexadecimal Reason Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td></td>
<td>Meaning: Successful completion.</td>
</tr>
<tr>
<td>04 0402</td>
<td></td>
<td>Meaning: Warning. Input monitoring token indicates no monitoring environment was established.</td>
</tr>
<tr>
<td>04 0407</td>
<td></td>
<td>Meaning: Warning. Switch return was from a monitoring environment with an outstanding continuation.</td>
</tr>
<tr>
<td>08 081C</td>
<td></td>
<td>Meaning: Program error. Outstanding continuation exists.</td>
</tr>
<tr>
<td>08 0820</td>
<td></td>
<td>Meaning: Program error. Monitoring environment does not pass short form verification.</td>
</tr>
</tbody>
</table>

Example

To indicate that the current monitoring environment continues only once elsewhere in the sysplex, specify:

```
IWMMSWCH FUNCTION=CONTINUE,WHERE=SYSPLEX,MONTKN=(R7),
  RETCODE=RCODE,RSNCODE=RSN
```
IWMMUPD — Update data for a work unit

The IWMMUPD service allows to update data about a work unit which has been started by IWMMSTRT. A work unit started by IWM4MINT is not affected by this service.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state or program key mask (PKM) allowing keys 0-7. |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No restrictions. |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of bits 0-31 of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNICODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. This macro may not be used before the completion of WLM address space initialization
2. The caller must have issued the IWMMSTRT macro successfully.
3. The caller is responsible for error recovery.
4. The current PSW key must be 0 or match the key specified on IWM4MCRE provided the latter is a system key (0-7).
5. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.

Input register information

Before issuing the IWMMUPD macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if the return code in GPR 15 is not 0, otherwise, used as a work register by the system. The reason code is stored in bits 0-31.</td>
</tr>
<tr>
<td>1</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged.</td>
</tr>
<tr>
<td>14</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>15</td>
<td>Return code is stored in bits 0-31.</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
<td>Used as a work register by the system.</td>
</tr>
<tr>
<td>2 - 13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14 - 15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMMUPD macro is as follows:

```
IWMMUPD \( \text{name} \) MONTKN=montkn,END_FLOW=NO
\( ,\text{END_FLOW=YES} \)
\( ,\text{MESSAGES_SENT=NO_MESSAGES_SENT} \)
\( ,\text{MESSAGES_SENT=messages_sent} \)
\( ,\text{EWLM_RCVD_CORR=NO_EWLM_RCVD_CORR} \)
\( ,\text{EWLM_RCVD_CORR=ewlm_rcvd_corr} \)
\( ,\text{AFTER_STMT=NO} \)
\( ,\text{AFTER_STMT=YES} \)
\( ,\text{RETCODE=retcode} \)
\( ,\text{PLISTVER=IMPLIED_VERSION} \)
\( ,\text{PLISTVER=MAX} \)
\( ,\text{PLISTVER=0} \)
```

IWMMUPD
The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMMUPD macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**AFTER_STRT=NO**  
**AFTER_STRT=YES**
When EWLM_RCVD_CORR=ewlm_rcvd_corr is specified, an optional parameter, which indicates the moment the correlator has been received. The default is AFTER_STRT=NO.

**AFTER_STRT=NO**
indicates that the correlator has been received before this work unit has been started by IWMMSTRT.

**AFTER_STRT=YES**
indicates that the correlator has arrived within the scope of this work unit that means after issuing IWMMSTRT.

**END_FLOW=NO**  
**END_FLOW=YES**
An optional parameter, which indicates the completion of a message flow. The default is END_FLOW=NO.

**END_FLOW=NO**
indicates that a message flow has not completed.

**END_FLOW=YES**
indicates that a message flow has completed. Specify END_FLOW=YES, if you know that the running work unit is the last one in a work unit flow. This indication cannot be cleared, if it has been set.

**EWLM_RCVD_CORR=ewlm_rcvd_corr**  
**EWLM_RCVD_CORR=NO_EWLM_RCVD_CORR**
An optional input parameter, which contains a cross-platform Enterprise Workload Management (EWLM) correlator received from another application. Workflows often have multiple parent work units that must complete before a new work unit can be initiated. You can pass only one parent correlator to the IWMMSTRT macro and one additional parent correlator to the IWMMUPD macro. You have to issue the IWMMUPD macro, if more than two parent correlators should be assigned to a work unit. This correlator is ignored, if it is an unknown EWLM correlator. The default is NO_EWLM_RCVD_CORR, which indicates that parameter EWLM_RCVD_CORR has not been specified.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.
MESSAGES_SENT=messages_sent
MESSAGES_SENT=NO_MESSAGES_SENT
An optional input parameter, which contains the number of messages sent to
other applications. This value is added to the total messages_sent value of the
work unit. The total messages_sent value should not exceed 32767. The default
is NO_MESSAGES_SENT, which indicates that parameter MESSAGES_SEND
has not been specified.

To code: Specify the RS-type address, or address in register (2)-(12), of a
fullword field.

MF=S
MF=(L,list addr)
MF=(L,list addr,attr)
MF=(L,list addr,0D)
MF=(E,list addr)
MF=(E,list addr,COMPLETE)
An optional input parameter that specifies the macro form.
Use MF=S to specify the standard form of the macro, which builds an inline
parameter list and generates the macro invocation to transfer control to the
service. MF=S is the default.
Use MF=L to specify the list form of the macro. Use the list form together with
the execute form of the macro for applications that require reentrant code. The
list form defines an area of storage that the execute form uses to store the
parameters. Only the PLISTVER parameter may be coded with the list form of
the macro.
Use MF=E to specify the execute form of the macro. Use the execute form
together with the list form of the macro for applications that require reentrant
code. The execute form of the macro stores the parameters into the storage area
defined by the list form, and generates the macro invocation to transfer control
to the service.

,list addr
The name of a storage area to contain the parameters. For MF=S and
MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary
alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword
boundary. If you do not code attr, the system provides a value of 0D.

,COMPLETE
Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

MONTKN=montkn
A required input parameter, which contains the delay monitoring token

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit
field.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

**To code:** Specify one of the following:
- IMPLIED_VERSION
- MAX
- A decimal value of 0

,**RETCODE=retcode**
An optional output parameter into which the return code is to be copied from GPR 15.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

,**RSNCODE=rsncode**
An optional output parameter into which the reason code is to be copied from GPR 0.

**To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

**ABEND codes**
None.

**Return codes and reason codes**

When the IWMMUPD macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains a reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>

</tbody>
</table>
IWMMXFER — Transfer monitoring environment

The purpose of this service is to reflect that the delay information for a work request may now also reside in a dependent monitoring environment (CONTINUE) OR that delay information is no longer present in a dependent monitoring environment (RETURN).

The two monitoring environments referred to above must be related by a previous IWMMRELA invocation. This service requires as input the monitoring token for the dependent environment, which is accessed, but the parent environment must also be updated. This implies that the user must have addressability and update access to the parent monitoring environment. PARENTKEYP and PARENTENV keywords are provided to accommodate these requirements. These restrictions apply even when the Relate was performed using the FINDACTIVE option, though when the monitoring environment is related to the address space characteristics, no key or addressability requirements exist beyond those for the dependent monitoring environment.

Environment

The requirements for the caller are:

Minimum authorization:
- Either problem state or supervisor state.
- PSW key must either be 0 or match the value supplied on IWM4MCRE for the (dependent) monitoring token.
- PARENTKEYP(VALUE) may only be specified in supervisor state or with PKM authority to the key specified by PARENTKEY. Note that the key for IWMMXFER is located in bit positions 0-3 (using 0 origin), which is the machine orientation to keeping keys, not the “natural” way of declaring the key value.
- PARENTKEYP(UNKNOWN) may only be specified in supervisor state or with PKM authority to key 0.
- When PARENTKEYP(PSWKEY) is specified, the PSW key must either be 0 or match the value supplied on IWM4MCRE for the parent monitoring environment.
- If FUNCTION=RETURN is specified and the passed MONTKN is associated with an ARM work request (EWLM=YES was specified on IWM4CON (or IWMCONN) and the monitoring environment was created using that CONNTKN), the caller must be in supervisor state or have PKM authority to key 0.

Dispatchable unit mode: Task or SRB
Cross memory mode: Any PASN, any HASN, any SASN
AMODE: 31-bit
ASC mode: Primary
Interrupt status: Enabled for I/O and external interrupts
Locks: No locks may be held.
Control parameters: Control parameters must be in the primary address space.

Programming requirements

1. The macro IWMYCON must be included to use this macro.
IWMMXFER

2. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
3. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
4. Note that specification of FUNCTION(CONTINUE) produces an inline expansion rather than an out-of-line service. Registers 0, 1, 14, and 15 are not preserved across the expansion.

Restrictions
1. If the key specified on IWM4MCRE for the dependent monitoring environment was a user key (8-F), then primary addressability must exist to the performance block IWM4MCRE obtained. This condition is satisfied by ensuring that current primary matches primary at the time that IWM4MCRE was invoked. If this service is invoked in a subspace, the condition may be satisfied by ensuring that the performance block is shared with the base space.
2. If the key specified on IWM4MCRE for the parent environment was a user key (8-F), then either primary OR secondary addressability must exist to the performance block for the parent environment.
3. When FUNCTION(CONTINUE|RETURN) are used, the caller is responsible for error recovery
4. When FUNCTION(CONTINUE) is used, the caller is responsible to ensure that the parent monitoring environment does not already have a continuation (via a previous IWMMXFER or IWMMSWCH) to another (or other) dependent monitoring environment(s).
5. Both monitoring environments must be established on the same MVS image.
6. The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the dependent monitoring environment.
7. The caller and/or the owner of the parent environment must ensure that parent environment is not deleted while between the time that IWMMXFER FUNCTION(CONTINUE) is used and the time that either IWMMXFER FUNCTION(RETURN) is used against the dependent monitoring environment OR IWMMSWCH FUNCTION(RETURN) is used against the parent monitoring environment.
8. Only limited validity checking is done on the input monitoring tokens.
9. This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

Input register information

Before issuing the IWMMXFER macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMMXFER macro is as follows:

```
+------------------------------------------------------------+
| name | IWMMXFER | RUNTIME_VER=SHORT_FORM | WORKREQ_STA=IWMEWLMARMSTATUSNONE |
|      | FUNCTION=CONTINUE | RUNTIME_VER=MINIMAL | WORKREQ_STA=workreq_sta |
|      | FUNCTION=RETURN | RUNTIME_VER=SHORT_FORM | WORKREQ_STA=workreq_sta |
|      | ,RUNTIME_VER=MINIMAL | WORKREQ_STA=workreq_sta |
|      | ,MONTKN=montkn | PARENTKEYP=VALUE | PARENTKEY=parentkey |
|      | ,PARENTKEYP=PARENTKEY | PARENTENV=SECONDARY |
|      | ,PARENTKEYP=PARENTKEY | PARENTENV=NOSWITCH |
|      | ,PARENTKEYP=PARENTKEY | ,PARENTKEYP=UNKNOWN |
|      | ,COMPCODE=YES | ,COMPCODE=NO | ,RETCODE=retcode |
|      | ,COMPCODE=NO | ,RSNCODE=rsncode | ,PLISTVER=IMPLIED_VERSION |
|      | ,COMPCODE=NO | ,PLISTVER=MAX | ,PLISTVER=0 |
|      | ,COMPCODE=NO | ,PLISTVER=1 |
|      | ,COMPLETE | ,NOCHECK | |
|      | ,MF=(M ,list addr) | ,MF=(M ,list addr) |
+------------------------------------------------------------+
```

**Parameters**

The parameters are explained as follows:
IWMMXFER

 name
 An optional symbol, starting in column 1, that is the name on the IWMMXFER
 macro invocation. The name must conform to the rules for an ordinary
 assembler language symbol.

 ,COMPCODE=YES
 ,COMPCODE=NO
 An optional parameter, which indicates whether completion status for this
 service is needed. The default is COMPCODE=YES.

 ,COMPCODE=YES
 indicates that completion status is needed.

 ,COMPCODE=NO
 indicates that completion status is not needed. Registers 0, 15 cannot be
 used as reason code and return code registers upon completion of the
 macro expansion. For this reason neither RETCODE NOR RSNCODE may
 be specified when COMPCODE(NO) is specified.

 FUNCTION=CONTINUE
 FUNCTION=RETURN
 A required parameter, which indicates whether the dependent environment is
 continuing from or returning to the parent environment.

 FUNCTION=CONTINUE
 indicates that this is a unique continuation of the work request which is
 reflected in the dependent monitoring environment.

 Note that the parent environment may continue to be active on behalf of
 the work request.

 Note that specification of FUNCTION(CONTINUE) produces an inline
 expansion rather than an out-of-line service. Registers 0, 1, 14, and 15 are
 not preserved across the expansion.

 FUNCTION=RETURN
 indicates that the work request is returning to a previously established
 parent monitoring environment.

 Use of this option indicates that the dependent environment no longer
 represents the work request.

 Note that specification of FUNCTION(RETURN) produces an inline
 expansion rather than an out-of-line service. Registers 0, 1, 14, and 15 are
 not preserved across the expansion.

 ,MONTKN=montkn
 A required input parameter, which contains the delay monitoring token for the
 dependent environment.

 To code: Specify the RS-type address, or address in register (2)-(12), of a 32-bit
 field.

 ,PARENTENV=NOSWITCH
 ,PARENTENV=SECONDARY
 A required parameter, which describes whether a space switch is needed to
 access the parent monitoring environment.

 ,PARENTENV=NOSWITCH
 indicates that NO space switch is needed to access the parent monitoring
 environment. This would be appropriate if the parent monitoring
environment was established (by IWM4MCRE) to be used by routines in a specific system key or if it was established to be used in a specific user key in the current primary.

,PARENTENV=SECONDARY
  indicates that the parent monitoring environment was established in current secondary (for use by a specific user key).

,PARENTKEY=parentkey
  When PARENTKEYP=VALUE is specified, a required input parameter, which contains the key in which the parent monitoring environment must be accessed. Use of this keyword value requires that the invoker be in supervisor state or that the caller have PKM authority to the key specified. The high-order 4 bits (i.e. bits 0-3) contain the key value.

Note that this is different from the "normal" way of declaring the key, and uses the machine orientation for keeping the storage key in the high-order bits.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-bit field.

,PARENTKEYP=VALUE
,PARENTKEYP=PSWKEY
,PARENTKEYP=UNKNOWN
  A required parameter, which describes whether a key switch is needed to access the parent monitoring environment.

,PARENTKEYP=VALUE
  indicates that the key is being passed explicitly via PARENTKEY.

,PARENTKEYP=PSWKEY
  indicates that the current PSW key should be used. Use of this keyword value requires that the parent monitoring environment was established with the same key as the current PSW.

,PARENTKEYP=UNKNOWN
  indicates that the key associated with the parent monitoring environment is unknown. Use of this keyword value requires that the invoker be in supervisor state or that the caller have PKM authority to key 0.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
,PLISTVER=1
  An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
  • IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
  • MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
    If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
IWMMXFER

- 0, which supports all parameters except those specifically referenced in higher versions.
- 1, which supports the following parameters and those from version 0:
  
  WORKREQ_STA
  
  To code: Specify one of the following:
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0, or 1

  ,RETCODE=retcode
  An optional output parameter into which the return code is to be copied from GPR 15.
  
  To code: Specify the RS-type address of a fullword field, or register (2)-(12).

  ,RSNCODE=rsncode
  An optional output parameter into which the reason code is to be copied from GPR 0.
  
  To code: Specify the RS-type address of a fullword field, or register (2)-(12).

  ,RUNTIME_VER=SHORT_FORM
  ,RUNTIME_VER=MINIMAL
  When FUNCTION=CONTINUE is specified, an optional parameter, which indicates what level of runtime verification will be performed. The default is RUNTIME_VER=SHORT_FORM.

  ,RUNTIME_VER=SHORT_FORM
  indicates that checking should verify that a monitoring environment is established and passes a short form of verification prior to being used.

  ,RUNTIME_VER=MINIMAL
  indicates that checking will only be done to verify that a monitoring environment may be established, assuming that it would be valid and usable if established.

  ,RUNTIME_VER=SHORT_FORM
  ,RUNTIME_VER=MINIMAL
  When FUNCTION=RETURN is specified, an optional parameter, which indicates what level of runtime verification will be performed. The default is RUNTIME_VER=SHORT_FORM.

  ,RUNTIME_VER=SHORT_FORM
  indicates that checking should verify that a monitoring environment is established and passes a short form of verification prior to being used.

  ,RUNTIME_VER=MINIMAL
  indicates that checking will only be done to verify that a monitoring environment may be established, assuming that it would be valid and usable if established.

  ,WORKREQ_STA=workreq_sta
  ,WORKREQ_STA=IWMNEWLMARMSTATUSNONE
  When FUNCTION=RETURN is specified, an optional input parameter, which contains the completion status code of the work request. Available completion status codes (defined in macro IWMYCON) are the following:
  - IwmEwlmArmStatusGood(0)
  - IwmEwlmArmStatusAborted(1)
IWMMXFER

- IwmEwlmArmStatusFailed(2)
- IwmEwlmArmStatusUnknown(3)

These codes correspond to status codes in the OpenGroup ARM 4.0 Standard. For further information about the meaning of the status codes, refer to the ARM 4.0 Standard at http://www.opengroup.org/management/arm. The default is IWMEWLMARMSTATUSNONE. This indicates that internal information in the monitoring environment are examined to determine the status of the work request. If no abnormal event was recorded for the monitoring environment with the IWMMABNL service, the completion status IwmEwlmArmStatusGood is reported to EWLM. If an abnormal event was reported with IWMMABNL, the completion status IwmEwlmArmStatusFailed is reported to EWLM.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

ABEND codes

None.

Return codes and reason codes

When the IWMMXFER macro returns control to your program:
- GPR 15 (and reetcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Table 124. Return and Reason Codes for the IWMMXFER Macro

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>

<tr>
<td></td>
<td></td>
<td>Action: Check the EWLM ARM interface specification for valid completion status values.</td>
</tr>
</tbody>
</table>
IWMQDEL — Delete a request from the queue for an execution address space

This service deletes a work request that was previously inserted using the IWMQINS service, if it has not been selected using the IWMSSEL service.

**Note:** It is recommended to use the equivalent service, IWM4QDE, which also supports 64-bit addressing. For more information, see “IWM4QDE — Delete a request from the queue for an execution address space” on page 683.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any HASN, any SASN. PASN must be the address space which connected to WLM (i.e. the address space that was home when IWMCONN was issued for Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue).</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

None.

**Input register information**

Before issuing the IWMQDEL macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.
Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMQDEL macro is as follows:

```
IWMQDEL CONNTKN=conntkn, WLMWUTKN=wlmwutkn, RETCODE=retcode

IWMQDEL

**name**
An optional symbol, starting in column 1, that is the name on the IWMQDEL macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**CONNTKN=conntkn**
A required input parameter, which contains the connect token associated with the use of WLM Work Queuing services as returned by IWMCONN (specifying Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue).

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

- **MF=S**
- **MF=(L,list addr)**
- **MF=(L,list addr,attr)**
- **MF=(L,list addr,0D)**
- **MF=(E,list addr)**
- **MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

- **list addr**
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

- **attr**
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

- **COMPLETE**
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

- **PLISTVER=IMPLIED_VERSION**
- **PLISTVER=MAX**
- **PLISTVER=0**

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:
IWMQDEL

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.

- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, if you use the currently available parameters.

  **To code:** Specify one of the following:
  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0

\`RETCODE=retcode\`

An optional output parameter into which the return code is to be copied from GPR 15.

  **To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

\`RSNCODE=rsncode\`

An optional output parameter into which the reason code is to be copied from GPR 0.

  **To code:** Specify the RS-type address of a fullword field, or register (2)-(12).

\`WLMWUTKN=wlmwutkn\`

A required input parameter, specifying the work unit to be deleted. This token must be a token that was returned on a prior IWMQINS request.

  **To code:** Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMQDEL macro returns control to your program:

- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.
<table>
<thead>
<tr>
<th>Return Code</th>

### Table 125. Return and Reason Codes for the IWMQDEL Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0827          | **Equate Symbol:** IwmRsnCodeRsvdNot0  
**Meaning:** Reserved field in parameter list was non-zero.  
**Action:** Check for use of keywords that are not supported by the MVS release on which the program is running. |
| 8           | xxxx0828          | **Equate Symbol:** IwmRsnCodeBadVersion  
**Meaning:** Version number in parameter list is not valid.  
**Action:** Check for possible storage overlay of the parameter list. |
| 8           | xxxx083F          | **Equate Symbol:** IwmRsnCodePrimaryNotOwnConn  
**Meaning:** Primary address space does not own the passed connect token.  
**Action:** Avoid requesting this function while primary address space does not own the connect token. |
| 8           | xxxx0840          | **Equate Symbol:** IwmRsnCodeServiceNotEnabled  
**Meaning:** Caller’s space connection is not enabled for this service  
**Action:** Make sure that Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue is specified on the IWMCONN request to enable this service. |
| 8           | xxxx0848          | **Equate Symbol:** IwmRsnCodeBadWorkUnitToken  
**Meaning:** The work unit token is not valid.  
**Action:** Check the specification of the WLMWUTKN parameter. |
| 8           | xxxx089E          | **Equate Symbol:** IwmRsnCodeServiceAModeMismatch  
**Meaning:** The caller is in 64-bit address mode and tried to invoke a service macro that is only enabled for a 31-bit environment.  
**Action:** Use the 64-bit enabled service macro (IWM4QDE) or change the address mode of the caller to 31-bit. |
| 10          |                   | **Equate Symbol:** IwmRetCodeCompError  
**Meaning:** Component error.  
**Action:** Contact your system programmer. |

### Example

To delete a work request from the WLM queue manager queues:

```
IWMQDEL CONNTKN=CONNTOKEN, X
WLMWUTKN=WLMWUTKN, RETCODE=RC, RSNCODE=RSN
```

* Storage areas

**CONNTOKEN** DS FL4  
Contains the connect token  
associated with the use of WLM  
Queueing services as returned by  
IWMCONN  
(specifying QUEUE_MANAGER=YES  
or SERVER_MANAGER=YES
### IWMQDEL

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WLMWUTKN</td>
<td>DS</td>
<td>Work unit token</td>
</tr>
<tr>
<td>RC</td>
<td>DS</td>
<td>Return code</td>
</tr>
<tr>
<td>RSN</td>
<td>DS</td>
<td>Reason code</td>
</tr>
</tbody>
</table>
IWMQINS — Insert a request onto the queue for an execution address space

The IWMQINS service inserts a work request onto workload management queues so its execution in a server address space can be managed by WLM.

Before using this service, the caller must connect to WLM using the IWMCONN service, specifying Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue.

The IWMQINS service requires the use of enclaves to manage the performance goals and reporting of work. It requires the use of application environments to associate types of work requests with servers capable of processing them.

Note: It is recommended to use the equivalent service, IWM4QIN, which also supports 64-bit addressing. For more information, see "IWM4QIN — Insert a request onto the queue for an execution address space" on page 696.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Supervisor state or program key mask (PKM) allowing keys 0-7.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task or SRB</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>Any HASN, any SASN. PASN must be the address space which connected to WLM (i.e. the address space that was home when IWMCONN was issued for Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue).</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Intercept status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.
Restrictions

None.

Input register information

Before issuing the IWMQINS macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMQINS macro is as follows:

```
IWMQINS CONNTKN=conntkn,ETOKEN=etoken,USERDATA=userdata
```

```
APPLENV=applenv
```

```
,DYNAMIC=YES,DEPENDENT=YES
```
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMQINS macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

,**APPLENV=applenv**
A required input parameter, which contains an application environment name. An application environment is defined in the workload manager service definition and instructs WLM how to create a server address space.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

**CONNTKN=conntkn**
A required input parameter, which contains the connect token returned by the IWMCONN macro.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

,**DEPENDENT=NO**
,**DEPENDENT=YES**
An optional parameter indicating whether the insert is for a dependent or a standard request. The default is DEPENDENT=NO.

,**DEPENDENT=NO**
The request is for an independent (standard) work request (default).

,**DEPENDENT=YES**
The insert is for a dependent work request which is required by already active server tasks to complete their processing. The request is prioritized above requests which are not marked as dependent.

,**DYNAMIC=NO**
, **DYNAMIC=YES**

An optional parameter indicating whether the insert is for a dynamic or static application environment. The default is DYNAMIC=NO.

, **DYNAMIC=NO**

The server manager connects to a static application environment according to the WLM service definition. This is the default.

, **DYNAMIC=YES**

The server manager connects to a dynamic application environment according to a prior definition via IWMAEDEF (IWM4AEDF for 64-bit environments) service.

, **ETOKEN=etoken**

A required input parameter, which contains the enclave token associated with the work request. An enclave token is obtained using either the IWMECREA or IWMESQRY macro.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

, **MF=S**

, **MF=(L,list addr)**

, **MF=(L,list addr,attr)**

, **MF=(L,list addr,0D)**

, **MF=(E,list addr)**

, **MF=(E,list addr,COMPLETE)**

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

, **list addr**

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

, **attr**

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

, **COMPLETE**

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

, **PLISTVER=IMPLIED_VERSION**

, **PLISTVER=MAX**

, **PLISTVER=0**
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports the following parameter and those from version 0:
  
  **SERVER_TOKEN**
- **2**, which supports the following parameter and those from version 0 and 1:
  
  **REGION_TOKEN**
- **3**, which supports the following parameter and those from version 0, 1, and 2:
  
  **DYNAMIC**

**To code:** Specify one of the following:

- **IMPLIED_VERSION**
- **MAX**
- A decimal value of 0, 1, 2, or 3

An optional input parameter, which contains a region token returned by the IWM4CON and IWM4SEL macro. Use REGION_TOKEN to queue a work request to a specific server region. Such a work request is considered to be part of a set of work requests which all need access to the same status information which is kept in the virtual storage of the server region.

The following qualifications apply when specifying a region token:

- The application is responsible for passing the region token to the queueing manager so that it can insert the work request to the region.
- WLM has to know that temporal affinities for work requests to a specific server region exist in order not to stop the server region. The application must use the IWMTAFF macro to tell WLM when a temporal affinity starts and when it ends.
Coding REGION_TOKEN=0 is equivalent to omitting the REGION_TOKEN keyword. The default is 0.

To code: Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,SECUSER=NO
,SECUSER=YES
An optional parameter, which specifies whether the security environment of the user should be associated with the request at run time. The default is SECUSER=NO.

,SECUSER=NO
No security environment to be established.

,SECUSER=YES
Use the specified user ID to establish a security environment.

,SERVER_TOKEN=server_token
,SERVER_TOKEN=0
An optional input parameter, which contains a server token returned by the IWMSSSEL macro. Use SERVER_TOKEN to queue a secondary work request to the same server task that selected a prior work request. A secondary work request is considered to be an extension of the prior work request.

The following qualifications apply when specifying a server token:
• The server task is responsible for passing the server token to the queueing manager so that it can insert a secondary work request.
• Coordination is required between the queueing manager and the server task so that the server task knows when to expect secondary work requests. The server task uses the IWMSSSEM macro to select secondary work requests. It must select all secondary work requests before it can resume normal selection using IWMSSSEL.
• The same application environment and enclave token passed for the original work request must be passed for each secondary work request.
• A secondary work request cannot be deleted using the IWMQDEL macro. IWMQINS does not return a work unit token (WLMWUTKN).
• The SECUSER keyword is ignored.

Coding SERVER_TOKEN=0 is equivalent to omitting the SERVER_TOKEN keyword. The default is 0.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.

,USERDATA=userdata
A required input parameter, which contains data to pass to the server address space. This user data is returned to the caller of the IWMSSSEL or IWMSSSEM macro. The format is undefined to MVS.
IWMQINS

To code: Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

,USERID='userid'
When SECUSER=YES is specified, a required input parameter, which contains the requester's user ID.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

,WLMWUTKN='wlmwutkn'
An optional output parameter, which will receive the work unit token. This token can be passed to the IWMQDEL service to delete the work request.

To code: Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

ABEND codes

None.

Return codes and reason codes

When the IWMQINS macro returns control to your program:
• GPR 15 (and retcode, when you code RETCODE) contains a return code.
• When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>

<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx083F    | **Equate Symbol:** IwmRsnCodePrimaryNotOwnConn  
 **Meaning:** Primary address space does not own the passed connect token.  
 **Action:** Ensure that the primary address space has previously connected to WLM using the IWMCONN macro. Ensure that the connect token returned by the IWMCONN macro is passed to the IWMQINS macro. |
| 8           | xxxx0840    | **Equate Symbol:** IwmRsnCodeServiceNotEnabled  
 **Meaning:** Caller's space connection is not enabled for this service  
 **Action:** Make sure that Queue_Manager=Yes, or Server_Manager=Yes with Server_Type=Queue is specified on the IWMCONN request to enable this service. |
| 8           | xxxx0842    | **Equate Symbol:** IwmRsnCodeNoWLMConnect  
 **Meaning:** Caller's space disconnected from WLM during processing of the insert request.  
 **Action:** None. |
| 8           | xxxx0845    | **Equate Symbol:** IwmRsnCodeWrongEnclave  
 **Meaning:** The caller tried to queue a secondary work request to a specific server task using the SERVER_TOKEN parameter. The caller's enclave token does not match the enclave token of the last work request selected by the server task.  
 **Action:** Check that the correct enclave token was specified. Check that the server task is invoking the IWMSSEL and IWMSSEM macros in the correct sequence. |
| 8           | xxxx089E    | **Equate Symbol:** IwmRsnCodeServiceAModeMismatch  
 **Meaning:** The caller is in 64-bit address mode and tried to invoke a service macro that is only enabled for a 31-bit environment.  
 **Action:** Use the 64-bit enabled service macro (IWM4QIN) or change the address mode of the caller to 31-bit. |
| C           |             | **Equate Symbol:** IwmRetCodeEnvError  
 **Meaning:** Environmental error. |
| C           | xxxx0C01    | **Equate Symbol:** IwmRsnCodeNoStg  
 **Meaning:** Storage is not available for the request.  
 **Action:** Contact your system programmer. There is a common storage shortage. |
### Table 126. Return and Reason Codes for the IWMQINS Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| C xxxx0C16  |             | **Equate Symbol**: IwmRsnCodeServerUnavail  
**Meaning**: A server cannot be started to process the work request. This is probably caused by one of the following:  
1. An error in the JCL procedure used to start the server address space.  
2. Repeated, unexpected terminations of the server address space.  
   
In either of these cases, workload management stops the application environment. A DISPLAY WLM command shows this state as INTERNALLY STOPPED.  
**Action**: Look at the system log to determine what caused the error:  
1. If it is a JCL error, correct the error in the procedure.  
2. If it is repeated terminations of the server address space, correct the application error causing the termination.  
   
In either case, the server environment can then be resumed using the VARY operator command:  
`V WLM,APPLENV=nnn,RESUME` where `nnn` is the applicable application environment name.  
**Note**: A re-IPL of some or all of the systems in the sysplex does not reset the stopped state of the application environment. The VARY command is the only way to resume the environment. |
| C xxxx0C1A  |             | **Equate Symbol**: IwmRsnCodeApplNotDefined  
**Meaning**: The application environment name is not defined in the active WLM policy.  
**Action**: Check whether the correct application environment name is being used. If so, a service administrator must define the application environment in the WLM service definition. |
| C xxxx0C1B  |             | **Equate Symbol**: IwmRsnCodeApplNotSST  
**Meaning**: The application environment name is defined for use by a different subsystem type in the active WLM policy.  
**Action**: Check whether the correct application environment name is being used. If so, a service administrator must change the application environment in the WLM service definition to specify the correct subsystem type. |
| C xxxx0C1D  |             | **Equate Symbol**: IwmRsnCodeQMgrNotActive  
**Meaning**: The required Queue Manager is not active.  
**Action**: The Queue Manager with the same subsystem type and name as the server must be started and connected to workload management before the request can be honored. |
| C xxxx0C22  |             | **Equate Symbol**: IwmRsnCodeApplEnvQuiesced  
**Meaning**: For server applications connecting to WLM with subsystem type IWEB only: The application environment has been quiesced. The work request is not inserted to the WLM work queue.  
**Action**: Resume the application environment. |
### Table 126: Return and Reason Codes for the IWMQINS Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| C           | xxxx0C40    | **Equate Symbol:** IwmRsnCodeNoSafCheckPossible  
**Meaning:** MLS is active but a security check could not be performed probably for one of the following reasons:  
• No security decision could be made. The RACF router was not loaded; the request, resource, subsystem combination could not be found in the RACF ROUTER table,...  
• A resource or class name is not defined to RACF or the class has not been RAClisted.  
• The class was RAClisted, but the data space cannot be accessed due to an ALESERV failure.  
• The class was RAClisted, but the data space has been deleted.  
• No security decision could be made. The RACF router was not loaded; the request, resource, subsystem combination could not be found in the RACF ROUTER table.  
**Action:** Contact your RACF Security Administrator. Check if RACF is properly installed, configured and tuned. Correct the eventual problems. |
| C           | xxxx0C41    | **Equate Symbol:** IwmRsnCodeSafCheckFailed  
**Meaning:** MLS is active. Queue Manager and Server Manager are not authorized to communicate.  
**Action:** Normally none. If QM and SM really must communicate, contact your RACF Security Administrator. Set the appropriate Security Labels. |
| C           | xxxx0C42    | **Equate Symbol:** IwmRsnCodeAletError  
**Meaning:** Error while accessing access list with ALESERV probably because of one of the following  
1.  
2. The current access list cannot be expanded. There are no free access list entries and the maximum size has been reached.  
3. ALESERV could not obtain storage for an expanded access list.  
**Action:** Delete unused entries and reissue the request in first case. Free some storage and retry the request in second case. Contact your System Programmer if none works |
| 10          | —           | **Equate Symbol:** IwmRetCodeCompError  
**Meaning:** Component error.  
**Action:** Contact your system programmer. |

### Example

To insert a work request onto the WLM queue manager queues:

```
IWMQINS CONNTKN=CONNTOKEN,ETOKEN=ENCTOKEN,  X
USERDATA=USERDATA,APPLENV=APPLENV,SECUSER=NO,  X
WLMWUTKN=WLMWUTKN,RETCODE=RC,RSNCODE=RSN
```

* Storage areas
| Field          | Type | Description                                                                
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>CONNTOKEN</td>
<td>FL4</td>
<td>Contains the connect token associated with the use of WLM</td>
</tr>
<tr>
<td>ENCTOKEN</td>
<td>CL8</td>
<td>Contains the enclave token associated with the work request as returned by IWMECREA</td>
</tr>
<tr>
<td>USERDATA</td>
<td>CL16</td>
<td>Contains data maintained by the user</td>
</tr>
<tr>
<td>APPLENV</td>
<td>CL32</td>
<td>Contains the application environment name</td>
</tr>
<tr>
<td>WLMWUTKN</td>
<td>CL16</td>
<td>Work unit token</td>

<tr>
<td>RC</td>
<td>F</td>
<td>Return code</td>
</tr>
<tr>
<td>RSN</td>
<td>F</td>
<td>Reason code</td>
</tr>
</tbody>
</table>

*WLM services supporting 31-bit addressing only*
IWMRPT

IWMRPT — Report on work request completion

The primary purpose of this service is to allow MVS to obtain the total response time for a completed work request and its corresponding service class and (when customer specified) its report class.

The second purpose in using this service is to allow MVS to know which address spaces were involved in serving the service class.

When a monitoring token is provided, the third purpose in using this service is to allow MVS to know that the monitoring environment should no longer be associated with the now completed work request. The use of this service will render the information associated with the monitoring environment unpredictable. To associate a work request with the monitoring environment following use of Report, first use Initialize Mode(Reset) or Relate/Transfer.

Environment

The requirements for the caller are:

| Minimum authorization: | Supervisor state. PSW key must either be 0 or match the value supplied on IWM4CON. PSW key must either be 0 or match the value supplied on IWM4MCRE when a monitoring token is passed. PSW key must be 0-7. See restrictions below. |
| Dispatchable unit mode: | Task or SRB |
| Cross memory mode: | Any PASN, any HASN, any SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | LOCAL lock held |
| Control parameters: | Control parameters must be in the primary address space. |

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.
5. All character data, unless otherwise specified, is assumed to be left-justified and padded with blanks on the right, as needed, to occupy the specified number of bytes.

Restrictions

1. The caller is responsible for error recovery
2. Though the caller is required to be enabled, this is not checked. Violation of this restriction may cause disabled program checks which would be the responsibility of the caller’s recovery to handle.

3. If a delay monitoring token is provided, then:
   - The caller must serialize to prevent any delay monitoring services from being invoked concurrently for the environment represented by the monitoring token.
   - The monitoring environment must contain the information saved by IWM4MINI, not IWM4MRLT.
   - If the key specified on IWM4MCRE was a system key (0-7), then the current PSW key must be 0 or match the key specified on IWM4MCRE.
   - If the key specified on IWM4MCRE was a user key (8-F), then:
     - PSW key must be 0.
     - Current primary must match the primary at the time that IWM4MCRE was invoked. Calling from a subspace is not supported.

4. If the key specified on IWM4CON for the input connect token was a user key (8-F), then:
   - PSW key must be 0.
   - Current primary must match the primary at the time that IWM4CON was invoked. Calling from a subspace is not supported.

5. This macro supports multiple versions. Some keywords are only supported by certain versions. Refer to the PLISTVER parameter description for further information.

### Input register information

Before issuing the IWMRPT macro, the caller must ensure that the following general purpose registers (GPRs) contain the specified information:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>The address of a 72-byte standard save area in the primary address space</td>
</tr>
</tbody>
</table>

Before issuing the IWMRPT macro, the caller does not have to place any information into any AR unless using it in register notation for a particular parameter, or using it as a base register.

### Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system.</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>
2-13 Unchanged
14-15 Used as work registers by the system.

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMRPT macro is as follows:

main diagram

EXSTARTTIME=exstarttime

RESERVED=RESERVED
Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMRPT macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**ARRIVALTIME=arrivaltime**

When MONTKNI=NO is specified, a required input parameter, which contains the arrival time for the work unit in STCK format.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64-bit field.

**BLOCK_TIME=block_time**

When MONTKNI=NO is specified, an optional input parameter, which contains the duration where the work request has been blocked. The format of the field is STCK. A work request is blocked, when the transaction processing is waiting on an external transaction processing or some other event to complete. The default is NO_BLOCK_TIME indicates that no block time is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**CONNTKN=conntkn**

A required input parameter, which is returned by IWM4CON.

If a monitoring token is passed (MONTKNI(YES)), AND this monitoring token was obtained using a connect token on IWM4MCRE, then the latter connect token is expected to be the same as that specified for IWMRPT.

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

**ENDTIME=endtime**

**ENDTIME=CURRENT**

An optional input parameter, which specifies the ending time for the transaction (typically, when the output is sent or available to be sent) in STCK format. The default is CURRENT, which indicates that the current time should be used.

To code: Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

**EWLM_CHCORR=ewlm_chcorr**

When MONTKNI=NO is specified, an optional input parameter, which contains the cross-platform Enterprise Workload Management (EWLM) correlator associated with the work request.
IWMRPT

**Note:** If this correlator is not a valid ARM correlator, return code 8 and reason code IwmRsnCnIdInvalidEWLMCorr is returned to the caller (see return code section below). If the correlator is valid, but cannot be understood by EWLM (no EWLM format), the correlator is silently ignored and the work request will not be reported to EWLM.

The EWLM_CHCORR and EWLM_CHCTKN parameters are mutually exclusive.

The default is NO_EWLM_CHCORR. It indicates that no EWLM correlator is passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

,EWLM_CHCTKN=ewlm_chctkn

,EWLM_CHCTKN=NO_EWLM_CHCTKN

When MONTKNI=NO is specified, an optional input parameter, which contains the cross-platform Enterprise Workload Management (EWLM) correlator token associated with the work request. The EWLM_CHCORR and EWLM_CHCTKN parameters are mutually exclusive. The default is NO_EWLM_CHCTKN. It indicates that no EWLM correlator token is passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

,EWLM_PACORR=ewlm_pacorr

,EWLM_PACORR=NO_EWLM_PACORR

When EWLM_CHCORR=ewlm_chcorr and MONTKNI=NO are specified, an optional input parameter, which contains the cross-platform Enterprise Workload Management (EWLM) parent correlator associated with the work request. The default is NO_EWLM_PACORR. It indicates that no EWLM parent correlator is passed.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a character field.

,EXSTARTTIME=exstarttime

When EXSTARTTIMEP=YES and MONTKNI=NO are specified, a required input parameter, which contains the start execution time in STCK format. Note that this should only be used when IWMMNFTY was NOT used to pass the execution time for this work request.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 64 bit field.

,EXSTARTTIMEP=NO

,EXSTARTTIMEP=YES

When MONTKNI=NO is specified, a required parameter, which indicates whether the start execution time value is passed.

,EXSTARTTIMEP=NO

indicates that the start execution time value is not passed.

,EXSTARTTIMEP=YES

indicates that the start execution time value is passed. Note that this should only be used when IWMMNFTY was NOT used to pass the execution time for this work request.

,MF=S

,MF=(L,list addr)

,MF=(L,list addr,attr)
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

When MONTKNI=YES is specified, a required input parameter, which contains the delay monitoring token

To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit field.

A required parameter, which indicates whether a delay monitoring token is provided.

indicates that a delay monitoring token is provided.

indicates that no delay monitoring token is provided.

When STATUS=NORMAL_LE_VAL is specified, a required input parameter, which contains the threshold value at which the work request is considered to have ended normally.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.
**OK_THRESHOLD=ok_threshold**

When STATUS=NORMAL_GE_VAL is specified, a required input parameter, which contains the threshold value at which the work request is considered to have ended normally.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**PLISTVER=IMPLIED_VERSION**

**PLISTVER=MAX**

**PLISTVER=0**

**PLISTVER=1**

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form; in this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports the following parameters and those from version 0:

  | BLOCK_TIME | EWLM_CHCTKN | WORK_AREA |
  | EWLM_CHCORR | EWLM_PACORR | WORKREQ_STA |

**To code:** Specify one of the following:

- IMPLIED_VERSION
- MAX
- A decimal value of 0, or 1

**PSWKEY=pswkey**

When PSWKEYP=VALUE and TRAXFRPT=NO are specified, a required input parameter, which contains the current PSW key. The low order 4 bits (bits 4-7) contain the key value. The high-order 4 bits (bits 0-3) contain zeros.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8 bit field.

**PSWKEYP=CURRENT**

**PSWKEYP=VALUE**

When TRAXFRPT=NO is specified, an optional parameter, which describes how to determine the current PSW key. The default is PSWKEYP=CURRENT.

**PSWKEYP=CURRENT**

indicates that the current PSW key should be determined.
\texttt{PSWKEYP=VALUE} \\
indicates that the key is being passed explicitly via PSWKEY.

\texttt{RETCODE=retcode} \\
An optional output parameter into which the return code is to be copied from 
GPR 15. \\
To code: Specify the RS-type address of a fullword field, or register (2)-(12).

\texttt{RSNCODE=rsncode} \\
An optional output parameter into which the reason code is to be copied from 
GPR 0. \\
To code: Specify the RS-type address of a fullword field, or register (2)-(12).

\texttt{SERVCLS=servcls} \\
When MONTKNI=NO is specified, a required input parameter, which contains 
the service class token. \\
To code: Specify the RS-type address, or address in register (2)-(12), of a 32 bit 
field.

\texttt{STATUS=NORMAL} \\
\texttt{STATUS=ABNORMAL} \\
\texttt{STATUS=NORMAL\_LE\_VAL} \\
\texttt{STATUS=NORMAL\_GE\_VAL} \\
An optional parameter, which indicates whether the portion of the work 
request associated with the Report call has completed normally or not. The 
default is STATUS=NORMAL.

\texttt{STATUS=NORMAL} \\
indicates that work request execution associated with the Report call has 
completed normally.

\texttt{STATUS=ABNORMAL} \\
indicates that work request execution associated with the Report call has 
completed abnormally.

\texttt{STATUS=NORMAL\_LE\_VAL} \\
indicates that work request execution associated with the Report call has 
completed normally PROVIDED the work completion code is below or at 
(<=) the threshold value given by OK\_THRESHOLD.

\texttt{STATUS=NORMAL\_GE\_VAL} \\
indicates that work request execution associated with the Report call has 
completed normally PROVIDED the work completion code is above or at 
(=>) the threshold value given by OK\_THRESHOLD.

\texttt{SYSEVPL=sysevpl} \\
When TRAXFRPT=YES is specified, a required input parameter, which is the 
fully initialized SYSEVENT parameter list, as mapped by IHATRBPL. \\
To code: Specify the RS-type address, or address in register (2)-(12), of a 
40-character field.

\texttt{TRAXFRPT=NO} \\
\texttt{TRAXFRPT=YES} \\
An optional parameter, which indicated prior to z/OS R3 whether a 
SYSEVENT TRAXFRPT should be issued when the system was in 
compatibility mode. This has become irrelevant. However, for compatibility 
reasons TRAXFRPT can still be set but has no effect. The default is 
TRAXFRPT=NO.
IWMRPT

**TRAXFRPT=NO**
indicates that no SYSEVENT TRAXFRPT should be issued.

**TRAXFRPT=YES**
indicated prior to z/OS R3 that a SYSEVENT TRAXFRPT should be issued when the system was in compatibility mode. This has become irrelevant. However, for compatibility reasons TRAXFRPT can still be set but has no effect.

**WORK_AREA**

When MONTKNI=NO is specified, an optional input parameter, which is used as a work area by WLM when MONTKNI(NO) is specified and either EWLM_CHCORR or EWLM_CHTKN is specified on the IWMRPT invocation (in these cases WORK_AREA is required). The work area must begin on a doubleword boundary and must be accessible in the current PSW key when the macro is invoked. The default is NO_WORK_AREA. It indicates that no work area is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a 256-character field.

**WORK_COMPCD**

When STATUS=NORMAL is specified, an optional input parameter, which contains the completion/return code for the work request execution associated with the Report call. The default is NO_WORK_COMPCD, which indicates that NO completion/return code is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

When STATUS=ABNORMAL is specified, an optional input parameter, which contains the completion/return code for the work request execution associated with the Report call. The default is NO_WORK_COMPCD, which indicates that NO completion/return code is passed.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

When STATUS=NORMAL LE VAL is specified, a required input parameter, which contains the completion/return code for the work request execution associated with the Report call.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

When STATUS=NORMAL GE VAL is specified, a required input parameter, which contains the completion/return code for the work request execution associated with the Report call.

To code: Specify the RS-type address, or address in register (2)-(12), of a fullword field.

**WORKREQ_STA**
An optional input parameter, which contains the completion status code of the work request. Available completion status codes (defined in macro IWMYCON) are the following:

- IwmEwlArmStatusGood(0)
- IwmEwlArmStatusAborted(1)
- IwmEwlArmStatusFailed(2)
- IwmEwlArmStatusUnknown(3)

These codes correspond to status codes in the OpenGroup ARM 4.0 Standard. For further information about the meaning of the status codes refer to the ARM 4.0 Standard at http://www.opengroup.org/management/arm. The default is IWMEWLMARMSTATUSNONE. This indicates that work request completion status should be derived from the passed STATUS parameter value.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a fullword field.

### ABEND codes

None.

### Return codes and reason codes

When the IWMRPT macro returns control to your program:

- GPR 15 (and *retcode*, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and *rsncode*, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the *xxxx* value.

**Table 127. Return and Reason Codes for the IWMRPT Macro**

<table>
<thead>

### Table 127. Return and Reason Codes for the IWMRPT Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0895    | Equate Symbol: IwmRsnCodeEWLMServNotEnabled  
**Meaning:** The service is not enabled because the caller invoked the IWMCONN service with EWLM=NO.  
**Action:** Specify the parameter EWLM_CHCORR, EWLM_PACORR, EWLM_CHCTKN, or WORKREQ_STA only when connected with EWLM=YES. |
| 8           | xxxx0897    | Equate Symbol: IwmRsnCodeTranStatusInvalid  
**Meaning:** Passed work request completion status is not valid.  
**Action:** Check the EWLM ARM interface specification for valid completion status values. |
| C           | —           | Equate Symbol: IwmRetCodeEnvError  
**Meaning:** Environmental error. |
| C           | xxxx0C02    | Equate Symbol: IwmRsnCodeReportingSusp  
**Meaning:** SYSEVENT TRAXFRPT invoked, but reporting is temporarily suspended for one of the following reasons:  
- RMF workload activity reporting is not active  
- There is no installation control specification (IEAICSxx parmlib member with RPGN specified for some subsystem other than TSO) in effect. No data reported but a later reissue could be successful.  
**Action:** Invoke the function when the conditions are alleviated. |
| C           | xxxx0C03    | Equate Symbol: IwmRsnCodeSyseventNoWorkElt  
**Meaning:** SYSEVENT TRAXFRPT invoked, but no work element was available to save the input information.  
**Action:** Invoke the function when the conditions are alleviated. This condition may be due to a common storage shortage condition. |
| C           | xxxx0C05    | Equate Symbol: IwmRsnCodeRptNoWorkElt  
**Meaning:** Report routine invoked, but no work element was available to save the input information.  
**Action:** Invoke the function when the conditions are alleviated. This condition may be due to a common storage shortage condition. |
| C           | xxxx0C06    | Equate Symbol: IwmRsnCodeNoEndTime  
**Meaning:** No end time was supplied to the service and STCK gave a non-zero condition code.  
**Action:** No action required. |
IWMSLIM — Application environment limit service

The IWMSLIM service should be used to tell WLM the total number of server instances which are supported by the application. WLM will ensure that no more server instances will be started in the system.

In addition the caller can define a minimum number of servers which should be made available by WLM regardless of whether work is available to execute or not. If the user defines multiple service classes to give the work of the application different service goals, the caller can define that the minimum number of servers is spread across these service classes to ensure that servers are available for all work executed by the application.

The caller must have previously connected to WLM using the IWMCONN service specifying SERVER_MANAGER=YES and SERVER_TYPE=QUEUE. It is recommended to use the IWMSLIM service directly after IWMCONN. If any server uses this service to define limits, the limits apply for all servers of the application environment regardless of whether other servers use the service or not.

If a server defines new limits during execution, WLM attempts to meet the new limit definitions as soon as possible. If the maximum limit for servers is reduced during execution it is not predictable when WLM is able to meet the new maximum definition. This depends highly on the execution time of the running work requests. Therefore changing the limits during execution should be used very carefully and primarily during times of low application utilization.

**Note:** It is recommended to use the equivalent service, IWM4SLI, which also supports 64-bit addressing. For more information, see “IWM4SLI — Application environment limit service” on page 720.

**Environment**

The requirements for the caller are:

| Minimum authorization: | Problem state. Any PSW key |
| Dispatchable unit mode: | Task |
| Cross memory mode: | PASN=HASN=SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |

**Programming requirements**

1. Make sure no EUT FRRs are established.
2. The macro CVT must be included to use this macro.
3. The macro IWMYCON must be included to use this macro.
4. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
5. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

1. This macro may not be used during task/address space termination.
2. Only a single invocation is allowed to be active for a given address space at any given time.
3. Before using this macro the caller must connect to WLM via IWMCONN
   Server_Manager=YES, Server_Type=Queue.
4. The macro must be used directly after using IWMCONN.

Input register information

Before issuing the IWMSLIM macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.
**Syntax**

The syntax of the IWMSLIM macro is as follows:

```
IWMSLIM
    name
    AE_SERVERMAX=ae_servermax
    AE_SERVERMIN=ae_servermin
    AE_SPREADMIN=YES
    RETCODE=retcode
    RSNCODE=rsncode
    PLISTVER=IMPLIED_VERSION
    PLISTVER=MAX
    PLISTVER=0
    MF=S
    MF=(L,list addr)
    MF=(E,list addr)
```

**Parameters**

The parameters are explained as follows:

- **name**
  An optional symbol, starting in column 1, that is the name on the IWMSLIM macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

- **AE_SERVERMAX=ae_servermax**
  **AE_SERVERMAX=0**
  An optional input parameter, which indicates the architectural limit for the total number of server instances which can run concurrently across the application environment for a given subsystem type and subsystem name.
  This parameter represents a physical limit, such as the maximum number of available connections to a back-end subsystem. WLM will not start more than this number of server instances, even if goals cannot be met because of the limit. This value should be an integral multiple of the PARALLEL_EU value defined on the IWMCONN service. If AE_SERVERMAX is not an even multiple of PARALLEL_EU, WLM will round this value down to the next integral multiple.
  The maximum limit and the number of service classes to execute work requests should be defined carefully. If the number of service classes exceeds the quotient of AE_SERVERMAX divided by PARALLEL_EU WLM cannot start enough server address spaces to execute the work requests for all service classes. The default is 0, indicating that no maximum limit has been specified.

- **To code:** Specify the RS-type address of a halfword field.

- **AE_SERVERMIN=ae_servermin**
An optional input parameter, which indicates the minimum number of servers which should be up and running at all times.

This parameter can be used to tell WLM that a certain amount of server tasks should always be kept available to select work. This value should be an integral multiple of the PARALLEL_EU value defined on IWMCONN service. If AE_SERVERMIN is not an even multiple of PARALLEL_EU, WLM will round this value down to the next integral multiple. The default is 0, indicating that no limit has been specified.

To code: Specify the RS-type address of a halfword field.

When AE_SERVERMIN=ae_servermin is specified, an optional parameter, which indicates whether WLM will distribute the minimum number of servers as evenly as possible across the service classes being used to process the work requests. The default is AE_SPREADMIN=NO.

The server tasks specified in AE_SERVERMIN will be distributed to service classes as needed in order to meet goals.

The server tasks specified in AE_SERVERMIN will be distributed as evenly as possible to all service classes being used to execute work requests.

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.
IWMSLIM

,COMPLETE
   Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
   An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and
with the same value on all of the macro forms. The values are:
   • IMPLIED_VERSION, which is the lowest version that allows all parameters
specified on the request to be processed. If you omit the PLISTVER
parameter, IMPLIED_VERSION is the default.
   • MAX, if you want the parameter list to be the largest size currently possible.
This size might grow from release to release and affect the amount of
storage that your program needs.
   • 0, if you use the currently available parameters.
To code: Specify one of the following:
   • IMPLIED_VERSION
   • MAX
   • A decimal value of 0

,RETCODE=retcode
   An optional output parameter into which the return code is to be copied from
GPR 15.
To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
   An optional output parameter into which the reason code is to be copied from
GPR 0.
To code: Specify the RS-type address of a fullword field, or register (2)-(12).

ABEND codes

None.

Return codes and reason codes

When the IWMSLIM macro returns control to your program:
   • GPR 15 (and retcode, when you code RETCODE) contains a return code.
   • When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code
   RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the
equate symbol associated with each reason code. IBM support personnel may
request the entire reason code, including the xxxx value.
### Table 128. Return and Reason Codes for the IWMSLIM Macro

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 0           | —           | Equate Symbol: IwmRetCodeOk  
Meaning: Successful completion.  
Action: None required. |
| 8           | —           | Equate Symbol: IwmRetCodeInvocError  
Meaning: Invalid invocation environment or parameters. |
| 8           | xxxx0801    | Equate Symbol: IwmRsnCodeSrbMode  
Meaning: Caller is in SRB mode.  
Action: Avoid requesting this function while in SRB mode. |
| 8           | xxxx0803    | Equate Symbol: IwmRsnCodeDisabled  
Meaning: Caller is disabled.  
Action: Avoid requesting this function while disabled. |
| 8           | xxxx0804    | Equate Symbol: IwmRsnCodeLocked  
Meaning: Caller is locked.  
Action: Avoid requesting this function while locked. |
| 8           | xxxx080B    | Equate Symbol: IwmRsnCodeBadPl  
Meaning: Error accessing parameter list.  
Action: Check for possible storage overlay. Also check if you call this macro in 64-bit address mode. Refer to the description of reason code xxxx089E for further information. |
| 8           | xxxx0824    | Equate Symbol: IwmRsnCodeAmode24  
Meaning: Caller invoked service but was in 24 bit addressing mode.  
Action: Request this function only when you are in 31 bit addressing mode. |
| 8           | xxxx0825    | Equate Symbol: IwmRsnCodeAscModeNotPrimary  
Meaning: Caller invoked service but was not in primary ASC mode.  
Action: Avoid requesting this function in this environment. |
| 8           | xxxx0828    | Equate Symbol: IwmRsnCodeBadVersion  
Meaning: Version number in parameter list is not valid.  
Action: Check for possible storage overlay of the parameter list. |
| 8           | xxxx0840    | Equate Symbol: IwmRsnCodeServiceNotEnabled  
Meaning: Caller’s space connection is not enabled for this service  
Action: Make sure that SERVER_MANAGER=YES and SERVER_TYPE=QUEUE is specified on the IWMCONN request to enable this service. |

### Example

To specify application limits to WLM.

```plaintext
IWMCNN WORK_MANAGER=YES,
SERVER_MANAGER=YES,
PARALLEL_EU=EUNITS,
SERVER_TYPE=QUEUE,
CONNTKN=CTKN,
CONNTKNKEY=PSWKEY,
RETCODE=RC,
RSNCODE=RSN

IWMSLIM AE_SERVERMAX=MAXSRVS,
AE_SERVERMIN=MINSRVS,
RETCODE=RC,
RSNCODE=RSN

* Storage areas
* EUNITS DS F   Number of Tasks which will be started per address space.
* MAXSRVS DS H  Maximum Number of Servers supported by the application.
* MINSRVS DS H  Minimum number of servers which should be up and running all time
* CTKN DS FL4   Connect Token
RC   DS F      Return code
RSN  DS F      Reason code
```

---

IWMSLIM
IWMSSEL — Select a request from a caller’s work manager queue

The IWMSSEL service selects the next work request from the queue associated with the caller’s application environment. The caller must have previously connected to WLM using the IWMCONN service specifying SERVER_MANAGER=YES.

If there are no queued work requests waiting for selection the calling task will be suspended, pending arrival of work to do. The caller cannot rely upon asynchronous exits receiving control while the task is suspended.

After a work request is selected, the caller uses the IWMSTBGN and IWMSTEND services to indicate the start and end of processing of the request.

Note: It is recommended to use the equivalent service, IWM4SSL, which also supports 64-bit addressing. For more information, see “IWM4SSL — Select a request from a caller’s work manager queue” on page 739.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state. Any PSW key</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

None.
**IWMSEL**

**Input register information**

Before issuing the IWMSEL macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMSEL macro is as follows:

```
IWMSSEL -USERDATA=userdata -WLMEUTKN=wlmeutkn -SERVER_TOKEN=server_token -REGION_TOKEN=region_token -RETCODE=retcode -RSNCODE=rsncode -PLISTVER=IMPLIED_VERSION -PLISTVER=MAX -PLISTVER=0 -PLISTVER=1
```
Parameters

The parameters are explained as follows:

name
An optional symbol, starting in column 1, that is the name on the IWMSSEL macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

, MF=S
, MF=(L, list addr)
, MF=(L, list addr, attr)
, MF=(L, list addr, 0D)
, MF=(E, list addr)
, MF=(E, list addr, COMPLETE)
An optional input parameter that specifies the macro form.
Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.
Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.
Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

,list addr
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

,attr
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

, COMPLETE
Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

, PLISTVER=IMPLIED VERSION
, PLISTVER=MAX
, PLISTVER=0
, PLISTVER=1
An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports the following parameter and those from version 0:

  **SERVER_TOKEN**

  To code: Specify one of the following:

  - IMPLIED_VERSION
  - MAX
  - A decimal value of 0 or 1

  **REGION_TOKEN**=region_token

  An optional output parameter, which contains a region token. A queueing manager can use the region token to queue work requests to a specific server region. These work requests are considered to belong to a set of work requests all needing access to same status information which exists only in the virtual storage of the server region. They are selected using the IWMSSEL macro. It is assumed that the application uses the service IWMTAFF to tell WLM when the temporary affinity to the defined server region begins and ends.

  To code: Specify the RS-type address of a fullword field, or register (2)-(12).

  **RETCODE**=retcode

  An optional output parameter into which the return code is to be copied from GPR 15.

  To code: Specify the RS-type address of a fullword field, or register (2)-(12).

  **RSNCODE**=rsncode

  An optional output parameter into which the reason code is to be copied from GPR 0.

  To code: Specify the RS-type address of a

  **SERVER_TOKEN**=server_token

  An optional output parameter, which contains a server token. A queueing manager can use the server token to queue secondary work requests to this server task. Secondary work requests are considered to be extensions of the work request selected by IWMSSEL. They are selected using the IWMSSEM macro. See the IWMSSEM macro for more information.

  To code: Specify the RS-type address, or address in register (2)-(12), of a 32-character field.
**USERDATA=userdata**

A required output parameter, which contains the user data previously passed to WLM via IWMQINS.

**To code:** Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

**,WLMEUTKN=wlmeutkn**

A required output parameter, which will receive the execution unit token. This token must be passed on subsequent IWMSBGN and IWMSSTEND requests.

**To code:** Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

**ABEND codes**

None.

**Return codes and reason codes**

When the IWMSSEL macro returns control to your program:

- GPR 15 (and `retnode`, when you code `RETCODE`) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and `rsncode`, when you code `RSNCODE`) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the `xxxx` value.

<table>

Table 129. Return and Reason Codes for the IWMSSEL Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0854    | Equate Symbol: IwmRsnCodeTooManySelect  
Meaning: The caller is attempting to select more work units than it has tasks to execute the work.  
Action: Wait until an execution task has issued IWMSSTEND before attempting to select more work units. |
| 8           | xxxx0864    | Equate Symbol: IwmRsnCodeSecondaryWorkExists  
Meaning: There are secondary work requests queued to this server task. The caller was expected to process them using IWMSSEM before calling IWMSSEL.  
Action: Select all secondary work requests before issuing IWMSSEL. |
| 8           | xxxx089E    | Equate Symbol: IwmRsnCodeServiceAModeMismatch  
Meaning: The caller is in 64-bit address mode and tried to invoke a service macro that is only enabled for a 31-bit environment.  
Action: Use the 64-bit enabled service macro (IWMSSSL) or change the address mode of the caller to 31-bit. |
| C           | —           | Equate Symbol: IwmRetCodeEnvError  
Meaning: Environmental error. |
| C           | xxxx0C01    | Equate Symbol: IwmRsnCodeNoStg  
Meaning: Storage is not available for the request.  
Action: Caller must disconnect by invoking the IWMDISC macro. |
| C           | xxxx0C14    | Equate Symbol: IwmRsnCodeNoWorkShutDown  
Meaning: No work selected. Caller is to shutdown.  
Action: Caller must disconnect by invoking the IWMDISC macro. |
| C           | xxxx0C3B    | Equate Symbol: IwmRsnCodeStopTask  
Meaning: WLM decided to stop the server instance.  
Action: Calling task must shutdown, but server address space must remain active. |
| 10          | —           | Equate Symbol: IwmRetCodeCompError  
Meaning: Component error.  
Action: Contact your system programmer. |

Example

To select a work request from the WLM queue manager queues:

IWMSSEL USERDATA=USERDATA, X  
WLMEUTKN=WLMEUTKN, RETCODE=RC, RSNCODE=RSN

* Storage areas
* USERDATA DS CL16 Contains the user-defined data that was passed to IWMSQINS  
WLMEUTKN DS CL8 Work unit token that must be
**IWMSEL**

Passed to IWMSTBGN and IWMSTEND

</table>

1054  z/OS V2R2 MVS Programming: Workload Management Services
IWMSSEM — WLM server select secondary service

The IWMSSEM service selects the next secondary work request from the queue associated with the caller's server task.

If there are no queued secondary work requests waiting for selection the calling task will be suspended, pending arrival of work to do. The caller cannot rely upon asynchronous exits receiving control while the task is suspended.

Secondary work requests are considered to be extensions of an original work request selected using IWMSSEL. The caller must invoke WLM services in the following sequence:

- The caller invokes the IWMSSEL macro to select an initial work request. IWMSSEL returns a token identifying the server task. The caller is responsible for passing the server token to the queueing manager so that it can insert secondary work requests.
- The caller invokes the IWMSTBGN macro to establish an environment for processing the work request selected using IWMSSEL. This environment also covers all secondary work requests.
- The caller invokes the IWMSSEM macro to select each secondary work request. The queueing manager is responsible for indicating the last secondary work request so that the server task knows when not to try to select another one.
- After the last secondary work request has been processed, the caller invokes the IWMSTEND macro to remove the environment created by IWMSTBGN.
- The caller invokes IWMSSEL to select a new primary work request, and repeats the above flow.

In the above flow, IWMSSEL, IWMSTBGN, IWMSSEM, and IWMSTEND must be invoked from the same task.

Note: It is recommended to use the equivalent service, IWM4SSM, which also supports 64-bit addressing. For more information, see “IWM4SSM — WLM server select secondary service” on page 746.

Environment

The requirements for the caller are:

| Minimum authorization: | Problem state. Any PSW key |
| Dispatchable unit mode: | Task |
| Cross memory mode: | PASN=HASN=SASN |
| AMODE: | 31-bit |
| ASC mode: | Primary |
| Interrupt status: | Enabled for I/O and external interrupts |
| Locks: | No locks may be held. |
| Control parameters: | Control parameters must be in the primary address space. |
Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNICODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

None.

Input register information

Before issuing the IWMSSEM macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.
Syntax

The syntax of the IWMSSEM macro is as follows:

```
name IWM SEM USERDATA=userdata RETCODE=retcode RSN CODE=rsncode
```

```
,MF=S,
,MF=(L,list addr,attr),
,MF=(L,list addr,0D),
,MF=(E,list addr),
,MF=(E,list addr,COMPLETE)
```

Parameters

The parameters are explained as follows:

**name**

An optional symbol, starting in column 1, that is the name on the IWMSSEM macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

```
,MF=S,
,MF=(L,list addr),
,MF=(L,list addr,attr),
,MF=(L,list addr,0D),
,MF=(E,list addr),
,MF=(E,list addr,COMPLETE)
```

An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**list addr**

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code *attr*, the system provides a value of 0D.
,COMPLETE
   Specifies that the system is to check for required parameters and supply
defaults for omitted optional parameters.

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0
   An optional input parameter that specifies the version of the macro. PLISTVER
determines which parameter list the system generates. PLISTVER is an
optional input parameter on all forms of the macro, including the list form.
When using PLISTVER, specify it on all macro forms used for a request and
with the same value on all of the macro forms. The values are:
   • IMPLIED_VERSION, which is the lowest version that allows all parameters
     specified on the request to be processed. If you omit the PLISTVER
     parameter, IMPLIED_VERSION is the default.
   • MAX, if you want the parameter list to be the largest size currently possible.
     This size might grow from release to release and affect the amount of
     storage that your program needs.
     If you can tolerate the size change, IBM recommends that you always
     specify PLISTVER=MAX on the list form of the macro. Specifying MAX
     ensures that the list-form parameter list is always long enough to hold all
     the parameters you might specify on the execute form, when both are
     assembled with the same level of the system. In this way, MAX ensures that
     the parameter list does not overwrite nearby storage.
   • 0, if you use the currently available parameters.

   To code: Specify one of the following:
   • IMPLIED_VERSION
   • MAX
   • A decimal value of 0

,RETCODE=retcode
   An optional output parameter into which the return code is to be copied from
   GPR 15.

   To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
   An optional output parameter into which the reason code is to be copied from
   GPR 0.

   To code: Specify the RS-type address of a fullword field, or register (2)-(12).

USERDATA=userdata
   A required output parameter, which contains the user data previously passed
to WLM via IWMQINS.

   To code: Specify the RS-type address, or address in register (2)-(12), of a
   16-character field.

ABEND codes

None.

Return codes and reason codes

When the IWMSSEM macro returns control to your program:
   • GPR 15 (and retcode, when you code RETCODE) contains a return code.
When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

**Table 130. Return and Reason Codes for the IWMSSEM Macro**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 0           | —           | Equate Symbol: IwmRetCodeOk  
Meaning: Successful completion.  
Action: None required. |
| 8           | —           | Equate Symbol: IwmRetCodeInvocError  
Meaning: Invalid invocation environment or parameters. |
| 8           | xxxx0801    | Equate Symbol: IwmRsnCodeSrbMode  
Meaning: Caller is in SRB mode.  
Action: Avoid requesting this function while in SRB mode. |
| 8           | xxxx0803    | Equate Symbol: IwmRsnCodeDisabled  
Meaning: Caller is disabled.  
Action: Avoid requesting this function while disabled. |

  **Action**: Invoke the IWMSSEL macro before invoking this macro. |
| 8           | xxxx0863    | **Equate Symbol**: IwmRsnCodeNoExecEnv  
  **Meaning**: The caller has not established an execution environment using IWMSTBGN.  
  **Action**: Invoke the IWMSTBGN macro before invoking this macro. |
| 8           | xxxx089E    | **Equate Symbol**: IwmRsnCodeServiceAModeMismatch  
  **Meaning**: The caller is in 64-bit address mode and tried to invoke a service macro that is only enabled for a 31-bit environment.  
  **Action**: Use the 64-bit enabled service macro (IWM4SSM) or change the address mode of the caller to 31-bit. |
| C           | —           | **Equate Symbol**: IwmRetCodeEnvError  
  **Meaning**: Environmental error. |
| C           | xxxx0C14    | **Equate Symbol**: IwmRsnCodeNoWorkShutDown  
  **Meaning**: No work selected. Caller is to shutdown.  
  **Action**: Caller must disconnect by invoking the IW DISC macro. |
| 10          | —           | **Equate Symbol**: IwmRetCodeCompError  
  **Meaning**: Component error.  
  **Action**: Contact your system programmer. |

### Example

To select a secondary work request from the WLM queue manager queues:
IWMSSEM

IWMSSEM USERDATA=USERDATA,RETCODE=RC,RSNCODE=RSN

* Storage areas
* USERDATA DS CL16 Contains the user-defined data that was passed to IWMSQINS
RC DS F Return code
RSN DS F Reason code
IWMSTBGN — Begin a request from a caller's work manager queue

IWMSTBGN establishes the environment to process a work request that was previously selected using IWMSSEL. The caller must invoke IWMSTBGN from the task in the server address space that will process the request. IWMSTBGN establishes a business unit-of-work relationship by joining the caller's task to the enclave associated with the request. IWMSTBGN creates a security environment if there is a user ID associated with the request previously selected.

Use IWMSTBGN together with IWMSTEND to begin and end the processing of a work request. A task can process only one work request at a time.

Note that a task may only join an enclave if it is not already part of an enclave. In particular, a subtask which inherited the enclave attribute from its mother task (which may happen either as a result of the mother task issuing IWMEJOIN or IWMSTBGN) is not allowed to use IWMEJOIN to explicitly join an enclave. This restriction is independent of whether the specified enclave is the same enclave as it is in, or a different enclave from the one it is in. Such a subtask which inherited the enclave attribute is also not allowed to use IWMELEAV to explicitly leave the enclave. The subtask would only leave the enclave upon its own (task) termination or when the enclave is deleted (IWMEDELE). Also, a task which successfully establishes a Begin environment (IWMSTBGN) may not invoke Enclave Join, nor is the task allowed to use Enclave Leave while this Begin environment exists.

Note: It is recommended to use the equivalent service, IWM4STBG, which also supports 64-bit addressing. For more information, see “IWM4STBG — WLM begin server transaction service” on page 752.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state. Any PSW key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>PASN=HASN=SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded.
from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

The caller cannot have an EUT FRR established.

**Input register information**

Before issuing the IWMSTBGN macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

**Output register information**

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work register by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

**Performance implications**

None.

**Syntax**

The syntax of the IWMSTBGN macro is as follows:

```
IWMSTBGN(name=wlmeutkn, ETOKEN=etoken, RETCODE=retcode)
```
Parameters

The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMSTBGN macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**,ETOKEN=etoken**
An optional output parameter, which will receive the enclave token.

To code: Specify the RS-type address, or register (2)-(12), of an 8-character field.

**,MF=S**
**,MF=(L,list addr)**
**,MF=(L,list addr,attr)**
**,MF=(L,list addr,0D)**
**,MF=(E,list addr)**
**,MF=(E,list addr,COMPLETE)**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**,list addr**
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**,attr**
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.
\texttt{完整的}

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\texttt{PLISTVER=IMPLIED\_VERSION}
\texttt{PLISTVER=MAX}
\texttt{PLISTVER=0}
\texttt{PLISTVER=1}

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- **IMPLIED\_VERSION**, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED\_VERSION is the default.
- **MAX**, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- **0**, which supports all parameters except those specifically referenced in higher versions.
- **1**, which supports the following parameter and those from version 0:

  \texttt{ETOKEN}

  \textbf{To code:} Specify one of the following:
  - IMPLIED\_VERSION
  - MAX
  - A decimal value of 0

\texttt{RETCODE=\textit{retcode}}

An optional output parameter into which the return code is to be copied from GPR 15.

\textbf{To code:} Specify the RS-type address of a fullword field, or register (2)-(12).

\texttt{RSNCODE=\textit{rsncode}}

An optional output parameter into which the reason code is to be copied from GPR 0.

\textbf{To code:} Specify the RS-type address of a fullword field, or register (2)-(12).

\texttt{WLMEUTKN=\textit{wlmeutkn}}

A required input parameter, execution unit token that was returned by a prior invocation of IWMSSEL.

\textbf{To code:} Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

\textbf{ABEND codes}

None.
Return codes and reason codes

When the IWMSTBGN macro returns control to your program:
- GPR 15 (and retcode, if you coded RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

Table 131. Return and Reason Codes for the IWMSTBGN Macro

| 10          | —           | **Equate Symbol**: IwmRetCodeCompError  
**Meaning**: Component error.  
**Action**: Contact your system programmer. |
Example

Suppose a work request was selected using IWMSSEL and the execution unit token returned by IWMSSEL is WLMEUTKN.

To establish the environment to process the work request:

```
IWMSTBGN WLMEUTKN=WLMEUTKN,RETCODE=RC,RSN榕子=RSN
```

* Storage areas
* WLMEUTKN DS CL8 Contains the execution unit token that was returned by IWMSSEL
  * RC   DS F Return code
  * RSN  DS F Reason code
IWMSTEND — End a request from a caller's work manager queue

IWMSTEND removes the environment which was previously established using IWMSTBGN to process a work request. The caller must invoke IWMSTEND from the same task that invoked IWMSTBGN. IWMSTEND removes the caller's task from the enclave associated with the request. IWMSTEND deletes the security environment if one was previously established by IWMSTBGN.

Note: It is recommended to use the equivalent service, IWM4STEN, which also supports 64-bit addressing. For more information, see “IWM4STEN — End a request from a caller's work manager queue” on page 760.

Environment

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum authorization</td>
<td>Problem state. Any PSW key</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>PASN=HASN=SASN</td>
</tr>
<tr>
<td>AMODE</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

Programming requirements

1. The macro CVT must be included to use this macro.
2. The macro IWMYCON must be included to use this macro.
3. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
4. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWMRSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

Restrictions

The caller cannot have an EUT FRR established.

Input register information

Before issuing the IWMSTEND macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:
IWMSTEND

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2-13</td>
</tr>
<tr>
<td>14</td>
</tr>
<tr>
<td>15</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

Register

<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
</tr>
<tr>
<td>2-13</td>
</tr>
<tr>
<td>14-15</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMSTEND macro is as follows:

```
name IWMSTENDWLMEUTKN=wlmeutkn,RETCODE=retcode,RSNCODE=rsncode

,PLISTVER=IMPLIED_VERSION
,PLISTVER=MAX
,PLISTVER=0

,LISTVER=IMPLIED_VERSION
,MF=S
,MF=(L,list addr,0D)
,MF=(L,list addr,attr)
,MF=(L,list addr,COMPLETE)
```

Parameters

The parameters are explained as follows:

- **name**: An optional symbol, starting in column 1, that is the name on the IWMSTEND macro invocation. The name must conform to the rules for an ordinary assembler language symbol.
- **,MF=S**
- **,MF=(L,list addr)**
- **,MF=(L,list addr,attr)**
- **,MF=(L,list addr,0D)**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- IMPLIED_VERSION, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED_VERSION is the default.
- MAX, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.
  
  If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.
- 0, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED_VERSION
MAX
A decimal value of 0

,RETCODE=retcode
An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

,RSNCODE=rsncode
An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

WLMEUTKN=wlmeutkn
A required input parameter, execution unit token that was specified on the prior invocation of IWMSTBGN.

To code: Specify the RS-type address, or address in register (2)-(12), of an 8-character field.

ABEND codes
None.

Return codes and reason codes
When the IWMSTEND macro returns control to your program:

• GPR 15 (and retcode, if you coded RETCODE) contains a return code.
• When the value in GPR 15 is not zero, GPR 0 (and rsncode, if you coded RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>

| 8           | —           | **Equate Symbol**: IwmRetCodeInvocError  
  **Meaning**: Invalid invocation environment or parameters. |
| 8           | xxxx0801    | **Equate Symbol**: IwmRsnCodeSrbMode  
  **Meaning**: The caller is in SRB mode.  
  **Action**: Avoid requesting this function while in SRB mode. |
| 8           | xxxx0803    | **Equate Symbol**: IwmRsnCodeDisabled  
  **Meaning**: Caller is disabled.  
  **Action**: Avoid requesting this function while disabled. |
| 8           | xxxx0804    | **Equate Symbol**: IwmRsnCodeLocked  
  **Meaning**: The caller is locked.  
  **Action**: Avoid requesting this function while locked. |
| 8           | xxxx080B    | **Equate Symbol**: IwmRsnCodeBadPl  
  **Meaning**: Error accessing parameter list.  
  **Action**: Check for possible storage overlay. Also check if you call this macro in 64-bit address mode. Refer to the description of reason code xxxx089E for further information. |
| 8           | xxxx0810    | **Equate Symbol**: IwmRsnCodeEutFrr  
  **Meaning**: The caller has EUT FRR established.  
  **Action**: Avoid requesting this function with an EUT FRR set. |
| 8           | xxxx0823    | **Equate Symbol**: IwmRsnCodeDatoff  
  **Meaning**: The caller invoked the service while DATOFF.  
  **Action**: Avoid requesting this function in this environment. |
| 8           | xxxx0824    | **Equate Symbol**: IwmRsnCodeAmode24  
  **Meaning**: The caller invoked service but was in 24-bit addressing mode.  
  **Action**: Request this function only when you are in 31-bit addressing mode. |
| 8           | xxxx0825    | **Equate Symbol**: IwmRsnCodeAscModeNotPrimary  
  **Meaning**: The caller invoked the service but was not DAT on Primary ASC mode.  
  **Action**: Avoid requesting this function in this environment. |
### IWMSTEND

**Table 132. Return and Reason Codes for the IWMSTEND Macro (continued)**

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0828    | Equate Symbol: IwmRsnCodeBadVersion  
Meaning: The Version number in the parameter list is not valid or version length field is not valid.  
Action: Check for possible storage overlay of the parameter list. |
| 8           | xxxx0841    | Equate Symbol: IwmRsnCodeXmemMode  
Meaning: Caller invoked service but was in cross-memory mode.  
Action: Avoid requesting this function in cross-memory mode. |
| 8           | xxxx084F    | Equate Symbol: IwmRsnCodeWrongExecToken  
Meaning: Current dispatchable work unit is not associated with the input execution unit token.  
Action: Check for possible storage overlay of the execution unit token. |
| 8           | xxxx0859    | Equate Symbol: IwmRsnCodeEnclaveSubTaskExists  
Meaning: The current dispatchable work unit has residual subtasks propagated to the enclave which are still associated with the enclave.  
Action: Avoid requesting this function in this environment. |
| 8           | xxxx089E    | Equate Symbol: IwmRsnCodeServiceAModeMismatch  
Meaning: The caller is in 64-bit address mode and tried to invoke a service macro that is only enabled for a 31-bit environment.  
Action: Use the 64-bit enabled service macro (IWM4STEN) or change the address mode of the caller to 31-bit. |
| 10          | —           | Equate Symbol: IwmRetCodeCompError  
Meaning: Component error.  
Action: Contact your system programmer. |

**Example**

To remove the environment which was previously established using IWMSTBGN:

```plaintext
IWMSTEND WLMEUTKN=WLMEUTKN,RETCODE=RC,RSNCODE=RSN

* Storage areas  
* WLMEUTKN DS CL8 Contains the execution unit token that was specified on the prior invocation of IWMSTBGN  
* RC DS F Return code  
* RSN DS F Reason code
```

Appendix E. WLM services supporting 31-bit addressing only 1075
**IWMTAFF** — WLM temporal affinity service

The IWMTAFF service should be used to inform WLM when a temporal affinity for a specific server region starts and when it ends. WLM will ensure that server regions will not be terminated as long as temporal affinities exist.

The caller must have previously connected to WLM using the IWMCONN as server or as queue manager.

**Note:** It is recommended to use the equivalent service, IWM4TAF, which also supports 64-bit addressing. For more information, see "IWM4TAF — WLM temporal affinity service" on page 766.

**Environment**

The requirements for the caller are:

<table>
<thead>
<tr>
<th>Minimum authorization:</th>
<th>Problem state. Any PSW key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatchable unit mode:</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode:</td>
<td>PASN=HASN=SASN</td>
</tr>
<tr>
<td>AMODE:</td>
<td>31-bit</td>
</tr>
<tr>
<td>ASC mode:</td>
<td>Primary</td>
</tr>
<tr>
<td>Interrupt status:</td>
<td>Enabled for I/O and external interrupts</td>
</tr>
<tr>
<td>Locks:</td>
<td>No locks may be held.</td>
</tr>
<tr>
<td>Control parameters:</td>
<td>Control parameters must be in the primary address space.</td>
</tr>
</tbody>
</table>

**Programming requirements**

1. Make sure no EUT FRRs are established.
2. The macro CVT must be included to use this macro.
3. The macro IWMYCON must be included to use this macro.
4. The macro IWMPB must be in the library concatenation, since it is included by IWMYCON.
5. Note that the high-order halfword of register 0, and the reason code variable when specified, may be non-zero and represents diagnostic data which is NOT part of the external interface. The high-order halfword should thus be excluded from comparison with the reason code values described above. The constant, IWRNSNCODE_MASK_CONST defined in IWMYCON, may be used for this purpose.

**Restrictions**

1. This macro may not be used during task/address space termination.
2. Before using this macro the caller must connect to WLM via IWMCONN
   Server_Manager=YES, Server_Type=Queue or IWMCONN
   Queue_Manager=YES.
Input register information

Before issuing the IWMTAFF macro, the caller does not have to place any information into any register unless using it in register notation for a particular parameter, or using it as a base register.

Output register information

When control returns to the caller, the GPRs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reason code if GR15 return code is non-zero</td>
</tr>
<tr>
<td>1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>15</td>
<td>Return code</td>
</tr>
</tbody>
</table>

When control returns to the caller, the ARs contain:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Used as work registers by the system</td>
</tr>
<tr>
<td>2-13</td>
<td>Unchanged</td>
</tr>
<tr>
<td>14-15</td>
<td>Used as work registers by the system</td>
</tr>
</tbody>
</table>

Some callers depend on register contents remaining the same before and after issuing a service. If the system changes the contents of registers on which the caller depends, the caller must save them before issuing the service, and restore them after the system returns control.

Performance implications

None.

Syntax

The syntax of the IWMTAFF macro is as follows:

```plaintext
IWMTAFF
```

```
name
```

```
AFFINITY=YES
```

```
REGION_TOKEN=0
```

```
,REGION_TOKEN=region_token
```

```
,RETCODE=retcode
```

```
,RSNCODE=rsncode
```

```
,PLISTVER=IMPLIED_VERSION
```

```
,PLISTVER=MAX
```

```
,PLISTVER=0
```
The parameters are explained as follows:

**name**
An optional symbol, starting in column 1, that is the name on the IWMTAFF macro invocation. The name must conform to the rules for an ordinary assembler language symbol.

**AFFINITY=**

**AFFINITY=**

**YES**
A new temporal affinity for the server region begins. WLM will ensure that the server regions is not terminated before all temporal affinity have ended.

**AFFINITY=**

**NO**
A temporal affinity for the server region has ended. WLM will start to terminate server regions if all temporal affinities have ended.

**MF=**

**S**
An optional input parameter that specifies the macro form.

Use MF=S to specify the standard form of the macro, which builds an inline parameter list and generates the macro invocation to transfer control to the service. MF=S is the default.

Use MF=L to specify the list form of the macro. Use the list form together with the execute form of the macro for applications that require reentrant code. The list form defines an area of storage that the execute form uses to store the parameters. Only the PLISTVER parameter may be coded with the list form of the macro.

Use MF=E to specify the execute form of the macro. Use the execute form together with the list form of the macro for applications that require reentrant code. The execute form of the macro stores the parameters into the storage area defined by the list form, and generates the macro invocation to transfer control to the service.

**list addr**
The name of a storage area to contain the parameters. For MF=S and MF=E, this can be an RS-type address or an address in register (1)-(12).

**attr**
An optional 1- to 60-character input string that you use to force boundary alignment of the parameter list. Use a value of 0F to force the parameter
list to a word boundary, or 0D to force the parameter list to a doubleword boundary. If you do not code attr, the system provides a value of 0D.

\textbf{\texttt{\textbackslash ,COMPLETE}}

Specifies that the system is to check for required parameters and supply defaults for omitted optional parameters.

\textbf{\texttt{\textbackslash ,PLISTVER=IMPLIED\_VERSION, PLISTVER=MAX, PLISTVER=0}}

An optional input parameter that specifies the version of the macro. PLISTVER determines which parameter list the system generates. PLISTVER is an optional input parameter on all forms of the macro, including the list form. When using PLISTVER, specify it on all macro forms used for a request and with the same value on all of the macro forms. The values are:

- \textbf{IMPLIED\_VERSION}, which is the lowest version that allows all parameters specified on the request to be processed. If you omit the PLISTVER parameter, IMPLIED\_VERSION is the default.
- \textbf{MAX}, if you want the parameter list to be the largest size currently possible. This size might grow from release to release and affect the amount of storage that your program needs.

If you can tolerate the size change, IBM recommends that you always specify PLISTVER=MAX on the list form of the macro. Specifying MAX ensures that the list-form parameter list is always long enough to hold all the parameters you might specify on the execute form, when both are assembled with the same level of the system. In this way, MAX ensures that the parameter list does not overwrite nearby storage.

- 0, if you use the currently available parameters.

To code: Specify one of the following:

- IMPLIED\_VERSION
- MAX
- A decimal value of 0

\textbf{\texttt{\textbackslash ,REGION\_TOKEN=region\_token, REGION\_TOKEN=0}}

An optional input parameter, which contains the region token. The region token is not required if the macro is invoked from the server region for which the temporal affinity should be started or stopped. The region token must be used if the service is used from the queueing manager. The region token is returned by the IWMS4CON and IWMSSEL macro.

The caller must be supervisor state or have PSW key mask 0-7 authority to use this service with the REGION\_TOKEN parameter.

Coding REGION\_TOKEN=0 is equivalent to omitting the REGION\_TOKEN keyword. The default is 0.

To code: Specify the RS-type address, or address in register (2)-(12), of a 16-character field.

\textbf{\texttt{\textbackslash ,RETCODE=retcode}}

An optional output parameter into which the return code is to be copied from GPR 15.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).
IWMTAFF

\( \text{RSNCODE}=rsncode \)

An optional output parameter into which the reason code is to be copied from GPR 0.

To code: Specify the RS-type address of a fullword field, or register (2)-(12).

ABEND codes

None.

Return codes and reason codes

When the IWMTAFF macro returns control to your program:

- GPR 15 (and retcode, when you code RETCODE) contains a return code.
- When the value in GPR 15 is not zero, GPR 0 (and rsncode, when you code RSNCODE) contains reason code.

The following table identifies the hexadecimal return and reason codes and the equate symbol associated with each reason code. IBM support personnel may request the entire reason code, including the xxxx value.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol</th>
<th>Meaning</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeOk</td>
<td>Meaning: Successful completion.</td>
<td>Action: None required.</td>
</tr>
<tr>
<td>4</td>
<td>—</td>
<td>Equate Symbol: IwmRetCodeWarning</td>
<td>Meaning: Successful completion, unusual conditions noted.</td>
<td>Action: None required.</td>
</tr>
<tr>
<td>4</td>
<td>xxxx0439</td>
<td>Equate Symbol: IwmRsnCodeNoAffinityFound</td>
<td>Meaning: The service has been invoked to tell WLM that an existing server region affinity has been terminated but WLM has no affinity defined for this server region.</td>
<td>Action: If region token was not specified make sure to use the service properly at the beginning and end of each affinity. If the region token has been defined make sure that it is used for the correct server region.</td>
</tr>
<tr>

<td>Meaning: Caller is in SRB mode.</td>
<td>Action: Avoid requesting this function while in SRB mode.</td>
</tr>
</tbody>
</table>
### Table 133. Return and Reason Codes for the IWMTAFF Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx0803      | **Equate Symbol:** IwmRsnCodeDisabled  
**Meaning:** Caller is disabled.  
**Action:** Avoid requesting this function while disabled. |
| 8           | xxxx0804      | **Equate Symbol:** IwmRsnCodeLocked  
**Meaning:** Caller is locked.  
**Action:** Avoid requesting this function while locked. |
| 8           | xxxx080B      | **Equate Symbol:** IwmRsnCodeBadPl  
**Meaning:** Error accessing parameter list.  
**Action:** Check for possible storage overlay. Also check if you call this macro in 64-bit address mode. Refer to the description of reason code xxxx089E for further information. |
| 8           | xxxx0824      | **Equate Symbol:** IwmRsnCodeAmode24  
**Meaning:** Caller invoked service but was in 24 bit addressing mode.  
**Action:** Request this function only when you are in 31 bit addressing mode. |
| 8           | xxxx0825      | **Equate Symbol:** IwmRsnCodeAscModeNotPrimary  
**Meaning:** Caller invoked service but was not in primary ASC mode.  
**Action:** Avoid requesting this function in this environment. |
| 8           | xxxx0828      | **Equate Symbol:** IwmRsnCodeBadVersion  
**Meaning:** Version number in parameter list is not valid.  
**Action:** Check for possible storage overlay of the parameter list. |
| 8           | xxxx0840      | **Equate Symbol:** IwmRsnCodeServiceNotEnabled  
**Meaning:** Caller’s space connection is not enabled for this service  
**Action:** Make sure that SERVER_MANAGER=YES and SERVER_TYPE=QUEUE is specified on the IWMCONN request to enable this service. |
| 8           | xxxx0841      | **Equate Symbol:** IwmRsnCodeXmemMode  
**Meaning:** Caller is in cross-memory mode.  
**Action:** Request this function only when you are not in cross-memory mode. |
| 8           | xxxx0842      | **Equate Symbol:** IwmRsnCodeNoWLMConnect  
**Meaning:** Caller’s space is not connected to WLM.  
**Action:** Invoke the IWMCONN macro before invoking this macro. |
### Table 133. Return and Reason Codes for the IWMTAFF Macro (continued)

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Equate Symbol, Meaning, and Action</th>
</tr>
</thead>
</table>
| 8           | xxxx084D    | **Equate Symbol:** IwmRsnCodeNotAuthConnect  
**Meaning:** The caller must be supervisor state or have PSW key mask 0-7 authority to use the requested WLM service. This applies only if the caller provides a region token for a server address space for which it wants to set the affinity.  
**Action:** Avoid requesting this function in this environment. |
| 8           | xxxx089E    | **Equate Symbol:** IwmRsnCodeServiceAModeMismatch  
**Meaning:** The caller is in 64-bit address mode and tried to invoke a service macro that is only enabled for a 31-bit environment.  
**Action:** Use the 64-bit enabled service macro (IWM4TAF) or change the address mode of the caller to 31-bit. |
| 10          | —           | **Equate Symbol:** IwmRetCodeCompError  
**Meaning:** Component error.  
**Action:** Contact your system programmer. |

### Example

To start a temporal affinity from the server region, specify the following:

```bash
IWMTAFF AFFINITY=YES  
RETCODE=RC,  
RSNCODE=RSN
```

* Storage areas
  * RC | DS F | Return code
  * RSN | DS F | Reason code
Appendix F. Accessibility

Accessible publications for this product are offered through [IBM Knowledge Center](http://www.ibm.com/support/knowledgecenter/SSLTBW/welcome).

If you experience difficulty with the accessibility of any z/OS information, send a detailed message to the "Contact us" web page for z/OS (http://www.ibm.com/systems/z/os/zos/webqs.html) or use the following mailing address.

IBM Corporation
Attention: MHVRCFS Reader Comments
Department H6MA, Building 707
2455 South Road
Poughkeepsie, NY 12601-5400
United States

Accessibility features

Accessibility features help users who have physical disabilities such as restricted mobility or limited vision use software products successfully. The accessibility features in z/OS can help users do the following tasks:

- Run assistive technology such as screen readers and screen magnifier software.
- Operate specific or equivalent features by using the keyboard.
- Customize display attributes such as color, contrast, and font size.

Consult assistive technologies

Assistive technology products such as screen readers function with the user interfaces found in z/OS. Consult the product information for the specific assistive technology product that is used to access z/OS interfaces.

Keyboard navigation of the user interface

You can access z/OS user interfaces with TSO/E or ISPF. The following information describes how to use TSO/E and ISPF, including the use of keyboard shortcuts and function keys (PF keys). Each guide includes the default settings for the PF keys.

- [z/OS TSO/E Primer](http://www.ibm.com/support/knowledgecenter/SSLTBW/welcome)
- [z/OS TSO/E User’s Guide](http://www.ibm.com/support/knowledgecenter/SSLTBW/welcome)
- [z/OS V2R2 ISPF User’s Guide Vol I](http://www.ibm.com/support/knowledgecenter/SSLTBW/welcome)

Dotted decimal syntax diagrams

Syntax diagrams are provided in dotted decimal format for users who access IBM Knowledge Center with a screen reader. In dotted decimal format, each syntax element is written on a separate line. If two or more syntax elements are always present together (or always absent together), they can appear on the same line because they are considered a single compound syntax element.

Each line starts with a dotted decimal number; for example, 3 or 3.1 or 3.1.1. To hear these numbers correctly, make sure that the screen reader is set to read out
The dotted decimal numbering level denotes the level of nesting. For example, if a syntax element with dotted decimal number 3 is followed by a series of syntax elements with dotted decimal number 3.1, all the syntax elements numbered 3.1 are subordinate to the syntax element numbered 3.

Certain words and symbols are used next to the dotted decimal numbers to add information about the syntax elements. Occasionally, these words and symbols might occur at the beginning of the element itself. For ease of identification, if the word or symbol is a part of the syntax element, it is preceded by the backslash (\) character. The * symbol is placed next to a dotted decimal number to indicate that the syntax element repeats. For example, syntax element *FILE with dotted decimal number 3 is given the format 3 \* FILE. Format 3* FILE indicates that syntax element FILE repeats. Format 3* \* FILE indicates that syntax element * FILE repeats.

Characters such as commas, which are used to separate a string of syntax elements, are shown in the syntax just before the items they separate. These characters can appear on the same line as each item, or on a separate line with the same dotted decimal number as the relevant items. The line can also show another symbol to provide information about the syntax elements. For example, the lines 5.1*, 5.1 LAISTRUN, and 5.1 DELETE mean that if you use more than one of the LAISTRUN and DELETE syntax elements, the elements must be separated by a comma. If no separator is given, assume that you use a blank to separate each syntax element.

If a syntax element is preceded by the % symbol, it indicates a reference that is defined elsewhere. The string that follows the % symbol is the name of a syntax fragment rather than a literal. For example, the line 2.1 %OP1 means that you must refer to separate syntax fragment OP1.

The following symbols are used next to the dotted decimal numbers.

? indicates an optional syntax element
The question mark (?) symbol indicates an optional syntax element. A dotted decimal number followed by the question mark symbol (?) indicates that all the syntax elements with a corresponding dotted decimal number, and any subordinate syntax elements, are optional. If there is only one syntax element with a dotted decimal number, the ? symbol is displayed on the same line as the syntax element, (for example 5? NOTIFY). If there is more than one syntax element with a dotted decimal number, the ? symbol is displayed on a line by itself, followed by the syntax elements that are optional. For example, if you hear the lines 5?, 5 NOTIFY, and 5 UPDATE, you know that the syntax elements NOTIFY and UPDATE are optional. That is, you can choose one or none of them. The ? symbol is equivalent to a bypass line in a railroad diagram.

! indicates a default syntax element
The exclamation mark (!) symbol indicates a default syntax element. A dotted decimal number followed by the ! symbol and a syntax element indicate that the syntax element is the default option for all syntax elements that share the same dotted decimal number. Only one of the syntax elements that share the dotted decimal number can specify the ! symbol. For example, if you hear the lines 2? FILE, 2.1! (KEEP), and 2.1 (DELETE), you know that (KEEP) is the
default option for the FILE keyword. In the example, if you include the FILE keyword, but do not specify an option, the default option KEEP is applied. A default option also applies to the next higher dotted decimal number. In this example, if the FILE keyword is omitted, the default FILE(KEEP) is used. However, if you hear the lines 2? FILE, 2.1, 2.1.1! (KEEP), and 2.1.1 (DELETE), the default option KEEP applies only to the next higher dotted decimal number, 2.1 (which does not have an associated keyword), and does not apply to 2? FILE. Nothing is used if the keyword FILE is omitted.

* indicates an optional syntax element that is repeatable

The asterisk or glyph (*) symbol indicates a syntax element that can be repeated zero or more times. A dotted decimal number followed by the * symbol indicates that this syntax element can be used zero or more times; that is, it is optional and can be repeated. For example, if you hear the line 5.1* data area, you know that you can include one data area, more than one data area, or no data area. If you hear the lines 3* , 3 HOST, 3 STATE, you know that you can include HOST, STATE, both together, or nothing.

Notes:

1. If a dotted decimal number has an asterisk (*) next to it and there is only one item with that dotted decimal number, you can repeat that same item more than once.
2. If a dotted decimal number has an asterisk next to it and several items have that dotted decimal number, you can use more than one item from the list, but you cannot use the items more than once each. In the previous example, you can write HOST STATE, but you cannot write HOST HOST.
3. The * symbol is equivalent to a loopback line in a railroad syntax diagram.

+ indicates a syntax element that must be included

The plus (+) symbol indicates a syntax element that must be included at least once. A dotted decimal number followed by the + symbol indicates that the syntax element must be included one or more times. That is, it must be included at least once and can be repeated. For example, if you hear the line 6.1+ data area, you must include at least one data area. If you hear the lines 2+, 2 HOST, and 2 STATE, you know that you must include HOST, STATE, or both. Similar to the + symbol, the + symbol can repeat a particular item if it is the only item with that dotted decimal number. The + symbol, like the * symbol, is equivalent to a loopback line in a railroad syntax diagram.

COPYRIGHT LICENSE:

This information might contain sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Policy for unsupported hardware

Various z/OS elements, such as DFSMS, HCD, JES2, JES3, and MVS, contain code that supports specific hardware servers or devices. In some cases, this device-related element support remains in the product even after the hardware devices pass their announced End of Service date. z/OS may continue to service element code; however, it will not provide service related to unsupported hardware devices. Software problems related to these devices will not be accepted
for service, and current service activity will cease if a problem is determined to be associated with out-of-support devices. In such cases, fixes will not be issued.

**Minimum supported hardware**

The minimum supported hardware for z/OS releases identified in z/OS announcements can subsequently change when service for particular servers or devices is withdrawn. Likewise, the levels of other software products supported on a particular release of z/OS are subject to the service support lifecycle of those products. Therefore, z/OS and its product publications (for example, panels, samples, messages, and product documentation) can include references to hardware and software that is no longer supported.

- For information about software support lifecycle, see: [IBM Lifecycle Support for z/OS](http://www.ibm.com/software/support/systemsz/lifecycle/)
- For information about currently-supported IBM hardware, contact your IBM representative.

**Programming interface information**

This information documents intended programming interfaces that allow you to write programs to obtain the services of z/OS.

**Trademarks**

IBM, the IBM logo, and ibm.com® are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies.

Adobe, the Adobe logo, PostScript, and the PostScript logo are either registered trademarks or trademarks of Adobe Systems Incorporated in the United States, and/or other countries.

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Java and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

Other company, product, and service names may be trademarks or service marks of others.
